This variant on `RANGE` was introduced in MySQL 5.5.0 to facilitate partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted;

columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
  PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
  PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 19.2.1, “RANGE Partitioning”](#), and [Section 19.4, “Partition Pruning”](#).

- `LIST(expr)`

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

**Note**

For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 5.5, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

- `LIST COLUMNS(column_list)`

This variant on `LIST` was introduced in MySQL 5.5.0 to facilitate partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the `COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- `PARTITIONS num`

The number of partitions may optionally be specified with a `PARTITIONS num` clause, where `num` is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, `num` must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

**Note**

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- `SUBPARTITION BY`

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may

be [LINEAR](#). These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by [LIST](#) or [RANGE](#).)

The number of subpartitions can be indicated using the [SUBPARTITIONS](#) keyword followed by an integer value.

- Rigorous checking of the value used in [PARTITIONS](#) or [SUBPARTITIONS](#) clauses is applied and this value must adhere to the following rules:
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, [PARTITIONS 0.2E+01](#) is not permitted, even though [0.2E+01](#) evaluates to 2. (Bug #15890)
- [partition\\_definition](#)

Each partition may be individually defined using a [partition\\_definition](#) clause. The individual parts making up this clause are as follows:

- [PARTITION partition\\_name](#)

Specifies a logical name for the partition.

- [VALUES](#)

For range partitioning, each partition must include a [VALUES LESS THAN](#) clause; for list partitioning, you must specify a [VALUES IN](#) clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 19, Partitioning](#), for syntax examples.

- [COMMENT](#)

An optional [COMMENT](#) clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

- [DATA DIRECTORY](#) and [INDEX DIRECTORY](#)

[DATA DIRECTORY](#) and [INDEX DIRECTORY](#) may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the [data\\_dir](#) and the [index\\_dir](#) must be absolute system path names.

As of MySQL 5.5.54, you must have the [FILE](#) privilege to use the [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) partition option.

Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
    DATA DIRECTORY = '/var/appdata/96/data'
```

```

INDEX DIRECTORY = '/var/appdata/96/idx',
PARTITION p2001 VALUES IN (1997, 2001, 2005)
DATA DIRECTORY = '/var/appdata/97/data'
INDEX DIRECTORY = '/var/appdata/97/idx',
PARTITION p2002 VALUES IN (1998, 2002, 2006)
DATA DIRECTORY = '/var/appdata/98/data'
INDEX DIRECTORY = '/var/appdata/98/idx'
);

```

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

#### Note

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect. (Bug #24633)

- `MAX_ROWS` and `MIN_ROWS`

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- `TABLESPACE`

The optional `TABLESPACE` clause may be used to designate a tablespace for the partition. Used for NDB Cluster only.

- `[STORAGE] ENGINE`

The partitioning handler accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL`. We expect to lift this restriction on partitioning in a future MySQL release.

- `NODEGROUP`

The `NODEGROUP` option can be used to make this partition act as part of the node group identified by `node_group_id`. This option is applicable only to NDB Cluster.

- `subpartition_definition`

The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by [HASH](#) or [KEY](#), and can be done only on [RANGE](#) or [LIST](#) partitions. See [Section 19.2.6, “Subpartitioning”](#).

### 13.1.17.1 CREATE TABLE Statement Retention

The original [CREATE TABLE](#) statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an [ALTER TABLE](#) statement, the original table options specified are retained. This enables you to change between [InnoDB](#) and [MyISAM](#) table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the [ROW\\_FORMAT](#)), the active table definition (accessible through [DESCRIBE](#) or with [SHOW TABLE STATUS](#)) and the table creation string (accessible through [SHOW CREATE TABLE](#)) will report different values.

### 13.1.17.2 Files Created by CREATE TABLE

MySQL represents each table by an [.frm](#) table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For [InnoDB](#) tables, the file storage is controlled by the [innodb\\_file\\_per\\_table](#) configuration option. For each [InnoDB](#) table created when this option is turned on, the table data and all associated indexes are stored in a [.ibd file](#) located inside the database directory. When this option is turned off, all [InnoDB](#) tables and indexes are stored in the [system tablespace](#), represented by one or more [ibdata\\* files](#).

For [MyISAM](#) tables, the storage engine creates data and index files. Thus, for each [MyISAM](#) table [tbl\\_name](#), there are three disk files.

| File                         | Purpose                        |
|------------------------------|--------------------------------|
| <a href="#">tbl_name.frm</a> | Table format (definition) file |
| <a href="#">tbl_name.MYD</a> | Data file                      |
| <a href="#">tbl_name.MYI</a> | Index file                     |

[Chapter 15, Alternative Storage Engines](#), describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

### 13.1.17.3 CREATE TEMPORARY TABLE Syntax

You can use the [TEMPORARY](#) keyword when creating a table. A [TEMPORARY](#) table is visible only to the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-[TEMPORARY](#) table of the same name. (The existing table is hidden until the temporary table is dropped.)

[CREATE TABLE](#) does not automatically commit the current active transaction if you use the [TEMPORARY](#) keyword.

[TEMPORARY](#) tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any [TEMPORARY](#) tables created within that database. Also, you can create a [TEMPORARY](#) table in a nonexistent database if you qualify the table name with the database name in the

`CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. However, other operations on a temporary table, such as `INSERT`, `UPDATE`, or `SELECT`, require additional privileges for those operations for the database containing the temporary table, or for the nontemporary table of the same name.

To keep privileges for temporary and nontemporary tables separate, a common workaround for this situation is to create a database dedicated to the use of temporary tables. Then for that database, a user can be granted the `CREATE TEMPORARY TABLES` privilege, along with any other privileges required for temporary table operations done by that user.

### 13.1.17.4 CREATE TABLE ... LIKE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

#### Important

Beginning with MySQL 5.5.3, you cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

Also as of MySQL 5.5.3, `CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

### 13.1.17.5 CREATE TABLE ... SELECT Syntax

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,  
-> PRIMARY KEY (a), KEY(b))  
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a [MyISAM](#) table with three columns, [a](#), [b](#), and [c](#). The [ENGINE](#) option is part of the [CREATE TABLE](#) statement, and should not be used following the [SELECT](#); this would result in a syntax error. The same is true for other [CREATE TABLE](#) options such as [CHARSET](#).

Notice that the columns from the [SELECT](#) statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n |
+----+
| 1 |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m      | n |
+-----+-----+
| NULL   | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table [foo](#), a row is inserted in [bar](#) with the values from [foo](#) and default values for the new columns.

In a table resulting from [CREATE TABLE ... SELECT](#), columns named only in the [CREATE TABLE](#) part come first. Columns named in both parts or only in the [SELECT](#) part come after that. The data type of [SELECT](#) columns can be overridden by also specifying the column in the [CREATE TABLE](#) part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the [SELECT](#) by [IGNORE](#) or [REPLACE](#) to indicate how to handle rows that duplicate unique key values. With [IGNORE](#), rows that duplicate an existing row on a unique key value are discarded. With [REPLACE](#), new rows replace rows that have the same unique key value. If neither [IGNORE](#) nor [REPLACE](#) is specified, duplicate unique key values result in an error.

Because the ordering of the rows in the underlying [SELECT](#) statements cannot always be determined, [CREATE TABLE ... IGNORE SELECT](#) and [CREATE TABLE ... REPLACE SELECT](#) statements in MySQL 5.5.18 and later are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using [MIXED](#) mode. See also [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

[CREATE TABLE ... SELECT](#) does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the [SELECT](#) statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the [AUTO\\_INCREMENT](#) attribute is not preserved, and [VARCHAR](#) columns can become [CHAR](#) columns. Retrained attributes are [NULL](#) (or [NOT NULL](#)) and, for those columns that have them, [CHARACTER SET](#), [COLLATION](#), [COMMENT](#), and the [DEFAULT](#) clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
  FROM artist LEFT JOIN work ON artist.id = work.artist_id
  GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the destination table already exists, the result is version dependent. Before MySQL 5.5.6, MySQL handles the statement as follows:

- The table definition given in the `CREATE TABLE` part is ignored. No error occurs, even if the definition does not match that of the existing table. MySQL attempts to insert the rows from the `SELECT` part anyway.
- If there is a mismatch between the number of columns in the table and the number of columns produced by the `SELECT` part, the selected values are assigned to the rightmost columns. For example, if the table contains  $n$  columns and the `SELECT` produces  $m$  columns, where  $m < n$ , the selected values are assigned to the  $m$  rightmost columns in the table. Each of the initial  $n - m$  columns is assigned its default value, either that specified explicitly in the column definition or the implicit column data type default if the definition contains no default. If the `SELECT` part produces too many columns ( $m > n$ ), an error occurs.
- If strict SQL mode is enabled and any of these initial columns do not have an explicit default value, the statement fails with an error.

The following example illustrates `IF NOT EXISTS` handling:

```
mysql> CREATE TABLE t1 (i1 INT DEFAULT 0, i2 INT, i3 INT, i4 INT);
Query OK, 0 rows affected (0.05 sec)

mysql> CREATE TABLE IF NOT EXISTS t1 (c1 CHAR(10)) SELECT 1, 2;
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+-----+-----+-----+-----+
| i1   | i2   | i3   | i4   |
+-----+-----+-----+-----+
| 0    | NULL | 1    | 2    |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

As of MySQL 5.5.6, handling of `CREATE TABLE IF NOT EXISTS ... SELECT` statements was changed for the case that the destination table already exists. This change also involves a change in MySQL 5.1 beginning with 5.1.51.

- Previously, for `CREATE TABLE IF NOT EXISTS ... SELECT`, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, `CREATE TABLE ... SELECT` (without `IF NOT EXISTS`) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.
- MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when `IF NOT EXISTS` is present and an error when it is not.

This change means that, for the preceding example, the `CREATE TABLE IF NOT EXISTS ... SELECT` statement inserts nothing into the destination table as of MySQL 5.5.6.

This change in handling of `IF NOT EXISTS` results in an incompatibility for statement-based replication from a MySQL 5.1 master with the original behavior and a MySQL 5.5 slave with the new behavior. Suppose that `CREATE TABLE IF NOT EXISTS ... SELECT` is executed on the master and the destination table exists. The result is that rows are inserted on the master but not on the slave. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.
- If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the master and slave. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the master first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the slave first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

### 13.1.17.6 Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and [foreign key constraints](#), which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a `CREATE TABLE` or `ALTER TABLE` statement looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name,...)
[ON DELETE reference_option]
[ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

*index\_name* represents a foreign key ID. The *index\_name* value is ignored if there is already an explicitly defined index on the child table that can support the foreign key. Otherwise, MySQL implicitly creates a foreign key index that is named according to the following rules:

- If defined, the `CONSTRAINT symbol` value is used. Otherwise, the `FOREIGN KEY index_name` value is used.
- If neither a `CONSTRAINT symbol` or `FOREIGN KEY index_name` is defined, the foreign key index name is generated using the name of the referencing foreign key column.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a `parent table` that holds the central data values, and a `child table` with identical values pointing back to its parent. The `FOREIGN KEY` clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be `TEMPORARY` tables.

In MySQL 5.5, creation of a foreign key constraint requires at least one of the `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `REFERENCES` privileges for the parent table as of 5.5.41.

- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is described in [Section 13.1.7, “ALTER TABLE Syntax”](#).
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.
- `InnoDB` permits a foreign key to reference any column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- If the `CONSTRAINT symbol` clause is given, the `symbol` value, if used, must be unique in the database. A duplicate `symbol` will result in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.#sql-211d_3' (errno: 121)`. If the clause is not given, or a `symbol` is not included following the `CONSTRAINT` keyword, a name for the constraint is created automatically.
- `InnoDB` does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

## Referential Actions

This section describes how foreign keys help guarantee [referential integrity](#).

For storage engines supporting foreign keys, MySQL rejects any `INSERT` or `UPDATE` operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an `UPDATE` or `DELETE` operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified using `ON UPDATE` and `ON DELETE`

subclauses of the `FOREIGN KEY` clause. MySQL supports five options regarding the action to be taken, listed here:

- `CASCADE`: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both `ON DELETE CASCADE` and `ON UPDATE CASCADE` are supported. Between two tables, do not define several `ON UPDATE CASCADE` clauses that act on the same column in the parent table or in the child table.

#### Note

Cascaded foreign key actions do not activate triggers.

- `SET NULL`: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to `NULL`. Both `ON DELETE SET NULL` and `ON UPDATE SET NULL` clauses are supported.

If you specify a `SET NULL` action, *make sure that you have not declared the columns in the child table as `NOT NULL`.*

- `RESTRICT`: Rejects the delete or update operation for the parent table. Specifying `RESTRICT` (or `NO ACTION`) is the same as omitting the `ON DELETE` or `ON UPDATE` clause.
- `NO ACTION`: A keyword from standard SQL. In MySQL, equivalent to `RESTRICT`. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and `NO ACTION` is a deferred check. In MySQL, foreign key constraints are checked immediately, so `NO ACTION` is the same as `RESTRICT`.
- `SET DEFAULT`: This action is recognized by the MySQL parser, but `InnoDB` rejects table definitions containing `ON DELETE SET DEFAULT` or `ON UPDATE SET DEFAULT` clauses.

For an `ON DELETE` or `ON UPDATE` that is not specified, the default action is always `RESTRICT`.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

## Examples of Foreign Key Clauses

Here is a simple example that relates `parent` and `child` tables through a single-column foreign key:

```
CREATE TABLE parent (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```
CREATE TABLE product (
  category INT NOT NULL, id INT NOT NULL,
  price DECIMAL,
  PRIMARY KEY(category, id)
) ENGINE=INNODB;

CREATE TABLE customer (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE product_order (
  no INT NOT NULL AUTO_INCREMENT,
  product_category INT NOT NULL,
  product_id INT NOT NULL,
  customer_id INT NOT NULL,

  PRIMARY KEY(no),
  INDEX (product_category, product_id),
  INDEX (customer_id),

  FOREIGN KEY (product_category, product_id)
    REFERENCES product(category, id)
    ON UPDATE CASCADE ON DELETE RESTRICT,

  FOREIGN KEY (customer_id)
    REFERENCES customer(id)
) ENGINE=INNODB;
```

## Adding foreign keys

You can add a new foreign key constraint to an existing table by using [ALTER TABLE](#). The syntax relating to foreign keys for this statement is shown here:

```
ALTER TABLE tbl_name
  ADD [CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using [ALTER TABLE](#), *remember to create the required indexes first*.

## Dropping Foreign Keys

You can also use [ALTER TABLE](#) to drop foreign keys, using the syntax shown here:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the [FOREIGN KEY](#) clause included a [CONSTRAINT](#) name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the *fk\_symbol* value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a [SHOW CREATE TABLE](#) statement, as shown here:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
```

```

`A` int(11) NOT NULL auto_increment,
`D` int(11) NOT NULL default '0',
`B` varchar(200) NOT NULL default '',
`C` varchar(175) default NULL,
PRIMARY KEY (`A`,`D`,`B`),
KEY `B` (`B`,`C`),
KEY `C` (`C`),
CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;

```

Adding and dropping a foreign key in separate clauses of a single `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Use separate statements for each operation.

If an `ALTER TABLE` statement results in changes to column values (for example, because a column is truncated), MySQL's foreign key constraint checks do not notice possible violations caused by changing the values.

## Foreign Keys and Other MySQL Statements

Table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause can be quoted within backticks (```). Alternatively, double quotation marks (`"`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The setting of the `lower_case_table_names` system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table.

`mysqldump` produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `foreign_key_checks` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```

mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;

```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `foreign_key_checks` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `foreign_key_checks = 0`, MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, `ALTER TABLE` cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue `DROP TABLE` for a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET foreign_key_checks = 0`. When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.

For `InnoDB` tables, you can obtain a detailed explanation of the most recent `InnoDB` foreign key error in the MySQL Server, by checking the output of `SHOW ENGINE INNODB STATUS`.

### Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. MySQL essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` (including `PRIMARY`) and `NOT NULL` keys.

Furthermore, MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For storage engines that do not support foreign keys (such as `MyISAM`), MySQL Server parses and ignores foreign key specifications.

## 13.1.17.7 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- `TIMESTAMP` display sizes are discarded.

Also note that `TIMESTAMP` columns are `NOT NULL` by default.

- Columns that are part of a `PRIMARY KEY` are made `NOT NULL` even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 11.9, “Using Data Types from Other Database Engines”](#).
- If you include a `USING` clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a `VARCHAR` column with a length specification greater than 65535 is converted to `TEXT`, and a `VARBINARY` column with a length specification greater than 65535 is converted to `BLOB`. Otherwise, an error occurs in either of these cases.
- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a `DESCRIBE` or `SHOW CREATE TABLE` statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using `myisampack`. See [Section 15.3.3.3, “Compressed Table Characteristics”](#).

### 13.1.18 CREATE TABLESPACE Syntax

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  USE LOGFILE GROUP logfile_group
  [EXTENT_SIZE [=] extent_size]
  [INITIAL_SIZE [=] initial_size]
  [AUTOEXTEND_SIZE [=] autoextend_size]
  [MAX_SIZE [=] max_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] comment_text]
  ENGINE [=] engine_name
```

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for tables. One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the [ALTER TABLESPACE](#) statement (see [Section 13.1.8, “ALTER TABLESPACE Syntax”](#)). For rules covering the naming of tablespaces, see [Section 9.2, “Schema Object Names”](#).

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more [UNDO](#) log files must be assigned to the tablespace to be created with the [USE LOGFILE GROUP](#) clause. *logfile\_group* must be an existing log file group created with [CREATE LOGFILE GROUP](#) (see [Section 13.1.14, “CREATE LOGFILE GROUP Syntax”](#)). Multiple tablespaces may use the same log file group for [UNDO](#) logging.

The [EXTENT\\_SIZE](#) sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An *extent* is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may be used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example, that a tablespace having a single datafile whose [INITIAL\\_SIZE](#) is 256 MB and whose [EXTENT\\_SIZE](#) is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the [INFORMATION\\_SCHEMA.FILES](#) table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see [Section 21.29.1, “The INFORMATION\\_SCHEMA FILES Table”](#).

The [INITIAL\\_SIZE](#) parameter sets the data file's total size in bytes. Once the file has been created, its size cannot be changed; however, you can add more data files to the tablespace using [ALTER TABLESPACE ... ADD DATAFILE](#). See [Section 13.1.8, “ALTER TABLESPACE Syntax”](#).

[INITIAL\\_SIZE](#) is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for [INITIAL\\_SIZE](#) is 4294967296 (4 GB). (Bug #29186)

When setting [EXTENT\\_SIZE](#), you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in *my.cnf*. Generally, this is one of the letters **M** (for megabytes) or **G** (for gigabytes). In MySQL NDB Cluster 7.2.14 and later, these abbreviations are also supported when specifying [INITIAL\\_SIZE](#) as well. (Bug #13116514, Bug #16104705, Bug #62858)

[INITIAL\\_SIZE](#), [EXTENT\\_SIZE](#), and [UNDO\\_BUFFER\\_SIZE](#) are subject to rounding as follows:

- [EXTENT\\_SIZE](#) and [UNDO\\_BUFFER\\_SIZE](#) are each rounded up to the nearest whole multiple of 32K.
- [INITIAL\\_SIZE](#) is rounded *down* to the nearest whole multiple of 32K.

For data files, *INITIAL\_SIZE* is subject to further rounding; the result just obtained is rounded up to the nearest whole multiple of *EXTENT\_SIZE* (after any rounding).

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating *INFORMATION\_SCHEMA.FILES* column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

*AUTOEXTEND\_SIZE*, *MAX\_SIZE*, *NODEGROUP*, *WAIT*, and *COMMENT* are parsed but ignored, and so currently have no effect. These options are intended for future expansion.

The *ENGINE* parameter determines the storage engine which uses this tablespace, with *engine\_name* being the name of the storage engine. Currently, *engine\_name* must be one of the values *NDB* or *NDBCLUSTER*.

When *CREATE TABLESPACE* is used with *ENGINE = NDB*, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the *INFORMATION\_SCHEMA.FILES* table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
       -> FROM INFORMATION_SCHEMA.FILES
       -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

| LOGFILE_GROUP_NAME | FILE_NAME   | EXTRA          |
|--------------------|-------------|----------------|
| lg_3               | newdata.dat | CLUSTER_NODE=3 |
| lg_3               | newdata.dat | CLUSTER_NODE=4 |

```
2 rows in set (0.01 sec)
```

(See [Section 21.29.1](#), “The *INFORMATION\_SCHEMA.FILES* Table”.)

*CREATE TABLESPACE* is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12](#), “NDB Cluster Disk Data Tables”.

### 13.1.19 CREATE TRIGGER Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  TRIGGER trigger_name
  trigger_time trigger_event
  ON tbl_name FOR EACH ROW
  trigger_body

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named *tbl\_name*, which must refer to a permanent table. You cannot associate a trigger with a *TEMPORARY* table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes *CREATE TRIGGER* syntax. For additional discussion, see [Section 20.3.1](#), “Trigger Syntax and Examples”.

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. The statement might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as described in [Section 20.7, “Binary Logging of Stored Programs”](#).

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

`trigger_event` indicates the kind of operation that activates the trigger. These `trigger_event` values are permitted:

- `INSERT`: The trigger activates whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`: The trigger activates whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`: The trigger activates whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. `DROP TABLE` and `TRUNCATE TABLE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

**Note**

Cascaded foreign key actions do not activate triggers.

There cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_body` is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permissible within stored routines. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#). Some statements are not permitted in triggers; see [Section C.1, “Restrictions on Stored Programs”](#).

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

MySQL stores the `sql_mode` system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, *regardless of the current server SQL mode when the trigger begins executing*.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `TRIGGER` privilege for the subject table.
  - The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
- Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see [Section 20.6, “Access Control for Stored Programs and Views”](#).

Within a trigger body, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 6.3.8, “SQL-Based MySQL Account Activity Auditing”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [Section 13.3.5.2, “LOCK TABLES and Triggers”](#).

For additional discussion of trigger use, see [Section 20.3.1, “Trigger Syntax and Examples”](#).

## 13.1.20 CREATE VIEW Syntax

```
CREATE
  [OR REPLACE]
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
```

```
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

For information about restrictions on view use, see [Section C.5, “Restrictions on Views”](#).

The *select\_statement* is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The *select\_statement* can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. `CREATE VIEW` might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use *db\_name.view\_name* syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional *column\_list* clause as a list of comma-separated identifiers. The number of names in *column\_list* must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY` or filtering or grouping. When `ORDER BY` is combined with `LIMIT` or `OFFSET` in a view definition, the ordering is always enforced before the query result is used by the outer query, but it does not guarantee that the same ordering is used in the end result. As a workaround, add an `ORDER BY` clause to the outer query.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
```

```
| mycol |
+-----+
| mycol |

```

The [DEFINER](#) and [SQL SECURITY](#) clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid [SQL SECURITY](#) characteristic values are [DEFINER](#) (the default) and [INVOKER](#). These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If a [user](#) value is given for the [DEFINER](#) clause, it should be a MySQL account specified as '[user\\_name](#)'@'[host\\_name](#)', [CURRENT\\_USER](#), or [CURRENT\\_USER\(\)](#). The default [DEFINER](#) value is the user who executes the [CREATE VIEW](#) statement. This is the same as specifying [DEFINER = CURRENT\\_USER](#) explicitly.

If the [DEFINER](#) clause is present, these rules determine the valid [DEFINER](#) user values:

- If you do not have the [SUPER](#) privilege, the only valid [user](#) value is your own account, either specified literally or by using [CURRENT\\_USER](#). You cannot set the definer to some other account.
- If you have the [SUPER](#) privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a view with a nonexistent [DEFINER](#) account, an error occurs when the view is referenced if the [SQL SECURITY](#) value is [DEFINER](#) but the definer account does not exist.

For more information about view security, see [Section 20.6, “Access Control for Stored Programs and Views”](#).

Within a view definition, [CURRENT\\_USER](#) returns the view's [DEFINER](#) value by default. For views defined with the [SQL SECURITY INVOKER](#) characteristic, [CURRENT\\_USER](#) returns the account for the view's invoker. For information about user auditing within views, see [Section 6.3.8, “SQL-Based MySQL Account Activity Auditing”](#).

Within a stored routine that is defined with the [SQL SECURITY DEFINER](#) characteristic, [CURRENT\\_USER](#) returns the routine's [DEFINER](#) value. This also affects a view defined within such a routine, if the view definition contains a [DEFINER](#) value of [CURRENT\\_USER](#).

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the [SELECT](#) privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it ([SELECT](#) to select from it, [INSERT](#) to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view [DEFINER](#) account or invoker, depending on whether the [SQL SECURITY](#) characteristic is [DEFINER](#) or [INVOKER](#), respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function [SQL SECURITY](#) characteristic is [DEFINER](#) or [INVOKER](#). If the security characteristic is [DEFINER](#), the function runs with the privileges of the [DEFINER](#) account. If the characteristic is [INVOKER](#), the function runs with the privileges determined by the view's [SQL SECURITY](#) characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the [SQL SECURITY](#) values of the view `v` and the function `f()`.

The [DEFINER](#) and [SQL SECURITY](#) clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for [SQL SECURITY DEFINER](#). The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, [SELECT](#)) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The [DEFINER](#) clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default [DEFINER](#) value is the account of the view creator.

The optional [ALGORITHM](#) clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. [ALGORITHM](#) takes three values: [MERGE](#), [TEMPTABLE](#), or [UNDEFINED](#). The default algorithm is [UNDEFINED](#) if no [ALGORITHM](#) clause is present. For more information, see [Section 20.5.2, “View Processing Algorithms”](#), as well as [Optimizing Derived Tables](#).

Some views are updatable. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

The [WITH CHECK OPTION](#) clause can be given for an updatable view to prevent inserts or updates to rows except those for which the [WHERE](#) clause in the *select\_statement* is true.

In a [WITH CHECK OPTION](#) clause for an updatable view, the [LOCAL](#) and [CASCADED](#) keywords determine the scope of check testing when the view is defined in terms of another view. The [LOCAL](#) keyword restricts the [CHECK OPTION](#) only to the view being defined. [CASCADED](#) causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is [CASCADED](#).

For more information about updatable views and the `WITH CHECK OPTION` clause, see [Section 20.5.3, “Updatable and Insertable Views”](#), and [Section 20.5.4, “The View WITH CHECK OPTION Clause”](#).

### 13.1.21 DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

#### Important

When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 13.7.1.3, “GRANT Syntax”](#).

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions.

|                   |                   |                   |                   |
|-------------------|-------------------|-------------------|-------------------|
| <code>.BAK</code> | <code>.DAT</code> | <code>.HSH</code> | <code>.MRG</code> |
| <code>.MYD</code> | <code>.MYI</code> | <code>.TRG</code> | <code>.TRN</code> |
| <code>.db</code>  | <code>.frm</code> | <code>.ibd</code> | <code>.ndb</code> |
| <code>.par</code> |                   |                   |                   |

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See [Section 13.1.17.3, “CREATE TEMPORARY TABLE Syntax”](#).

You can also drop databases with `mysqladmin`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

### 13.1.22 DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

### 13.1.23 DROP FUNCTION Syntax

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see [Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”](#).
- For information about dropping user-defined functions, see [Section 13.7.3.2, “DROP FUNCTION Syntax”](#).

### 13.1.24 DROP INDEX Syntax

```
DROP [ONLINE|OFFLINE] INDEX index_name ON tbl_name
```

`DROP INDEX` drops the index named *index\_name* from the table *tbl\_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 13.1.7, “ALTER TABLE Syntax”](#).

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

Indexes on variable-width columns of `NDB` tables are dropped online; that is, without any table copying. The table is not locked against access from other `NDB` Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.5 releases, it is not possible to override the server when it determines that an index is to be dropped without table copying. In `NDB` Cluster, you can drop indexes offline (which causes the table to be locked for all API nodes in the cluster) using the `OFFLINE` keyword. The rules and limitations governing `DROP OFFLINE INDEX` and `DROP ONLINE INDEX` are the same as for `ALTER OFFLINE TABLE ... DROP INDEX` and `ALTER ONLINE TABLE ... DROP INDEX`. You cannot cause the noncopying dropping of an index that would normally be dropped offline by using the `ONLINE` keyword: If it is not possible to perform the `DROP` operation without table copying, the server ignores the `ONLINE` keyword. For more information, see [Section 13.1.7.2, “ALTER TABLE Online Operations in NDB Cluster 7.2”](#).

The `ONLINE` and `OFFLINE` keywords are available only in `NDB` Cluster; attempting to use these keywords in standard MySQL Server 5.5 releases results in a syntax error.

### 13.1.25 DROP LOGFILE GROUP Syntax

```
DROP LOGFILE GROUP logfile_group  
ENGINE [=] engine_name
```

This statement drops the log file group named *logfile\_group*. The log file group must already exist or an error results. (For information on creating log file groups, see [Section 13.1.14, “CREATE LOGFILE GROUP Syntax”](#).)

### Important

Before dropping a log file group, you must drop all tablespaces that use that log file group for [UNDO](#) logging.

The required [ENGINE](#) clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for *engine\_name* are [NDB](#) and [NDBCLUSTER](#).

[DROP LOGFILE GROUP](#) is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

## 13.1.26 DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the [ALTER ROUTINE](#) privilege for the routine. (If the [automatic\\_sp\\_privileges](#) system variable is enabled, that privilege and [EXECUTE](#) are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See [Section 20.2.2, “Stored Routines and MySQL Privileges”](#).)

The [IF EXISTS](#) clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with [SHOW WARNINGS](#).

[DROP FUNCTION](#) is also used to drop user-defined functions (see [Section 13.7.3.2, “DROP FUNCTION Syntax”](#)).

## 13.1.27 DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server\_name*. The corresponding row in the [mysql.servers](#) table is deleted. This statement requires the [SUPER](#) privilege.

Dropping a server for a table does not affect any [FEDERATED](#) tables that used this connection information when they were created. See [Section 13.1.16, “CREATE SERVER Syntax”](#).

[DROP SERVER](#) does not cause an automatic commit.

In MySQL 5.5, [DROP SERVER](#) is not written to the binary log, regardless of the logging format that is in use.

## 13.1.28 DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
  tbl_name [, tbl_name] ...
  [RESTRICT | CASCADE]
```

[DROP TABLE](#) removes one or more tables. You must have the [DROP](#) privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent tables it was unable to drop, but it also drops all of the tables in the list that do exist.

### Important

When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 13.7.1.3, “GRANT Syntax”](#).

For a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (`.par`) file associated with the dropped table.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each nonexistent table when using `IF EXISTS`. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

`IF EXISTS` can be useful for dropping tables in unusual circumstances under which there is an `.frm` file but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before `.frm` file removal.)

`RESTRICT` and `CASCADE` are permitted to make porting easier. In MySQL 5.5, they do nothing.

#### Note

`DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A `TEMPORARY` table is visible only to the session that created it, so no check is necessary.)

Using `TEMPORARY` is a good way to ensure that you do not accidentally drop a non-`TEMPORARY` table.

## 13.1.29 DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace_name
ENGINE [=] engine_name
```

This statement drops a tablespace that was previously created using `CREATE TABLESPACE` (see [Section 13.1.18, “CREATE TABLESPACE Syntax”](#)).

#### Important

The tablespace to be dropped must not contain any data files; in other words, before you can drop a tablespace, you must first drop each of its data files using `ALTER TABLESPACE ... DROP DATAFILE` (see [Section 13.1.8, “ALTER TABLESPACE Syntax”](#)).

The `ENGINE` clause (required) specifies the storage engine used by the tablespace. Currently, the only accepted values for `engine_name` are `NDB` and `NDBCLUSTER`.

`DROP TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See [Section 18.5.12, “NDB Cluster Disk Data Tables”](#).

## 13.1.30 DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A **NOTE** is generated for a nonexistent trigger when using `IF EXISTS`. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

Triggers for a table are also dropped if you drop the table.

#### Note

When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or higher—including all MySQL 5.5 releases—you must drop all triggers and re-create them. Otherwise, `DROP TRIGGER` does not work for older triggers after the upgrade. See [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.5”](#), for a suggested upgrade procedure.

## 13.1.31 DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
    [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a **NOTE** is generated for each nonexistent view. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

## 13.1.32 RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables. The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running.

For example, a table named `old_table` can be renamed to `new_table` as shown here:

```
RENAME TABLE old_table TO new_table;
```

This statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
    new_table TO old_table,
    tmp_table TO new_table;
```

MySQL checks the destination table name before checking whether the source table exists. For example, if `new_table` already exists and `old_table` does not, the following statement fails as shown here:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_mydb |
+-----+
| table_a         |
+-----+
1 row in set (0.00 sec)

mysql> RENAME TABLE table_b TO table_a;
ERROR 1050 (42S01): Table 'table_a' already exists
```

As long as two databases are on the same file system, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

You can use this method to move all tables from one database to a different one, in effect renaming the database. (MySQL has no single statement to perform this task.)

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `Trigger in wrong schema`.

`RENAME TABLE` changes internally generated foreign key constraint names and user-defined foreign key constraint names that contain the string `"tbl_name_ibfk_"` to reflect the new table name. `InnoDB` interprets foreign key constraint names that contain the string `"tbl_name_ibfk_"` as internally generated names.

Foreign keys that point to the renamed table are not automatically updated. In such cases, you must drop and re-create the foreign keys in order for them to function properly.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME TABLE`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

You cannot use `RENAME TABLE` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` with temporary tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used to perform the rename, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move the table files.

### 13.1.33 TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege.

Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements. To achieve high performance, it bypasses the DML method of

deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for `InnoDB` tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways in MySQL 5.5:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back.
- Truncation operations cannot be performed if the session holds an active table lock.
- `TRUNCATE TABLE` fails for an `InnoDB` table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.
- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using `InnoDB` and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using `InnoDB` in the manner described previously.

On a system with a large `InnoDB` buffer pool and `innodb_adaptive_hash_index` enabled, `TRUNCATE TABLE` operations may cause a temporary drop in system performance due to an LRU scan that occurs when removing an `InnoDB` table's adaptive hash index entries. The problem was addressed for `DROP TABLE` in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for `TRUNCATE TABLE` (Bug #68184).

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See [Section 22.9.5, “Performance Schema Summary Tables”](#).

## 13.2 Data Manipulation Statements

### 13.2.1 CALL Syntax

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
    # Set value of OUT parameter
    SELECT VERSION() INTO ver_param;
    # Increment value of INOUT parameter
    SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version      | @increment |
+-----+-----+
| 5.5.3-m3-log  |          11 |
+-----+-----+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholders can be used for `IN` parameters. For `OUT` and `INOUT` parameters, placeholder support is available as of MySQL 5.5.3. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+-----+-----+
| @version      | @increment |
+-----+-----+
| 5.5.3-m3-log  |          11 |
+-----+-----+
```

Before MySQL 5.5.3, placeholder support is not available for `OUT` or `INOUT` parameters. To work around this limitation for `OUT` and `INOUT` parameters, forego the use of placeholders; instead, refer to user variables in the `CALL` statement itself and do not specify them in the `EXECUTE` statement:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(@version, @increment)';
mysql> EXECUTE s;
```

```
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.0-m2-log | 11 |
+-----+-----+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). As of MySQL 5.5.3, `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 23.8.17, “C API Support for Multiple Statement Execution”](#).

For programs written in a language that provides a MySQL interface, there is no native method prior to MySQL 5.5.3 for directly retrieving the results of `OUT` or `INOUT` parameters from `CALL` statements. To get the parameter values, pass user-defined variables to the procedure in the `CALL` statement and then execute a `SELECT` statement to produce a result set containing the variable values. To handle an `INOUT` parameter, execute a statement prior to the `CALL` that sets the corresponding user variable to the value to be passed to the procedure.

The following example illustrates the technique (without error checking) for the stored procedure `p` described earlier that has an `OUT` parameter and an `INOUT` parameter:

```
mysql_query(mysql, "SET @increment = 10");
mysql_query(mysql, "CALL p(@version, @increment)");
mysql_query(mysql, "SELECT @version, @increment");
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@version` and `@increment`, respectively.

As of MySQL 5.5.3, C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see [Section 23.8.20, “C API Support for Prepared CALL Statements”](#). Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

## 13.2.2 DELETE Syntax

`DELETE` is a DML statement that removes rows from a table.

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
```

```
[WHERE where_condition]  
[ORDER BY ...]  
[LIMIT row_count]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]  
  tbl_name[.*] [, tbl_name[.*]] ...  
FROM table_references  
[WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]  
FROM tbl_name[.*] [, tbl_name[.*]] ...  
USING table_references  
[WHERE where_condition]
```

For the single-table syntax, the `DELETE` statement deletes rows from *tbl\_name* and returns a count of the number of deleted rows. This count can be obtained by calling the `ROW_COUNT()` function (see [Section 12.14, “Information Functions”](#)). The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each *tbl\_name* the rows that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

*where\_condition* is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 13.2.9, “SELECT Syntax”](#).

You cannot delete from a table and select from the same table in a subquery.

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause.

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use `TRUNCATE TABLE`. However, within a transaction or if you have a lock on the table, `TRUNCATE TABLE` cannot be used whereas `DELETE` can. See [Section 13.1.33, “TRUNCATE TABLE Syntax”](#), and [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 14.11.1.5, “AUTO\\_INCREMENT Handling in InnoDB”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 3.6.9, “Using AUTO\\_INCREMENT”](#).

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- For [MyISAM](#) tables, if you use the [QUICK](#) modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The [IGNORE](#) modifier causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of [IGNORE](#) are returned as warnings.

The speed of delete operations may also be affected by factors discussed in [Section 8.2.4.3, “Optimizing DELETE Statements”](#).

In [MyISAM](#) tables, deleted rows are maintained in a linked list and subsequent [INSERT](#) operations reuse old row positions. To reclaim unused space and reduce file sizes, use the [OPTIMIZE TABLE](#) statement or the [myisamchk](#) utility to reorganize tables. [OPTIMIZE TABLE](#) is easier to use, but [myisamchk](#) is faster. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The [QUICK](#) modifier affects whether index leaves are merged for delete operations. [DELETE QUICK](#) is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

[DELETE QUICK](#) is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of [QUICK](#) can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed [AUTO\\_INCREMENT](#) column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using [DELETE QUICK](#).

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of [QUICK](#). They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use [DELETE](#) without [QUICK](#), unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use [OPTIMIZE TABLE](#).

If you are going to delete many rows from a table, it might be faster to use [DELETE QUICK](#) followed by [OPTIMIZE TABLE](#). This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific [LIMIT row\\_count](#) option to [DELETE](#) tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a given [DELETE](#) statement does not take too much time. You can simply repeat the [DELETE](#) statement until the number of affected rows is less than the [LIMIT](#) value.

If the [DELETE](#) statement includes an [ORDER BY](#) clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with [LIMIT](#). For example, the following statement finds rows matching the [WHERE](#) clause, sorts them by [timestamp\\_column](#), and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

[ORDER BY](#) may also be useful in some cases to delete rows in an order required to avoid referential integrity violations.

If you are deleting many rows from a large table, you may exceed the lock table size for an [InnoDB](#) table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use [DELETE](#) at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use [RENAME TABLE](#) to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while [RENAME TABLE](#) executes, so the rename operation is not subject to concurrency problems. See [Section 13.1.32, “RENAME TABLE Syntax”](#).

You can specify multiple tables in a [DELETE](#) statement to delete rows from one or more tables depending on the particular condition in the [WHERE](#) clause. However, you cannot use [ORDER BY](#) or [LIMIT](#) in a multiple-table [DELETE](#). The *table\_references* clause lists the tables involved in the join. Its syntax is described in [Section 13.2.9.2, “JOIN Syntax”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the [FROM](#) clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the [FROM](#) clause (before the [USING](#) clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables [t1](#) and [t2](#).

The preceding examples use [INNER JOIN](#), but multiple-table [DELETE](#) statements can use other types of join permitted in [SELECT](#) statements, such as [LEFT JOIN](#). For example, to delete rows that exist in [t1](#) that have no match in [t2](#), use a [LEFT JOIN](#):

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits [.\\*](#) after each *tbl\_name* for compatibility with [Access](#).

If you use a multiple-table [DELETE](#) statement involving [InnoDB](#) tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the [ON DELETE](#) capabilities that [InnoDB](#) provides to cause the other tables to be modified accordingly.

**Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table **DELETE** should be declared only in the *table\_references* part of the statement.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

Declaration of aliases other than in the *table\_references* part of the statement should be avoided because that can lead to ambiguous statements that have unexpected results such as deleting rows from the wrong table. This is such a statement:

```
DELETE t1 AS a2 FROM t1 AS a1 INNER JOIN t2 AS a2;
```

Before MySQL 5.5.3, alias declarations outside the *table\_references* part of the statement are disallowed for the **USING** variant of multiple-table **DELETE** syntax. As of MySQL 5.5.3, alias declarations outside *table\_references* are disallowed for all multiple-table **DELETE** statements.

Before MySQL 5.5.3, for alias references in the list of tables from which to delete rows in a multiple-table delete, the default database is used unless one is specified explicitly. For example, if the default database is **db1**, the following statement does not work because the unqualified alias reference **a2** is interpreted as having a database of **db1**:

```
DELETE a1, a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

To correctly match an alias that refers to a table outside the default database, you must explicitly qualify the reference with the name of the proper database:

```
DELETE a1, db2.a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

As of MySQL 5.5.3, alias resolution does not require qualification and alias references should not be qualified with the database name. Qualified names are interpreted as referring to tables, not aliases.

### 13.2.3 DO Syntax

```
DO expr [, expr] ...
```

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

Example: This `SELECT` statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+-----+
| SLEEP(5) |
+-----+
|         0 |
+-----+
1 row in set (5.02 sec)
```

`DO`, on the other hand, pauses without producing a result set.:

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

`DO` only executes expressions. It cannot be used in all cases where `SELECT` can be used. For example, `DO id FROM t1` is invalid because it references a table.

## 13.2.4 HANDLER Syntax

```
HANDLER tbl_name OPEN [ [AS] alias ]

HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]

HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `InnoDB` and `MyISAM` tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible using subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates.

If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`,

and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 13.2.9, "SELECT Syntax"](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
  - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
  - The handler interface does not have to provide a consistent look of the data (for example, [dirty reads](#) are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
- `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface.
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.

- The session in which the handler is open executes non-HANDLER statements that use tables.

TRUNCATE TABLE for a table closes all handlers for the table that were opened with HANDLER OPEN.

If a table is flushed with FLUSH TABLES *tbl\_name* WITH READ LOCK was opened with HANDLER, the handler is implicitly flushed and loses its position.

HANDLER is not supported with partitioned tables.

## 13.2.5 INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[ ON DUPLICATE KEY UPDATE
  col_name=expr
  [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
SET col_name={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col_name=expr
  [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col_name=expr
  [, col_name=expr] ... ]
```

INSERT inserts new rows into an existing table. The INSERT ... VALUES and INSERT ... SET forms of the statement insert rows based on explicitly specified values. The INSERT ... SELECT form inserts rows selected from another table or tables. INSERT ... SELECT is discussed further in [Section 13.2.5.1, “INSERT ... SELECT Syntax”](#).

You can use REPLACE instead of INSERT to overwrite old rows. REPLACE is the counterpart to INSERT IGNORE in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 13.2.8, “REPLACE Syntax”](#).

*tbl\_name* is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the VALUES list or the SELECT statement.
- If you do not specify a list of column names for INSERT ... VALUES or INSERT ... SELECT, values for every column in the table must be provided by the VALUES list or the SELECT statement. If you do not know the order of the columns in the table, use DESCRIBE *tbl\_name* to find out.
- The SET clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 11.6, “Data Type Default Values”](#). See also [Section 1.7.3.3, “Constraints on Invalid Data”](#).

If you want an `INSERT` statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 5.1.8, “Server SQL Modes”](#).

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the `VALUES` list.

You can also use `DEFAULT(col_name)` as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression `expr` to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column results in the values `1999`, `19.9921`, `19.992100`, and `1999` being inserted, respectively. The reason the value stored in the `INT` and `YEAR` columns is `1999` is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a `0`.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

**VALUE** is a synonym for **VALUES** in this context. Neither implies anything about the number of values lists, and either may be used whether there is a single values list or multiple lists.

The affected-rows value for an **INSERT** can be obtained using the **ROW\_COUNT()** function (see [Section 12.14, “Information Functions”](#)), or the **mysql\_affected\_rows()** C API function (see [Section 23.8.7.1, “mysql\\_affected\\_rows\(\)”](#)).

If you use an **INSERT ... VALUES** statement with multiple value lists or **INSERT ... SELECT**, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

**Records** indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because **Duplicates** can be nonzero.) **Duplicates** indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. **Warnings** indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting **NULL** into a column that has been declared **NOT NULL**. For multiple-row **INSERT** statements or **INSERT INTO ... SELECT** statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ( ' ' ) for string types, and the “zero” value for date and time types. **INSERT INTO ... SELECT** statements are handled the same way as multiple-row inserts because the server does not examine the result set from the **SELECT** to see whether it returns a single row. (For a single-row **INSERT**, no warning occurs when **NULL** is inserted into a **NOT NULL** column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
- Inserting a string into a string column (**CHAR**, **VARCHAR**, **TEXT**, or **BLOB**) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the **mysql\_info()** function. See [Section 23.8.7.35, “mysql\\_info\(\)”](#).

If **INSERT** inserts a row into a table that has an **AUTO\_INCREMENT** column, you can find the value used for that column by using the SQL **LAST\_INSERT\_ID()** function. From within the C API, use the **mysql\_insert\_id()** function. However, you should note that the two functions do not always behave identically. The behavior of **INSERT** statements with respect to **AUTO\_INCREMENT** columns is discussed further in [Section 12.14, “Information Functions”](#), and [Section 23.8.7.37, “mysql\\_insert\\_id\(\)”](#).

The **INSERT** statement supports the following modifiers:

- If you use the **DELAYED** modifier, the server puts the row or rows to be inserted into a buffer, and the client issuing the **INSERT DELAYED** statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically

to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#).

`DELAYED` is ignored with `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE`.

`DELAYED` is also disregarded for an `INSERT` that uses functions accessing tables or triggers, or that is called from a function or a trigger.

- If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to `INSERT DELAYED`, which lets the client continue at once.)

**Note**

`LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 8.11.3, “Concurrent Inserts”](#).

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 8.11.3, “Concurrent Inserts”](#).

`LOW_PRIORITY` and `HIGH_PRIORITY` affect only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` modifier, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors may generate warnings instead, although duplicate-key errors do not.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error; however, when `INSERT IGNORE` is used, the insert operation fails silently for the row containing the unmatched value, but any rows that are matched are inserted. For an example, see [Section 19.2.2, “LIST Partitioning”](#).

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

An `INSERT` statement that acts on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines

such as [InnoDB](#) that employ row-level locking. This issue is resolved in MySQL 5.6. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#), for more information.

### 13.2.5.1 INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
      [INTO] tbl_name [(col_name,...)]
      SELECT ...
      [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- `DELAYED` is ignored with `INSERT ... SELECT`.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.) However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into a table at the same time, MySQL creates a temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, it remains true that you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement (see [Section B.5.6.2, “TEMPORARY Table Problems”](#)).

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements (see [Section 8.11.3, “Concurrent Inserts”](#)).
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify nonunique column names in the values part.

The order in which rows are returned by a `SELECT` statement with no `ORDER BY` clause is not determined. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave; this can lead to inconsistencies between them. To prevent this from occurring, you should always write `INSERT ... SELECT` statements that are to be replicated as `INSERT ... SELECT ... ORDER BY column`. The choice of `column` does not matter as long as the same order for returning the rows is enforced on both the master and the slave. See also [Section 17.4.1.16, “Replication and LIMIT”](#).

Due to this issue, beginning with MySQL 5.5.18, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication.

With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

An `INSERT ... SELECT` statement that acts on partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the source and target tables. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#), for more information.

### 13.2.5.2 INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MySQL for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, `ARCHIVE`, and `BLACKHOLE` tables. For engines that do not support `DELAYED`, an error occurs.
- An error occurs for `INSERT DELAYED` if used with a table that has been locked with `LOCK TABLES` because the insert must be handled by a separate thread, not by the session that holds the lock.
- For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.
- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.
- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.

- Prior to MySQL 5.5.7, `INSERT DELAYED` was treated as a normal `INSERT` if the statement inserted multiple rows, binary logging was enabled, and the global logging format was statement-based (that is, whenever `binlog_format` was set to `STATEMENT`). Beginning with MySQL 5.5.7, `INSERT DELAYED` is always handled as a simple `INSERT` (that is, without the `DELAYED` option) whenever the value of `binlog_format` is `STATEMENT` or `MIXED`. (In the latter case, the statement no longer triggers a switch to row-based logging, and so is logged using the statement-based format.)

This does not apply when using row-based binary logging mode (`binlog_format` set to `ROW`), in which `INSERT DELAYED` statements are always executed using the `DELAYED` option as specified, and logged as row-update events.

- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- `INSERT DELAYED` is not supported for views.
- `INSERT DELAYED` is not supported for partitioned tables.

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the “thread” is the thread that received an `INSERT DELAYED` statement and “handler” is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler already exists.
- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` statements to finish, to ensure that the table structure is up to date.
- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
- The client cannot obtain from the server the number of duplicate rows or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)
- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.
- Each time that `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it permits these to execute before continuing.
- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.
- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.
- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before

exiting, it first stores all queued rows into the table. During this time it does not accept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

Note that this means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements.

| Status Variable                       | Meaning   |
|---------------------------------------|---|
| <code>Delayed_insert_threads</code>   | Number of handler threads                               |
| <code>Delayed_writes</code>           | Number of rows written with <code>INSERT DELAYED</code> |
| <code>Not_flushed_delayed_rows</code> | Number of rows waiting to be written                    |

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

### 13.2.5.3 INSERT ... ON DUPLICATE KEY UPDATE Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, MySQL performs an `UPDATE` of the old row. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an [AUTO\\_INCREMENT](#) column and [INSERT ... ON DUPLICATE KEY UPDATE](#) inserts or updates a row, the [LAST\\_INSERT\\_ID\(\)](#) function returns the [AUTO\\_INCREMENT](#) value.

The [DELAYED](#) option is ignored when you use [ON DUPLICATE KEY UPDATE](#).

Because the results of [INSERT ... SELECT](#) statements depend on the ordering of rows from the [SELECT](#) and this order cannot always be guaranteed, it is possible when logging [INSERT ... SELECT ON DUPLICATE KEY UPDATE](#) statements for the master and the slave to diverge. Thus, in MySQL 5.5.18 and later, [INSERT ... SELECT ON DUPLICATE KEY UPDATE](#) statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using [MIXED](#) mode. In addition, beginning with MySQL 5.5.24, an [INSERT ... ON DUPLICATE KEY UPDATE](#) statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637) See also [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

An [INSERT ... ON DUPLICATE KEY UPDATE](#) on a partitioned table using a storage engine such as [MyISAM](#) that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as [InnoDB](#) that employ row-level locking. This issue is resolved in MySQL 5.6. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#), for more information.

## 13.2.6 LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[CHARACTER SET charset_name]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

The [LOAD DATA INFILE](#) statement reads rows from a text file into a table at a very high speed. [LOAD DATA INFILE](#) is the complement of [SELECT ... INTO OUTFILE](#). (See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).) To write data from a table to a file, use [SELECT ... INTO OUTFILE](#). To read the file back into a table, use [LOAD DATA INFILE](#). The syntax of the [FIELDS](#) and [LINES](#) clauses is the same for both statements. Both clauses are optional, but [FIELDS](#) must precede [LINES](#) if both are specified.

You can also load data files by using the [mysqlimport](#) utility; it operates by sending a [LOAD DATA INFILE](#) statement to the server. The [--local](#) option causes [mysqlimport](#) to read data files from the

client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name.

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

**Note**

It is not possible to load data files that use the `ucs2`, `utf16`, or `utf32` character set.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

With row-based replication, `CONCURRENT` is replicated regardless of MySQL version. With statement-based replication `CONCURRENT` is not replicated prior to MySQL 5.5.1 (see Bug #34628). For more information, see [Section 17.4.1.17, “Replication and LOAD DATA INFILE”](#).

The `LOCAL` keyword affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` does not work. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

The `LOCAL` keyword affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the server's temporary directory. This is *not* the directory determined by the value of `tmpdir` or `slave_load_tmpdir`, but rather the operating system's temporary directory, and is not configurable in the MySQL Server. (Typically the

system temporary directory is `/tmp` on Linux systems and `C:\WINDOWS\TEMP` on Windows.) Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
  - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Non-`LOCAL` load operations read text files located on the server. For security reasons, such operations require that you have the `FILE` privilege. See [Section 6.2.1, “Privileges Provided by MySQL”](#). Also, non-`LOCAL` load operations are subject to the `secure_file_priv` system variable setting. If the variable value is a nonempty directory name, the file to be loaded must be located in that directory. If the variable value is empty (which is insecure), the file need only be readable by the server.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

`LOCAL` also affects error handling:

- With `LOAD DATA INFILE`, data-interpretation and duplicate-key errors terminate the operation.
- With `LOAD DATA LOCAL INFILE`, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if `IGNORE` is specified. `IGNORE` is explained further later in this section.

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 13.2.8, “REPLACE Syntax”](#).
- If you specify `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.
- If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

To ignore foreign key constraints during the load operation, issue a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

(Backslash is the MySQL escape character within strings in SQL statements, so to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.)

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character `\` as escape sequences. For example, `\t`, `\n`, and `\\` signify tab, newline, and backslash, respectively. See the discussion of `FIELDS ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `\` to escape instances of tab, newline, or `\` that occur within field values.
- Write newlines at the ends of lines.

#### Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be ( "abc",1 ) and ( "def",2 ). The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' ENCLOSED BY '"'
LINES TERMINATED BY '\r\n'
IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` keywords.

Any of the field- or line-handling options can specify an empty string (' '). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values from columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Occurrences of the `ENCLOSED BY` character within a field value are escaped by prefixing them with the `ESCAPED BY` character. Also, if you specify an empty `ESCAPED BY` value, it is possible to inadvertently generate output that cannot be read properly by `LOAD DATA INFILE`. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the `ENCLOSED BY` character, if present, is stripped from the ends of field values. (This is true regardless of whether `OPTIONALLY` is specified; `OPTIONALLY` has no effect on input interpretation.) Occurrences of the `ENCLOSED BY` character preceded by the `ESCAPED BY` character are interpreted as part of the current field value.

If the field begins with the `ENCLOSED BY` character, instances of that character are recognized as terminating a field value only if followed by the field or line `TERMINATED BY` sequence. To avoid ambiguity, occurrences of the `ENCLOSED BY` character within a field value can be doubled and are interpreted as a single instance of the character. For example, if `ENCLOSED BY ''` is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss"    -> The "BIG" boss
```

```
The "BIG" boss -> The "BIG" boss
```

**FIELDS ESCAPED BY** controls how to read or write special characters:

- For input, if the **FIELDS ESCAPED BY** character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using `\` for the escape character). The rules for **NULL** handling are described later in this section.

| Character       | Escape Sequence                |
|-----------------|--------------------------------|
| <code>\0</code> | An ASCII NUL (x'00') character |
| <code>\b</code> | A backspace character          |
| <code>\n</code> | A newline (linefeed) character |
| <code>\r</code> | A carriage return character    |
| <code>\t</code> | A tab character.               |
| <code>\z</code> | ASCII 26 (Control+Z)           |
| <code>\N</code> | NULL                           |

For more information about `\`-escape syntax, see [Section 9.1.1, “String Literals”](#).

If the **FIELDS ESCAPED BY** character is empty, escape-sequence interpretation does not occur.

- For output, if the **FIELDS ESCAPED BY** character is not empty, it is used to prefix the following characters on output:
  - The **FIELDS ESCAPED BY** character
  - The **FIELDS [OPTIONALLY] ENCLOSED BY** character
  - The first character of the **FIELDS TERMINATED BY** and **LINES TERMINATED BY** values
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte)

If the **FIELDS ESCAPED BY** character is empty, no characters are escaped and **NULL** is output as **NULL**, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If **LINES TERMINATED BY** is an empty string and **FIELDS TERMINATED BY** is nonempty, lines are also terminated with **FIELDS TERMINATED BY**.
- If the **FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** values are both empty (`' '`), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For **TINYINT**, **SMALLINT**, **MEDIUMINT**, **INT**, and **BIGINT**, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

**LINES TERMINATED BY** is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `' '`. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of **NULL** values, as described later.

**Note**

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 11.6, “Data Type Default Values”](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '"' ENCLOSED BY '"'
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the [SET](#) clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The [SET](#) clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and [SET](#) clause is subject to the following restrictions:

- Assignments in the [SET](#) clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of [SET](#) assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an [IGNORE](#) clause are not processed for the column/variable list or [SET](#) clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, [LOAD DATA](#) splits it into fields and uses the values according to the column/variable list and the [SET](#) clause, if they are present. Then the resulting row is inserted into the table. If there are [BEFORE INSERT](#) or [AFTER INSERT](#) triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 11.6, “Data Type Default Values”](#).

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to `0`.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 11.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an [INSERT](#) or [UPDATE](#) statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded directly using binary notation (for example, `b'011010'`). To work around this, use the `SET` clause to strip off the leading `b'` and trailing `'` and perform a base-2 to base-10 conversion so that MySQL loads the values into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
      INTO TABLE bit_test (@var1)
      SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| BIN(b+0) |
+-----+
| 10      |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

For `BIT` values in `0b` binary notation (for example, `0b011010`), use this `SET` clause instead to strip off the leading `0b`:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the [INSERT](#) statement (see [Section 13.2.5, “INSERT Syntax”](#)), except that [LOAD DATA INFILE](#) also generates warnings when there are too few or too many fields in the input row.

You can use [SHOW WARNINGS](#) to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 23.8.7.35, “mysql\\_info\(\)”](#).

For partitioned tables using storage engines that employ table locks, such as [MyISAM](#), any locks caused by [LOAD DATA](#) perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as [InnoDB](#). For more information, see [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

## 13.2.7 LOAD XML Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE [db_name.]tbl_name
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<tagname>']
[IGNORE number {LINES | ROWS}]
[(field_name_or_user_var,...)]
[SET col_name = expr,...]
```

The [LOAD XML](#) statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional [ROWS IDENTIFIED BY](#) clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

[LOAD XML](#) acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
shell> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use [LOAD XML INFILE](#). By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the [ROWS IDENTIFIED BY](#) clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
```

```
<field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

Prior to MySQL 5.5.46, `LOAD XML` did not handle empty XML elements in the form `<element/>` correctly. (Bug #67542, Bug #16171518)

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `CHARACTER SET`
- `SET`

See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#), for more information about these clauses.

`(field_name_or_user_var, ...)` is a comma-separated list of one or more XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```
USE test;

CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
    <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field></person>
  <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';

Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likame | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read in using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>

  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>
```

```

<row>
<field name="person_id">3</field>
<field name="fname">Likema</field>
<field name="lname">Örrtmons</field>
</row>

<row>
<field name="person_id">4</field>
<field name="fname">Slar</field>
<field name="lname">Manlanth</field>
</row>

<row>
<field name="person_id">5</field>
<field name="fname">Stoma</field>
<field name="lname">Nilu</field>
</row>

<row>
<field name="person_id">6</field>
<field name="fname">Nirtam</field>
<field name="lname">Sklöd</field>
</row>

<row>
<field name="person_id">7</field>
<field name="fname">Sungam</field>
<field name="lname">Dulbåd</field>
</row>

<row>
<field name="person_id">8</field>
<field name="fname">Sreraf</field>
<field name="lname">Encmelt</field>
</row>
</resultset>

```

### Note

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```

mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |

```

```

+-----+-----+-----+
|          7 | Sungam | Dulbád | 2007-07-13 16:18:47 |
|          8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+
8 rows in set (0.00 sec)

```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```

mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
***** 1. row *****
      Table: person2
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  PRIMARY KEY (`person_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+
| person_id | fname | lname |
+-----+-----+-----+
|          1 | Kapek | Sainnouine |
|          2 | Sajon | Rondela |
|          3 | Likema | Örrtmons |
|          4 | Slar | Manlanth |
|          5 | Stoma | Nilu |
|          6 | Nirtam | Sklöð |
|          7 | Sungam | Dulbád |
|          8 | Sreraf | Encmelt |
+-----+-----+-----+
8 rows in set (0.00 sec)

```

The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```

mysql> CREATE TABLE individual (
->     individual_id INT NOT NULL PRIMARY KEY,
->     name1 VARCHAR(40) NULL,

```

```
-> name2 VARCHAR(40) NULL,
-> made TIMESTAMP
-> );
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml'
-> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
-> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM individual;
+-----+-----+-----+-----+
| individual_id | name1 | name2 | made |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |

+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

The names of the user variables *must* match those of the corresponding fields from the XML file, with the addition of the required `@` prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```
<?xml version="1.0"?>

<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
```

```
</list>
```

You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person\G
***** 1. row *****
      Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
|          1 | Robert | Jones | 2007-07-24 17:37:06 |
|          2 | Mary  | Smith | 2007-07-24 17:37:06 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE address
-> ROWS IDENTIFIED BY '<address>';
```

```
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
```

You can see that the data was imported using a [SELECT](#) statement such as this one:

```
mysql> SELECT * FROM address;
+-----+-----+-----+-----+-----+-----+
| address_id | person_id | street      | zip   | city      | created      |
+-----+-----+-----+-----+-----+-----+
| 1          | 1         | Mill Creek Road | 45365 | Sidney    | 2007-07-24 17:37:37 |
| 2          | 1         | Main Street    | 28681 | Taylorsville | 2007-07-24 17:37:37 |
| 3          | 2         | River Road     | 80239 | Denver     | 2007-07-24 17:37:37 |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the [LOAD DATA](#) statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the [LOAD XML](#) statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use [LOAD XML LOCAL](#) to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable [LOAD XML](#) for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the [FILE](#) privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

### Important

Revoking the [FILE](#) privilege (or not granting it in the first place) keeps the user only from executing the [LOAD XML INFILE](#) statement (as well as the [LOAD\\_FILE\(\)](#) function; it does *not* prevent the user from executing [LOAD XML LOCAL INFILE](#). To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the [FILE](#) privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as [MyISAM](#), any locks caused by [LOAD XML](#) perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as [InnoDB](#). For more information, see [Section 19.5.4, "Partitioning and Table-Level Locking"](#).

## 13.2.8 REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
```

```
[INTO] tbl_name [(col_name,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
SET col_name=({expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [(col_name,...)]
SELECT ...
```

**REPLACE** works exactly like **INSERT**, except that if an old row in the table has the same value as a new row for a **PRIMARY KEY** or a **UNIQUE** index, the old row is deleted before the new row is inserted. See [Section 13.2.5, “INSERT Syntax”](#).

**REPLACE** is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

#### Note

**REPLACE** makes sense only if a table has a **PRIMARY KEY** or **UNIQUE** index. Otherwise, it becomes equivalent to **INSERT**, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the **REPLACE** statement. Any missing columns are set to their default values, just as happens for **INSERT**. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as **SET *col\_name* = *col\_name* + 1**, the reference to the column name on the right hand side is treated as **DEFAULT(*col\_name*)**, so the assignment is equivalent to **SET *col\_name* = DEFAULT(*col\_name*) + 1**.

To use **REPLACE**, you must have both the **INSERT** and **DELETE** privileges for the table.

The **REPLACE** statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row **REPLACE**, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether **REPLACE** only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for **REPLACE** (and **LOAD DATA ... REPLACE**):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
  - a. Delete from the table the conflicting row that has the duplicate key value

- b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, in MySQL 5.5.18 and later, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using the `STATEMENT` binary logging mode, and are logged using the row-based format when using `MIXED` mode. See also [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see [Section 19.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```
CREATE TABLE test (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+-----+-----+
| id | data | ts                |
+----+-----+-----+
|  1 | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```
CREATE TABLE test2 (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
```

```
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+-----+-----+-----+
| id | data | ts |
+-----+-----+-----+
| 1 | old | 2014-08-20 18:47:00 |
| 1 | New | 2014-08-20 18:47:42 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement that acts on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#), for more information.

### 13.2.9 SELECT Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
   [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
   [ASC | DESC], ...]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [INTO OUTFILE 'file_name'
   [CHARACTER SET charset_name]
   export_options
   | INTO DUMPFILE 'file_name'
   | INTO var_name [, var_name]]
  [FOR UPDATE | LOCK IN SHARE MODE]]
```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See [Section 13.2.9.3, “UNION Syntax”](#), and [Section 13.2.10, “Subquery Syntax”](#).

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.
- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 13.2.9.2, “JOIN Syntax”](#).
- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

In the [WHERE](#) expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Section 9.5, “Expression Syntax”](#), and [Chapter 12, Functions and Operators](#).

[SELECT](#) can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;  
-> 2
```

You are permitted to specify [DUAL](#) as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;  
-> 2
```

[DUAL](#) is purely for the convenience of people who require that all [SELECT](#) statements should have [FROM](#) and possibly other clauses. MySQL may ignore the clauses. MySQL does not require [FROM DUAL](#) if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a [HAVING](#) clause must come after any [GROUP BY](#) clause and before any [ORDER BY](#) clause. The exception is that the [INTO](#) clause can appear either as shown in the syntax description or immediately following the [select\\_expr](#) list. For more information about [INTO](#), see [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).

The list of [select\\_expr](#) terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use [\\*-shorthand](#):

- A select list consisting only of a single unqualified [\\*](#) can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- [tbl\\_name.\\*](#) can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified [\\*](#) with other items in the select list may produce a parse error. To avoid this problem, use a qualified [tbl\\_name.\\*](#) reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other [SELECT](#) clauses:

- A [select\\_expr](#) can be given an alias using [AS alias\\_name](#). The alias is used as the expression's column name and can be used in [GROUP BY](#), [ORDER BY](#), or [HAVING](#) clauses. For example:

```
SELECT CONCAT(last_name, ' ', first_name) AS full_name  
FROM mytable ORDER BY full_name;
```

The [AS](#) keyword is optional when aliasing a [select\\_expr](#) with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ' ', first_name) full_name
```

```
FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two `select_expr` expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section B.5.4.4, “Problems with Column Aliases”](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 13.2.9.2, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 8.9.3, “Index Hints”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.1.5, “Server System Variables”](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 9.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
  WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
  WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
  ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
  ORDER BY r, s;

SELECT college, region, seed FROM tournament
  ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a subquery and also is applied in the outer query, the outermost `ORDER BY` takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

Relying on implicit `GROUP BY` sorting (that is, sorting in the absence of `ASC` or `DESC` designators) is deprecated. To produce a given sort order, use explicit `ASC` or `DESC` designators for `GROUP BY` columns or provide an `ORDER BY` clause.

- When you use `ORDER BY` or `GROUP BY` to sort a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.
- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in [Section 12.16, “Aggregate \(GROUP BY\) Functions”](#).
- `GROUP BY` permits a `WITH ROLLUP` modifier. See [Section 12.16.2, “GROUP BY Modifiers”](#).
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The **HAVING** clause can refer to aggregate functions, which the **WHERE** clause cannot:

```
SELECT user, MAX(salary) FROM users  
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one *select\_expr* with the same name. This is an extension to standard SQL. Because MySQL also permits **GROUP BY** and **HAVING** to refer to *select\_expr* values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name *a*. To ensure that the correct column is used for grouping, use different names for each *select\_expr*.

- MySQL resolves unqualified column or alias references in **ORDER BY** clauses by searching in the *select\_expr* values, then in the columns of the tables in the **FROM** clause. For **GROUP BY** or **HAVING** clauses, it searches the **FROM** clause before searching in the *select\_expr* values. (For **GROUP BY** and **HAVING**, this differs from the pre-MySQL 5.0 behavior that used the same rules as for **ORDER BY**.)
- The **LIMIT** clause can be used to constrain the number of rows returned by the **SELECT** statement. **LIMIT** takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
  - Within prepared statements, **LIMIT** parameters can be specified using **?** placeholder markers.
  - Within stored programs, **LIMIT** parameters can be specified using integer-valued routine parameters or local variables as of MySQL 5.5.6.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, **LIMIT row\_count** is equivalent to **LIMIT 0, row\_count**.

For prepared statements, you can use placeholders. The following statements will return one row from the *tbl* table:

```
SET @a=1;  
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
```

```
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 8.4.2.4, “Using PROCEDURE ANALYSE”](#), which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See [Section 14.8.2.4, “Locking Reads”](#).

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.
- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 13.2.9.2, “JOIN Syntax”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 8.8.1,](#)

“[Optimizing Queries with EXPLAIN](#)”. This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.14, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` modifiers affect caching of query results in the query cache (see [Section 8.10.3, “The MySQL Query Cache”](#)). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is `2` or `DEMAND`. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the `SQL_NO_CACHE` keyword; a nonspace such as a newline causes the server to check the query cache to see whether the result is already cached.)

For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

As of MySQL 5.5.3, these two modifiers are mutually exclusive and an error occurs if they are both specified. Also, these modifiers are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

Before MySQL 5.5.3, for a query that uses `UNION` or subqueries, the following rules apply:

- `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query.
- For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of the query.

A `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#), for more information.

### 13.2.9.1 SELECT ... INTO Syntax

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.
- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.
- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

The `SELECT` syntax description (see [Section 13.2.9, “SELECT Syntax”](#)) shows the `INTO` clause near the end of the statement. It is also possible to use `INTO` immediately following the `select_expr` list.

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context.

The `INTO` clause can name a list of one or more variables, which can be user-defined variables, stored procedure or function parameters, or stored program local variables. (Within a prepared `SELECT ... INTO OUTFILE` statement, only user-defined variables are permitted; see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).)

The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 9.4, “User-Defined Variables”](#).

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some other host than the server host, you normally cannot use `SELECT ... INTO OUTFILE` since there is no way to write a path to the file relative to the server host's file system.

However, if the MySQL client software is installed on the remote machine, you can instead use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

It is also possible to create the resulting file on a different host other than the server host, if the location of the file on the remote host can be accessed using a network-mapped path on the server's file system. In this case, the presence of `mysql` (or some other MySQL client program) is not required on the target host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#), for information about the `FIELDS` and `LINES` clauses, including their default values and permissible values.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values

- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII `0`, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some paggers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

#### Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 20.4.5, “Event Scheduler Status”](#).

### 13.2.9.2 JOIN Syntax

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
  table_reference
| { OJ table_reference }

table_reference:
  table_factor
| join_table

table_factor:
  tbl_name [[AS] alias] [index_hint_list]
```

```

| table_subquery [AS] alias
| ( table_references )

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
| table_reference STRAIGHT_JOIN table_factor
| table_reference STRAIGHT_JOIN table_factor ON conditional_expr
| table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
| table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
| USING (column_list)

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
| IGNORE {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
| FORCE {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
    index_name [, index_name] ...

```

A table reference is also known as a join expression.

The syntax of *table\_factor* is extended in MySQL in comparison with standard SQL. The standard accepts only *table\_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of *table\_reference* items is considered as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
    ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
    ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)

```

In MySQL, **JOIN**, **CROSS JOIN**, and **INNER JOIN** are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. **INNER JOIN** is used with an **ON** clause, **CROSS JOIN** is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See [Section 8.2.1.6, “Nested Join Optimization”](#).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 8.9.3, “Index Hints”](#). The `optimizer_switch` system variable is another way to influence optimizer use of indexes. See [Section 8.9.2, “Switchable Optimizations”](#).

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using *tbl\_name AS alias\_name* or *tbl\_name alias\_name*:

```

SELECT t1.name, t2.salary
    FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

```

```
SELECT t1.name, t2.salary
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A *table\_subquery* is also known as a derived table or subquery in the `FROM` clause. See [Section 13.2.10.8, “Derived Tables \(Subqueries in the FROM Clause\)”](#). Such subqueries *must* include an alias to give the subquery result a table name. A trivial example follows:

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The *conditional\_expr* used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, the `ON` clause serves for conditions that specify how to join tables, and the `WHERE` clause restricts which rows to include in the result set.
- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See [Section 8.2.1.7, “Left Join and Right Join Optimization”](#).

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1, c2, c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

The parser does not permit nested { `OJ ...` } constructs (which are not legal ODBC syntax, anyway). Queries that use such constructs should be rewritten.

- `STRAIGHT_JOIN` is similar to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```
SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a `NATURAL` join do not appear. Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table

- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN x IS NOT NULL THEN x ELSE y END)
```

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a `JOIN`. Suppose that the tables `t1(a, b)` and `t2(a, c)` have the following contents:

```
t1      t2
----
1 x    2 z
2 y    3 w
```

Then, for this join, column `a` contains the values of `t1.a`:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

By contrast, for this join, column `a` contains the values of `t2.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
| 2     | z     | y     |
| 3     | w     | NULL  |
+-----+-----+-----+
```

Compare those results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 1     | x     | NULL  | NULL  |
| 2     | y     | 2     | z     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
```

|      |      |   |   |
|------|------|---|---|
| 2    | y    | 2 | z |
| NULL | NULL | 3 | w |

- A **USING** clause can be rewritten as an **ON** clause that compares corresponding columns. However, although **USING** and **ON** are similar, they are not quite the same. Consider the following two queries:

```
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3
```

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for **SELECT \*** expansion, the two joins are not semantically identical. The **USING** join selects the coalesced value of corresponding columns, whereas the **ON** join selects all columns from all tables. For the **USING** join, **SELECT \*** selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the **ON** join, **SELECT \*** selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, **COALESCE(a.c1, b.c1)** is the same as either **a.c1** or **b.c1** because both columns will have the same value. With an outer join (such as **LEFT JOIN**), one of the two columns can be **NULL**. That column is omitted from the result.

- An **ON** clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an **Unknown column 'i3' in 'on clause'** error because **i3** is a column in **t3**, which is not an operand of the **ON** clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- **JOIN** has higher precedence than the comma operator (**,**), so the join expression **t1, t2 JOIN t3** is interpreted as **(t1, (t2 JOIN t3))**, not as **((t1, t2) JOIN t3)**. This affects statements that use an **ON** clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The `JOIN` takes precedence over the comma operator, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

- Avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The same precedence interpretation also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins, whereas the standard disallows that.

### 13.2.9.3 UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` is used to combine the result from multiple `SELECT` statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all of the `SELECT` statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a             |
| bbbbbbbbbb    |
+-----+
```

The `SELECT` statements are normal select statements, but with the following restrictions:

- Only the last `SELECT` statement can use `INTO OUTFILE`. (However, the entire `UNION` result is written to the file.)
- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

However, use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, colla;
```

Use of an additional column also enables you to determine which [SELECT](#) each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

## 13.2.10 Subquery Syntax

A subquery is a [SELECT](#) statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, [SELECT \\* FROM t1 ...](#) is the *outer query* (or *outer statement*), and [\(SELECT column1 FROM t2\)](#) is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
   WHERE NOT EXISTS
    (SELECT * FROM t3
     WHERE ROW(5*t2.s1,77)=
      (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
       (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary [SELECT](#) can contain: [DISTINCT](#), [GROUP BY](#), [ORDER BY](#), [LIMIT](#), joins, index hints, [UNION](#) constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: [SELECT](#), [INSERT](#), [UPDATE](#), [DELETE](#), [SET](#), or [DO](#).

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as [DELETE](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and (because subqueries can be used in the [SET](#) clause) [LOAD DATA INFILE](#).

For information about how the optimizer handles subqueries, see [Section 8.2.2, “Subquery Optimization”](#). For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see [Section C.4, “Restrictions on Subqueries”](#).

### 13.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be [NULL](#), and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this [SELECT](#) returns a single value ('abcde') that has a data type of [CHAR](#), a length of 5, a character set and collation equal to the defaults in effect at [CREATE TABLE](#) time, and an indication that the value in the column can be [NULL](#). Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is [NULL](#). For the subquery just shown, if [t1](#) were empty, the result would be [NULL](#) even though [s2](#) is [NOT NULL](#).

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, [LIMIT](#) requires literal integer arguments, and [LOAD DATA INFILE](#) requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct ([SELECT column1 FROM t1](#)), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a [SELECT](#):

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is [2](#) because there is a row in [t2](#) containing a column [s1](#) that has a value of [2](#).

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table *t1* for which the *column1* value is equal to a maximum value in table *t2*:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table *t1* containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 13.2.10.5, “Row Subqueries”](#).

### 13.2.10.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> !=
```

The *ANY* keyword, which must follow a comparison operator, means “return *TRUE* if the comparison is *TRUE* for *ANY* of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table *t1* containing (10). The expression is *TRUE* if table *t2* contains (21,14,7) because there is a value 7 in *t2* that is less than 10. The expression is *FALSE* if table *t2* contains (20,10), or if table *t2* is empty. The expression is *unknown* (that is, *NULL*) if table *t2* contains (NULL,NULL,NULL).

When used with a subquery, the word **IN** is an alias for **= ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

**IN** and **= ANY** are not synonyms when used with an expression list. **IN** can take an expression list, but **= ANY** cannot. See [Section 12.3.2, “Comparison Functions and Operators”](#).

**NOT IN** is not an alias for **<> ANY**, but for **<> ALL**. See [Section 13.2.10.4, “Subqueries with ALL”](#).

The word **SOME** is an alias for **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word **SOME** is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using **<> SOME** instead helps ensure that everyone understands the true meaning of the query.

### 13.2.10.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ALL** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing **(10)**. The expression is **TRUE** if table **t2** contains **(-5, 0, +5)** because **10** is greater than all three values in **t2**. The expression is **FALSE** if table **t2** contains **(12, 6, NULL, -100)** because there is a single value **12** in table **t2** that is greater than **10**. The expression is *unknown* (that is, **NULL**) if table **t2** contains **(0, NULL, 1)**.

Finally, the expression is **TRUE** if table **t2** is empty. So, the following expression is **TRUE** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

**NOT IN** is an alias for **<> ALL**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

### 13.2.10.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1
WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table `t2` contains a single row with `id = 10`, the subquery returns a single row. If this row has `col3` and `col4` values equal to the `col1` and `col2` values of any rows in `t1`, the `WHERE` expression is `TRUE` and each query returns those `t1` rows. If the `t2` row `col3` and `col4` values are not equal the `col1` and `col2` values of any `t1` row, the expression is `FALSE` and the query returns an empty result set. The expression is *unknown* (that is, `NULL`) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see [Section 12.3.2, “Comparison Functions and Operators”](#).

The expressions `(1,2)` and `ROW(1,2)` are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
      (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see [Section 8.2.1.15, “Row Constructor Expression Optimization”](#)

### 13.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is `x` `TRUE` for all `y`?”

### 13.2.10.7 Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
                    WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5, 6)` is not equal to `(5, 7)`), so the expression as a whole is `FALSE`.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
  WHERE x.column1 = (SELECT column1 FROM t2 AS x
    WHERE x.column1 = (SELECT column1 FROM t3
      WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

### 13.2.10.8 Derived Tables (Subqueries in the FROM Clause)

A derived table is a subquery in a `SELECT` statement `FROM` clause:

```
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The `[AS] tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the `subquery` select list must have unique names.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
  FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
 WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
  FROM (SELECT SUM(column1) AS sum_column1
```

```
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

Derived tables can return a scalar, column, row, or table.

Derived tables cannot be correlated subqueries, or contain outer references or references to other tables of the same `SELECT`.

Subqueries in the `FROM` clause are executed even for the `EXPLAIN` statement (that is, derived temporary tables are materialized). This occurs because upper-level queries need information about all tables during the optimization phase, and the table represented by a subquery in the `FROM` clause is unavailable unless the subquery is executed.

It is possible under certain circumstances that using `EXPLAIN SELECT` will modify table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: NULL
         type: NULL
possible_keys: NULL
         key: NULL
        key_len: NULL
         ref: NULL
         rows: NULL
      Extra: No tables used
1 row in set (0.01 sec)

mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
***** 1. row *****
      id: 1
    select_type: PRIMARY
        table: NULL
         type: NULL
```

```

possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1249 | Select 2 was reduced during optimization |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)

```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well:

```

mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
***** 1. row *****
      id: 1
    select_type: PRIMARY
      table: <derived2>
      type: system
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  Extra:
***** 2. row *****
      id: 1
    select_type: PRIMARY
      table: a1
      type: ALL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  Extra:
***** 3. row *****
      id: 2
    select_type: DERIVED
      table: NULL
      type: NULL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  Extra: No tables used
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+
| c1   |
+-----+
|    5 |
+-----+
1 row in set (0.00 sec)

```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

### 13.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that MySQL does not support statements of the following form:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See [Section 13.2.10.5, “Row Subqueries”](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
```

```
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an [UPDATE](#) statement because subqueries are legal in [UPDATE](#) and [DELETE](#) statements as well as in [SELECT](#) statements. However, you cannot use the same table (in this case, table [t1](#)) for both the subquery [FROM](#) clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

### 13.2.10.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also [Section 8.2.2, “Subquery Optimization”](#).

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
  SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 13.2.10.11, “Rewriting Subqueries as Joins”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1
WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1
WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 12.14, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (uncorrelated_subquery)
```

For example, this [WHERE](#) clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also [MySQL Internals: How MySQL Transforms Subqueries](#).

### 13.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the [IN\( \)](#) construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);  
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*  
FROM table1 LEFT JOIN table2 ON table1.id=table2.id  
WHERE table2.id IS NULL;
```

A [LEFT \[OUTER\] JOIN](#) can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table [DELETE](#) statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table [UPDATE](#) statements are also supported. See [Section 13.2.2, “DELETE Syntax”](#), and [Section 13.2.11, “UPDATE Syntax”](#).

## 13.2.11 UPDATE Syntax

[UPDATE](#) is a DML statement that modifies rows in a table.

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference  
SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
```

```
[WHERE where_condition]  
[ORDER BY ...]  
[LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references  
  SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...  
  [WHERE where_condition]
```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in *table\_references* that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, `ORDER BY` and `LIMIT` cannot be used.

*where\_condition* is an expression that evaluates to true for each row to be updated. For expression syntax, see [Section 9.5, “Expression Syntax”](#).

*table\_references* and *where\_condition* are specified as described in [Section 13.2.9, “SELECT Syntax”](#).

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` modifier, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- With the `IGNORE` modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

In MySQL 5.5.18 and later, `UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439) See [Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#), for more information.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table [UPDATE](#) assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared [NOT NULL](#) by setting to [NULL](#), an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string ( ' ' ) for string types, and the “zero” value for date and time types. See [Section 11.6, “Data Type Default Values”](#).

[UPDATE](#) returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the [UPDATE](#).

You can use [LIMIT row\\_count](#) to restrict the scope of the [UPDATE](#). A [LIMIT](#) clause is a rows-matched restriction. The statement stops as soon as it has found [row\\_count](#) rows that satisfy the [WHERE](#) clause, whether or not they actually were changed.

If an [UPDATE](#) statement includes an [ORDER BY](#) clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an [ORDER BY](#) clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform [UPDATE](#) operations covering multiple tables. However, you cannot use [ORDER BY](#) or [LIMIT](#) with a multiple-table [UPDATE](#). The [table\\_references](#) clause lists the tables involved in the join. Its syntax is described in [Section 13.2.9.2, “JOIN Syntax”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table [UPDATE](#) statements can use any type of join permitted in [SELECT](#) statements, such as [LEFT JOIN](#).

If you use a multiple-table [UPDATE](#) statement involving [InnoDB](#) tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the [ON UPDATE](#) capabilities that [InnoDB](#) provides to cause the other tables to be modified accordingly. See [Section 14.11.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

You cannot update a table and select from the same table in a subquery.

Index hints (see [Section 8.9.3, “Index Hints”](#)) are accepted for [UPDATE](#) statements, but are ignored prior to MySQL 5.5.6.

An [UPDATE](#) on a partitioned table using a storage engine such as [MyISAM](#) that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as [InnoDB](#) that

employ row-level locking. This issue is resolved in MySQL 5.6. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#), for more information.

## 13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 13.3.7, “XA Transactions”](#).

### 13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION [WITH CONSISTENT SNAPSHOT]
BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of [transactions](#):

- `START TRANSACTION` or `BEGIN` start a new transaction.
- `COMMIT` commits the current transaction, making its changes permanent.
- `ROLLBACK` rolls back the current transaction, canceling its changes.
- `SET autocommit` disables or enables the default autocommit mode for the current session.

By default, MySQL runs with [autocommit](#) mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk to make it permanent. The change cannot be rolled back.

To disable autocommit mode implicitly for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

You can also begin a transaction like this:

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The `WITH CONSISTENT SNAPSHOT` option starts a [consistent read](#) for storage engines that are capable of it. This applies only to [InnoDB](#). The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any [InnoDB](#) table. See [Section 14.8.2.3, “Consistent Nonlocking Reads”](#). The `WITH CONSISTENT SNAPSHOT` option does not change the current transaction [isolation level](#), so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is `REPEATABLE READ`. For all other isolation levels, the `WITH CONSISTENT SNAPSHOT` clause is ignored. As of MySQL 5.5.34, a warning is generated when the `WITH CONSISTENT SNAPSHOT` is ignored.

**Important**

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See [Chapter 23, Connectors and APIs](#), or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for `InnoDB` or `NDBCLUSTER`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at [Section 5.1.5, “Server System Variables”](#).

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax and is the recommended way to start an ad-hoc transaction.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

**Note**

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.1.5, “Server System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits,

another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)

- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See [Section 5.4.4, “The Binary Log”](#).

You can change the isolation level for transactions with the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

**Note**

In MySQL 5.5, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

## 13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

## 13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement. As of MySQL 5.5.3, most of these statements also cause an implicit commit after executing; for additional details, see the end of this section.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER SERVER`, `ALTER TABLE`, `ALTER VIEW`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE SERVER`, `CREATE TABLE`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP DATABASE`, `DROP EVENT`, `DROP INDEX`, `DROP PROCEDURE`, `DROP SERVER`, `DROP TABLE`, `DROP TRIGGER`, `DROP VIEW`, `RENAME TABLE`, `TRUNCATE TABLE`.

`ALTER FUNCTION`, `CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with user-defined functions. (`ALTER FUNCTION` can only be used with stored functions.)

`CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

`CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.) This is to prevent an issue during replication where the table could be created on the master after a rollback, but fail to be recorded in the binary log, and therefore not replicated to the slave. For more information, see Bug #22865.

- **Statements that implicitly use or modify tables in the `mysql` database.** `CREATE USER`, `DROP USER`, `GRANT`, `RENAME USER`, `REVOKE`, `SET PASSWORD`.
- **Transaction-control and locking statements.** `BEGIN`, `LOCK TABLES`, `SET autocommit = 1` (if the value is not already 1), `START TRANSACTION`, `UNLOCK TABLES`.

`UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES` to acquire nontransactional table locks. A commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

- **Data loading statements.** `LOAD DATA INFILE`. `LOAD DATA INFILE` causes an implicit commit only for tables using the `NDB` storage engine. For more information, see Bug #11151.
- **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`.

As of MySQL 5.5.3, most statements that previously caused an implicit commit before executing also do so after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. The following list provides additional details pertaining to this change:

- The `CREATE TABLE` variants (`CREATE TABLE` for `InnoDB` tables and `CREATE TABLE ... SELECT`) that previously were special cases no longer are so because `CREATE TABLE` uniformly causes an implicit commit before and after executing.
- The `FLUSH` and `RESET` statements cause an implicit commit.

- Transaction-control and locking statements behave as before. If an implicit commit occurs before execution, another does not occur after.

### 13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 13.3.5 LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
  tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...

lock_type:
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE

UNLOCK TABLES
```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail later in this section.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [Section 13.3.5.2, “LOCK TABLES and Triggers”](#).

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See [Section 13.7.6.3, “FLUSH Syntax”](#). (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock only protects against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

For information about other conditions on the use of `LOCK TABLES` and statements that cannot be used while `LOCK TABLES` is in effect, see [Section 13.3.5.3, “Table-Locking Restrictions and Conditions”](#)

### Rules for Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement. The following lock types are available:

`READ [LOCAL]` lock:

- The session that holds the lock can read the table (but not write it).
- Multiple sessions can acquire a `READ` lock for the table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.
- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See [Section 8.11.3, “Concurrent Inserts”](#).) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:

- The session that holds the lock can read and write the table.
- Only the session that holds the lock can access the table. No other session can access it until the lock is released.
- Lock requests for the table by other sessions block while the `WRITE` lock is held.

- The `LOW_PRIORITY` modifier has no effect as of MySQL 5.5.3. Before 5.5.3, it affects lock scheduling if the `WRITE` lock request must wait, as described later.

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+-----+
| COUNT(*) |
+-----+
|          3 |
+-----+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it. Before MySQL 5.5.3, the `LOW_PRIORITY` modifier can be given to affect locking behavior as follows (as of 5.5.3, it has no effect): A request for a `LOW_PRIORITY WRITE` lock permits subsequent `READ` lock requests by other sessions to be satisfied first if they occur while the `LOW_PRIORITY WRITE` request is waiting. You should use `LOW_PRIORITY WRITE` locks only if you

are sure that eventually there will be a time when no sessions have a [READ](#) lock. For [InnoDB](#) tables in transactional mode (`autocommit = 0`), a waiting [LOW\\_PRIORITY WRITE](#) lock acts like a regular [WRITE](#) lock and causes subsequent [READ](#) lock requests to wait.

[LOCK TABLES](#) acquires locks as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the session gets all locks.

This policy ensures that table locking is deadlock free. There are, however, other things you need to be aware of about this policy: If you are using a [LOW\\_PRIORITY WRITE](#) lock for a table, it means only that MySQL waits for this particular lock until there are no other sessions that want a [READ](#) lock. When the session has gotten the [WRITE](#) lock and is waiting to get the lock for the next table in the lock table list, all other sessions wait for the [WRITE](#) lock to be released. If this becomes a serious problem with your application, you should consider converting some of your tables to transaction-safe tables.

**Note**

[LOCK TABLES](#) or [UNLOCK TABLES](#), when applied to a partitioned table, always locks or unlocks the entire table. See [Section 19.5.4, “Partitioning and Table-Level Locking”](#).

**Rules for Lock Release**

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with [UNLOCK TABLES](#).
- If a session issues a [LOCK TABLES](#) statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with [START TRANSACTION](#)), an implicit [UNLOCK TABLES](#) is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see [Section 13.3.5.1, “Interaction of Table Locking and Transactions”](#).)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with `autocommit` enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See [Section 23.8.16, “Controlling Automatic Reconnection Behavior”](#).

**Note**

If you use [ALTER TABLE](#) on a locked table, it may become unlocked. For example, if you attempt a second [ALTER TABLE](#) operation, the result may be an error [Table](#)

`'tbl_name'` was not locked with `LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

### 13.3.5.1 Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.
- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See [Section 13.7.6.3, “FLUSH Syntax”](#).
- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).
- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, `InnoDB` internally takes its own table lock, and MySQL takes its own table lock. `InnoDB` releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then `InnoDB` releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. `InnoDB` does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

### 13.3.5.2 LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken at the same time as those acquired explicitly with the `LOCK TABLES` statement.

- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.
- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for writing because it might be updated within the trigger.

### 13.3.5.3 Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See [Section 13.7.6.4, “KILL Syntax”](#).

You should *not* lock any tables that you are using with `INSERT DELAYED`. An `INSERT DELAYED` in this case results in an error because the insert must be handled by a separate thread, not by the session which holds the lock.

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The following statements are prohibited while a `LOCK TABLES` statement is in effect:

- As of MySQL 5.5.3, `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored procedures and functions.
- As of MySQL 5.5.8, DDL statements on events

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the

time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a [WRITE](#) lock on any of those tables with a [LOCK TABLES](#) statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single [UPDATE](#) statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of [MyISAM](#) tables, it is much faster to lock the tables you are going to use. Locking [MyISAM](#) tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until [UNLOCK TABLES](#) is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a [READ](#)-locked table (including the one holding the lock) and no session can access a [WRITE](#)-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use [LOCK TABLES](#) if you want to ensure that no other session modifies the tables between a [SELECT](#) and an [UPDATE](#). The example shown here requires [LOCK TABLES](#) to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without [LOCK TABLES](#), it is possible that another session might insert a new row in the [trans](#) table between execution of the [SELECT](#) and [UPDATE](#) statements.

You can avoid using [LOCK TABLES](#) in many cases by using relative updates ([UPDATE customer SET value=value+new\\_value](#)) or the [LAST\\_INSERT\\_ID\(\)](#) function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions [GET\\_LOCK\(\)](#) and [RELEASE\\_LOCK\(\)](#). These locks are saved in a hash table in the server and implemented with [pthread\\_mutex\\_lock\(\)](#) and [pthread\\_mutex\\_unlock\(\)](#) for high speed. See [Section 12.17](#), “Miscellaneous Functions”.

See [Section 8.11.1](#), “Internal Locking Methods”, for more information on locking policy.

## 13.3.6 SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL
{
    REPEATABLE READ
```

```

| READ COMMITTED
| READ UNCOMMITTED
| SERIALIZABLE
}

```

This statement sets the transaction isolation level, used for operations on [InnoDB](#) tables.

## Scope of the Isolation Level

You can set the isolation level globally, for the current session, or for the next transaction:

- With the [GLOBAL](#) keyword, the statement sets the default transaction level globally for all subsequent sessions. Existing sessions are unaffected.
- With the [SESSION](#) keyword, the statement sets the default transaction level for all subsequent transactions performed within the current session.
- Without any [SESSION](#) or [GLOBAL](#) keyword, the statement sets the isolation level for the next (not started) transaction performed within the current session. Subsequent transactions revert to using the [SESSION](#) isolation level.

A change to the global default isolation level requires the [SUPER](#) privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction.

[SET TRANSACTION ISOLATION LEVEL](#) without [GLOBAL](#) or [SESSION](#) is not permitted while there is an active transaction:

```

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction isolation level can't be changed
while a transaction is in progress

```

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option to `mysqld` on the command line or in an option file. Values of *level* for this option use dashes rather than spaces, so the permissible values are [READ-UNCOMMITTED](#), [READ-COMMITTED](#), [REPEATABLE-READ](#), or [SERIALIZABLE](#). For example, to set the default isolation level to [REPEATABLE-READ](#), use these lines in the `[mysqld]` section of an option file:

```

[mysqld]
transaction-isolation = REPEATABLE-READ

```

It is possible to check or set the global and session transaction isolation levels at runtime by using the `tx_isolation` system variable:

```

SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
SET GLOBAL tx_isolation='REPEATABLE-READ';
SET SESSION tx_isolation='SERIALIZABLE';

```

## Transaction Isolation Levels

For information about transaction isolation levels, see [Section 14.8.2.1, “Transaction Isolation Levels”](#).

### 13.3.7 XA Transactions

Support for XA transactions is available for the [InnoDB](#) storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This

document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section C.6, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (by means of a class interface that handles the XA SQL statement interface for you).

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, [SERIALIZABLE](#) may be preferred if your applications are sensitive to read phenomena. [REPEATABLE READ](#) may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component

reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

### 13.3.7.1 XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER
```

For **XA START**, the **JOIN** and **RESUME** clauses are not supported.

For **XA END** the **SUSPEND [FOR MIGRATE]** clause is not supported.

Each XA statement begins with the **XA** keyword, and most of them require an *xid* value. An *xid* is an XA transaction identifier. It indicates which transaction the statement applies to. *xid* values are supplied by the client, or generated by the MySQL server. An *xid* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

*gtrid* is a global transaction identifier, *bqual* is a branch qualifier, and *formatID* is a number that identifies the format used by the *gtrid* and *bqual* values. As indicated by the syntax, *bqual* and *formatID* are optional. The default *bqual* value is '' if not given. The default *formatID* value is 1 if not given.

*gtrid* and *bqual* must be string literals, each up to 64 bytes (not characters) long. *gtrid* and *bqual* can be specified in several ways. You can use a quoted string ('ab'), hex string (x'6162', 0x6162), or bit value (b'nnnn').

*formatID* is an unsigned integer.

The *gtrid* and *bqual* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *gtrid* and *bqual* as hex strings.

*xid* values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *xid* values in a list of values returned by the `XA RECOVER` statement.

For `XA START xid` starts an XA transaction with the given *xid* value. Each XA transaction must have a unique *xid* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *gtrid* and *bqual* values. All following XA statements for the XA transaction must be specified using the same *xid* value as that given in the `XA START` statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See [Section 13.3.7.2, "XA Transaction States"](#).) The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` output rows look like this (for an example *xid* value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          7 |          3 |          3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- *formatID* is the *formatID* part of the transaction *xid*
- *gtrid\_length* is the length in bytes of the *gtrid* part of the *xid*
- *bqual\_length* is the length in bytes of the *bqual* part of the *xid*
- *data* is the concatenation of the *gtrid* and *bqual* parts of the *xid*

### 13.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:

- `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's `xid` value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
  - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The `xid` value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

## 13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. One group of statements controls master servers, the other controls slave servers.

### 13.4.1 SQL Statements for Controlling Master Servers

This section discusses statements for managing master replication servers. [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

In addition to the statements described here, the following `SHOW` statements are used with master servers in replication. For information about these statements, see [Section 13.7.5, “SHOW Syntax”](#).

- `SHOW BINARY LOGS`

- `SHOW BINLOG EVENTS`
- `SHOW MASTER STATUS`
- `SHOW SLAVE HOSTS`

### 13.4.1.1 PURGE BINARY LOGS Syntax

```
PURGE { BINARY | MASTER } LOGS
      { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see [Section 5.4.4, “The Binary Log”](#)).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2008-04-02 22:46:26';
```

The `BEFORE` variant's *datetime\_expr* argument should evaluate to a `DATETIME` value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

This statement is safe to run while slaves are replicating. You need not stop them. If you have an active slave that currently is reading one of the log files you are trying to delete, this statement does nothing and fails with an error. However, if a slave is not connected and you happen to purge one of the log files it has yet to read, the slave will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the slaves. This is the target file. If all the slaves are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.5, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

### 13.4.1.2 RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. This statement is intended to be used only when the master is started for the first time.

#### Important

The effects of `RESET MASTER` differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes *all* binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replication slaves are running.

See also [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

`RESET MASTER` can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see [Section 17.1.1, “How to Set Up Replication”](#)).
2. Execute a few test queries on the master.
3. Check that the queries were replicated to the slave.
4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the slave, then verify that any unwanted data no longer exists on the slave.
5. Issue `RESET MASTER` on the master to clean up the test queries.

After verifying the setup and getting rid of any unwanted and log files generated by testing, you can start the slave and begin replicating.

### 13.4.1.3 SET sql\_log\_bin Syntax

```
SET sql_log_bin = {0|1}
```

The `sql_log_bin` variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` privilege to set this variable. Set this variable to 0 for a session to temporarily disable binary logging while making changes to the master which you do not want to replicate to the slave.

As of MySQL 5.5, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

#### Warning

Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are *still* being recorded to the binary log and therefore

replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

Beginning with MySQL 5.5.5, it is no longer possible to set `@@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

## 13.4.2 SQL Statements for Controlling Slave Servers

This section discusses statements for managing slave replication servers. [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replication slaves. For information about these statements, see [Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”](#), and [Section 13.7.5.33, “SHOW RELAYLOG EVENTS Syntax”](#).

### 13.4.2.1 CHANGE MASTER TO Syntax

```
CHANGE MASTER TO option [, option] ...

option:
  MASTER_BIND = 'interface_name'
  MASTER_HOST = 'host_name'
  MASTER_USER = 'user_name'
  MASTER_PASSWORD = 'password'
  MASTER_PORT = port_num
  MASTER_CONNECT_RETRY = interval
  MASTER_HEARTBEAT_PERIOD = interval
  MASTER_LOG_FILE = 'master_log_name'
  MASTER_LOG_POS = master_log_pos
  RELAY_LOG_FILE = 'relay_log_name'
  RELAY_LOG_POS = relay_log_pos
  MASTER_SSL = {0|1}
  MASTER_SSL_CA = 'ca_file_name'
  MASTER_SSL_CAPATH = 'ca_directory_name'
  MASTER_SSL_CERT = 'cert_file_name'
  MASTER_SSL_KEY = 'key_file_name'
  MASTER_SSL_CIPHER = 'cipher_list'
  MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
  IGNORE_SERVER_IDS = (server_id_list)

server_id_list:
  [server_id [, server_id] ... ]
```

`CHANGE MASTER TO` changes the parameters that the slave server uses for connecting to the master server, for reading the master binary log, and reading the slave relay log. It also updates the contents of the `master.info` and `relay-log.info` files. `CHANGE MASTER TO` requires the `SUPER` privilege.

To use `CHANGE MASTER TO`, the slave replication threads must be stopped (use `STOP SLAVE` if necessary).

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

`MASTER_HOST`, `MASTER_USER`, `MASTER_PASSWORD`, and `MASTER_PORT` provide information to the slave about how to connect to its master:

- `MASTER_HOST` and `MASTER_PORT` are the host name (or IP address) of the master host and its TCP/IP port.

**Note**

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify the `MASTER_HOST` or `MASTER_PORT` option, the slave assumes that the master server is different from before (even if the option value is the same as its current value.) In this case, the old values for the master binary log file name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE= ''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST= ''` (that is, setting its value explicitly to an empty string) is *not* the same as not setting `MASTER_HOST` at all. Beginning with MySQL 5.5, trying to set `MASTER_HOST` to an empty string fails with an error. Previously, setting `MASTER_HOST` to an empty string caused `START SLAVE` subsequently to fail. (Bug #28796)

- `MASTER_USER` and `MASTER_PASSWORD` are the user name and password of the account to use for connecting to the master.

In MySQL 5.5.20 and later, `MASTER_USER` cannot be made empty; setting `MASTER_USER = ''` or leaving it unset when setting a value for `MASTER_PASSWORD` causes an error (Bug #13427949).

The password used for a MySQL Replication slave account in a `CHANGE MASTER TO` statement is limited to 32 characters in length; if the password is longer, the statement succeeds, but any excess characters are silently truncated. This is an issue specific to MySQL Replication, which is fixed in MySQL 5.7. (Bug #11752299, Bug #43439)

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement.

The `MASTER_SSL_XXX` options provide information about using SSL for the connection. They correspond to the `--ssl-xxx` options described in [Section 6.4.5, “Command Options for Secure Connections”](#), and [Section 17.3.7, “Setting Up Replication to Use Secure Connections”](#). These options can be changed even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored if the slave does not have SSL support enabled.

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60. The *number* of reconnection attempts is limited by the `--master-retry-count` server option; for more information, see [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).

The `MASTER_BIND` option is available in MySQL NDB Cluster 7.2 and later, but is not supported in mainline MySQL 5.5.

`MASTER_BIND` is for use on replication slaves having multiple network interfaces, and determines which of the slave's network interfaces is chosen for connecting to the master.

`MASTER_HEARTBEAT_PERIOD` sets the interval in seconds between replication heartbeats. Whenever the master's binary log is updated with an event, the waiting period for the next heartbeat is reset. *interval* is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binary log file for a period longer than *interval*.

Setting `interval` to 0 disables heartbeats altogether. The default value for `interval` is equal to the value of `slave_net_timeout` divided by 2.

Setting `@@global.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the slave SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

`CHANGE MASTER TO` *deletes all relay log files* and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay log files are kept; the `relay_log_purge` global variable is set silently to 0.

Prior to MySQL 5.5, `RELAY_LOG_FILE` required an absolute path. In MySQL 5.5, the path can be relative, in which case the path is assumed to be relative to the slave's data directory. (Bug #12190)

`IGNORE_SERVER_IDS` was added in MySQL 5.5. This option takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its master instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

When a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ( );
```

`RESET SLAVE ALL` has no effect on the server ID list. This issue is fixed in MySQL 5.7. (Bug #18816897)

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

Also beginning with MySQL 5.5, the `master.info` file and the output of `SHOW SLAVE STATUS` are extended to provide the list of servers that are currently ignored. For more information, see [Section 17.2.2.2, “Slave Status Logs”](#), and [Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”](#).

Beginning with MySQL 5.5.5, invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the slave's state prior to execution.

`CHANGE MASTER TO` is useful for setting up a slave when you have the snapshot of the master and have recorded the master binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the slave to synchronize it with the master, you can run `CHANGE MASTER TO`

`MASTER_LOG_FILE='log_name'`, `MASTER_LOG_POS=log_pos` on the slave to specify the coordinates at which the slave should begin reading the master binary log.

The following example changes the master server the slave uses and establishes the master binary log coordinates from which the slave begins reading. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay log files that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a nonreplication setup with a standalone, nonslave server for recovery following a crash. Suppose that your server has crashed and you have restored it from a backup. You want to replay the server's own binary log files (not relay log files, but regular binary log files), named (for example) `myhost-bin.*`. First, make a backup copy of these binary log files in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary log. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option. Instead, use the `--replicate-same-server-id`, `--relay-log=myhost-bin` (to make the server believe that these regular binary log files are relay log files) and `--skip-slave-start` options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary log files, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, delete the `master.info` and `relay-log.info` files, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

The following table shows the maximum permissible length for the string-valued options.

| Option                       | Maximum Length |
|------------------------------|----------------|
| <code>MASTER_HOST</code>     | 60             |
| <code>MASTER_USER</code>     | 16             |
| <code>MASTER_PASSWORD</code> | 32             |
| <code>MASTER_LOG_FILE</code> | 255            |

| Option                         | Maximum Length |
|--------------------------------|----------------|
| <code>RELAY_LOG_FILE</code>    | 255            |
| <code>MASTER_SSL_CA</code>     | 255            |
| <code>MASTER_SSL_CAPATH</code> | 255            |
| <code>MASTER_SSL_CERT</code>   | 255            |
| <code>MASTER_SSL_KEY</code>    | 255            |
| <code>MASTER_SSL_CIPHER</code> | 511            |

### 13.4.2.2 MASTER\_POS\_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 12.17, “Miscellaneous Functions”](#), for a full description.

### 13.4.2.3 RESET SLAVE Syntax

```
RESET SLAVE [ALL]
```

`RESET SLAVE` makes the slave forget its replication position in the master's binary log. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay log files, and starts a new relay log file. To use `RESET SLAVE`, the slave replication threads must be stopped (use `STOP SLAVE` if necessary).

#### Note

All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

In MySQL 5.5 (unlike the case in MySQL 5.1 and earlier), `RESET SLAVE` does not change any replication connection parameters such as master host, master port, master user, or master password, which are retained in memory. This means that `START SLAVE` can be issued without requiring a `CHANGE MASTER TO` statement following `RESET SLAVE`.

Connection parameters are reset if the slave `mysqld` is shut down following `RESET SLAVE`. In MySQL 5.5.16 and later, you can instead use `RESET SLAVE ALL` to reset these connection parameters (Bug #11809016).

`RESET SLAVE ALL` does not clear the `IGNORE_SERVER_IDS` list set by `CHANGE MASTER TO`. This issue is fixed in MySQL 5.7. (Bug #18816897)

If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

#### Note

When used on an NDB Cluster replication slave SQL node, `RESET SLAVE` clears the `mysql.ndb_apply_status` table. You should keep in mind when using this statement that `ndb_apply_status` uses the NDB storage engine and so is shared by all SQL nodes attached to the slave cluster.

### 13.4.2.4 SET GLOBAL sql\_slave\_skip\_counter Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

#### Note

A single transaction can contain changes to both transactional and nontransactional tables.

When you use `SET GLOBAL sql_slave_skip_counter` to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

### 13.4.2.5 START SLAVE Syntax

```
START SLAVE [thread_types]

START SLAVE [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos

START SLAVE [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos

thread_types:
  [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD
```

`START SLAVE` with no *thread\_type* options starts both of the slave threads. The I/O thread reads events from the master server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the `SUPER` privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

`START SLAVE` sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the I/O thread is running *and connected*). For more information, see [Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”](#), and [Section 17.1.4.1, “Checking Replication Status”](#).

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start.

An `UNTIL` clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary log or in the slave relay log. When the SQL thread reaches that point, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued.

For an `UNTIL` clause, you must specify both a log file name and position. Do not mix master and relay log options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master binary log or slave relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. This usage is still accepted in MySQL 5.5 for backward compatibility, but is deprecated and is removed in MySQL 5.6.

### 13.4.2.6 STOP SLAVE Syntax

```
STOP SLAVE [thread_types]  
  
thread_types:  
    [thread_type [, thread_type] ... ]  
  
thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. `STOP SLAVE` requires the `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the slave before stopping the slave server (see [Section 5.1.12, “The Server Shutdown Process”](#), for more information).

*When using the row-based logging format:* You should execute `STOP SLAVE` on the slave prior to shutting down the slave server if you are replicating any tables that use a nontransactional storage engine (see the *Note* later in this section). In MySQL 5.5.9 and later, you can also use `STOP SLAVE SQL_THREAD` for this purpose.

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

#### Note

In MySQL 5.5, `STOP SLAVE` waits until the current replication event group affecting one or more nontransactional tables has finished executing (if there is any such replication group), or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. (Bug #319, Bug #38205)

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE STOP`. This usage is still accepted in MySQL 5.5 for backward compatibility, but is deprecated and is removed in MySQL 5.6.

## 13.5 Prepared SQL Statement Syntax

MySQL 5.5 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/Net. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 23.8.8, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysql_i` extension, available in PHP 5.0 and later.

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that enables you to send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You want to test how prepared statements work in your application before coding it.
- An application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see [Section 13.5.1, “PREPARE Syntax”](#)).
- `EXECUTE` executes a prepared statement (see [Section 13.5.2, “EXECUTE Syntax”](#)).
- `DEALLOCATE PREPARE` releases a prepared statement (see [Section 13.5.3, “DEALLOCATE PREPARE Syntax”](#)).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
```

```
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);

mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+----+
| a  |
+----+
|  4 |
|  8 |
| 11 |
| 32 |
| 80 |
+----+

mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

The following SQL statements can be used as prepared statements:

```
ALTER TABLE
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
```

```

COMMIT
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE | QUERY CACHE}
REVOKE
SELECT
SET
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE

```

Other statements are not supported in MySQL 5.5.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in [Section C.1, “Restrictions on Stored Programs”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 13.5.4, “Automatic Prepared Statement Repreparation”](#).

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 13.2.9, “SELECT Syntax”](#).

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 5.5. See [Section 13.2.1, “CALL Syntax”](#), for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Prepared statements use the query cache under the conditions described in [Section 8.10.3.1, “How the Query Cache Operates”](#).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see [Section 13.2.1, “CALL Syntax”](#).

## 13.5.1 PREPARE Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, *stmt\_name*, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

Statement names are not case sensitive. *preparable\_stmt* is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which has several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See [Section 23.8.16, “Controlling Automatic Reconnection Behavior”](#).
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see [Section 9.4, “User-Defined Variables”](#).

## 13.5.2 EXECUTE Syntax

```
EXECUTE stmt_name  
[USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must

supply a [USING](#) clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the [USING](#) clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

### 13.5.3 DEALLOCATE PREPARE Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with [PREPARE](#), use a [DEALLOCATE PREPARE](#) statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error.

For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

### 13.5.4 Automatic Prepared Statement Repreparation

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. This applies to prepared statements processed at the SQL level (using the [PREPARE](#) statement) and those processed using the binary client/server protocol (using the [mysql\\_stmt\\_prepare\(\)](#) C API function).

The server attempts reparation up to three times. An error occurs if all attempts fail.

Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Repreparation also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to [FLUSH TABLES](#).

Table content changes (for example, with [INSERT](#) or [UPDATE](#)) do not cause reparation, nor do [SELECT](#) statements.

Reparation is automatic, but to the extent that it occurs, diminishes prepared statement performance.

Reparation uses the default database and SQL mode that were in effect for the original preparation.

The [Com\\_stmt\\_reprepare](#) status variable tracks the number of re Preparations.

## 13.6 Compound-Statement Syntax

This section describes the syntax for the [BEGIN ... END](#) compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see [Chapter 20, \*Stored Programs and Views\*](#)).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

### 13.6.1 BEGIN ... END Compound-Statement Syntax

```
[begin_label:] BEGIN  
    [statement_list]  
END [end_label]
```

**BEGIN ... END** syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the **BEGIN** and **END** keywords. *statement\_list* represents a list of one or more statements, each terminated by a semicolon (;) statement delimiter. The *statement\_list* itself is optional, so the empty compound statement (**BEGIN END**) is legal.

**BEGIN ... END** blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. In the **mysql** command-line client, this is handled with the **delimiter** command. Changing the ; end-of-statement delimiter (for example, to //) permit ; to be used in a program body. For an example, see [Section 20.1, “Defining Stored Programs”](#).

A **BEGIN ... END** block can be labeled. See [Section 13.6.2, “Statement Label Syntax”](#).

The optional **[NOT] ATOMIC** clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the **BEGIN** clause used in this context has no effect on the current transaction.

**Note**

Within all stored programs, the parser treats **BEGIN [WORK]** as the beginning of a **BEGIN ... END** block. To begin a transaction in this context, use **START TRANSACTION** instead.

## 13.6.2 Statement Label Syntax

```
[begin_label:] BEGIN  
    [statement_list]  
END [end_label]  
  
[begin_label:] LOOP  
    statement_list  
END LOOP [end_label]  
  
[begin_label:] REPEAT  
    statement_list  
UNTIL search_condition  
END REPEAT [end_label]  
  
[begin_label:] WHILE search_condition DO  
    statement_list  
END WHILE [end_label]
```

Labels are permitted for **BEGIN ... END** blocks and for the **LOOP**, **REPEAT**, and **WHILE** statements. Label use for those statements follows these rules:

- *begin\_label* must be followed by a colon.
- *begin\_label* can be given without *end\_label*. If *end\_label* is present, it must be the same as *begin\_label*.
- *end\_label* cannot be given without *begin\_label*.
- Labels at the same nesting level must be distinct.

- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an [ITERATE](#) or [LEAVE](#) statement. The following example uses those statements to continue iterating or terminate the loop:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

### 13.6.3 DECLARE Syntax

The [DECLARE](#) statement is used to define various items local to a program:

- Local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).
- Conditions and handlers. See [Section 13.6.7, “Condition Handling”](#).
- Cursors. See [Section 13.6.6, “Cursors”](#).

[DECLARE](#) is permitted only inside a [BEGIN ... END](#) compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use [DECLARE](#) to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the [DECLARE](#) statement, as described in [Section 13.6.4.1, “Local Variable DECLARE Syntax”](#).
- Variables can be set directly with the [SET](#) statement. See [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).
- Results from queries can be retrieved into local variables using [SELECT ... INTO var\\_list](#) or by opening a cursor and using [FETCH ... INTO var\\_list](#). See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#), and [Section 13.6.6, “Cursors”](#).

For information about the scope of local variables and how MySQL resolves ambiguous names, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

#### 13.6.4.1 Local Variable DECLARE Syntax

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in [Section 9.2, “Schema Object Names”](#).

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

### 13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Syntax”](#).

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname, id INTO newname, xid
    FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
```

```

DECLARE newname VARCHAR(5);
DECLARE xid INT;
DECLARE done TINYINT DEFAULT 0;
DECLARE curl CURSOR FOR SELECT xname, id FROM table1;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

OPEN curl;
read_loop: LOOP
    FETCH FROM curl INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
END LOOP;
CLOSE curl;
END;

```

See also [Section C.1, “Restrictions on Stored Programs”](#).

## 13.6.5 Flow Control Statements

MySQL supports the [IF](#), [CASE](#), [ITERATE](#), [LEAVE LOOP](#), [WHILE](#), and [REPEAT](#) constructs for flow control within stored programs. It also supports [RETURN](#) within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an [IF](#) statement might contain a [WHILE](#) loop, which itself contains a [CASE](#) statement.

MySQL does not support [FOR](#) loops.

### 13.6.5.1 CASE Syntax

```

CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE

```

Or:

```

CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE

```

The [CASE](#) statement for stored programs implements a complex conditional construct.

#### Note

There is also a [CASE expression](#), which differs from the [CASE statement](#) described here. See [Section 12.4, “Control Flow Functions”](#). The [CASE](#) statement cannot have an [ELSE NULL](#) clause, and it is terminated with [END CASE](#) instead of [END](#).

For the first syntax, *case\_value* is an expression. This value is compared to the *when\_value* expression in each [WHEN](#) clause until one of them is equal. When an equal *when\_value* is found, the corresponding [THEN](#) clause *statement\_list* executes. If no *when\_value* is equal, the [ELSE](#) clause *statement\_list* executes, if there is one.

This syntax cannot be used to test for equality with [NULL](#) because [NULL = NULL](#) is false. See [Section 3.3.4.6, “Working with NULL Values”](#).

For the second syntax, each `WHEN` clause `search_condition` expression is evaluated until one is true, at which point its corresponding `THEN` clause `statement_list` executes. If no `search_condition` is equal, the `ELSE` clause `statement_list` executes, if there is one.

If no `when_value` or `search_condition` matches the value tested and the `CASE` statement contains no `ELSE` clause, a `Case not found for CASE statement` error results.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |

CREATE PROCEDURE p()
BEGIN
    DECLARE v INT DEFAULT 1;

    CASE v
        WHEN 2 THEN SELECT v;
        WHEN 3 THEN SELECT 0;
        ELSE
            BEGIN
                END;
            END CASE;
    END;
|
```

### 13.6.5.2 IF Syntax

```
IF search_condition THEN statement_list
    [ELSEIF search_condition THEN statement_list] ...
    [ELSE statement_list]
END IF
```

The `IF` statement for stored programs implements a basic conditional construct.

#### Note

There is also an `IF()` function, which differs from the `IF` statement described here. See [Section 12.4, “Control Flow Functions”](#). The `IF` statement can have `THEN`, `ELSE`, and `ELSEIF` clauses, and it is terminated with `END IF`.

If the `search_condition` evaluates to true, the corresponding `THEN` or `ELSEIF` clause `statement_list` executes. If no `search_condition` matches, the `ELSE` clause `statement_list` executes.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //
```

```
CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)

  BEGIN
    DECLARE s VARCHAR(20);

    IF n > m THEN SET s = '>';
    ELSEIF n = m THEN SET s = '=';
    ELSE SET s = '<';
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m);

    RETURN s;
  END //

DELIMITER ;
```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```
DELIMITER //

CREATE FUNCTION VerboseCompare (n INT, m INT)
  RETURNS VARCHAR(50)

  BEGIN
    DECLARE s VARCHAR(50);

    IF n = m THEN SET s = 'equals';
    ELSE
      IF n > m THEN SET s = 'greater';
      ELSE SET s = 'less';
      END IF;

    SET s = CONCAT('is ', s, ' than');
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m, '.');

    RETURN s;
  END //

DELIMITER ;
```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

### 13.6.5.3 ITERATE Syntax

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means “start the loop again.”

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

### 13.6.5.4 LEAVE Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, `LEAVE` exits the program.

`LEAVE` can be used within `BEGIN . . . END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

### 13.6.5.5 LOOP Syntax

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a `LEAVE` statement. Within a stored function, `RETURN` can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A `LOOP` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
CREATE PROCEDURE doitrate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN
            ITERATE label1;
        END IF;
        LEAVE label1;
    END LOOP label1;
    SET @x = p1;
END;
```

### 13.6.5.6 REPEAT Syntax

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the `search_condition` expression is true. Thus, a `REPEAT` always enters the loop at least once. `statement_list` consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter.

A `REPEAT` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
```

```

-> SET @x = 0;
-> REPEAT
->     SET @x = @x + 1;
-> UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)

```

### 13.6.5.7 RETURN Syntax

```
RETURN expr
```

The **RETURN** statement terminates execution of a stored function and returns the value *expr* to the function caller. There must be at least one **RETURN** statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The **LEAVE** statement can be used to exit a stored program of those types.

### 13.6.5.8 WHILE Syntax

```

[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]

```

The statement list within a **WHILE** statement is repeated as long as the *search\_condition* expression is true. *statement\_list* consists of one or more SQL statements, each terminated by a semicolon (;) statement delimiter.

A **WHILE** statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```

CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;

    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END;

```

## 13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()  
BEGIN  
  DECLARE done INT DEFAULT FALSE;  
  DECLARE a CHAR(16);  
  DECLARE b, c INT;  
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;  
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;  
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;  
  
  OPEN cur1;  
  OPEN cur2;  
  
  read_loop: LOOP  
    FETCH cur1 INTO a, b;  
    FETCH cur2 INTO c;  
    IF done THEN  
      LEAVE read_loop;  
    END IF;  
    IF b < c THEN  
      INSERT INTO test.t3 VALUES (a,b);  
    ELSE  
      INSERT INTO test.t3 VALUES (a,c);  
    END IF;  
  END LOOP;  
  
  CLOSE cur1;  
  CLOSE cur2;  
END;
```

### 13.6.6.1 Cursor CLOSE Syntax

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see [Section 13.6.6, “Cursors”](#).

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN . . . END` block in which it was declared.

### 13.6.6.2 Cursor DECLARE Syntax

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see [Section 13.6.6, “Cursors”](#).

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

### 13.6.6.3 Cursor FETCH Syntax

```
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see [Section 13.6.6, “Cursors”](#).

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

### 13.6.6.4 Cursor OPEN Syntax

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see [Section 13.6.6, “Cursors”](#).

## 13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

Another statement related to conditions is `GET DIAGNOSTICS`. The `GET DIAGNOSTICS` statement is not supported until MySQL 5.6.

Before MySQL 5.6.3, if a statement that generates a warning or error causes a condition handler to be invoked, the handler may not clear the diagnostic area. This might lead to the appearance that the handler was not invoked. The following discussion demonstrates the issue and provides a workaround.

Suppose that a table `t1` is empty. The following procedure selects from it, raising a No Data condition:

```
CREATE PROCEDURE p1()  
BEGIN
```

```

DECLARE a INT;
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
    SET @handler_invoked = 1;
END;
SELECT c1 INTO a FROM t1;
END;

```

As can be seen from the following sequence of statements, the condition is not cleared by handler invocation (otherwise, the `SHOW WARNINGS` output would be empty). But as can be seen by the value of `@handler_invoked`, the handler was indeed invoked (otherwise its value would be 0).

```

mysql> SET @handler_invoked = 0;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p1();
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1329 | No data - zero rows fetched, selected, or processed |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @handler_invoked;
+-----+
| @handler_invoked |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

```

To work around this issue, use a condition handler containing a statement that clears warnings:

```

CREATE PROCEDURE p1()
BEGIN
    DECLARE a INT;
    DECLARE CONTINUE HANDLER FOR NOT FOUND
    BEGIN
        SELECT 1 INTO @handler_invoked FROM (SELECT 1) AS t;
    END;
    SELECT c1 INTO a FROM t1;
END;

```

This works for `CONTINUE` and `EXIT` handlers.

This issue is resolved as of MySQL 5.6.3 and no workaround is needed.

### 13.6.7.1 DECLARE ... CONDITION Syntax

```

DECLARE condition_name CONDITION FOR condition_value

condition_value:
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value

```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#)).

Condition declarations must appear before cursor or handler declarations.

The *condition\_value* for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- *mysql\_error\_code*: An integer literal indicating a MySQL error code.

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- `SQLSTATE [VALUE] sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

### 13.6.7.2 DECLARE ... HANDLER Syntax

```
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action:
    CONTINUE
  | EXIT
  | UNDO

condition_value:
    mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
```

```
| condition_name
| SQLWARNING
| NOT FOUND
| SQLEXCEPTION
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified *statement* executes. *statement* can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#)).

Handler declarations must appear after variable or condition declarations.

The *handler\_action* value indicates what action the handler takes after execution of the handler statement:

- `CONTINUE`: Execution of the current program continues.
- `EXIT`: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- `UNDO`: Not supported.

The *condition\_value* for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- *mysql\_error\_code*: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- `SQLSTATE [VALUE]` *sqlstate\_value*: A 5-character string literal indicating an SQLSTATE value, such as '42S01' to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
BEGIN
    -- body of handler
END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

- *condition\_name*: A condition name previously specified with `DECLARE ... CONDITION`. A condition name can be associated with a MySQL error code or SQLSTATE value. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#).
- `SQLWARNING`: Shorthand for the class of SQLSTATE values that begin with '01'.

```
DECLARE CONTINUE HANDLER FOR SQLWARNING
BEGIN
    -- body of handler
END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a **NOT FOUND** condition.

```
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
    -- body of handler
END;
```

For another example, see [Section 13.6.6, “Cursors”](#). The **NOT FOUND** condition also occurs for **SELECT ... INTO var\_list** statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
    -- body of handler
END;
```

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For **SQLEXCEPTION** conditions, the stored program terminates at the statement that raised the condition, as if there were an **EXIT** handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For **SQLWARNING** conditions, the program continues executing, as if there were a **CONTINUE** handler.
- For **NOT FOUND** conditions, if the condition was raised normally, the action is **CONTINUE**. If it was raised by **SIGNAL** or **RESIGNAL**, the action is **EXIT**.

The following example uses a handler for SQLSTATE '23000', which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->     DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->     SET @x = 1;
->     INSERT INTO test.t VALUES (1);
->     SET @x = 2;
->     INSERT INTO test.t VALUES (1);
->     SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS//
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1062 | Duplicate entry '1' for key 'PRIMARY'      |
```

```

+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)

```

Notice that `@x` is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the `DECLARE ... HANDLER` statement had not been present, MySQL would have taken the default action (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

To ignore a condition, declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the `REPEAT` block has a label of `retry`:

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      ITERATE retry;    # illegal
    END;
    IF i < 0 THEN
      LEAVE retry;      # legal
    END IF;
    SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
END;

```

The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```

DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
    block cleanup statements
END;

```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```

CREATE PROCEDURE p ( )
BEGIN
    DECLARE i INT DEFAULT 3;
    DECLARE done INT DEFAULT FALSE;
    retry:
    REPEAT
    BEGIN
        DECLARE CONTINUE HANDLER FOR SQLWARNING
        BEGIN
            SET done = TRUE;
        END;
        IF done OR i < 0 THEN
            LEAVE retry;
        END IF;
        SET i = i - 1;
    END;
    UNTIL FALSE END REPEAT;
END;

```

### 13.6.7.3 RESIGNAL Syntax

```

RESIGNAL [condition_value]
    [SET signal_information_item
    [, signal_information_item] ...]

condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | condition_name

signal_information_item:
    condition_information_item_name = simple_value_specification

condition_information_item_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

condition_name, simple_value_specification:
    (see following discussion)

```

`RESIGNAL` passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. `RESIGNAL` may change some or all information before passing it on. `RESIGNAL` is related to `SIGNAL`, but instead of originating a condition as `SIGNAL` does, `RESIGNAL` relays existing condition information, possibly after modifying it.

`RESIGNAL` makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. `RESIGNAL` also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No special privileges are required to execute the `RESIGNAL` statement.

All forms of `RESIGNAL` require that the current context be a condition handler. Otherwise, `RESIGNAL` is illegal and a `RESIGNAL when handler not active` error occurs.

For `condition_value` and `signal_information_item`, the definitions and rules are the same for `RESIGNAL` as for `SIGNAL`. For example, the `condition_value` can be an `SQLSTATE` value, and the value can indicate errors, warnings, or “not found.” For additional information, see [Section 13.6.7.4, “SIGNAL Syntax”](#).

The `RESIGNAL` statement takes `condition_value` and `SET` clauses, both of which are optional. This leads to several possible uses:

- `RESIGNAL` alone:

```
RESIGNAL;
```

- `RESIGNAL` with new signal information:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

- `RESIGNAL` with a condition value and possibly new signal information:

```
RESIGNAL condition_value  
  [SET signal_information_item [, signal_information_item] ...];
```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the `SQLSTATE` value, `MYSQL_ERRNO`, or `MESSAGE_TEXT`.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable.

## RESIGNAL Alone

A simple `RESIGNAL` alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for `RESIGNAL` alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```
DROP TABLE IF EXISTS xx;  
delimiter //  
CREATE PROCEDURE p ()
```

```

BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();

```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

Usually a procedure statement clears the first diagnostics area (also called the “current” diagnostics area). `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

And that is what the caller sees.

If `@a` is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
```

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

## RESIGNAL with New Signal Information

`RESIGNAL` with a `SET` clause provides new signal information, so the statement means “pass on the error with changes”:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with `RESIGNAL` alone, the idea is to pop the diagnostics area stack so that the original information will go out. Unlike `RESIGNAL` alone, anything specified in the `SET` clause changes.

Example:

```

DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
    END;
    DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();

```

Remember from the previous discussion that `RESIGNAL` alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The `RESIGNAL SET MYSQL_ERRNO = 5` statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The `RESIGNAL` statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

## RESIGNAL with a Condition Value and Optional New Signal Information

`RESIGNAL` with a condition value means “push a condition into the current diagnostics area.” If the `SET` clause is present, it also changes the error information.

```

RESIGNAL condition_value
    [SET signal_information_item [, signal_information_item] ...];

```

This form of `RESIGNAL` restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple `RESIGNAL` alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```

DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
    END;
    DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;

```

```
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;
```

This is similar to the previous example, and the effects are the same, except that if `RESIGNAL` happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The `RESIGNAL` statement includes a condition value (`SQLSTATE '45000'`), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

```
DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
      (condition 1) ERROR 5 (45000) Unknown table 'xx'
```

The result of `CALL p()` and `SHOW ERRORS` for this example is:

```
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-----+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+-----+
| Error | 1051 | Unknown table 'xx'                   |
| Error | 5    | Unknown table 'xx'                   |
+-----+-----+-----+-----+
```

## RESIGNAL Requires Condition Handler Context

All forms of `RESIGNAL` require that the current context be a condition handler. Otherwise, `RESIGNAL` is illegal and a `RESIGNAL when handler not active` error occurs. For example:

```
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
```

Here is a more difficult example:

```
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
    RESIGNAL;
    RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
    SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();
```

`RESIGNAL` occurs within the stored function `f()`, which is invoked from within the `EXIT` handler. Thus, a handler is active at the time `RESIGNAL` executes, even though `RESIGNAL` is not defined inside the handler.

### 13.6.7.4 SIGNAL Syntax

```

SIGNAL condition_value
    [SET signal_information_item
      [, signal_information_item] ...]

condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | condition_name

signal_information_item:
    condition_information_item_name = simple_value_specification

condition_information_item_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

condition_name, simple_value_specification:
    (see following discussion)

```

**SIGNAL** is the way to “return” an error. **SIGNAL** provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error's characteristics (error number, **SQLSTATE** value, message). Without **SIGNAL**, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No special privileges are required to execute the **SIGNAL** statement.

The *condition\_value* in a **SIGNAL** statement indicates the error value to be returned. It can be an **SQLSTATE** value (a 5-character string literal) or a *condition\_name* that refers to a named condition previously defined with **DECLARE ... CONDITION** (see [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#)).

An **SQLSTATE** value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in [Signal Condition Information Items](#). Some signal values cause statement termination; see [Effect of Signals on Handlers, Cursors, and Statements](#).

The **SQLSTATE** value for a **SIGNAL** statement should not start with '00' because such values indicate success and are not valid for signaling an error. This is true whether the **SQLSTATE** value is specified directly in the **SIGNAL** statement or in a named condition referred to in the statement. If the value is invalid, a **Bad SQLSTATE** error occurs.

To signal a generic **SQLSTATE** value, use '45000', which means “unhandled user-defined exception.”

The **SIGNAL** statement optionally includes a **SET** clause that contains multiple signal items, in a comma-separated list of *condition\_information\_item\_name* = *simple\_value\_specification* assignments.

Each *condition\_information\_item\_name* may be specified only once in the **SET** clause. Otherwise, a **Duplicate condition information item** error occurs.

Valid *simple\_value\_specification* designators can be specified using stored procedure or function parameters, stored program local variables declared with **DECLARE**, user-defined variables, system variables, or literals. A character literal may include a *\_charset* introducer.

For information about permissible *condition\_information\_item\_name* values, see [Signal Condition Information Items](#).

The following procedure signals an error or warning depending on the value of *pval*, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If *pval* is 0, *p()* signals a warning because *SQLSTATE* values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with [SHOW WARNINGS](#) after the procedure returns.

If *pval* is 1, *p()* signals an error and sets the *MESSAGE\_TEXT* condition information item. The error terminates the procedure, and the text is returned with the error information.

If *pval* is 2, the same error is signaled, although the *SQLSTATE* value is specified using a named condition in this case.

If *pval* is anything else, *p()* first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and *p()* then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

*SIGNAL* is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the *mysql* client program, you can enter any of these statements at the prompt:

```
mysql> SIGNAL SQLSTATE '77777';
mysql> CREATE TRIGGER t_bi BEFORE INSERT ON t
-> FOR EACH ROW SIGNAL SQLSTATE '77777';
mysql> CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
-> DO SIGNAL SQLSTATE '77777';
```

*SIGNAL* executes according to the following rules:

If the *SIGNAL* statement indicates a particular *SQLSTATE* value, that value is used to signal the condition specified. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the `SIGNAL` statement, an `Undefined CONDITION` error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL can only use a CONDITION defined with SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

Signals can be raised within exception handlers:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;
```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with `SQLSTATE '99999'` and message `An error occurred`.

## Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a [SIGNAL](#) (or [RESIGNAL](#)) statement. All items are standard SQL except [MYSQL\\_ERRNO](#), which is a MySQL extension.

| Item Name          | Definition        |
|--------------------|-------------------|
| -----              | -----             |
| CLASS_ORIGIN       | VARCHAR(64)       |
| SUBCLASS_ORIGIN    | VARCHAR(64)       |
| CONSTRAINT_CATALOG | VARCHAR(64)       |
| CONSTRAINT_SCHEMA  | VARCHAR(64)       |
| CONSTRAINT_NAME    | VARCHAR(64)       |
| CATALOG_NAME       | VARCHAR(64)       |
| SCHEMA_NAME        | VARCHAR(64)       |
| TABLE_NAME         | VARCHAR(64)       |
| COLUMN_NAME        | VARCHAR(64)       |
| CURSOR_NAME        | VARCHAR(64)       |
| MESSAGE_TEXT       | VARCHAR(128)      |
| MYSQL_ERRNO        | SMALLINT UNSIGNED |

The character set for character items is UTF-8.

It is illegal to assign [NULL](#) to a condition information item in a [SIGNAL](#) statement.

A [SIGNAL](#) statement always specifies an [SQLSTATE](#) value, either directly, or indirectly by referring to a named condition defined with an [SQLSTATE](#) value. The first two characters of an [SQLSTATE](#) value are its class, and the class determines the default value for the condition information items:

- Class = '00' (success)

Illegal. [SQLSTATE](#) values that begin with '00' indicate success and are not valid for [SIGNAL](#).

- Class = '01' (warning)

```
MESSAGE_TEXT = 'Unhandled user-defined warning condition';
MYSQL_ERRNO = ER_SIGNAL_WARN
```

- Class = '02' (not found)

```
MESSAGE_TEXT = 'Unhandled user-defined not found condition';
MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
```

- Class > '02' (exception)

```
MESSAGE_TEXT = 'Unhandled user-defined exception condition';
MYSQL_ERRNO = ER_SIGNAL_EXCEPTION
```

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after [SIGNAL](#) executes are the [SQLSTATE](#) value raised by the [SIGNAL](#) statement and the [MESSAGE\\_TEXT](#) and [MYSQL\\_ERRNO](#) items. These values are available from the C API:

- [SQLSTATE](#) value: Call `mysql_sqlstate()`

- `MYSQL_ERRNO` value: Call `mysql_errno()`
- `MESSAGE_TEXT` value: Call `mysql_error()`

From SQL, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

Other condition information items can be set, but currently have no effect, in the sense that they are not accessible from error returns. For example, you can set `CLASS_ORIGIN` in a `SIGNAL` statement, but cannot see it after `SIGNAL` executes. In MySQL 5.6, condition information can be inspected with the `GET DIAGNOSTICS` statement.

## Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled `SQLSTATE` value has been defined with `DECLARE ... HANDLER`.

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. `SQLWARNING` handlers catch the signal. If the signal is unhandled in a function, statements do not end.

- Class = '02' (not found)

`NOT FOUND` handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a function, statements end.

- Class > '02' (exception)

`SQLEXCEPTION` handlers catch the signal. If the signal is unhandled in a function, statements end.

- Class = '40'

Treated as an ordinary exception.

Example:

```
mysql> delimiter //
mysql> CREATE FUNCTION f () RETURNS INT
-> BEGIN
->   SIGNAL SQLSTATE '01234'; -- signal a warning
->   RETURN 5;
-> END//
mysql> delimiter ;
mysql> CREATE TABLE t (s1 INT);
mysql> INSERT INTO t VALUES (f());
```

The result is that a row containing 5 is inserted into table `t`. The warning that is signaled can be viewed with `SHOW WARNINGS`.

## 13.7 Database Administration Statements

### 13.7.1 Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, MySQL Server Administration](#), which you should consult for additional details.

#### Important

Some MySQL releases introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you upgrade MySQL. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

When the `read_only` system variable is enabled, account-management statements require the `SUPER` privilege, in addition to any other required privileges. This is because they modify tables in the `mysql` database.

#### 13.7.1.1 CREATE USER Syntax

```
CREATE USER
    user [auth_option] [, user [auth_option]] ...

user:
    (see Section 6.2.3, “Specifying Account Names”)

auth_option: {
    IDENTIFIED BY 'auth_string'
    | IDENTIFIED BY PASSWORD 'hash_string'
    | IDENTIFIED WITH auth_plugin
    | IDENTIFIED WITH auth_plugin AS 'hash_string'
}
```

The `CREATE USER` statement creates new MySQL accounts. An error occurs if you try to create an account that already exists.

An account when first created has no privileges.

To use `CREATE USER`, you must have the global `CREATE USER` privilege, or the `INSERT` privilege for the `mysql` database. When the `read_only` system variable is enabled, `CREATE USER` additionally requires the `SUPER` privilege.

For each account, `CREATE USER` creates a new row in the `mysql.user` table with no privileges and (as of MySQL 5.5.7) assigns the account an authentication plugin. Depending on the syntax used, `CREATE USER` may also assign the account a password.

Each `user` value naming an account may be followed by an optional `auth_option` value that specifies how authentication occurs for clients that use the account. This part of `CREATE USER` syntax is shared with `GRANT`, so the description here applies to `GRANT` as well.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The host name part of the account name, if omitted, defaults to `'%'`.

The server assigns an authentication plugin and password to each account as follows, depending on whether the user specification clause includes `IDENTIFIED WITH` to specify a plugin or `IDENTIFIED BY` to specify a password:

**Note**

`IDENTIFIED WITH` is available as of MySQL 5.5.7. Before 5.5.7, authentication plugins are not used, so only the remarks about `IDENTIFIED BY` apply.

- With `IDENTIFIED WITH`, the server assigns the specified plugin and the account has no password. If the optional `AS 'hash_string'` clause is also given, the string is stored as is in the `authentication_string` column (it is assumed to be already hashed in the format required by the plugin).
- With `IDENTIFIED BY`, the server assigns no plugin and assigns the specified password.
- With neither `IDENTIFIED WITH` nor `IDENTIFIED BY`, the server assigns no plugin and the account has no password.

If the account has no password, the `Password` column in the account's `mysql.user` table row remains empty, which is insecure. To set the password, use `SET PASSWORD`. See [Section 13.7.1.6, “SET PASSWORD Syntax”](#).

If the server assigns no plugin to the account, the `plugin` column in the account's `mysql.user` table row remains empty.

For client connections that use a given account, the server invokes the authentication plugin assigned to the account and the client must provide credentials as required by the authentication method that the plugin implements. If the server cannot find the plugin, either at account-creation time or connect time, an error occurs.

If an account's `mysql.user` table row has a nonempty `plugin` column:

- The server authenticates client connection attempts using the named plugin.
- Changes to the account password using `SET PASSWORD` with `PASSWORD( )` must be made with the `old_passwords` system variable set to the value required by the authentication plugin, so that `PASSWORD( )` uses the appropriate password hashing method. If the plugin is `mysql_old_password`, the password can also be changed using `SET PASSWORD` with `OLD_PASSWORD( )`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`.

If an account's `mysql.user` table row has an empty `plugin` column:

- The server authenticates client connection attempts using the `mysql_native_password` or `mysql_old_password` authentication plugin, depending on the hash format of the password stored in the `Password` column.
- Changes to the account password using `SET PASSWORD` can be made with `PASSWORD( )`, with `old_passwords` set to 0 or 1 for 4.1 or pre-4.1 password hashing, respectively, or with `OLD_PASSWORD( )`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`.

`CREATE USER` examples:

- To specify an authentication plugin for an account, use `IDENTIFIED WITH auth_plugin`. The plugin name can be a quoted string literal or an unquoted name. `'auth_string'` is an optional quoted string literal to pass to the plugin. The plugin interprets the meaning of the string, so its format is plugin specific and it is stored in the `authentication_string` column as given. (This value is meaningful only for

plugins that use that column.) Consult the documentation for a given plugin for information about the authentication string values it accepts, if any.

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
```

The server assigns the given authentication plugin to the account but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To ensure that an account uses a specific authentication plugin and has a password with the corresponding hash format, specify the plugin explicitly with `IDENTIFIED WITH`, then use `SET PASSWORD` to set the password:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
SET old_passwords = 0;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

Changes to the account password using `SET PASSWORD` with `PASSWORD( )` must be made with the `old_passwords` system variable set to the value required by the account's authentication plugin, so that `PASSWORD( )` uses the appropriate password hashing method. Therefore, to use the `mysql_old_password` plugin instead, name that plugin in the `CREATE USER` statement and set `old_passwords` to 1 before using `SET PASSWORD`.

- To specify a password for an account at account-creation time, use `IDENTIFIED BY` with the literal cleartext password value:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The server assigns the given password to the account but no authentication plugin. Clients must provide the password when they connect.

- To avoid specifying the cleartext password if you know its hash value (the value that `PASSWORD( )` would return for the password), specify the hash value preceded by the keyword `PASSWORD`:

```
CREATE USER 'jeffrey'@'localhost'
IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

The server assigns the given password to the account but no authentication plugin. Clients must provide the password when they connect.

- To enable the user to connect with no password, include no `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost';
```

The server assigns no authentication plugin or password to the account. Clients must provide no password when they connect. However, an account with no password is insecure. To avoid this, use `SET PASSWORD` to set the account password.

For additional information about setting passwords and authentication plugins, see [Section 6.3.5, “Assigning Account Passwords”](#), and [Section 6.3.6, “Pluggable Authentication”](#).

### Important

`CREATE USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

### 13.7.1.2 DROP USER Syntax

```
DROP USER user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables. An error occurs for accounts that do not exist.

To use `DROP USER`, you must have the global `CREATE USER` privilege, or the `DELETE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `DROP USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

#### Important

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 20.6, “Access Control for Stored Programs and Views”](#).)

### 13.7.1.3 GRANT Syntax

```
GRANT
  priv_type [(column_list)]
    [, priv_type [(column_list)]] ...
  ON [object_type] priv_level
  TO user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH {GRANT OPTION | resource_option} ...]

GRANT PROXY ON user
  TO user [, user] ...
  [WITH GRANT OPTION]

object_type: {
  TABLE
| FUNCTION
| PROCEDURE
}

priv_level: {
  *
| *.*
| db_name.*
| db_name.tbl_name
| tbl_name
| db_name.routine_name
}

user:
```

```

    (see Section 6.2.3, “Specifying Account Names”)

auth_option: {
    IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

tls_option: {
    SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
}

resource_option: {
  | MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
}

```

The [GRANT](#) statement grants privileges to MySQL user accounts. [GRANT](#) also serves to specify other account characteristics such as use of secure connections and limits on access to server resources.

To use [GRANT](#), you must have the [GRANT OPTION](#) privilege, and you must have the privileges that you are granting. When the [read\\_only](#) system variable is enabled, [GRANT](#) additionally requires the [SUPER](#) privilege.

The [REVOKE](#) statement is related to [GRANT](#) and enables administrators to remove account privileges. See [Section 13.7.1.5, “REVOKE Syntax”](#).

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
```

The host name part of the account, if omitted, defaults to `'%'`.

Normally, a database administrator first uses [CREATE USER](#) to create an account, then [GRANT](#) to define its privileges and characteristics. For example:

```

CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
GRANT USAGE ON *.* TO 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;

```

#### Note

Examples shown here include no [IDENTIFIED](#) clause. It is assumed that you establish passwords with [CREATE USER](#) at account-creation time to avoid creating insecure accounts.

If an account named in a [GRANT](#) statement does not already exist, [GRANT](#) may create it under the conditions described later in the discussion of the [NO\\_AUTO\\_CREATE\\_USER](#) SQL mode.

From the `mysql` program, [GRANT](#) responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use [SHOW GRANTS](#). See [Section 13.7.5.22, “SHOW GRANTS Syntax”](#).

There are several aspects to the [GRANT](#) statement, described under the following topics in this section:

- [Object Quoting Guidelines](#)
- [Privileges Supported by MySQL](#)
- [Global Privileges](#)
- [Database Privileges](#)
- [Table Privileges](#)
- [Column Privileges](#)
- [Stored Routine Privileges](#)
- [Proxy User Privileges](#)
- [Account Names and Passwords](#)
- [Implicit Account Creation](#)
- [Other Account Characteristics](#)
- [MySQL and Standard SQL Versions of GRANT](#)

[GRANT](#) supports host names up to 60 characters long. User names can be up to 16 characters. Database, table, column, and routine names can be up to 64 characters.

#### Warning

*Do not attempt to change the permissible length for user names by altering the [mysql.user](#) table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the [mysql](#) database in any manner except by means of the procedure described in [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).*

#### Important

[GRANT](#) may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

## Object Quoting Guidelines

Several objects within [GRANT](#) statements are subject to quoting, although quoting is optional in many cases: Account, database, table, column, and routine names. For example, if a [user\\_name](#) or [host\\_name](#) value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a [user\\_name](#) string containing special characters (such as `-`), or a [host\\_name](#) string containing special characters or wildcard characters (such as `%`); for example, `'test-user'@'%.com'`. Quote the user name and host name separately.

To specify quoted values, quote database, table, column, and routine names as identifiers. Quote user names and host names as identifiers or as strings. Quote passwords as strings. For string-quoting and identifier-quoting guidelines, see [Section 9.1.1, “String Literals”](#), and [Section 9.2, “Schema Object Names”](#).

The `_` and `%` wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the database level. This means, for example, that if you want to use a `_` character as part of a database name, you should specify it as `\_` in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo\_bar`. * TO ....`

## Privileges Supported by MySQL

The following table summarizes the permissible `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about each privilege, see [Section 6.2.1, “Privileges Provided by MySQL”](#).

**Table 13.3 Permissible Privileges for GRANT and REVOKE**

| Privilege                            | Meaning and Grantable Levels   |
|--------------------------------------|--|
| <code>ALL [PRIVILEGES]</code>        | Grant all privileges at specified access level except <code>GRANT OPTION</code> and <code>PROXY</code> .   |
| <code>ALTER</code>                   | Enable use of <code>ALTER TABLE</code> . Levels: Global, database, table.  |
| <code>ALTER ROUTINE</code>           | Enable stored routines to be altered or dropped. Levels: Global, database, procedure.  |
| <code>CREATE</code>                  | Enable database and table creation. Levels: Global, database, table.   |
| <code>CREATE ROUTINE</code>          | Enable stored routine creation. Levels: Global, database.  |
| <code>CREATE TABLESPACE</code>       | Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.  |
| <code>CREATE TEMPORARY TABLES</code> | Enable use of <code>CREATE TEMPORARY TABLE</code> . Levels: Global, database.  |
| <code>CREATE USER</code>             | Enable use of <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code> . Level: Global. |
| <code>CREATE VIEW</code>             | Enable views to be created or altered. Levels: Global, database, table.  |
| <code>DELETE</code>                  | Enable use of <code>DELETE</code> . Level: Global, database, table.  |
| <code>DROP</code>                    | Enable databases, tables, and views to be dropped. Levels: Global, database, table.  |
| <code>EVENT</code>                   | Enable use of events for the Event Scheduler. Levels: Global, database.  |
| <code>EXECUTE</code>                 | Enable the user to execute stored routines. Levels: Global, database, table.   |
| <code>FILE</code>                    | Enable the user to cause the server to read or write files. Level: Global.   |
| <code>GRANT OPTION</code>            | Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, procedure, proxy.                                |
| <code>INDEX</code>                   | Enable indexes to be created or dropped. Levels: Global, database, table.  |
| <code>INSERT</code>                  | Enable use of <code>INSERT</code> . Levels: Global, database, table, column.   |
| <code>LOCK TABLES</code>             | Enable use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege. Levels: Global, database.                     |
| <code>PROCESS</code>                 | Enable the user to see all processes with <code>SHOW PROCESSLIST</code> . Level: Global.   |
| <code>PROXY</code>                   | Enable user proxying. Level: From user to user.  |
| <code>REFERENCES</code>              | Enable foreign key creation. Levels: Global, database, table, column.  |

| Privilege          | Meaning and Grantable Levels   |
|--------------------|--|
| RELOAD             | Enable use of <code>FLUSH</code> operations. Level: Global.  |
| REPLICATION CLIENT | Enable the user to ask where master or slave servers are. Level: Global.   |
| REPLICATION SLAVE  | Enable replication slaves to read binary log events from the master. Level: Global.  |
| SELECT             | Enable use of <code>SELECT</code> . Levels: Global, database, table, column.   |
| SHOW DATABASES     | Enable <code>SHOW DATABASES</code> to show all databases. Level: Global.   |
| SHOW VIEW          | Enable use of <code>SHOW CREATE VIEW</code> . Levels: Global, database, table.   |
| SHUTDOWN           | Enable use of <code>mysqladmin shutdown</code> . Level: Global.  |
| SUPER              | Enable use of other administrative operations such as <code>CHANGE MASTER TO</code> , <code>KILL</code> , <code>PURGE BINARY LOGS</code> , <code>SET GLOBAL</code> , and <code>mysqladmin debug</code> command. Level: Global. |
| TRIGGER            | Enable trigger operations. Levels: Global, database, table.  |
| UPDATE             | Enable use of <code>UPDATE</code> . Levels: Global, database, table, column.   |
| USAGE              | Synonym for “no privileges”  |

The `PROXY` privilege was added in MySQL 5.5.7.

A trigger is associated with a table. To create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger.

In `GRANT` statements, the `ALL [PRIVILEGES]` or `PROXY` privilege must be named by itself and cannot be specified along with other privileges. `ALL [PRIVILEGES]` stands for all privileges available for the level at which privileges are to be granted except for the `GRANT OPTION` and `PROXY` privileges.

`USAGE` can be specified to create a user that has no privileges, or to specify the `REQUIRE` or `WITH` clauses for an account without changing its existing privileges.

MySQL account information is stored in the tables of the `mysql` database. For additional details, consult [Section 6.2, “The MySQL Access Privilege System”](#), which discusses the `mysql` database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the `ON` clause. For `REVOKE`, the same `ON` syntax specifies which privileges to remove.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON db_name.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`. Granting `ALL` does not assign the `GRANT OPTION` or `PROXY` privilege.

The `object_type` clause, if present, should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

The privileges for a database, table, column, or routine are formed additively as the logical `OR` of the privileges at each of the privilege levels. For example, if a user has a global `SELECT` privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details

of the privilege-checking procedure are presented in [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#).

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the [CREATE](#) privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

### Important

*MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.*

## Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use [ON \\*.\\*](#) syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The [CREATE TABLESPACE](#), [CREATE USER](#), [FILE](#), [PROCESS](#), [RELOAD](#), [REPLICATION CLIENT](#), [REPLICATION SLAVE](#), [SHOW DATABASES](#), [SHUTDOWN](#), and [SUPER](#) privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

[GRANT OPTION](#) granted at the global level for any global privilege applies to all global privileges.

MySQL stores global privileges in the [mysql.user](#) table.

## Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use [ON db\\_name.\\*](#) syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use [ON \\*](#) syntax (rather than [ON \\*.\\*](#)) and you have selected a default database, privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The [CREATE](#), [DROP](#), [EVENT](#), [GRANT OPTION](#), [LOCK TABLES](#), and [REFERENCES](#) privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the [mysql.db](#) table.

## Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use [ON db\\_name.tbl\\_name](#) syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify *tbl\_name* rather than *db\_name.tbl\_name*, the statement applies to *tbl\_name* in the default database. An error occurs if there is no default database.

The permissible *priv\_type* values at the table level are [ALTER](#), [CREATE VIEW](#), [CREATE](#), [DELETE](#), [DROP](#), [GRANT OPTION](#), [INDEX](#), [INSERT](#), [REFERENCES](#), [SELECT](#), [SHOW VIEW](#), [TRIGGER](#), and [UPDATE](#).

MySQL stores table privileges in the [mysql.tables\\_priv](#) table.

## Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1,col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible *priv\_type* values for a column (that is, when you use a *column\_list* clause) are [INSERT](#), [REFERENCES](#), [SELECT](#), and [UPDATE](#).

MySQL stores column privileges in the [mysql.columns\\_priv](#) table.

## Stored Routine Privileges

The [ALTER ROUTINE](#), [CREATE ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#) privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for [CREATE ROUTINE](#), these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible *priv\_type* values at the routine level are [ALTER ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#). [CREATE ROUTINE](#) is not a routine-level privilege because you must have this privilege to create a routine in the first place.

MySQL stores routine-level privileges in the [mysql.procs\\_priv](#) table.

## Proxy User Privileges

The [PROXY](#) privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user.

```
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When [PROXY](#) is granted, it must be the only privilege named in the [GRANT](#) statement, the [REQUIRE](#) clause cannot be given, and the only permitted [WITH](#) option is [WITH GRANT OPTION](#).

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the [PROXY](#) privilege for the proxied user. For details and examples, see [Section 6.3.7, “Proxy Users”](#).

MySQL stores proxy privileges in the [mysql.proxies\\_priv](#) table.

## Account Names and Passwords

A [user](#) value in a [GRANT](#) statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the [user](#) value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to [user\\_name](#) for any host in the `example.com` domain, and `'user_name'@'192.168.1.%'` applies to [user\\_name](#) for any host in the `192.168.1` class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%'`.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the [GRANT](#) statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see [Section 6.2.3](#), “Specifying Account Names”.

### Warning

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `'user_name'@'localhost'`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 6.2.4](#), “Access Control, Stage 1: Connection Verification”.

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

For [GRANT](#) syntaxes that permit an [auth\\_option](#) value to follow a [user](#) value, [auth\\_option](#) begins with [IDENTIFIED](#) and indicates how the account authenticates by specifying an account authentication plugin, credentials (password), or both. Syntax of the [auth\\_option](#) clause is the same as for the [CREATE USER](#) statement. For details, see [Section 13.7.1.1](#), “CREATE USER Syntax”.

When [IDENTIFIED](#) is present and you have the global grant privilege ([GRANT OPTION](#)), any password specified becomes the new password for the account, even if the account exists and already has a password. Without [IDENTIFIED](#), the account password remains unchanged.

## Implicit Account Creation

If an account named in a [GRANT](#) statement does not exist, the action taken depends on the [NO\\_AUTO\\_CREATE\\_USER](#) SQL mode:

- If `NO_AUTO_CREATE_USER` is not enabled, `GRANT` creates the account. *This is very insecure* unless you specify a nonempty password using `IDENTIFIED BY`.
- If `NO_AUTO_CREATE_USER` is enabled, `GRANT` fails and does not create the account, unless you specify a nonempty password using `IDENTIFIED BY` or name an authentication plugin using `IDENTIFIED WITH`.

## Other Account Characteristics

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 6.4](#), “Using Secure Connections”.

The optional `REQUIRE` clause specifies SSL-related options for a MySQL account, using one or more `tls_option` values.

`GRANT` permits these `tls_option` values:

- `NONE`

Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files. That is, the client need not specify any SSL command options, in which case the connection will be unencrypted. To use an encrypted connection, the client must specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.

`NONE` is the default if no SSL-related `REQUIRE` options are specified.

- `SSL`

Tells the server to permit only encrypted connections for the account.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'  
  REQUIRE SSL;
```

To connect, the client must specify the `--ssl-ca` option to authenticate the server certificate, and may additionally specify the `--ssl-key` and `--ssl-cert` options. If neither the `--ssl-ca` option nor `--ssl-capath` option is specified, the client does not authenticate the server certificate.

- `X509`

Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'  
  REQUIRE X509;
```

The client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- `ISSUER 'issuer'`

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA '*issuer*'. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the [SSL](#) option is unnecessary in this case.

Because [ISSUER](#) implies the requirements of [X509](#), the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com';
```

#### Note

If MySQL is linked against a version of OpenSSL older than 0.9.6h, use [Email](#) rather than [emailAddress](#) in the '*issuer*' value.

- [SUBJECT](#) '*subject*'

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject *subject*. If the client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the [SSL](#) option is unnecessary in this case.

Because [SUBJECT](#) implies the requirements of [X509](#), the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the '*subject*' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

#### Note

Regarding [emailAddress](#), see the note in the description of [REQUIRE ISSUER](#).

- [CIPHER](#) '*cipher*'

Requests a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The [SUBJECT](#), [ISSUER](#), and [CIPHER](#) options can be combined in the [REQUIRE](#) clause like this:

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
```

```
CN=client/emailAddress=client@example.com'  
AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/  
O=MySQL/CN=CA/emailAddress=ca@example.com'  
AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The order of the options does not matter, but no option can be specified twice. The [AND](#) keyword is optional between [REQUIRE](#) options.

The optional [WITH](#) clause is used for these purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user

The [WITH GRANT OPTION](#) clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the [GRANT OPTION](#) privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the [GRANT OPTION](#) privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the [GRANT OPTION](#) privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the [GRANT OPTION](#) privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the [INSERT](#) privilege on a database. If you then grant the [SELECT](#) privilege on the database and specify [WITH GRANT OPTION](#), that user can give to other users not only the [SELECT](#) privilege, but also [INSERT](#). If you then grant the [UPDATE](#) privilege to the user on the database, the user can grant [INSERT](#), [SELECT](#), and [UPDATE](#).

For a nonadministrative user, you should not grant the [ALTER](#) privilege globally or for the [mysql](#) database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see [Section 6.2.1](#), “Privileges Provided by MySQL”.

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.4](#), “Setting Account Resource Limits”. To do so, use a [WITH](#) clause that specifies one or more [resource\\_option](#) values. Limits not specified retain their current values.

[GRANT](#) permits these [resource\\_option](#) values:

- [MAX\\_QUERIES\\_PER\\_HOUR count](#), [MAX\\_UPDATES\\_PER\\_HOUR count](#),  
[MAX\\_CONNECTIONS\\_PER\\_HOUR count](#)

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the [MAX\\_QUERIES\\_PER\\_HOUR](#) limit.) If *count* is 0 (the default), this means that there is no limitation for the account.

- [MAX\\_USER\\_CONNECTIONS count](#)

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero *count* specifies the limit for the account explicitly. If *count* is 0 (the default), the server

determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

If a given resource limit is specified multiple times, the last instance takes precedence.

To specify resource limits for an existing user without affecting existing privileges, use `GRANT USAGE` at the global level (`ON *.*`) and name the limits to be changed. For example:

```
GRANT USAGE ON *.* TO ...  
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

## MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See [Section 13.7.1.2, “DROP USER Syntax”](#).
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit `DROP USER` or `REVOKE` statements or by manipulating the MySQL grant tables directly.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see [Section 5.1.8, “Server SQL Modes”](#), and [Section 11.6, “Data Type Default Values”](#).

### 13.7.1.4 RENAME USER Syntax

```
RENAME USER old_user TO new_user  
  [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to `'%'`.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 20.6, “Access Control for Stored Programs and Views”](#).)

The privilege changes take effect as indicated in [Section 6.2.6, “When Privilege Changes Take Effect”](#).

### 13.7.1.5 REVOKE Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
  ON [object_type] priv_level
  FROM user [, user] ...

REVOKE ALL [PRIVILEGES], GRANT OPTION
  FROM user [, user] ...

REVOKE PROXY ON user
  FROM user [, user] ...
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts.

When the `read_only` system variable is enabled, `REVOKE` requires the `SUPER` privilege in addition to any other required privileges described in the following discussion.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

For details on the levels at which privileges exist, the permissible `priv_type`, `priv_level`, and `object_type` values, and the syntax for specifying users and passwords, see [Section 13.7.1.3, “GRANT Syntax”](#)

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` database.

User accounts from which privileges are to be revoked must exist.

`REVOKE` removes privileges, but does not drop `mysql.user` table entries. To remove a user account entirely, use `DROP USER`. See [Section 13.7.1.2, “DROP USER Syntax”](#).

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges remain after the operation, use `SHOW GRANTS`. See [Section 13.7.5.22, “SHOW GRANTS Syntax”](#).

### 13.7.1.6 SET PASSWORD Syntax

```
SET PASSWORD [FOR user] = password_option
```

```
password_option: {  
  PASSWORD('auth_string')  
  | OLD_PASSWORD('auth_string')  
  | 'hash_string'  
}
```

The `SET PASSWORD` statement assigns a password to a MySQL user account, specified as either a cleartext (unencrypted) or encrypted value:

- `'auth_string'` represents a cleartext password.
- `'hash_string'` represents an encrypted password.

`SET PASSWORD` can be used with or without an explicitly named user account:

- With a `FOR user` clause, the statement sets the password for the named account, which must exist:

```
SET PASSWORD FOR 'jeffrey'@'localhost' = password_option;
```

In this case, you must have the `UPDATE` privilege for the `mysql` database.

- With no `FOR user` clause, the statement sets the password for the current user:

```
SET PASSWORD = password_option;
```

Any client who connects to the server using a nonanonymous account can change the password for that account. To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

When the `read_only` system variable is enabled, `SET PASSWORD` requires the `SUPER` privilege in addition to any other required privileges.

If a `FOR user` clause is given, the account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). The `user` value should be given as `'user_name'@'host_name'`, where `'user_name'` and `'host_name'` are exactly as listed in the `User` and `Host` columns of the account's `mysql.user` table row. The host name part of the account name, if omitted, defaults to `'%'`. For example, to set the password for an account with `User` and `Host` column values of `'bob'` and `'%.example.org'`, write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('auth_string');
```

The password can be specified in these ways:

- Using the `PASSWORD()` function

The `'auth_string'` function argument is the cleartext (unencrypted) password. `PASSWORD()` hashes the password and returns the encrypted password string for storage in the `mysql.user` account row.

The `PASSWORD()` function hashes the password using the hashing method determined by the value of the `old_passwords` system variable value. It should be set to a value compatible with the hash format required by the account authentication plugin. For example, if the account uses the `mysql_native_password` authentication plugin, `old_passwords` should be 0 for `PASSWORD()` to produce a hash value in the correct format. For `mysql_old_password`, `old_passwords` should be 1.

- Using the `OLD_PASSWORD()` function:

The `'auth_string'` function argument is the cleartext (unencrypted) password. `OLD_PASSWORD()` hashes the password using pre-4.1 hashing and returns the encrypted password string for storage in the `mysql.user` account row. This hashing method is appropriate only for accounts that use the `mysql_old_password` authentication plugin.

- Using an already encrypted password string

The password is specified as a string literal. It must represent the already encrypted password value, in the hash format required by the authentication method used for the account.

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

| Value    | Password Hashing Method  | Associated Authentication Plugin   |
|----------|--------------------------|------------------------------------|
| 0 or OFF | MySQL 4.1 native hashing | <code>mysql_native_password</code> |
| 1 or ON  | Pre-4.1 ("old") hashing  | <code>mysql_old_password</code>    |

For more information about setting passwords, see [Section 6.3.5, "Assigning Account Passwords"](#).

#### Important

`SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see [Section 6.1.2.3, "Passwords and Logging"](#). For similar information about client-side logging, see [Section 4.5.1.3, "mysql Logging"](#).

#### Caution

If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not change your password without first reading [Section 6.1.2.4, "Password Hashing in MySQL"](#). The default password hashing format changed in MySQL 4.1, and if you change your password, it might be stored using a hashing format that pre-4.1 clients cannot generate, thus preventing you from connecting to the server afterward.

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

## 13.7.2 Table Maintenance Statements

### 13.7.2.1 ANALYZE TABLE Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
```

**ANALYZE TABLE** analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for [InnoDB](#) and [MyISAM](#). This statement works with [InnoDB](#), [NDB](#), and [MyISAM](#) tables. For [MyISAM](#) tables, this statement is equivalent to using `myisamchk --analyze`. This statement does not work with views.

For more information on how the analysis works within [InnoDB](#), see [Section 14.9.11, “Configuring Optimizer Statistics for InnoDB”](#). Also see [Section 14.9.11.1, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#) and [Section 14.11.1.7, “Limits on InnoDB Tables”](#).

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

**ANALYZE TABLE** is supported for partitioned tables, and you can use [ALTER TABLE ... ANALYZE PARTITION](#) to analyze one or more partitions; for more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 19.3.3, “Maintenance of Partitions”](#).

**ANALYZE TABLE** returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>analyze</code>  |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |
| Msg_text | An informational message   |

You can check the stored key distribution with the [SHOW INDEX](#) statement. See [Section 13.7.5.23, “SHOW INDEX Syntax”](#).

If the table has not changed since the last **ANALYZE TABLE** statement, the table is not analyzed again.

By default, the server writes **ANALYZE TABLE** statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

### 13.7.2.2 CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

```
option = {
    FOR UPGRADE
  | QUICK
  | FAST
  | MEDIUM
  | EXTENDED
  | CHANGED
}
```

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for `InnoDB`, `MyISAM`, `ARCHIVE`, and `CSV` tables. For `MyISAM` tables, the key statistics are updated as well.

Before running `CHECK TABLE` on `InnoDB` tables, see [CHECK TABLE Usage Notes for InnoDB Tables](#).

To check a table, you must have some privilege for it.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 19.3.3, “Maintenance of Partitions”](#).

## Output

`CHECK TABLE` returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>check</code>  |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |
| Msg_text | An informational message   |

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. If you don't get `OK`, or `Table is already up to date` for a `MyISAM` table, you should normally run a repair of the table. See [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#). `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

## Checking Version Compatibility

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

`FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.
- If your table was created by a different version of the MySQL server than the one you are currently running, `FOR UPGRADE` indicates that the table has an `.frm` file with an incompatible version. In this case, the result set returned by `CHECK TABLE` contains a line with a `Msg_type` value of `error` and a

Msg\_text value of Table upgrade required. Please do "REPAIR TABLE `tbl\_name`" to fix it!

- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.5”](#). For information about rebuilding tables, see [Section 2.11.3, “Rebuilding or Repairing Tables or Indexes”](#).

## Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use them or not.

| Type     | Meaning  |
|----------|--|
| QUICK    | Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.  |
| FAST     | Check only tables that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.   |
| CHANGED  | Check only tables that have been changed since the last check or that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.  |
| MEDIUM   | Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to MyISAM tables and views; ignored for InnoDB. |
| EXTENDED | Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to MyISAM tables and views; ignored for InnoDB.  |

If none of the options `QUICK`, `MEDIUM`, or `EXTENDED` are specified, the default check type for dynamic-format MyISAM tables is `MEDIUM`. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is `MEDIUM` for static-format MyISAM tables, unless `CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

### Note

If `CHECK TABLE` finds no problems with a table that is marked as “corrupted” or “not closed properly”, `CHECK TABLE` may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) if you want to check tables from time to time. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)

`EXTENDED` is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of `CHECK TABLE ... EXTENDED` might influence the execution plan generated by the query optimizer.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- Found row where the `auto_increment` column has the value 0.

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, execute an `UPDATE` statement to set the column to some value other than 0.

## CHECK TABLE Usage Notes for InnoDB Tables

The following notes apply to `InnoDB` tables:

- If `CHECK TABLE` encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running `CHECK TABLE` can still cause a server exit.
- If `CHECK TABLE` encounters a corrupted `DB_TRX_ID` or `DB_ROLL_PTR` field in a clustered index, `CHECK TABLE` can cause `InnoDB` to access an invalid undo log record, resulting in an `MVCC`-related server exit.
- If `CHECK TABLE` encounters errors in `InnoDB` tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.
- If `CHECK TABLE` finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.
- `CHECK TABLE` surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for `BLOB` pointers.
- When an `InnoDB` table is stored in its own `.ibd` file, the first 3 pages of the `.ibd` file contain header information rather than table or index data. The `CHECK TABLE` statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an `InnoDB .ibd` file, use the `innochecksum` command.
- When running `CHECK TABLE` on large `InnoDB` tables, other threads may be blocked during `CHECK TABLE` execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for `CHECK TABLE` operations. If `InnoDB` detects semaphore waits of 240 seconds or more it starts printing `InnoDB` monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, `InnoDB` aborts the process. To avoid the possibility of a semaphore wait timeout entirely, you can run `CHECK TABLE QUICK` instead of `CHECK TABLE`.

### 13.7.2.3 CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED]
```

**CHECKSUM TABLE** reports a table checksum. During the checksum operation, the table is locked with a read lock for **InnoDB** and **MyISAM**. This statement requires the **SELECT** privilege for the table.

This statement is not supported for views. If you run **CHECKSUM TABLE** against a view, the **Checksum** value is always **NULL**, and a warning is returned.

With **QUICK**, the live table checksum is reported if it is available, or **NULL** otherwise. This is very fast. A live checksum is enabled by specifying the **CHECKSUM=1** table option when you create the table; currently, this is supported only for **MyISAM** tables. See [Section 13.1.17, “CREATE TABLE Syntax”](#).

With **EXTENDED**, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither **QUICK** nor **EXTENDED** is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

For a nonexistent table, **CHECKSUM TABLE** returns **NULL** and generates a warning.

In MySQL 5.5, **CHECKSUM TABLE** returns 0 for partitioned tables unless you include the **EXTENDED** option. This issue is resolved in MySQL 5.6. (Bug #11933226, Bug #60681)

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as **TIME**, **DATETIME**, and **TIMESTAMP** changes in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

#### Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by **CHECKSUM TABLE** is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

### 13.7.2.4 OPTIMIZE TABLE Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE  
  tbl_name [, tbl_name] ...
```

Reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the **storage engine** used by that table. This statement does not work with views.

Use **OPTIMIZE TABLE** in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an **InnoDB** table that has its own **.ibd** file because it was created with the **innodb\_file\_per\_table** option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.
- After deleting a large part of a **MyISAM** or **ARCHIVE** table, or making many changes to a **MyISAM** or **ARCHIVE** table with variable-length rows (tables that have **VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT** columns). Deleted rows are maintained in a linked list and subsequent **INSERT** operations reuse old row positions. You can use **OPTIMIZE TABLE** to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

[OPTIMIZE TABLE](#) is also supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see [Section 19.3.3, “Maintenance of Partitions”](#).

[OPTIMIZE TABLE](#) works for [InnoDB](#), [MyISAM](#), and [ARCHIVE](#) tables. [OPTIMIZE TABLE](#) is also supported for dynamic columns of in-memory [NDB](#) tables. It does not work for Disk Data tables. The performance of [OPTIMIZE](#) on Cluster tables can be tuned by adjusting the value of the [ndb\\_optimization\\_delay](#) system variable, which controls the number of milliseconds to wait between processing batches of rows by [OPTIMIZE TABLE](#). For more information, see [Section 18.1.6.11, “Previous NDB Cluster Issues Resolved in MySQL 5.1, NDB Cluster 6.x, and NDB Cluster 7.x”](#).

For [NDB Cluster](#) tables, [OPTIMIZE TABLE](#) can be interrupted by (for example) killing the SQL thread performing the [OPTIMIZE](#) operation.

By default, [OPTIMIZE TABLE](#) does *not* work for tables created using any other storage engine and returns a result indicating this lack of support. You can make [OPTIMIZE TABLE](#) work for other storage engines by starting [mysqld](#) with the [--skip-new](#) option. In this case, [OPTIMIZE TABLE](#) is just mapped to [ALTER TABLE](#).

## InnoDB Details

For [InnoDB](#) tables, [OPTIMIZE TABLE](#) is mapped to [ALTER TABLE](#), which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of [OPTIMIZE TABLE](#) when you run it on an [InnoDB](#) table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
```

| Table    | Op       | Msg_type | Msg_text  |
|----------|----------|----------|---|
| test.foo | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status   | OK  |

This operation does not use fast index creation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. See [Section 14.16.6, “Limitations of Fast Index Creation”](#).

[InnoDB](#) stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as [MyISAM](#)) will. When considering whether or not to run optimize, consider the workload of transactions that your server will process:

- Some level of fragmentation is expected. [InnoDB](#) only fills [pages](#) 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See [Section 14.12.5, “How Compression Works for InnoDB Tables”](#) and [Section 14.14.1, “Overview of InnoDB Row Storage”](#).
- High-concurrency workloads might leave gaps in indexes over time, as [InnoDB](#) retains multiple versions of the same data due through its [MVCC](#) mechanism. See [Section 14.6, “InnoDB Multi-Versioning”](#).

## MyISAM Details

For [MyISAM](#) tables, [OPTIMIZE TABLE](#) works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

## Other Considerations

`OPTIMIZE TABLE` returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>optimize</code>   |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |
| Msg_text | An informational message   |

Note that MySQL **locks the table** during the time `OPTIMIZE TABLE` is running.

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on `POINT` columns. (Bug #23578)

As of MySQL 5.5.6, `OPTIMIZE TABLE` catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

### 13.7.2.5 REPAIR TABLE Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
      tbl_name [, tbl_name] ...
      [QUICK] [EXTENDED] [USE_FRM]
```

`REPAIR TABLE` repairs a possibly corrupted table. By default, it has the same effect as `myisamchk --recover tbl_name`. `REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables. See [Section 15.3, “The MyISAM Storage Engine”](#), [Section 15.6, “The ARCHIVE Storage Engine”](#), and [Section 15.5, “The CSV Storage Engine”](#). This statement does not work with views.

This statement requires `SELECT` and `INSERT` privileges for the table.

`REPAIR TABLE` is supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 19.3.3, “Maintenance of Partitions”](#).

Normally, you should never have to run `REPAIR TABLE`. However, if disaster strikes, this statement is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 15.3.4, “MyISAM Table Problems”](#).

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See [Chapter 7, Backup and Recovery](#).

**Warning**

If the server crashes during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

`REPAIR TABLE` returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>repair</code>   |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |
| Msg_text | An informational message   |

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. If you do not get `OK` for a `MyISAM` table, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.

If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

**Caution**

Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used

with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

#### Caution

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` will not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is *not* used, `REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), for more information. `REPAIR TABLE` without `USE_FRM` upgrades the `.frm` file to the current version.

By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

#### Important

In the event that a table on the master becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are *not* propagated to slaves.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See [Section 8.6.3, “Optimizing REPAIR TABLE Statements”](#).

As of MySQL 5.5.6, `REPAIR TABLE` catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

## 13.7.3 Plugin and User-Defined Function Statements

### 13.7.3.1 CREATE FUNCTION Syntax for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL|DECIMAL}
    SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

*function\_name* is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

*shared\_library\_name* is the base name of the shared library file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see [Section 24.4.2.5, “UDF Compiling and Installing”](#).

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see [Section 24.4.2, “Adding a New User-Defined Function”](#). For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#)).

#### Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

### 13.7.3.2 DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *function\_name*.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

#### Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see [Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)).

### 13.7.3.3 INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table.

*plugin\_name* is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see [Section 24.2.4.2, “Plugin Data Structures”](#)). Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

*shared\_library\_name* is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` table. At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see [Section 5.5.2, “Installing and Uninstalling Plugins”](#). If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See [Section 5.1.4, “Server Command Options”](#).

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.3.4 UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. It requires the `DELETE` privilege for the `mysql.plugin` system table. `UNINSTALL PLUGIN` is the complement of `INSTALL PLUGIN`.

`plugin_name` must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

## 13.7.4 SET Syntax

The `SET` statement has several forms:

- `SET var_name = value` enables you to assign values to variables that affect the operation of the server or clients. See [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).
- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the current connection to the server. See [Section 13.7.4.2, “SET CHARACTER SET Syntax”](#), and [Section 13.7.4.3, “SET NAMES Syntax”](#).
- `SET PASSWORD` assigns account passwords. See [Section 13.7.1.6, “SET PASSWORD Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

### 13.7.4.1 SET Syntax for Variable Assignment

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
    user_var_name = expr
  | param_name = expr
  | local_var_name = expr
  | [GLOBAL | SESSION]
    system_var_name = expr
  | [@@global. | @@session. | @@]
    system_var_name = expr

SET ONE_SHOT system_var_name = expr
```

`SET` syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- System variables. See [Section 5.1.5, “Server System Variables”](#). System variables also can be set at server startup, as described in [Section 5.1.6, “Using System Variables”](#). (To *display* system variable

names and values, use the `SHOW VARIABLES` statement; see [Section 13.7.5.40, “SHOW VARIABLES Syntax”](#).)

- User-defined variables. See [Section 9.4, “User-Defined Variables”](#).
- Stored procedure and function parameters, and stored program local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).

Older versions of MySQL employed `SET OPTION`, but this syntax is deprecated in favor of `SET` without `OPTION`.

A `SET` statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each one.

The following examples illustrate `SET` syntax for setting variables. They use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.

A user variable is written as `@var_name` and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

The `expr` can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `counter` local variable as a loop counter:

```
CREATE PROCEDURE p()
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + 1;
  END WHILE;
END;
```

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see [Section 5.1.6.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier:

- To indicate that a variable is a global variable, precede its name by the `GLOBAL` keyword or the `@@global.` qualifier:

```
SET GLOBAL max_connections = 1000;
SET @@global.max_connections = 1000;
```

The `SUPER` privilege is required to set global variables.

- To indicate that a variable is a session variable, precede its name by the `SESSION` keyword or either the `@@session.` or `@@` qualifier:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

Setting a session variable normally requires no special privilege, although there are exceptions that require the [SUPER](#) privilege (such as [sql\\_log\\_bin](#)). A client can change its own session variables, but not those of any other client.

- [LOCAL](#) and [@@local.](#) are synonyms for [SESSION](#) and [@@session..](#)
- If no modifier is present, [SET](#) changes the session variable.
- An error occurs under these circumstances:
  - Use of [SET GLOBAL](#) (or [@@global.](#)) when setting a variable that has only a session value:

```
mysql> SET GLOBAL sql_log_bin = ON;
ERROR 1231 (42000): Variable 'sql_log_bin' can't be
set to the value of 'ON'
```

- Omission of [GLOBAL](#) (or [@@global.](#)) when setting a variable that has only a global value:

```
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- Use of [SET SESSION](#) (or [@@SESSION.](#)) when setting a variable that has only a global value:

```
mysql> SET SESSION max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

The preceding modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

A [SET](#) statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables, the most recent [GLOBAL](#) or [SESSION](#) modifier in the statement is used for following assignments that have no modifier specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@global.sort_buffer_size = 1000000, @@local.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

If any variable assignment in a [SET](#) statement fails, the entire statement fails and no variables are changed.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any current client sessions (not even the session within which the `SET GLOBAL` statement occurred).

To make a global system variable setting permanent so that it applies across server restarts, you should also set it in an option file.

To set a `GLOBAL` value to the compiled-in MySQL default value or a `SESSION` variable to the current corresponding `GLOBAL` value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```
SET @@session.max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

It is not permitted to assign `DEFAULT` to user-defined variables, and not supported for stored procedure or function parameters or stored program local variables. This results in an error for user-defined variables, and the results are undefined for parameters or local variables.

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

For a reference to a system variable in an expression as `@@var_name` (rather than with `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

The `SET ONE_SHOT` syntax is *only* for internal use for replication: `mysqlbinlog` uses `SET ONE_SHOT` to modify temporarily the values of character set, collation, and time zone variables to reflect at rollforward what they were originally. `ONE_SHOT` is for internal use only and is deprecated for MySQL 5.0 and up.

`ONE_SHOT` is intended for use only with the permitted set of variables. It changes the variables as requested, but only for the next non-`SET` statement. After that, the server resets all character set, collation, and time zone-related system variables to their previous values. Example:

```
mysql> SET ONE_SHOT character_set_connection = latin5;

mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;

mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin5 |
| collation_connection | latin5_turkish_ci |
+-----+-----+

mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin1 |
| collation_connection | latin1_swedish_ci |
+-----+-----+
```

### 13.7.4.2 SET CHARACTER SET Syntax

```
SET {CHARACTER SET | CHARSET}
    {'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See [Section 10.1.4, “Connection Character Sets and Collations”](#).

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET CHARACTER SET`.

### 13.7.4.3 SET NAMES Syntax

```
SET NAMES {'charset_name'
          [COLLATE 'collation_name'] | DEFAULT}
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See [Section 10.1.4, “Connection Character Sets and Collations”](#).

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for `charset_name`.

`charset_name` and `collation_name` may be quoted or unquoted.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES`.

## 13.7.5 SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW AUTHORS
SHOW {BINARY | MASTER} LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CONTRIBUTORS
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
```

```

SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where:
    LIKE 'pattern'
    | WHERE expr

```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, '*pattern*' is a string that can contain the SQL `%` and `_` wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 21.31, “Extensions to SHOW Statements”](#).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see [Chapter 23, Connectors and APIs](#), or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See [Chapter 21, INFORMATION\\_SCHEMA Tables](#).

### 13.7.5.1 SHOW AUTHORS Syntax

```
SHOW AUTHORS
```

The `SHOW AUTHORS` statement displays information about the people who work on MySQL. For each author, it displays `Name`, `Location`, and `Comment` values.

This statement is deprecated as of MySQL 5.5.29 and is removed in MySQL 5.6.

### 13.7.5.2 SHOW BINARY LOGS Syntax

```
SHOW BINARY LOGS
```

**SHOW MASTER LOGS**

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#), that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015     | 724935   |
| binlog.000016     | 733481   |
+-----+-----+
```

**SHOW MASTER LOGS** is equivalent to **SHOW BINARY LOGS**.

In MySQL 5.5.24 and earlier, the **SUPER** privilege was required to use this statement. Starting with MySQL 5.5.25, a user with the **REPLICATION CLIENT** privilege may also execute this statement.

### 13.7.5.3 SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS
[IN 'log_name']
[FROM pos]
[LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify `'log_name'`, the first binary log is displayed.

The **LIMIT** clause has the same syntax as for the **SELECT** statement. See [Section 13.2.9, “SELECT Syntax”](#).

#### Note

Issuing a **SHOW BINLOG EVENTS** with no **LIMIT** clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to **SHOW BINLOG EVENTS**, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

#### Note

Some events relating to the setting of user and system variables are not included in the output from **SHOW BINLOG EVENTS**. To get complete coverage of events within a binary log, use `mysqlbinlog`.

#### Note

**SHOW BINLOG EVENTS** does *not* work with relay log files. You can use **SHOW RELAYLOG EVENTS** for this purpose.

### 13.7.5.4 SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

| Charset | Description                 | Default collation | Maxlen |
|---------|-----------------------------|-------------------|--------|
| latin1  | cp1252 West European        | latin1_swedish_ci | 1      |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1      |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci | 1      |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci | 1      |

The `Maxlen` column shows the maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

You can also obtain information about character sets from `INFORMATION_SCHEMA`, which contains a `CHARACTER_SETS` table. See [Section 21.1, “The INFORMATION\\_SCHEMA CHARACTER\\_SETS Table”](#).

### 13.7.5.5 SHOW COLLATION Syntax

```
SHOW COLLATION
  [LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

| Collation         | Charset | Id | Default | Compiled | Sortlen |
|-------------------|---------|----|---------|----------|---------|
| latin1_german1_ci | latin1  | 5  |         | Yes      | 1       |
| latin1_swedish_ci | latin1  | 8  | Yes     | Yes      | 1       |
| latin1_danish_ci  | latin1  | 15 |         | Yes      | 1       |
| latin1_german2_ci | latin1  | 31 |         | Yes      | 2       |
| latin1_bin        | latin1  | 47 |         | Yes      | 1       |
| latin1_general_ci | latin1  | 48 |         | Yes      | 1       |
| latin1_general_cs | latin1  | 49 |         | Yes      | 1       |
| latin1_spanish_ci | latin1  | 94 |         | Yes      | 1       |

The `Collation` and `Charset` columns indicate the names of the collation and the character set with which it is associated. `Id` is the collation ID. `Default` indicates whether the collation is the default for its character set. `Compiled` indicates whether the character set is compiled into the server. `Sortlen` is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
```

| Collation | Charset | Id | Default | Compiled | Sortlen |
|-----------|---------|----|---------|----------|---------|
|-----------|---------|----|---------|----------|---------|

|                   |        |   |     |     |   |
|-------------------|--------|---|-----|-----|---|
| big5_chinese_ci   | big5   | 1 | Yes | Yes | 1 |
| dec8_swedish_ci   | dec8   | 3 | Yes | Yes | 1 |
| cp850_general_ci  | cp850  | 4 | Yes | Yes | 1 |
| hp8_english_ci    | hp8    | 6 | Yes | Yes | 1 |
| koi8r_general_ci  | koi8r  | 7 | Yes | Yes | 1 |
| latin1_swedish_ci | latin1 | 8 | Yes | Yes | 1 |
| ...               |        |   |     |     |   |

You can also obtain information about collations from [INFORMATION\\_SCHEMA](#), which contains a [COLLATIONS](#) table. See [Section 21.2, “The INFORMATION\\_SCHEMA COLLATIONS Table”](#).

### 13.7.5.6 SHOW COLUMNS Syntax

```
SHOW [FULL] {COLUMNS | FIELDS}
  {FROM | IN} tbl_name
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

[SHOW COLUMNS](#) displays information about the columns in a given table. It also works for views. [SHOW COLUMNS](#) displays information only for those columns for which you have some privilege.

You can use [db\\_name.tbl\\_name](#) as an alternative to the [tbl\\_name FROM db\\_name](#) syntax. In other words, these two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

The optional [FULL](#) keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The [LIKE](#) clause, if present, indicates which column names to match. The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#).

```
mysql> SHOW COLUMNS FROM City;
```

| Field       | Type     | Null | Key | Default | Extra          |
|-------------|----------|------|-----|---------|----------------|
| ID          | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name        | char(35) | NO   |     |         |                |
| CountryCode | char(3)  | NO   | MUL |         |                |
| District    | char(20) | NO   |     |         |                |
| Population  | int(11)  | NO   |     | 0       |                |

The data types may differ from what you expect them to be based on a [CREATE TABLE](#) statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in [Section 13.1.17.7, “Silent Column Specification Changes”](#).

[SHOW COLUMNS](#) displays the following values for each table column:

- [Field](#)

The column name.

- [Type](#)

The column data type.

- **Collation**

The collation for nonbinary string columns, or **NULL** for other columns. This value is displayed only if you use the **FULL** keyword.

- **Null**

Column nullability. The value is **YES** if **NULL** values can be stored in the column, **NO** if not.

- **Key**

Whether the column is indexed:

- If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If **Key** is **PRI**, the column is a **PRIMARY KEY** or is one of the columns in a multiple-column **PRIMARY KEY**.
- If **Key** is **UNI**, the column is the first column of a **UNIQUE** index. (A **UNIQUE** index permits multiple **NULL** values, but you can tell whether the column permits **NULL** by checking the **Null** field.)
- If **Key** is **MUL**, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order **PRI**, **UNI**, **MUL**.

A **UNIQUE** index may be displayed as **PRI** if it cannot contain **NULL** values and there is no **PRIMARY KEY** in the table. A **UNIQUE** index may display as **MUL** if several columns form a composite **UNIQUE** index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **Default**

The default value for the column. This is **NULL** if the column has an explicit default of **NULL**, or if the column definition includes no **DEFAULT** clause.

- **Extra**

Any additional information that is available about a given column. The value is nonempty in these cases: **auto\_increment** for columns that have the **AUTO\_INCREMENT** attribute; **on update CURRENT\_TIMESTAMP** for **TIMESTAMP** columns that have the **ON UPDATE CURRENT\_TIMESTAMP** attribute.

- **Privileges**

The privileges you have for the column. This value is displayed only if you use the **FULL** keyword.

- **Comment**

Any comment included in the column definition. This value is displayed only if you use the **FULL** keyword.

You can also obtain information about table columns from **INFORMATION\_SCHEMA**, which contains a **COLUMNS** table. See [Section 21.4, “The INFORMATION\\_SCHEMA COLUMNS Table”](#).

You can list a table's columns with the **mysqlshow db\_name tbl\_name** command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See [Section 13.8.1, “DESCRIBE Syntax”](#).

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.5, “SHOW Syntax”](#).

### 13.7.5.7 SHOW CONTRIBUTORS Syntax

```
SHOW CONTRIBUTORS
```

The `SHOW CONTRIBUTORS` statement displays information about the people who contribute to MySQL source or to causes that we support. For each contributor, it displays `Name`, `Location`, and `Comment` values.

This statement is deprecated as of MySQL 5.5.29 and is removed in MySQL 5.6.

### 13.7.5.8 SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.5, “Server System Variables”](#).

### 13.7.5.9 SHOW CREATE EVENT Syntax

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in [Section 13.7.5.19, “SHOW EVENTS Syntax”](#)):

```
mysql> SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
      sql_mode:
      time_zone: SYSTEM
Create Event: CREATE EVENT `e_daily`
                ON SCHEDULE EVERY 1 DAY
                STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
                ON COMPLETION NOT PRESERVE
                ENABLE
```

```

        COMMENT 'Saves total number of sessions then
                clears the table each day'
    DO BEGIN
        INSERT INTO site_activity.totals (time, total)
            SELECT CURRENT_TIMESTAMP, COUNT(*)
            FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
    END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated.

Note that the output reflects the current status of the event (`ENABLE`) rather than the status with which it was created.

### 13.7.5.10 SHOW CREATE FUNCTION Syntax

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to `SHOW CREATE PROCEDURE` but for stored functions. See [Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”](#).

### 13.7.5.11 SHOW CREATE PROCEDURE Syntax

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions (see [Section 13.7.5.10, “SHOW CREATE FUNCTION Syntax”](#)).

To use either statement, you must be the user named in the routine `DEFINER` clause or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `Create Procedure` or `Create Function` field will be `NULL`.

```

mysql> SHOW CREATE PROCEDURE test.simpleproc\G
***** 1. row *****
      Procedure: simpleproc
      sql_mode:
  Create Procedure: CREATE PROCEDURE `simpleproc` (OUT param1 INT)
                    BEGIN
                    SELECT COUNT(*) INTO param1 FROM t;
                    END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
  Create Function: CREATE FUNCTION `hello` (s CHAR(20))
                  RETURNS CHAR(50)
                  RETURN CONCAT('Hello, ',s, '!')
character_set_client: latin1
collation_connection: latin1_swedish_ci

```

```
Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

### 13.7.5.12 SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `s` char(60) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.5, “Server System Variables”](#).

### 13.7.5.13 SHOW CREATE TRIGGER Syntax

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows the `CREATE TRIGGER` statement that creates the named trigger. This statement requires the `TRIGGER` privilege for the table associated with the trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
***** 1. row *****
      Trigger: ins_sum
      sql_mode:
SQL Original Statement: CREATE DEFINER=`bob`@`localhost` TRIGGER ins_sum
                        BEFORE INSERT ON account
                        FOR EACH ROW SET @sum = @sum + NEW.amount
      character_set_client: latin1
      collation_connection: latin1_swedish_ci
      Database Collation: latin1_swedish_ci
```

`SHOW CREATE TRIGGER` output has the following columns:

- **Trigger:** The trigger name.
- **sql\_mode:** The SQL mode in effect when the trigger executes.
- **SQL Original Statement:** The `CREATE TRIGGER` statement that defines the trigger.
- **character\_set\_client:** The session value of the `character_set_client` system variable when the trigger was created.
- **collation\_connection:** The session value of the `collation_connection` system variable when the trigger was created.

- [Database Collation](#): The collation of the database with which the trigger is associated.

You can also obtain information about trigger objects from [INFORMATION\\_SCHEMA](#), which contains a [TRIGGERS](#) table. See [Section 21.25](#), “The [INFORMATION\\_SCHEMA TRIGGERS Table](#)”.

### 13.7.5.14 SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows the [CREATE VIEW](#) statement that creates the named view.

```
mysql> SHOW CREATE VIEW v\G
***** 1. row *****
          View: v
      Create View: CREATE ALGORITHM=UNDEFINED
                  DEFINER=`bob`@`localhost`
                  SQL SECURITY DEFINER VIEW
                  `v` AS select 1 AS `a`,2 AS `b`
character_set_client: latin1
collation_connection: latin1_swedish_ci
```

[character\\_set\\_client](#) is the session value of the [character\\_set\\_client](#) system variable when the view was created. [collation\\_connection](#) is the session value of the [collation\\_connection](#) system variable when the view was created.

Use of [SHOW CREATE VIEW](#) requires the [SHOW VIEW](#) privilege, and the [SELECT](#) privilege for the view in question.

You can also obtain information about view objects from [INFORMATION\\_SCHEMA](#), which contains a [VIEWS](#) table. See [Section 21.27](#), “The [INFORMATION\\_SCHEMA VIEWS Table](#)”.

MySQL lets you use different [sql\\_mode](#) settings to tell the server the type of SQL syntax to support. For example, you might use the [ANSI](#) SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the [sql\\_mode](#) setting to a value different from [ANSI](#) could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a [CONCAT\(\)](#) function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
***** 1. row *****
          View: v
      Create View: CREATE VIEW "v" AS select concat('a','b') AS "coll"
...
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of [sql\\_mode](#) will not affect the results from the view. However an additional consequence is that comments prior to [SELECT](#) are stripped from the definition by the server.

### 13.7.5.15 SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

### 13.7.5.16 SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE {NDB | NDBCLUSTER} STATUS
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
```

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard `InnoDB` Monitor about the state of the `InnoDB` storage engine. For information about the standard monitor and other `InnoDB` Monitors that provide information about `InnoDB` processing, see [Section 14.20, “InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays `InnoDB mutex` and `rw-lock` statistics. Statement output has the following columns:

- `Type`

Always `InnoDB`.

- `Name`

The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of MySQL.

- `Status`

The mutex status. This field displays several values if `UNIV_DEBUG` was defined at MySQL compilation time (for example, in `include/univ.i` in the `InnoDB` part of the MySQL source tree). If `UNIV_DEBUG` was not defined, the statement displays only the `os_waits` value. In the latter case (without `UNIV_DEBUG`), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect `rw-locks` (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.

- `count` indicates how many times the mutex was requested.

- `spin_waits` indicates how many times the spinlock had to run.
- `spin_rounds` indicates the number of spinlock rounds. (`spin_rounds` divided by `spin_waits` provides the average round count.)
- `os_waits` indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
- `os_yields` indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run will free the mutex so that it can be locked).
- `os_wait_times` indicates the amount of time (in ms) spent in operating system waits. In MySQL 5.5 timing is disabled and this value is always 0.

As of MySQL 5.5, `SHOW ENGINE INNODB MUTEX` skips the `mutexes` and `rw-locks` of `buffer pool` blocks, as the amount of output can be overwhelming on systems with a large buffer pool. (There is one mutex and one rw-lock in each 16K buffer pool block, and there are 65,536 blocks per gigabyte.) `SHOW ENGINE INNODB MUTEX` also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level `wait`.

`SHOW ENGINE INNODB MUTEX` information can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.row_size
  Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.row_count
  Status: 10000
***** 5. row *****
  Type: performance_schema
  Name: events_waits_history.memory
  Status: 760000
...
***** 57. row *****
  Type: performance_schema
  Name: performance_schema.memory
  Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

`Name` values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: `(pfs_cond_class).row_size`, `(pfs_mutex_class).memory`.

- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.row_size`, `mutex_instances.row_count`.
- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example: `performance_schema.memory`.

Buffer attributes have these meanings:

- `row_size` is the size of the internal record used by the implementation, such as the size of a row in a table. `row_size` values cannot be changed.
- `row_count` is the number of internal records, such as the number of rows in a table. `row_count` values can be changed using Performance Schema configuration options.
- For a table, `tbl_name.memory` is the product of `row_size` and `row_count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.row_count` corresponds to `performance_schema_events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.row_count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` ( the number of threads).

If the server has the `NDBCLUSTER` storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
```

| Type       | Name                  | Status   |
|------------|-----------------------|--|
| ndbcluster | connection            | cluster_node_id=7,<br>connected_host=192.168.0.103, connected_port=1186, number_of_data_nodes=4,<br>number_of_ready_data_nodes=3, connect_count=0  |
| ndbcluster | NdbTransaction        | created=6, free=0, sizeof=212  |
| ndbcluster | NdbOperation          | created=8, free=8, sizeof=660  |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744  |
| ndbcluster | NdbIndexOperation     | created=0, free=0, sizeof=664  |
| ndbcluster | NdbRecAttr            | created=1285, free=1285, sizeof=60   |
| ndbcluster | NdbApiSignal          | created=16, free=16, sizeof=136  |
| ndbcluster | NdbLabel              | created=0, free=0, sizeof=196  |
| ndbcluster | NdbBranch             | created=0, free=0, sizeof=24   |
| ndbcluster | NdbSubroutine         | created=0, free=0, sizeof=68   |
| ndbcluster | NdbCall               | created=0, free=0, sizeof=16   |
| ndbcluster | NdbBlob               | created=1, free=1, sizeof=264  |
| ndbcluster | NdbReceiver           | created=4, free=0, sizeof=68   |
| ndbcluster | binlog                | latest_epoch=155467, latest_trans_epoch=148126,<br>latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0,<br>latest_applied_binlog_epoch=0 |

The rows with `connection` and `binlog` in the `Name` column were added to the output of this statement in MySQL 5.1. The `Status` column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The `Status` information is in the form of comma-delimited set of name/value pairs.

The `connection` row's `Status` column contains the name/value pairs described in the following table.

| Name                                    | Value   |
|---|---|
| <code>cluster_node_id</code>            | The node ID of the MySQL server in the cluster  |
| <code>connected_host</code>             | The host name or IP address of the cluster management server to which the MySQL server is connected   |
| <code>connected_port</code>             | The port used by the MySQL server to connect to the management server ( <code>connected_host</code> )   |
| <code>number_of_data_nodes</code>       | The number of data nodes configured for the cluster (that is, the number of <code>[ndbd]</code> sections in the cluster <code>config.ini</code> file) |
| <code>number_of_ready_data_nodes</code> | The number of data nodes in the cluster that are actually running   |
| <code>connect_count</code>              | The number of times this <code>mysqld</code> has connected or reconnected to cluster data nodes   |

The `binlog` row's `Status` column contains information relating to NDB Cluster Replication. The name/value pairs it contains are described in the following table.

| Name                                      | Value  |
|---|--|
| <code>latest_epoch</code>                 | The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server) |
| <code>latest_trans_epoch</code>           | The most recent epoch processed by the cluster's data nodes  |
| <code>latest_received_binlog_epoch</code> | The most recent epoch received by the binary log thread  |
| <code>latest_handled_binlog_epoch</code>  | The most recent epoch processed by the binary log thread (for writing to the binary log)   |
| <code>latest_applied_binlog_epoch</code>  | The most recent epoch actually written to the binlog   |

See [Section 18.6, “NDB Cluster Replication”](#), for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by `Name`:

- `NdbTransaction`: The number and size of `NdbTransaction` objects that have been created. An `NdbTransaction` is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an NDB table.
- `NdbOperation`: The number and size of `NdbOperation` objects that have been created.
- `NdbIndexScanOperation`: The number and size of `NdbIndexScanOperation` objects that have been created.
- `NdbIndexOperation`: The number and size of `NdbIndexOperation` objects that have been created.
- `NdbRecAttr`: The number and size of `NdbRecAttr` objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.
- `NdbBlob`: The number and size of `NdbBlob` objects that have been created. An `NdbBlob` is created for each new operation involving a `BLOB` column in an NDB table.

- **NdbReceiver**: The number and size of any **NdbReceiver** object that have been created. The number in the **created** column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

#### Note

**SHOW ENGINE NDB STATUS** returns an empty result if no operations involving **NDB** tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

### 13.7.5.17 SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

**SHOW ENGINES** displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. This information can also be obtained from the **INFORMATION\_SCHEMA ENGINES** table. See [Section 21.6, “The INFORMATION\\_SCHEMA ENGINES Table”](#).

```
mysql> SHOW ENGINES\G
***** 1. row *****
      Engine: FEDERATED
      Support: NO
      Comment: Federated MySQL storage engine
Transactions: NULL
           XA: NULL
      Savepoints: NULL
***** 2. row *****
      Engine: MRG_MYISAM
      Support: YES
      Comment: Collection of identical MyISAM tables
Transactions: NO
           XA: NO
      Savepoints: NO
***** 3. row *****
      Engine: MyISAM
      Support: YES
      Comment: MyISAM storage engine
Transactions: NO
           XA: NO
      Savepoints: NO
***** 4. row *****
      Engine: BLACKHOLE
      Support: YES
      Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
           XA: NO
      Savepoints: NO
***** 5. row *****
      Engine: CSV
      Support: YES
      Comment: CSV storage engine
Transactions: NO
           XA: NO
      Savepoints: NO
***** 6. row *****
      Engine: MEMORY
      Support: YES
      Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
           XA: NO
      Savepoints: NO
```

```

***** 7. row *****
      Engine: ARCHIVE
      Support: YES
      Comment: Archive storage engine
Transactions: NO
      XA: NO
      Savepoints: NO
***** 8. row *****
      Engine: InnoDB
      Support: DEFAULT
      Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
      XA: YES
      Savepoints: YES
***** 9. row *****
      Engine: PERFORMANCE_SCHEMA
      Support: YES
      Comment: Performance Schema
Transactions: NO
      XA: NO
      Savepoints: NO

```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for the storage engine, as shown in the following table.

| Value    | Meaning                                       |
|----------|---|
| YES      | The engine is supported and is active         |
| DEFAULT  | Like YES, plus this is the default engine     |
| NO       | The engine is not supported                   |
| DISABLED | The engine is supported but has been disabled |

A value of `NO` means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See [Section 5.4.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the `NDBCLUSTER` storage engine, `DISABLED` means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support `MyISAM` tables. It is not possible to disable `MyISAM`.

The `Transactions`, `XA`, and `Savepoints` columns indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

### 13.7.5.18 SHOW ERRORS Syntax

```

SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS

```

`SHOW ERRORS` is a diagnostic statement that is similar to `SHOW WARNINGS`, except that it displays information only for errors, rather than for errors, warnings, and notes.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Syntax”](#).

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

`SHOW ERRORS` and `error_count` apply only to errors, not warnings or notes. In other respects, they are similar to `SHOW WARNINGS` and `warning_count`. In particular, `SHOW ERRORS` cannot display information for more than `max_error_count` messages, and `error_count` can exceed the value of `max_error_count` if the number of errors exceeds `max_error_count`.

For more information, see [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

### 13.7.5.19 SHOW EVENTS Syntax

```
SHOW EVENTS
  [{FROM | IN} schema_name]
  [LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events. It requires the `EVENT` privilege for the database from which the events are to be shown.

In its simplest form, `SHOW EVENTS` lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora   | myschema |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Time zone: SYSTEM
      Type: RECURRING
      Execute at: NULL
      Interval value: 10
      Interval field: SECOND
      Starts: 2006-02-09 10:41:23
      Ends: NULL
      Status: ENABLED
      Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#).

`SHOW EVENTS` output has the following columns:

- **Db:** The schema (database) on which the event is defined.
- **Name:** The name of the event.
- **Time zone:** The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
- **Definer:** The account of the user who created the event, in `'user_name'@'host_name'` format.
- **Type:** The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- **Execute At:** The date and time when a transient event is set to execute. Shown as a `DATETIME` value.  
For a recurring event, the value of this column is always `NULL`.
- **Interval Value:** For a recurring event, the number of intervals to wait between event executions.  
For a transient event, the value of this column is always `NULL`.
- **Interval Field:** The time units used for the interval which a recurring event waits before repeating.  
For a transient event, the value of this column is always `NULL`.
- **Starts:** The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event.  
For a transient event, this column is always `NULL`.
- **Ends:** The end date and time for a recurring event. This is displayed as a `DATETIME` value, and defaults to `NULL` if no end date and time is defined for the event.  
For a transient event, this column is always `NULL`.
- **Status:** The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.  
`SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.
- **Originator:** The server ID of the MySQL server on which the event was created. Defaults to 0.
- **character\_set\_client** is the session value of the `character_set_client` system variable when the routine was created. **collation\_connection** is the session value of the `collation_connection` system variable when the routine was created. **Database Collation** is the collation of the database with which the routine is associated.

For more information about `SLAVE_DISABLED` and the **Originator** column, see [Section 17.4.1.12, “Replication of Invoked Features”](#).

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA.EVENTS` table.

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in [Section 20.4.4, “Event Metadata”](#).

The columns in the output of `SHOW EVENTS` are similar to, but not identical to the columns in the `INFORMATION_SCHEMA.EVENTS` table. See [Section 21.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).

### 13.7.5.20 SHOW FUNCTION CODE Syntax

```
SHOW FUNCTION CODE func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See [Section 13.7.5.28](#), “`SHOW PROCEDURE CODE Syntax`”.

### 13.7.5.21 SHOW FUNCTION STATUS Syntax

```
SHOW FUNCTION STATUS
  [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See [Section 13.7.5.29](#), “`SHOW PROCEDURE STATUS Syntax`”.

### 13.7.5.22 SHOW GRANTS Syntax

```
SHOW GRANTS [FOR user]
```

This statement displays the privileges that are assigned to a MySQL user account, in the form of `GRANT` statements that must be executed to duplicate the privilege assignments. `SHOW GRANTS` requires the `SELECT` privilege for the `mysql` database, except to see the privileges for the current user.

For output that includes an `IDENTIFIED BY PASSWORD` clause displaying an account password hash value, the `SUPER` privilege is required to see the actual hash value. Otherwise, the value displays as `<secret>`.

To name the account, use the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see [Section 13.7.1.3](#), “`GRANT Syntax`”.

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+
| Grants for root@localhost                                     |
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

To display the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context, such as within a stored procedure that is defined with `SQL SECURITY DEFINER`, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges that might be available to the account are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

### 13.7.5.23 SHOW INDEX Syntax

```
SHOW {INDEX | INDEXES | KEYS}
    {FROM | IN} tbl_name
    [{FROM | IN} db_name]
    [WHERE expr]
```

**SHOW INDEX** returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#).

```
mysql> SHOW INDEX FROM City\G
***** 1. row *****
      Table: city
      Non_unique: 0
      Key_name: PRIMARY
      Seq_in_index: 1
      Column_name: ID
      Collation: A
      Cardinality: 4321
      Sub_part: NULL
      Packed: NULL
      Null:
      Index_type: BTREE
      Comment:
      Index_comment:
***** 2. row *****
      Table: city
      Non_unique: 1
      Key_name: CountryCode
      Seq_in_index: 1
      Column_name: CountryCode
      Collation: A
      Cardinality: 4321
      Sub_part: NULL
      Packed: NULL
      Null:
      Index_type: BTREE
      Comment:
      Index_comment:
```

**SHOW INDEX** returns the following fields:

- **Table**

The name of the table.

- **Non\_unique**

0 if the index cannot contain duplicates, 1 if it can.

- **Key\_name**

The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- `Seq_in_index`

The column sequence number in the index, starting with 1.

- `Column_name`

The column name.

- `Collation`

How the column is sorted in the index. This can have values `A` (ascending) or `NULL` (not sorted).

- `Cardinality`

An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

`Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- `Sub_part`

The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

**Note**

Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see [Section 8.3.4, “Column Indexes”](#), and [Section 13.1.13, “CREATE INDEX Syntax”](#).

- `Packed`

Indicates how the key is packed. `NULL` if it is not.

- `Null`

Contains `YES` if the column may contain `NULL` values and `' '` if not.

- `Index_type`

The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- `Comment`

Information about the index not described in its own column, such as `disabled` if the index is disabled.

- `Index_comment`

Any comment provided for the index with a [COMMENT](#) attribute when the index was created.

You can also obtain information about table indexes from [INFORMATION\\_SCHEMA](#), which contains a [STATISTICS](#) table. See [Section 21.20](#), “The [INFORMATION\\_SCHEMA STATISTICS](#) Table”.

You can list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.7.5.24 SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the master. It requires either the [SUPER](#) or [REPLICATION CLIENT](#) privilege.

Example:

```
mysql> SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003  | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

### 13.7.5.25 SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

[SHOW OPEN TABLES](#) lists the non-[TEMPORARY](#) tables that are currently open in the table cache. See [Section 8.4.3.1](#), “How MySQL Opens and Closes Tables”. The [FROM](#) clause, if present, restricts the tables shown to those present in the [db\\_name](#) database. The [LIKE](#) clause, if present, indicates which table names to match. The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 21.31](#), “Extensions to [SHOW](#) Statements”.

[SHOW OPEN TABLES](#) output has the following columns:

- [Database](#)

The database containing the table.

- [Table](#)

The table name.

- [In\\_use](#)

The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using [LOCK TABLE t1 WRITE](#), [In\\_use](#) will be 1. If another client issues [LOCK TABLE t1 WRITE](#) while the table remains locked, the client will block waiting for the lock, but the lock request causes [In\\_use](#) to be 2. If the count is zero, the table is open but not currently being used. [In\\_use](#) is also increased by the [HANDLER ... OPEN](#) statement and decreased by [HANDLER ... CLOSE](#).

- [Name\\_locked](#)

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

### 13.7.5.26 SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins. Plugin information is also available in the `INFORMATION_SCHEMA.PLUGINS` table. See [Section 21.13](#), “The `INFORMATION_SCHEMA.PLUGINS` Table”.

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
***** 1. row *****
  Name: binlog
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 2. row *****
  Name: CSV
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 3. row *****
  Name: MEMORY
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 4. row *****
  Name: MyISAM
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
...
```

`SHOW PLUGINS` output has the following columns:

- **Name:** The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- **Status:** The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- **Type:** The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- **Library:** The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- **License:** How the plugin is licensed; for example, `GPL`.

For plugins installed with `INSTALL PLUGIN`, the `Name` and `Library` values are also registered in the `mysql.plugin` table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see [Section 24.2, “The MySQL Plugin API”](#).

### 13.7.5.27 SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Databases
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...
```

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See [Section 13.7.5.22, “SHOW GRANTS Syntax”](#), for more information.

### 13.7.5.28 SHOW PROCEDURE CODE Syntax

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see [Section 13.7.5.20, “SHOW FUNCTION CODE Syntax”](#)).

To use either statement, you must be the owner of the routine or have `SELECT` access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is `Pos`, which is an ordinal number beginning with 0. The second column is `Instruction`, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
-> BEGIN
->   DECLARE fanta INT DEFAULT 55;
->   DROP TABLE t2;
```

```

-> LOOP
->     INSERT INTO t3 VALUES (fanta);
->     END LOOP;
-> END//
Query OK, 0 rows affected (0.00 sec)

```

```
mysql> SHOW PROCEDURE CODE p1//
```

```

+-----+-----+
| Pos | Instruction |
+-----+-----+
| 0 | set fanta@0 55 |
| 1 | stmt 9 "DROP TABLE t2" |
| 2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
| 3 | jump 2 |
+-----+-----+
4 rows in set (0.00 sec)

```

In this example, the nonexecutable `BEGIN` and `END` statements have disappeared, and for the `DECLARE variable_name` statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word `stmt` followed by a type (9 means `DROP`, 5 means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO instruction #2`.

### 13.7.5.29 SHOW PROCEDURE STATUS Syntax

```

SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]

```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW FUNCTION STATUS`, displays information about stored functions (see [Section 13.7.5.21](#), “`SHOW FUNCTION STATUS Syntax`”).

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 21.31](#), “`Extensions to SHOW Statements`”.

```

mysql> SHOW PROCEDURE STATUS LIKE 'spl'\G
***** 1. row *****
      Db: test
     Name: spl
    Type: PROCEDURE
  Definer: testuser@localhost
 Modified: 2004-08-03 15:29:37
   Created: 2004-08-03 15:29:37
Security_type: DEFINER
   Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See [Section 21.17](#), “`The INFORMATION_SCHEMA ROUTINES Table`”.

### 13.7.5.30 SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the `INFORMATION_SCHEMA PROCESSLIST` table or the `mysqladmin processlist` command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

This statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See [Section 13.7.6.4, “KILL Syntax”](#).

Here is an example of `SHOW PROCESSLIST` output:

```
mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave
      I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
```

```
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)
```

The columns produced by `SHOW PROCESSLIST` have the following meanings:

- `Id`

The connection identifier. This is the same type of value displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function.

- `User`

The MySQL user who issued the statement. If this is `system user`, it refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. `event_scheduler` refers to the thread that monitors scheduled events. For `system user`, there is no host specified in the `Host` column.

- `Host`

The host name of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the host name for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- `db`

The default database, if one is selected, otherwise `NULL`.

- `Command`

The type of command the thread is executing. For descriptions for thread commands, see [Section 8.14, “Examining Thread Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 5.1.7, “Server Status Variables”](#)

- `Time`

The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See [Section 17.2.1, “Replication Implementation Details”](#).

- `State`

An action, event, or state that indicates what the thread is doing. Descriptions for `State` values can be found at [Section 8.14, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the `SHOW PROCESSLIST` statement, the value of `State` is `NULL`.

- `Info`

The statement the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For

example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `Info` value shows the `SELECT` statement.

### 13.7.5.31 SHOW PROFILE Syntax

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]
```

*type*:

- ALL
- | BLOCK IO
- | CONTEXT SWITCHES
- | CPU
- | IPC
- | MEMORY
- | PAGE FAULTS
- | SOURCE
- | SWAPS

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Profiling is controlled by the `profiling` session variable, which has a default value of 0 (`OFF`). Profiling is enabled by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement *n*. The values of *n* correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to *row\_count* rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output *offset* rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see [Section 8.14, “Examining Thread Information”](#)).

Optional *type* values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times

- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-----+
| @@profiling |
+-----+
|          0 |
+-----+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE t1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+-----+-----+-----+
| Query_ID | Duration | Query |

+-----+-----+
| Status | Duration |
+-----+-----+
| query end | 0.000107 |
| freeing items | 0.000008 |
| logging slow query | 0.000015 |
| cleaning up | 0.000006 |
+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SHOW PROFILE CPU FOR QUERY 2;
```

| Status               | Duration | CPU_user | CPU_system |
|----------------------|----------|----------|------------|
| checking permissions | 0.000040 | 0.000038 | 0.000002   |
| creating table       | 0.000056 | 0.000028 | 0.000028   |
| After create         | 0.011363 | 0.000217 | 0.001571   |
| query end            | 0.000375 | 0.000013 | 0.000028   |
| freeing items        | 0.000089 | 0.000010 | 0.000014   |
| logging slow query   | 0.000019 | 0.000009 | 0.000010   |
| cleaning up          | 0.000005 | 0.000003 | 0.000002   |

```
7 rows in set (0.00 sec)
```

#### Note

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

You can also get profiling information from the `PROFILING` table in `INFORMATION_SCHEMA`. See [Section 21.15, “The INFORMATION\\_SCHEMA PROFILING Table”](#). For example, the following queries produce the same result:

```
SHOW PROFILE FOR QUERY 2;
```

```
SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

### 13.7.5.32 SHOW PROFILES Syntax

```
SHOW PROFILES
```

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see [Section 13.7.5.31, “SHOW PROFILE Syntax”](#).

### 13.7.5.33 SHOW RELAYLOG EVENTS Syntax

```
SHOW RELAYLOG EVENTS
[IN 'log_name']
[FROM pos]
[LIMIT [offset,] row_count]
```

Shows the events in the relay log of a replication slave. If you do not specify `'log_name'`, the first relay log is displayed. This statement has no effect on the master.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Syntax”](#).

#### Note

Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the

complete contents of the relay log (including all statements modifying data that have been received by the slave).

#### Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

### 13.7.5.34 SHOW SLAVE HOSTS Syntax

`SHOW SLAVE HOSTS`

Displays a list of replication slaves currently registered with the master. (Before MySQL 5.5.3, only slaves started with the `--report-host=host_name` option are visible in this list.)

`SHOW SLAVE HOSTS` should be executed on a server that acts as a replication master. The statement displays information about servers that are or have been connected as replication slaves, with each row of the result corresponding to one slave server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
```

| Server_id  | Host      | Port | Master_id |
|------------|-----------|------|-----------|
| 192168010  | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena    | 3306 | 192168011 |

- **Server\_id**: The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the slave server as specified on the slave with the `--report-host` option. This can differ from the machine name as configured in the operating system.
- **User**: The slave server user name as, specified on the slave with the `--report-user` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Password**: The slave server password as, specified on the slave with the `--report-password` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Port**: The port on the master to which the slave server is listening, as specified on the slave with the `--report-port` option.

In MySQL 5.5.23 and later, a zero in this column means that the slave port (`--report-port`) was not set. Prior to MySQL 5.5.23, 3306 was used as the default in such cases (Bug #13333431).

- **Master\_id**: The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.

Some MySQL versions report another variable, `Rpl_recovery_rank`. This variable was never used, and was removed in MySQL 5.5.3. (Bug #13963)

### 13.7.5.35 SHOW SLAVE STATUS Syntax

## SHOW SLAVE STATUS

This statement provides status information on essential parameters of the slave threads. It requires either the [SUPER](#) or [REPLICATION CLIENT](#) privilege.

If you issue this statement using the [mysql](#) client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: localhost
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 3
      Master_Log_File: gbichot-bin.005
      Read_Master_Log_Pos: 79
      Relay_Log_File: gbichot-relay-bin.005
      Relay_Log_Pos: 548
      Relay_Master_Log_File: gbichot-bin.005
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
      Last_Errno: 0
      Last_Error:
      Skip_Counter: 0
      Exec_Master_Log_Pos: 79
      Relay_Log_Space: 552
      Until_Condition: None
      Until_Log_File:
      Until_Log_Pos: 0
      Master_SSL_Allowed: No
      Master_SSL_CA_File:
      Master_SSL_CA_Path:
      Master_SSL_Cert:
      Master_SSL_Cipher:
      Master_SSL_Key:
      Seconds_Behind_Master: 8
      Master_SSL_Verify_Server_Cert: No
      Last_IO_Errno: 0
      Last_IO_Error:
      Last_SQL_Errno: 0
      Last_SQL_Error:
      Replicate_Ignore_Server_Ids: 0
      Master_Server_Id: 1
```

The following list describes the fields returned by [SHOW SLAVE STATUS](#). For additional information about interpreting their meanings, see [Section 8.14.6, “Replication Slave I/O Thread States”](#).

- [Slave\\_IO\\_State](#)

A copy of the [State](#) field of the [SHOW PROCESSLIST](#) output for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. For a listing of possible states, see [Section 8.14.6, “Replication Slave I/O Thread States”](#).

- [Master\\_Host](#)

The master host that the slave is connected to.

- `Master_User`

The user name of the account used to connect to the master.

- `Master_Port`

The port used to connect to the master.

- `Connect_Retry`

The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement.

- `Master_Log_File`

The name of the master binary log file from which the I/O thread is currently reading.

- `Read_Master_Log_Pos`

The position in the current master binary log file up to which the I/O thread has read.

- `Relay_Log_File`

The name of the relay log file from which the SQL thread is currently reading and executing.

- `Relay_Log_Pos`

The position in the current relay log file up to which the SQL thread has read and executed.

- `Relay_Master_Log_File`

The name of the master binary log file containing the most recent event executed by the SQL thread.

- `Slave_IO_Running`

Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of the following three values:

- **MYSQL\_SLAVE\_NOT\_RUN.** The slave I/O thread is not running. For this state, `Slave_IO_Running` is `No`.
- **MYSQL\_SLAVE\_RUN\_NOT\_CONNECT.** The slave I/O thread is running, but is not connected to a replication master. For this state, `Slave_IO_Running` depends on the server version as shown in the following table.

| MySQL Version                                      | <code>Slave_IO_Running</code> |
|--|-------------------------------|
| 4.1 (4.1.13 and earlier); 5.0 (5.0.11 and earlier) | <code>Yes</code>              |
| 4.1 (4.1.14 and later); 5.0 (5.0.12 and later)     | <code>No</code>               |
| 5.1 (5.1.45 and earlier)                           | <code>No</code>               |
| 5.1 (5.1.46 and later); 5.5                        | <code>Connecting</code>       |

- **MYSQL\_SLAVE\_RUN\_CONNECT.** The slave I/O thread is running, and is connected to a replication master. For this state, `Slave_IO_Running` is `Yes`.

The value of the `Slave_running` system status variable corresponds with this value.

- `Slave_SQL_Running`

Whether the SQL thread is started.

- `Replicate_Do_DB`, `Replicate_Ignore_DB`

The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- `Replicate_Do_Table`, `Replicate_Ignore_Table`, `Replicate_Wild_Do_Table`, `Replicate_Wild_Ignore_Table`

The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- `Last_Errno`, `Last_Error`

These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

**Note**

When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- `Skip_Counter`

The current value of the `sql_slave_skip_counter` system variable. See [Section 13.4.2.4, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

- `Exec_Master_Log_Pos`

The position in the current master binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option when starting a new slave from an existing slave, so that the new slave reads from this point. The coordinates given by (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log correspond to the coordinates given by (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

- `Relay_Log_Space`

The total combined size of all existing relay log files.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary log

- `Relay` if the slave is reading until a given position in its relay log

`Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_Key`, `Master_SSL_Verify_Server_Cert`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave is actively processing updates, this field shows the difference between the current timestamp on the slave and the original timestamp logged on the master for the event currently being processed on the slave.
- When no event is currently being processed on the slave, this value is 0.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread. If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even if the master and slave do not have identical clock times, provided that the difference, computed when the slave I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of `Seconds_Behind_Master` less reliable.

This field is `NULL` (undefined or unknown) if the slave SQL thread is not running, or if the slave I/O thread is not running or is not connected to the master. For example, if the slave I/O thread is running but is not connected to the master and is sleeping for the number of seconds given by the `CHANGE MASTER TO` statement or `--master-connect-retry` option (default 60) before reconnecting, the value is `NULL`. This is because the slave cannot know what the master is doing, and so cannot say reliably how late it is.

The value of `Seconds_Behind_Master` is based on the timestamps stored in events, which are preserved through replication. This means that if a master M1 is itself a slave of M0, any event from M1's binary log that originates from M0's binary log has M0's timestamp for that event. This enables MySQL

to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Master` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

- `Last_IO_Errno`, `Last_IO_Error`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the slave's error log.

Prior to MySQL 5.5, `Last_IO_Error` and `Last_IO_Errno` were not set in the event that replication failed due to exceeding `max_allowed_packet` (Bug #42914).

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Last_SQL_Errno`, `Last_SQL_Error`

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_SQL_Error` value is not empty, the error values also appear in the slave's error log.

Example:

```
Last_SQL_Errno: 1051
Last_SQL_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table `z` existed on the master and was dropped there, but it did not exist on the slave, so `DROP TABLE` failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Replicate_Ignore_Server_Ids`

Beginning with MySQL 5.5, you can tell a slave to ignore events from 0 or more masters using the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement. This is normally of interest only when using a circular or other multi-master replication setup.

The message shown for `Replicate_Ignore_Server_Ids` consists of a space-delimited list of one or more numbers, the first value indicating the number of servers to be ignored; if not 0 (the default), this server-count value is followed by the actual server IDs. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2,6,9)` option has been issued to tell a slave to ignore masters having the server ID 2, 6, or 9, that information appears as shown here:

```
Replicate_Ignore_Server_Ids: 3 2 6 9
```

`Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

- `Master_Server_Id`

The `server_id` value from the master.

### 13.7.5.36 SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
    [LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information (see [Section 5.1.7, “Server Status Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- The `GLOBAL_STATUS` and `SESSION_STATUS` tables. See [Section 21.8, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#).
- The `mysqladmin extended-status` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#).

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at [Section 5.1.7, “Server Status Variables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in [Section 5.1.7, “Server Status Variables”](#).

```
mysql> SHOW STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
| Connections | 30023 |
| Created_tmp_disk_tables | 0 |
| Created_tmp_tables | 8340 |
| Created_tmp_files | 60 |
| ... |
| Open_tables | 1 |
| Open_files | 2 |
| Open_streams | 0 |
| Opened_tables | 44600 |
| Questions | 2026873 |
| ... |
```

|                       |         |
|-----------------------|---------|
| Table_locks_immediate | 1920382 |
| Table_locks_waited    | 0       |
| Threads_cached        | 0       |
| Threads_created       | 30022   |
| Threads_connected     | 1       |
| Threads_running       | 1       |
| Uptime                | 80380   |

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
```

| Variable_name      | Value    |
|--------------------|----------|
| Key_blocks_used    | 14955    |
| Key_read_requests  | 96854827 |
| Key_reads          | 162040   |
| Key_write_requests | 7589728  |
| Key_writes         | 3813196  |

### 13.7.5.37 SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-`TEMPORARY` table. You can also get this list using the `mysqlshow --status db_name` command. The [LIKE](#) clause, if present, indicates which table names to match. The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 21.31](#), “Extensions to `SHOW` Statements”.

This statement also displays information about views.

`SHOW TABLE STATUS` output has the following columns:

- [Name](#)

The name of the table.

- [Engine](#)

The storage engine for the table. See [Chapter 15, Alternative Storage Engines](#).

- [Version](#)

The version number of the table's `.frm` file.

- [Row\\_format](#)

The row-storage format ([Fixed](#), [Dynamic](#), [Compressed](#), [Redundant](#), [Compact](#)). For [MyISAM](#) tables, ([Dynamic](#) corresponds to what `myisamchk -dvv` reports as [Packed](#). The format of [InnoDB](#) tables is reported as [Redundant](#) or [Compact](#). For the [Barracuda](#) file format of the [InnoDB Plugin](#), the format may be [Compressed](#) or [Dynamic](#).

- [Rows](#)

The number of rows. Some storage engines, such as [MyISAM](#), store the exact count. For other storage engines, such as [InnoDB](#), this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is `NULL` for tables in the `INFORMATION_SCHEMA` database.

- [Avg\\_row\\_length](#)

The average row length.

Refer to the notes at the end of this section for related information.

- [Data\\_length](#)

For [MyISAM](#), `Data_length` is the length of the data file, in bytes.

For [InnoDB](#), `Data_length` is the approximate amount of memory allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the [InnoDB](#) page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- [Max\\_data\\_length](#)

For [MyISAM](#), `Max_data_length` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for [InnoDB](#).

Refer to the notes at the end of this section for information regarding other storage engines.

- [Index\\_length](#)

For [MyISAM](#), `Index_length` is the length of the index file, in bytes.

For [InnoDB](#), `Index_length` is the approximate amount of memory allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the [InnoDB](#) page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- [Data\\_free](#)

The number of allocated but unused bytes.

This information is also shown for [InnoDB](#) tables (previously, it was in the `Comment` value). [InnoDB](#) tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA.PARTITIONS` table, as shown in this example:

```
SELECT      SUM(DATA_FREE)
FROM        INFORMATION_SCHEMA.PARTITIONS
```

```
WHERE TABLE_SCHEMA = 'mydb'
AND TABLE_NAME = 'mytable';
```

For more information, see [Section 21.12, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).

- [Auto\\_increment](#)

The next `AUTO_INCREMENT` value.

- [Create\\_time](#)

When the table was created.

- [Update\\_time](#)

When the data file was last updated. For some storage engines, this value is `NULL`. For example, [InnoDB](#) stores multiple tables in its [system tablespace](#) and the data file timestamp does not apply. Even with [file-per-table](#) mode with each [InnoDB](#) table in a separate `.ibd` file, [change buffering](#) can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For [MyISAM](#), the data file timestamp is used; however, on Windows the timestamp is not updated by updates so the value is inaccurate.

- [Check\\_time](#)

When the table was last checked. Not all storage engines update this time, in which case the value is always `NULL`.

- [Collation](#)

The table's character set and collation.

- [Checksum](#)

The live checksum value (if any).

- [Create\\_options](#)

Extra options used with `CREATE TABLE`. The original options supplied when `CREATE TABLE` is called are retained and the options reported here may differ from the active table settings and options.

- [Comment](#)

The comment used when creating the table (or information as to why MySQL could not access the table information).

**Notes:**

- For [MEMORY](#) tables, the [Data\\_length](#), [Max\\_data\\_length](#), and [Index\\_length](#) values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.
- For [NDBCLUSTER](#) tables, the output of this statement shows appropriate values for the [Avg\\_row\\_length](#) and [Data\\_length](#) columns, with the exception that [BLOB](#) columns are not taken into account
- For views, all the fields displayed by `SHOW TABLE STATUS` are `NULL` except that [Name](#) indicates the view name and [Comment](#) says `view`.

### 13.7.5.38 SHOW TABLES Syntax

```
SHOW [FULL] TABLES
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

**SHOW TABLES** lists the non-**TEMPORARY** tables in a given database. You can also get this list using the `mysqlshow db_name` command. The **LIKE** clause, if present, indicates which table names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 21.31](#), “Extensions to SHOW Statements”.

Matching performed by the **LIKE** clause is dependent on the setting of the `lower_case_table_names` system variable.

This statement also lists any views in the database. The **FULL** modifier is supported such that **SHOW FULL TABLES** displays a second output column. Values for the second column are **BASE TABLE** for a table and **VIEW** for a view.

If you have no privileges for a base table or view, it does not show up in the output from **SHOW TABLES** or `mysqlshow db_name`.

### 13.7.5.39 SHOW TRIGGERS Syntax

```
SHOW TRIGGERS
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

**SHOW TRIGGERS** lists the triggers currently defined for tables in a database (the default database unless a **FROM** clause is given). This statement returns results only for databases and tables for which you have the **TRIGGER** privilege. The **LIKE** clause, if present, indicates which table names to match (not trigger names) and causes the statement to display triggers for those tables. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 21.31](#), “Extensions to SHOW Statements”.

For the trigger `ins_sum` as defined in [Section 20.3](#), “Using Triggers”, the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'\G
***** 1. row *****
      Trigger: ins_sum
      Event: INSERT
      Table: account
      Statement: SET @sum = @sum + NEW.amount
      Timing: BEFORE
      Created: NULL
      sql_mode:
      Definer: myname@localhost
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

**SHOW TRIGGERS** output has the following columns:

- **Trigger**: The trigger name.
- **Event**: The type of operation that causes trigger activation. The value is '**INSERT**', '**UPDATE**', or '**DELETE**'.
- **Table**: The table for which the trigger is defined.
- **Statement**: The trigger body; that is, the statement executed when the trigger activates.

- **Timing:** Whether the trigger activates before or after the triggering event. The value is `'BEFORE'` or `'AFTER'`.
- **Created:** The value of this column is always `NULL`.
- **sql\_mode:** The SQL mode in effect when the trigger executes.
- **Definer:** The account of the user who created the trigger, in `'user_name'@'host_name'` format.
- **character\_set\_client:** The session value of the `character_set_client` system variable when the trigger was created.
- **collation\_connection:** The session value of the `collation_connection` system variable when the trigger was created.
- **Database Collation:** The collation of the database with which the trigger is associated.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 21.25, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

### 13.7.5.40 SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
    [LIKE 'pattern' | WHERE expr]
```

`SHOW VARIABLES` shows the values of MySQL system variables (see [Section 5.1.5, “Server System Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables. See [Section 21.9, “The INFORMATION\\_SCHEMA GLOBAL\\_VARIABLES and SESSION\\_VARIABLES Tables”](#).
- The `mysqladmin variables` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#).

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. As of MySQL 5.5.3, if a variable has no global value, no value is displayed. Before 5.5.3, the session value is displayed.
- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at [Section 5.1.5, “Server System Variables”](#).

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See [Section 5.1.6, “Using System Variables”](#), and [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).

Partial output is shown here. The list of names and values may differ for your server. [Section 5.1.5, “Server System Variables”](#), describes the meaning of each variable, and [Section 5.1.1, “Configuring the Server”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

| Variable_name                           | Value                     |
|---|---------------------------|
| auto_increment_increment                | 1                         |
| auto_increment_offset                   | 1                         |
| autocommit                              | ON                        |
| automatic_sp_privileges                 | ON                        |
| back_log                                | 50                        |

| tmpdir                                  | /tmp                      |
| transaction_alloc_block_size            | 8192                      |
| transaction_prealloc_size               | 4096                      |
| tx_isolation                            | REPEATABLE-READ           |
| unique_checks                           | ON                        |
| updatable_views_with_limit              | YES                       |
| version                                 | 5.5.17-log                |
| version_comment                         | Source distribution       |
| version_compile_machine                 | x86_64                    |
| version_compile_os                      | Linux                     |
| wait_timeout                            | 28800                     |
| warning_count                           | 0                         |

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `\_` to match it literally. In practice, this is rarely necessary.

### 13.7.5.41 SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as [INSERT](#), [UPDATE](#), and [LOAD DATA INFILE](#) as well as DDL statements such as [CREATE TABLE](#) and [ALTER TABLE](#).

The `LIMIT` clause has the same syntax as for the [SELECT](#) statement. See [Section 13.2.9, “SELECT Syntax”](#).

`SHOW WARNINGS` is also used following [EXPLAIN EXTENDED](#), to display the extra information generated by [EXPLAIN](#) when the `EXTENDED` keyword is used. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).

`SHOW WARNINGS` displays information about the conditions resulting from the most recent statement in the current session that generated messages. It shows nothing if the most recent statement used a table and generated no messages. (That is, statements that use a table but generate no messages clear the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

The `SHOW COUNT(*) WARNINGS` diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See [Section 13.7.5.18, “SHOW ERRORS Syntax”](#).

Here is a simple example that shows data-conversion warnings for [INSERT](#):

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
```

```

Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1048
Message: Column 'a' cannot be null
***** 3. row *****
Level: Warning
Code: 1264
Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)

```

The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`. The default is 64.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```

mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3               |
+-----+
1 row in set (0.01 sec)

```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'no_such_table' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See [Section 23.8.7.72](#), “`mysql_warning_count()`”.

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see [Section 4.5.1.2](#), “`mysql Commands`”). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+-----+
| 1/0 |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.03 sec)

Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

## 13.7.6 Other Administrative Statements

### 13.7.6.1 BINLOG Syntax

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See [Section 4.6.7](#), “`mysqlbinlog` — Utility for Processing Binary Log Files”.) The '*str*' value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

### 13.7.6.2 CACHE INDEX Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  [PARTITION (partition_list | ALL)]
  IN key_cache_name

tbl_index_list:
```

```
tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]

partition_list:
  partition_name[, partition_name][, ...]
```

The **CACHE INDEX** statement assigns table indexes to a specific key cache. It is used only for **MyISAM** tables. After the indexes have been assigned, they can be preloaded into the cache if desired with **LOAD INDEX INTO CACHE**.

The following statement assigns indexes from the tables **t1**, **t2**, and **t3** to the key cache named **hot\_cache**:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

| Table   | Op                 | Msg_type | Msg_text |
|---------|--------------------|----------|----------|
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |

The syntax of **CACHE INDEX** enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a **CACHE INDEX** statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See [Section 5.1.6.1, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

In MySQL 5.5, this statement is also supported for partitioned **MyISAM** tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
ENGINE=MyISAM
PARTITION BY HASH(c1)
PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either one of the following 2 statements:

```
CACHE INDEX pt PARTITION (ALL) IN kc_all;
CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, then the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions do not have to be contiguous, and you are not required to list their names in any particular order. Indexes for any partitions that are not explicitly assigned to a key cache automatically use the server's default key cache.

As of MySQL 5.5, index preloading is also supported for partitioned `MyISAM` tables. For more information, see [Section 13.7.6.5, “LOAD INDEX INTO CACHE Syntax”](#).

### 13.7.6.3 FLUSH Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
      flush_option [, flush_option] ...
```

The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege. Specific flush options might require additional privileges, as described later.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

#### Note

`FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` (with or without a table list) are not written to the binary log in any case because they would cause problems if replicated to a slave.

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. See [Section 5.1.11, “Server Response to Signals”](#).

The `FLUSH` statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

The `RESET` statement is similar to `FLUSH`. See [Section 13.7.6.6, “RESET Syntax”](#), for information about using the `RESET` statement with replication.

`flush_option` can be any of the following items.

- `DES_KEY_FILE`

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- **HOSTS**

Empties the host cache. You should flush the host cache if some of your hosts change IP address or if the error message `Host 'host_name' is blocked` occurs. (See [Section B.5.2.6, “Host 'host\\_name' is blocked”](#).) When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of `max_connect_errors` is 10. To avoid this error message, start the server with `max_connect_errors` set to a large value.

- **[log\_type] LOGS**

With no `log_type` option, `FLUSH LOGS` closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

Prior to MySQL 5.5.7, if you flush the logs using `FLUSH LOGS` and `mysqld` is writing the error log to a file (for example, if it was started with the `--log-error` option), log file renaming may occur, as described in [Section 5.4.2, “The Error Log”](#).

`FLUSH LOGS` has no effect on tables used for the general query log or for the slow query log (see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

With a `log_type` option, only the specified log type is flushed. These `log_type` options are permitted:

- **BINARY** closes and reopens the binary log files.
- **ENGINE** closes and reopens any flushable logs for installed storage engines. This causes **InnoDB** to flush its logs to disk.
- **ERROR** closes and reopens the error log file.
- **GENERAL** closes and reopens the general query log file.
- **RELAY** closes and reopens the relay log files.
- **SLOW** closes and reopens the slow query log file.

The `log_type` options were added in MySQL 5.5.3.

- **MASTER**

Deletes all binary logs, resets the binary log index file and creates a new binary log. `FLUSH MASTER` is deprecated in favor of `RESET MASTER`. `FLUSH MASTER` is still accepted in MySQL 5.5 for backward compatibility, but is removed in MySQL 5.6. See [Section 13.4.1.2, “RESET MASTER Syntax”](#).

- **PRIVILEGES**

Reloads the privileges from the grant tables in the `mysql` database.

The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

- [QUERY CACHE](#)

Defragment the query cache to better utilize its memory. [FLUSH QUERY CACHE](#) does not remove any queries from the cache, unlike [FLUSH TABLES](#) or [RESET QUERY CACHE](#).

- [SLAVE](#)

Resets all replication slave parameters, including relay log files and replication position in the master's binary logs. [FLUSH SLAVE](#) is deprecated in favor of [RESET SLAVE](#). [FLUSH SLAVE](#) is still accepted in MySQL 5.5 for backward compatibility, but is removed in MySQL 5.6. See [Section 13.4.2.3, “RESET SLAVE Syntax”](#).

- [STATUS](#)

This option adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets [Max\\_used\\_connections](#) to the current number of open connections. This is something that may be of use when debugging a query. See [Section 1.6, “How to Report Bugs or Problems”](#).

- [TABLES](#)

[FLUSH TABLES](#) flushes tables, and, depending on the variant used, acquires locks. The permitted syntax is discussed later in this section.

- [USER\\_RESOURCES](#)

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. [FLUSH USER\\_RESOURCES](#) does not apply to the limit on maximum simultaneous connections. See [Section 6.3.4, “Setting Account Resource Limits”](#).

The [mysqladmin](#) utility provides a command-line interface to some flush operations, using commands such as [flush-hosts](#), [flush-logs](#), [flush-privileges](#), [flush-status](#), and [flush-tables](#). See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

**Note**

It is not possible to issue [FLUSH](#) statements within stored functions or triggers. However, you may use [FLUSH](#) in stored procedures, so long as these are not called from stored functions or triggers. See [Section C.1, “Restrictions on Stored Programs”](#).

## FLUSH TABLES Syntax

[FLUSH TABLES](#) has several forms, described following. As of MySQL 5.5.3, if any variant of the [TABLES](#) option is used in a [FLUSH](#) statement, it must be the only option used. [FLUSH TABLE](#) is a synonym for [FLUSH TABLES](#), except that [TABLE](#) does not work with the [WITH READ LOCK](#) variants prior to MySQL 5.5.3.

- [FLUSH TABLES](#)

Closes all open tables, forces all tables in use to be closed, and flushes the query cache. [FLUSH TABLES](#) also removes all query results from the query cache, like the [RESET QUERY CACHE](#) statement.

As of MySQL 5.5.3, [FLUSH TABLES](#) is not permitted when there is an active [LOCK TABLES ... READ](#). To flush and lock tables, use [FLUSH TABLES tbl\\_name ... WITH READ LOCK](#) instead.

- `FLUSH TABLES tbl_name [, tbl_name] ...`

With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. No error occurs if a named table does not exist.

- `FLUSH TABLES WITH READ LOCK`

Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.
- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see [Section 5.4.1](#), “[Selecting General Query and Slow Query Log Output Destinations](#)”).

`FLUSH TABLES WITH READ LOCK` is not compatible with XA transactions.

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

This statement flushes and acquires read locks for the named tables. The statement first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the statement flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the statement acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

Because this statement acquires table locks, you must have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This variant of `FLUSH` enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction as of MySQL 5.5.3 that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This statement does not perform an implicit `UNLOCK TABLES`, so an error results if you use the statement while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.

If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

This variant of `FLUSH` is available as of MySQL 5.5.3.

### 13.7.6.4 KILL Syntax

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *processlist\_id*, after terminating any statement the connection is executing.
- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

#### Note

You cannot use `KILL` with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.

- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

### Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

## 13.7.6.5 LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [PARTITION (partition_list | ALL)]
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]

partition_list:
  partition_name[, partition_name][, ...]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` is used only for `MyISAM` tables. In MySQL 5.5, it is also supported for partitioned `MyISAM` tables; in addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

In MySQL 5.5, it is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table `pt`, you can use either one of the following 2 statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);  
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, then the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions do not have to be contiguous, and you are not required to list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

### 13.7.6.6 RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See [Section 13.7.6.3, “FLUSH Syntax”](#).

The `RESET` statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

*reset\_option* can be any of the following:

- `MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- `QUERY CACHE`

Removes all query results from the query cache.

- `SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

## 13.8 Utility Statements

### 13.8.1 DESCRIBE Syntax

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see [Section 13.7.5.6, “SHOW COLUMNS Syntax”](#), and [Section 13.8.2, “EXPLAIN Syntax”](#).

### 13.8.2 EXPLAIN Syntax

```
{EXPLAIN | DESCRIBE | DESC}
    tbl_name [col_name | wild]

{EXPLAIN | DESCRIBE | DESC}
    [explain_type] SELECT select_options

explain_type: {EXTENDED | PARTITIONS}
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- [Obtaining Table Structure Information](#)
- [Obtaining Execution Plan Information](#)

## Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
+-----+-----+-----+-----+-----+-----+
| Field      | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| Id         | int(11)   | NO   | PRI | NULL    | auto_increment |
| Name       | char(35)  | NO   |     |         |                |
| Country    | char(3)   | NO   |     |         |                |
| District   | char(20)  | YES  | MUL |         |                |
| Population | int(11)   | NO   |     | 0       |                |
+-----+-----+-----+-----+-----+-----+
```

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See [Section 13.7.5.6, “SHOW COLUMNS Syntax”](#).

By default, `DESCRIBE` displays information about all columns in the table. `col_name`, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. `wild`, if given, is a pattern string. It can contain the SQL `%` and `_` wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.5, “SHOW Syntax”](#).

## Obtaining Execution Plan Information

The `EXPLAIN` statement provides information about how MySQL executes statements:

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 8.8.2, “EXPLAIN Output Format”](#).

- `EXPLAIN EXTENDED` can be used to obtain additional execution plan information. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).
- `EXPLAIN PARTITIONS` is useful for examining queries involving partitioned tables. See [Section 19.3.4, “Obtaining Information About Partitions”](#).

`EXPLAIN` requires the `SELECT` privilege for any tables or views accessed, including any underlying tables of views. For views, `EXPLAIN` also requires the `SHOW VIEW` privilege.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 13.2.9, “SELECT Syntax”](#).)

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#).

#### Note

MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See [Tutorial: Using Visual Explain to Improve Query Performance](#).

## 13.8.3 HELP Syntax

```
HELP 'search_string'
```

The `HELP` statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.10, “Server-Side Help”](#)).

The `HELP` statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The `HELP` statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as `Data Types`, use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the `ASCII()` function or the `CREATE TABLE` statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response `HELP` returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the `mysql` client, but note that `mysql` itself reformats `HELP` result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- `name`: The topic name.
- `description`: Descriptive help text for the topic.
- `example`: Usage example or examples. This column might be blank.

Example: `HELP 'replace'`

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
        -> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- `name`: The help topic name.
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'status'`

Yields:

| name                  | is_it_category |
|-----------------------|----------------|
| SHOW                  | N              |
| SHOW ENGINE           | N              |
| SHOW MASTER STATUS    | N              |
| SHOW PROCEDURE STATUS | N              |

|                   |   |  |
|-------------------|---|--|
| SHOW SLAVE STATUS | N |  |
| SHOW STATUS       | N |  |
| SHOW TABLE STATUS | N |  |

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- `source_category_name`: The help category name.
- `name`: The category or topic name
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'`

Yields:

| source_category_name | name                    | is_it_category |
|----------------------|-------------------------|----------------|
| Functions            | CREATE FUNCTION         | N              |
| Functions            | DROP FUNCTION           | N              |
| Functions            | Bit Functions           | Y              |
| Functions            | Comparison operators    | Y              |
| Functions            | Control flow functions  | Y              |
| Functions            | Date and Time Functions | Y              |
| Functions            | Encryption Functions    | Y              |
| Functions            | Information Functions   | Y              |
| Functions            | Logical operators       | Y              |
| Functions            | Miscellaneous Functions | Y              |
| Functions            | Numeric Functions       | Y              |
| Functions            | String Functions        | Y              |

## 13.8.4 USE Syntax

`USE db_name`

The `USE db_name` statement tells MySQL to use the `db_name` database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable
```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name, editor_name FROM author, db2.editor
WHERE author.editor_id = db2.editor.editor_id;
```

---

## 14.1 Introduction to InnoDB

**InnoDB** is a general-purpose storage engine that balances high reliability and high performance. Starting from MySQL 5.5.5, the default storage engine for new tables is **InnoDB** rather than **MyISAM**. Unless you have configured a different default storage engine, issuing a **CREATE TABLE** statement without an **ENGINE=** clause creates an **InnoDB** table. Given this change of default behavior, MySQL 5.5 might be a logical point to evaluate whether tables that use **MyISAM** could benefit from switching to **InnoDB**.

**InnoDB** includes all the features that were part of the InnoDB Plugin for MySQL 5.1, plus new features specific to MySQL 5.5 and higher.

### Note

The **mysql** and **INFORMATION\_SCHEMA** databases that implement some of the MySQL internals still use **MyISAM**. In particular, you cannot switch the grant tables to use **InnoDB**.

## Key Advantages of InnoDB

Key advantages of **InnoDB** include:

- Its **DML** operations follow the **ACID** model, with **transactions** featuring **commit**, **rollback**, and **crash-recovery** capabilities to protect user data. See [Section 14.5, “InnoDB and the ACID Model”](#) for more information.
- Row-level **locking** and Oracle-style **consistent reads** increase multi-user concurrency and performance. See [Section 14.8, “InnoDB Locking and Transaction Model”](#) for more information.
- **InnoDB** tables arrange your data on disk to optimize queries based on **primary keys**. Each **InnoDB** table has a primary key index called the **clustered index** that organizes the data to minimize I/O for primary key lookups. See [Section 14.11.2.1, “Clustered and Secondary Indexes”](#) for more information.
- To maintain data **integrity**, **InnoDB** supports **FOREIGN KEY** constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across different tables. See [Section 14.11.1.6, “InnoDB and FOREIGN KEY Constraints”](#) for more information.

**Table 14.1 InnoDB Storage Engine Features**

|  |                  |  |                  |  |                  |
|--|------------------|--|------------------|--|------------------|
| <b>Storage limits</b>                              | 64TB             | <b>Transactions</b>                    | Yes              | <b>Locking granularity</b>                   | Row              |
| <b>MVCC</b>  | Yes              | <b>Geospatial data type support</b>    | Yes              | <b>Geospatial indexing support</b>           | Yes <sup>a</sup> |
| <b>B-tree indexes</b>                              | Yes              | <b>T-tree indexes</b>                  | No               | <b>Hash indexes</b>                          | No <sup>b</sup>  |
| <b>Full-text search indexes</b>                    | Yes <sup>c</sup> | <b>Clustered indexes</b>               | Yes              | <b>Data caches</b>                           | Yes              |
| <b>Index caches</b>                                | Yes              | <b>Compressed data</b>                 | Yes <sup>d</sup> | <b>Encrypted data<sup>e</sup></b>            | Yes              |
| <b>Cluster database support</b>                    | No               | <b>Replication support<sup>f</sup></b> | Yes              | <b>Foreign key support</b>                   | Yes              |
| <b>Backup / point-in-time recovery<sup>g</sup></b> | Yes              | <b>Query cache support</b>             | Yes              | <b>Update statistics for data dictionary</b> | Yes              |

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and later.

<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and later.

<sup>d</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>e</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

<sup>f</sup>Implemented in the server, rather than in the storage engine.

<sup>g</sup>Implemented in the server, rather than in the storage engine.

To compare the features of [InnoDB](#) with other storage engines provided with MySQL, see the *Storage Engine Features* table in [Chapter 15, Alternative Storage Engines](#).

## InnoDB Enhancements and New Features

The [InnoDB](#) storage engine in MySQL 5.5 releases includes a number performance improvements that in MySQL 5.1 were only available by installing the [InnoDB](#) Plugin. This latest [InnoDB](#) offers new features, improved performance and scalability, enhanced reliability and new capabilities for flexibility and ease of use.

For information about [InnoDB](#) enhancements and new features in MySQL 5.5, refer to:

- The [InnoDB](#) enhancements list in [Section 1.4, “What Is New in MySQL 5.5”](#).
- The [Release Notes](#).

## Additional InnoDB Information and Resources

- For [InnoDB](#)-related terms and definitions, see [MySQL Glossary](#).
- For a forum dedicated to the [InnoDB](#) storage engine, see [MySQL Forums::InnoDB](#).
- [InnoDB](#) is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

### 14.1.1 Benefits of Using InnoDB Tables

If you use [MyISAM](#) tables but are not committed to them for technical reasons, you may find [InnoDB](#) tables beneficial for the following reasons:

- If your server crashes because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. [InnoDB crash recovery](#) automatically finalizes any changes that were committed before the time of the crash, and undoes any changes that were in process but not committed. Just restart and continue where you left off. This process is now much faster than in MySQL 5.1 and earlier.
- The [InnoDB](#) storage engine maintains its own [buffer pool](#) that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the [InnoDB](#) buffer pool.
- If you split up related data into different tables, you can set up [foreign keys](#) that enforce [referential integrity](#). Update or delete data, and the related data in other tables is updated or deleted automatically. Try to insert data into a secondary table without corresponding data in the primary table, and the bad data gets kicked out automatically.
- If data becomes corrupted on disk or in memory, a [checksum](#) mechanism alerts you to the bogus data before you use it.
- When you design your database with appropriate [primary key](#) columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in [WHERE](#) clauses, [ORDER BY](#) clauses, [GROUP BY](#) clauses, and [join](#) operations.

- Inserts, updates, deletes are optimized by an automatic mechanism called [change buffering](#). [InnoDB](#) not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O.
- Performance benefits are not limited to giant tables with long-running queries. When the same rows are accessed over and over from a table, a feature called the [Adaptive Hash Index](#) takes over to make these lookups even faster, as if they came out of a hash table.
- You can freely mix [InnoDB](#) tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a [join](#) operation to combine data from [InnoDB](#) and [MEMORY](#) tables in a single query.
- [InnoDB](#) has been designed for CPU efficiency and maximum performance when processing large data volumes.
- [InnoDB](#) tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For [InnoDB](#)-specific tuning techniques you can apply in your application code, see [Section 8.5](#), “[Optimizing for InnoDB Tables](#)”.

### 14.1.2 Best Practices for InnoDB Tables

This section describes best practices when using [InnoDB](#) tables.

- Specify a [primary key](#) for every table using the most frequently queried column or columns, or an [auto-increment](#) value if there is no obvious primary key.
- Using [joins](#) wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define [foreign keys](#) on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes or updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.
- Turning off [autocommit](#). Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).
- Grouping sets of related [DML](#) operations into [transactions](#), by bracketing them with [START TRANSACTION](#) and [COMMIT](#) statements. While you don't want to commit too often, you also don't want to issue huge batches of [INSERT](#), [UPDATE](#), or [DELETE](#) statements that run for hours without committing.
- Not using [LOCK TABLES](#) statements. [InnoDB](#) can handle multiple sessions all reading and writing to the same table at once, without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the [SELECT ... FOR UPDATE](#) syntax to lock just the rows you intend to update.
- Enabling the [innodb\\_file\\_per\\_table](#) option to put the data and indexes for individual tables into separate files, instead of in a single giant [system tablespace](#). This setting is required to use some of the other features, such as table [compression](#) and fast [truncation](#).
- Evaluating whether your data and access patterns benefit from the [InnoDB](#) table [compression](#) feature ([ROW\\_FORMAT=COMPRESSED](#)) on the [CREATE TABLE](#) statement. You can compress [InnoDB](#) tables without sacrificing read/write capability.
- Running your server with the option [--sql\\_mode=NO\\_ENGINE\\_SUBSTITUTION](#) to prevent tables being created with a different storage engine if there is an issue with the one specified in the [ENGINE=](#) clause of [CREATE TABLE](#).

### 14.1.3 Checking InnoDB Availability

To determine whether your server supports [InnoDB](#):

- Issue the command `SHOW ENGINES;` to see all the different MySQL storage engines. Look for [DEFAULT](#) in the [InnoDB](#) line. Alternatively, query the [INFORMATION\\_SCHEMA.ENGINES](#) table. (Now that [InnoDB](#) is the default MySQL storage engine, only very specialized environments might not support it.)
- Issue the command `SHOW VARIABLES LIKE 'have_innodb';` to confirm that [InnoDB](#) is available.
- If [InnoDB](#) is not present, you have a `mysqld` binary that was compiled without [InnoDB](#) support and you need to get a different one.
- If [InnoDB](#) is present but disabled, go back through your startup options and configuration file and get rid of any `skip-innodb` option.

### 14.1.4 Upward and Downward Compatibility

The ability to use the [InnoDB table compression](#) feature introduced in MySQL 5.5 and the new row format require the use of a new [InnoDB](#) file format called [Barracuda](#). The previous file format, used by the built-in [InnoDB](#) in MySQL 5.1 and earlier, is now called [Antelope](#) and does not support these features, but does support the other features introduced with the [InnoDB](#) storage engine.

The [InnoDB](#) storage engine is upward compatible from standard [InnoDB](#) as built in to, and distributed with, MySQL. Existing databases can be used with the [InnoDB](#) Storage Engine for MySQL. The new parameter [innodb\\_file\\_format](#) can help protect upward and downward compatibility between [InnoDB](#) versions and database files, allowing users to enable or disable use of new features that can only be used with certain versions of [InnoDB](#).

[InnoDB](#) since version 5.0.21 has a safety feature that prevents it from opening tables that are in an unknown format. However, the system tablespace may contain references to new-format tables that confuse the built-in [InnoDB](#) in MySQL 5.1 and earlier. These references are cleared in a [slow shutdown](#).

With previous versions of [InnoDB](#), no error would be returned until you try to access a table that is in a format “too new” for the software. To provide early feedback, [InnoDB](#) now checks the system tablespace before startup to ensure that the file format used in the database is supported by the storage engine. See [Section 14.13.2.1, “Compatibility Check When InnoDB Is Started”](#) for the details.

### 14.1.5 Testing and Benchmarking with InnoDB

Even before completing your upgrade to MySQL 5.5, you can preview whether your database server or application works correctly with [InnoDB](#) as the default storage engine. To set up [InnoDB](#) as the default storage engine with an earlier MySQL release, either specify on the command line `--default-storage-engine=InnoDB`, or add to your `my.cnf` file `default-storage-engine=innodb` in the `[mysqld]` section, then restart the server.

Since changing the default storage engine only affects new tables as they are created, run all your application installation and setup steps to confirm that everything installs properly. Then exercise all the application features to make sure all the data loading, editing, and querying features work. If a table relies on some [MyISAM](#)-specific feature, you'll receive an error; add the `ENGINE=MyISAM` clause to the `CREATE TABLE` statement to avoid the error (for example, tables that rely on full-text search must be [MyISAM](#) tables rather than [InnoDB](#) ones).

If you did not make a deliberate decision about the storage engine, and you just want to preview how certain tables work when they're created under [InnoDB](#), issue the command `ALTER TABLE table_name`

`ENGINE=InnoDB;` for each table. Or, to run test queries and other statements without disturbing the original table, make a copy like so:

```
CREATE TABLE InnoDB_Table (...) ENGINE=InnoDB AS SELECT * FROM MyISAM_Table;
```

Since there are so many performance enhancements in the `InnoDB` that is part of MySQL 5.5, to get a true idea of the performance with a full application under a realistic workload, install the real MySQL 5.5 and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the master and the slaves.

## 14.1.6 Turning Off InnoDB

Oracle recommends `InnoDB` as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. As of MySQL 5.5, `InnoDB` is the default storage engine for new tables.

If you do not want to use `InnoDB` tables:

- Start the server with the `--innodb=OFF` or `--skip-innodb` option to disable the `InnoDB` storage engine.
- Because the default storage engine is `InnoDB`, the server will not start unless you also use `--default-storage-engine` to set the default to some other engine.
- To prevent the server from crashing when the `InnoDB-related information_schema tables` are queried, also disable the plugins associated with those tables. Specify in the `[mysqld]` section of the MySQL configuration file:

```
loose-innodb-trx=0
loose-innodb-locks=0
loose-innodb-lock-waits=0
loose-innodb-cmp=0
loose-innodb-cmp-per-index=0
loose-innodb-cmp-per-index-reset=0
loose-innodb-cmp-reset=0
loose-innodb-cmpmem=0
loose-innodb-cmpmem-reset=0
loose-innodb-buffer-page=0
loose-innodb-buffer-page-lru=0
loose-innodb-buffer-pool-stats=0
```

## 14.1.7 Third-Party Software Contributions

Oracle acknowledges that certain Third Party and Open Source software has been used to develop or is incorporated in the `InnoDB` storage engine. This appendix includes required third-party license information.

### 14.1.7.1 Performance Patches from Google

Oracle gratefully acknowledges the following contributions from Google, Inc. to improve `InnoDB` performance:

- Replacing InnoDB's use of Pthreads mutexes with calls to GCC atomic builtins. This change means that InnoDB mutex and rw-lock operations take less CPU time, and improves throughput on those platforms where the atomic operations are available.
- Controlling master thread I/O rate, as discussed in [Section 14.9.8, “Configuring the InnoDB Master Thread I/O Rate”](#). The master thread in InnoDB is a thread that performs various tasks in the background. Historically, InnoDB has used a hard coded value as the total I/O capacity of the server. With this change, user can control the number of I/O operations that can be performed per second based on their own workload.

Changes from the Google contributions were incorporated in the following source code files: [btr0cur.c](#), [btr0sea.c](#), [buf0buf.c](#), [buf0buf.ic](#), [ha\\_innodb.cc](#), [log0log.c](#), [log0log.h](#), [os0sync.h](#), [row0sel.c](#), [srv0srv.c](#), [srv0srv.h](#), [srv0start.c](#), [sync0arr.c](#), [sync0rw.c](#), [sync0rw.h](#), [sync0rw.ic](#), [sync0sync.c](#), [sync0sync.h](#), [sync0sync.ic](#), and [univ.i](#).

These contributions are incorporated subject to the conditions contained in the file [COPYING.Google](#), which are reproduced here.

POSSIBILITY OF SUCH DAMAGE.
```

#### 14.1.7.2 Multiple Background I/O Threads Patch from Percona

Oracle gratefully acknowledges the contribution of Percona, Inc. to improve InnoDB performance by implementing configurable background threads, as discussed in [Section 14.9.6, “Configuring the Number of Background InnoDB I/O Threads”](#). InnoDB uses background threads to service various types of I/O requests. The change provides another way to make InnoDB more scalable on high end systems.

Changes from the Percona, Inc. contribution were incorporated in the following source code files: [ha\\_innodb.cc](#), [os0file.c](#), [os0file.h](#), [srv0srv.c](#), [srv0srv.h](#), and [srv0start.c](#).

This contribution is incorporated subject to the conditions contained in the file [COPYING.Percona](#), which are reproduced here.

### 14.1.7.3 Performance Patches from Sun Microsystems

Oracle gratefully acknowledges the following contributions from Sun Microsystems, Inc. to improve InnoDB performance:

- Introducing the [PAUSE](#) instruction inside spin loops. This change increases performance in high concurrency, CPU-bound workloads.
- Enabling inlining of functions and prefetch with Sun Studio.

## 14.2 Installing the InnoDB Storage Engine

When you use the InnoDB storage engine 1.1 and above, with MySQL 5.5 and above, you do not need to do anything special to install: everything comes configured as part of the MySQL source and binary distributions. This is a change from earlier releases of the InnoDB Plugin, where you were required to match up MySQL and InnoDB version numbers and update your build and configuration processes.

The InnoDB storage engine is included in the MySQL distribution, starting from MySQL 5.1.38. From MySQL 5.1.46 and up, this is the only download location for the InnoDB storage engine; it is not available from the InnoDB web site.

If you used any scripts or configuration files with the earlier InnoDB storage engine from the InnoDB web site, be aware that the filename of the shared library as supplied by MySQL is `ha_innodb_plugin.so` or `ha_innodb_plugin.dll`, as opposed to `ha_innodb.so` or `ha_innodb.dll` in the older Plugin downloaded from the InnoDB web site. You might need to change the applicable file names in your startup or configuration scripts.

Because the InnoDB storage engine has now replaced the built-in InnoDB, you no longer need to specify options like `--ignore-builtin-innodb` and `--plugin-load` during startup.

To take best advantage of current InnoDB features, we recommend specifying the following options in your configuration file:

```
innodb_file_per_table=1
innodb_file_format=barracuda
innodb_strict_mode=1
```

For information about these features, see [Section 14.17, “InnoDB Startup Options and System Variables”](#), [Section 14.13, “InnoDB File-Format Management”](#), and `innodb_strict_mode`. You might need to continue to use the previous values for these parameters in some replication and similar configurations involving both new and older versions of MySQL.

## 14.3 Upgrading the InnoDB Storage Engine

Prior to MySQL 5.5, some upgrade scenarios involved upgrading the separate instance of InnoDB known as the InnoDB Plugin. In MySQL 5.5 and higher, the features of the InnoDB Plugin have been folded back into built-in InnoDB, so the upgrade procedure for InnoDB is the same as the one for the MySQL server. For details, see [Section 2.11.1, “Upgrading MySQL”](#).

## 14.4 Downgrading the InnoDB Storage Engine

Prior to MySQL 5.5, some downgrade scenarios involved switching the separate instance of InnoDB known as the InnoDB Plugin back to the built-in InnoDB storage engine. In MySQL 5.5 and higher, the features of the InnoDB Plugin have been folded back into built-in InnoDB, so the downgrade procedure for InnoDB is the same as the one for the MySQL server. For details, see [Section 2.11.2, “Downgrading MySQL”](#).

## 14.5 InnoDB and the ACID Model

The [ACID](#) model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the [InnoDB](#) storage engine that adhere closely to the ACID model, so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the [InnoDB](#) storage engine, interact with the categories of the ACID model:

- **A:** atomicity.
- **C:** consistency.
- **I::** isolation.
- **D:** durability.

### Atomicity

The **atomicity** aspect of the ACID model mainly involves [InnoDB transactions](#). Related MySQL features include:

- Autocommit setting.
- [COMMIT](#) statement.
- [ROLLBACK](#) statement.
- Operational data from the [INFORMATION\\_SCHEMA](#) tables.

### Consistency

The **consistency** aspect of the ACID model mainly involves internal [InnoDB](#) processing to protect data from crashes. Related MySQL features include:

- [InnoDB doublewrite buffer](#).
- [InnoDB crash recovery](#).

### Isolation

The **isolation** aspect of the ACID model mainly involves [InnoDB transactions](#), in particular the [isolation level](#) that applies to each transaction. Related MySQL features include:

- [Autocommit](#) setting.
- [SET ISOLATION LEVEL](#) statement.
- The low-level details of [InnoDB locking](#). During performance tuning, you see these details through [INFORMATION\\_SCHEMA](#) tables.

---

## Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of buy “new hardware”.) Related MySQL features include:

- [InnoDB doublewrite buffer](#), turned on and off by the `innodb_doublewrite` configuration option.
- Configuration option `innodb_flush_log_at_trx_commit`.
- Configuration option `sync_binlog`.
- Configuration option `innodb_file_per_table`.
- Write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- Battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the `fsync( )` system call.
- Uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

## 14.6 InnoDB Multi-Versioning

[InnoDB](#) is a [multi-versioned storage engine](#): it keeps information about old versions of changed rows, to support transactional features such as concurrency and [rollback](#). This information is stored in the tablespace in a data structure called a [rollback segment](#) (after an analogous data structure in Oracle). [InnoDB](#) uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a [consistent read](#).

Internally, [InnoDB](#) adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If [InnoDB](#) generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which [InnoDB](#) has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, [InnoDB](#) cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the [InnoDB](#) multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. [InnoDB](#) only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a [purge](#), and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the [innodb\\_max\\_purge\\_lag](#) system variable. See [Section 14.17, “InnoDB Startup Options and System Variables”](#) for more information.

## Multi-Versioning and Secondary Indexes

[InnoDB](#) multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, [InnoDB](#) looks up the database record in the clustered index. In the clustered index, the record's [DB\\_TRX\\_ID](#) is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the [covering index](#) technique is not used. Instead of returning values from the index structure, [InnoDB](#) looks up the record in the clustered index.

## 14.7 InnoDB Architecture

This section provides an introduction to major components of the [InnoDB](#) storage engine architecture.

### 14.7.1 Buffer Pool

The buffer pool is an area in main memory where [InnoDB](#) caches table and index data as data is accessed. The buffer pool allows frequently used data to be processed directly from memory, which speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the [InnoDB](#) buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into [pages](#) that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the [LRU](#) algorithm.

For more information, see [Section 14.9.2.1, “The InnoDB Buffer Pool”](#), and [Section 14.9.2, “InnoDB Buffer Pool Configuration”](#).

### 14.7.2 Change Buffer

The change buffer is a special data structure that caches changes to [secondary index](#) pages when affected pages are not in the [buffer pool](#). The buffered changes, which may result from [INSERT](#), [UPDATE](#), or

[DELETE](#) operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

Unlike [clustered indexes](#), secondary indexes are usually non-unique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read-in secondary index pages from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are numerous secondary indexes to update and many affected rows. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed. In fact, change buffer merging may continue to occur after a server shutdown and restart (see [Section 14.23.2, “Forcing InnoDB Recovery”](#) for more information).

In memory, the change buffer occupies part of the [InnoDB](#) buffer pool. On disk, the change buffer is part of the system tablespace, so that index changes remain buffered across database restarts.

The type of data cached in the change buffer is governed by the [innodb\\_change\\_buffering](#) configuration option. For more information, see [Section 14.9.4, “Configuring InnoDB Change Buffering”](#).

## Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- [InnoDB](#) Standard Monitor output includes status information for the change buffer. To view monitor data, issue the [SHOW ENGINE INNODB STATUS](#) command.

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Change buffer status information is located under the [INSERT BUFFER AND ADAPTIVE HASH INDEX](#) heading and appears similar to the following:

```
-----
INSERT BUFFER AND ADAPTIVE HASH INDEX
-----
Ibuf: size 1, free list len 0, seg size 2, 0 merges
merged operations:
  insert 0, delete mark 0, delete 0
discarded operations:
  insert 0, delete mark 0, delete 0
Hash table size 276707, node heap has 1 buffer(s)
15.81 hash searches/s, 46.33 non-hash searches/s
```

For more information, see [Section 14.20.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

- The [INFORMATION\\_SCHEMA.INNODB\\_BUFFER\\_PAGE](#) table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by [PAGE\\_TYPE](#). [IBUF\\_INDEX](#) is the page type for change buffer index pages, and [IBUF\\_BITMAP](#) is the page type for change buffer bitmap pages.

### Warning

Querying the [INNODB\\_BUFFER\\_PAGE](#) table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

For example, you can query the `INNODB_BUFFER_PAGE` table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

```
SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE PAGE_TYPE LIKE 'IBUF%'
  ) AS change_buffer_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ((change_buffer_pages/total_pages)*100)
  ) AS change_buffer_page_percentage;
```

| change_buffer_pages | total_pages | change_buffer_page_percentage |
|---------------------|-------------|-------------------------------|
| 25                  | 8192        | 0.3052                        |

For information about other data provided by the `INNODB_BUFFER_PAGE` table, see [Section 21.28.1, “The INFORMATION\\_SCHEMA INNODB\\_BUFFER\\_PAGE Table”](#). For related usage information, see [Section 14.18.3, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

- [Performance Schema](#) provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query (Performance Schema must be enabled):

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
```

| NAME  | ENABLED | TIMED |
|---|---------|-------|
| wait/synch/mutex/innodb/ibuf_bitmap_mutex             | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_mutex                    | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex | YES     | YES   |

For information about monitoring `InnoDB` mutex waits, see [Section 14.19.1, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

### 14.7.3 Adaptive Hash Index

The [adaptive hash index](#) (AHI) lets `InnoDB` perform more like an in-memory database on systems with appropriate combinations of workload and ample memory for the [buffer pool](#), without sacrificing any transactional features or reliability. This feature is enabled by the `innodb_adaptive_hash_index` option, or turned off by `--skip-innodb_adaptive_hash_index` at server startup.

Based on the observed pattern of searches, MySQL builds a hash index using a prefix of the index key. The prefix of the key can be any length, and it may be that only some of the values in the B-tree appear in the hash index. Hash indexes are built on demand for those pages of the index that are often accessed.

If a table fits almost entirely in main memory, a hash index can speed up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. `InnoDB` has a mechanism that monitors index searches. If `InnoDB` notices that queries could benefit from building a hash index, it does so automatically.

With some [workloads](#), the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Sometimes, the read/write lock that guards access to the adaptive hash index can become a source of contention under heavy workloads, such as multiple

concurrent joins. Queries with [LIKE](#) operators and [%](#) wildcards also tend not to benefit from the AHI. For workloads where the adaptive hash index is not needed, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether this feature is appropriate for a particular system, consider running benchmarks with it both enabled and disabled, using a realistic workload.

The hash index is always built based on an existing [B-tree](#) index on the table. [InnoDB](#) can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that [InnoDB](#) observes for the B-tree index. A hash index can be partial, covering only those pages of the index that are often accessed.

You can monitor the use of the adaptive hash index and the contention for its use in the [SEMAPHORES](#) section of the output of the [SHOW ENGINE INNODB STATUS](#) command. If you see many threads waiting on an RW-latch created in [btr0sea.c](#), then it might be useful to disable adaptive hash indexing.

For more information about the performance characteristics of hash indexes, see [Section 8.3.8](#), “Comparison of B-Tree and Hash Indexes”.

## 14.7.4 Redo Log Buffer

The redo log buffer is the memory area that holds data to be written to the [redo log](#). Redo log buffer size is defined by the [innodb\\_log\\_buffer\\_size](#) configuration option. The redo log buffer is periodically flushed to the log file on disk. A large redo log buffer enables large transactions to run without the need to write redo log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O.

The [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) option controls how the contents of the redo log buffer are written to the log file. The [innodb\\_flush\\_log\\_at\\_timeout](#) option controls redo log flushing frequency.

## 14.7.5 System Tablespace

The [InnoDB](#) system tablespace contains the [InnoDB](#) data dictionary (metadata for [InnoDB](#)-related objects) and is the storage area for the doublewrite buffer, the change buffer, and undo logs. The system tablespace also contains table and index data for any user-created tables that are created in the system tablespace. The system tablespace is considered a shared tablespace since it is shared by multiple tables.

The system tablespace is represented by one or more data files. By default, one system data file, named [ibdata1](#), is created in the MySQL [data](#) directory. The size and number of system data files is controlled by the [innodb\\_data\\_file\\_path](#) startup option.

For related information, see [Section 14.9.1](#), “InnoDB Startup Configuration”, and [Section 14.10.1](#), “Resizing the InnoDB System Tablespace”.

## 14.7.6 InnoDB Data Dictionary

The [InnoDB](#) data dictionary is comprised of internal system tables that contain metadata used to keep track of objects such as tables, indexes, and table columns. The metadata is physically located in the [InnoDB](#) system tablespace. For historical reasons, data dictionary metadata overlaps to some degree with information stored in [InnoDB](#) table metadata files ([.frm](#) files).

## 14.7.7 Doublewrite Buffer

The doublewrite buffer is a storage area located in the system tablespace where [InnoDB](#) writes pages that are flushed from the [InnoDB](#) buffer pool, before the pages are written to their proper positions in the data file. Only after flushing and writing pages to the doublewrite buffer, does [InnoDB](#) write pages to their

proper positions. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write, `InnoDB` can later find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer itself as a large sequential chunk, with a single `fsync()` call to the operating system.

The doublewrite buffer is enabled by default. To disable the doublewrite buffer, set `innodb_doublewrite` to 0.

## 14.7.8 Undo Logs

An undo log is a collection of undo log records associated with a single transaction. An undo log record contains information about how to undo the latest change by a transaction to a `clustered index` record. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from the undo log records. Undo logs exist within `undo log segments`, which are contained within `rollback segments`. Rollback segments are physically part of the `system tablespace`. For related information, see [Section 14.6, “InnoDB Multi-Versioning”](#).

Prior to MySQL 5.5.4, `InnoDB` supported a single rollback segment which supported a maximum of 1023 concurrent data-modifying transactions (read-only transactions do not count against the maximum limit). In MySQL 5.5.4, the single rollback segment was divided into 128 rollback segments, each supporting up to 1023 concurrent data-modifying transactions, creating a new limit of approximately 128K concurrent data-modifying transactions. The `innodb_rollback_segments` option defines how many of the rollback segments in the system tablespace are used for `InnoDB` transactions.

Each transaction is assigned to one of the rollback segments, and remains tied to that rollback segment for the duration. The increased limit for concurrent data-modifying transactions improves both scalability (higher number of concurrent transactions) and performance (less contention when different transactions access the rollback segments).

## 14.7.9 File-Per-Table Tablespaces

A file-per-table tablespace is a single-table tablespace that is created in its own data file rather than in the system tablespace. Tables are created in file-per-table tablespaces when the `innodb_file_per_table` option is enabled. Otherwise, `InnoDB` tables are created in the system tablespace. Each file-per-table tablespace is represented by a single `.ibd` data file, which is created in the database directory by default.

File per-table tablespaces support `DYNAMIC` and `COMPRESSED` row formats which support features such as off-page storage for variable length data and table compression. For information about these features, and about other advantages of file-per-table tablespaces, see [Section 14.10.4, “InnoDB File-Per-Table Tablespaces”](#).

## 14.7.10 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change `InnoDB` table data that result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before the connections are accepted. For information about the role of the redo log in crash recovery, see [Section 14.21.2, “InnoDB Recovery”](#).

By default, the redo log is physically represented on disk as a set of files, named `ib_logfile0` and `ib_logfile1`. MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in

terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing [LSN](#) value.

For related information, see:

- [Section 14.9.1, “InnoDB Startup Configuration”](#)
- [Section 8.5.3, “Optimizing InnoDB Redo Logging”](#)
- [Section 14.10.2, “Changing the Number or Size of InnoDB Redo Log Files”](#)
- [InnoDB Crash Recovery](#)

### 14.7.10.1 Group Commit for Redo Log Flushing

[InnoDB](#), like any other [ACID](#)-compliant database engine, flushes the [redo log](#) of a transaction before it is committed. [InnoDB](#) uses [group commit](#) functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, [InnoDB](#) issues a single write to the redo log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

Group commit in [InnoDB](#) worked in earlier releases of MySQL and works once again with MySQL 5.1 with the [InnoDB](#) Plugin, and MySQL 5.5 and higher. The introduction of support for the distributed transactions and Two Phase Commit (2PC) in MySQL 5.0 interfered with the [InnoDB](#) group commit functionality. This issue is now resolved.

The group commit functionality inside [InnoDB](#) works with the Two Phase Commit protocol in MySQL. Re-enabling of the group commit functionality fully ensures that the ordering of commit in the MySQL binary log and the [InnoDB](#) logfile is the same as it was before. It means it is safe to use the MySQL Enterprise Backup product with [InnoDB](#) 1.0.4 (that is, the [InnoDB](#) Plugin with MySQL 5.1) and above.

For more information about performance of [COMMIT](#) and other transactional operations, see [Section 8.5.2, “Optimizing InnoDB Transaction Management”](#).

## 14.8 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand [InnoDB](#) locking and the [InnoDB](#) transaction model.

This section discusses several topics related to [InnoDB](#) locking and the [InnoDB](#) transaction model with which you should be familiar.

- [Section 14.8.1, “InnoDB Locking”](#) describes lock types used by [InnoDB](#).
- [Section 14.8.2, “InnoDB Transaction Model”](#) describes transaction isolation levels and the locking strategies used by each. It also discusses the use of [autocommit](#), consistent non-locking reads, and locking reads.
- [Section 14.8.3, “Locks Set by Different SQL Statements in InnoDB”](#) discusses specific types of locks set in [InnoDB](#) for various statements.
- [Section 14.8.4, “Phantom Rows”](#) describes how [InnoDB](#) uses next-key locking to avoid phantom rows.
- [Section 14.8.5, “Deadlocks in InnoDB”](#) provides a deadlock example, discusses deadlock detection and rollback, and provides tips for minimizing and handling deadlocks in [InnoDB](#).

## 14.8.1 InnoDB Locking

This section describes lock types used by InnoDB.

- [Shared and Exclusive Locks](#)
- [Intention Locks](#)
- [Record Locks](#)
- [Gap Locks](#)
- [Next-Key Locks](#)
- [Insert Intention Locks](#)
- [AUTO-INC Locks](#)

### Shared and Exclusive Locks

InnoDB implements standard row-level locking where there are two types of locks, [shared \(S\) locks](#) and [exclusive \(X\) locks](#).

- A [shared \(S\) lock](#) permits the transaction that holds the lock to read a row.
- An [exclusive \(X\) lock](#) permits the transaction that holds the lock to update or delete a row.

If transaction T1 holds a shared (S) lock on row *r*, then requests from some distinct transaction T2 for a lock on row *r* are handled as follows:

- A request by T2 for an S lock can be granted immediately. As a result, both T1 and T2 hold an S lock on *r*.
- A request by T2 for an X lock cannot be granted immediately.

If a transaction T1 holds an exclusive (X) lock on row *r*, a request from some distinct transaction T2 for a lock of either type on *r* cannot be granted immediately. Instead, transaction T2 has to wait for transaction T1 to release its lock on row *r*.

### Intention Locks

InnoDB supports *multiple granularity locking* which permits coexistence of row-level locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called [intention locks](#) are used. Intention locks are table-level locks in InnoDB that indicate which type of lock (shared or exclusive) a transaction requires later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction T has requested a lock of the indicated type on table *t*):

- [Intention shared \(IS\)](#): Transaction T intends to set S locks on individual rows in table *t*.
- [Intention exclusive \(IX\)](#): Transaction T intends to set X locks on those rows.

For example, `SELECT ... LOCK IN SHARE MODE` sets an IS lock and `SELECT ... FOR UPDATE` sets an IX lock.

The intention locking protocol is as follows:

- Before a transaction can acquire an S lock on a row in table *t*, it must first acquire an IS or stronger lock on *t*.

- Before a transaction can acquire an *X* lock on a row, it must first acquire an *IX* lock on *t*.

These rules can be conveniently summarized by means of the following *lock type compatibility matrix*.

|           | <i>X</i> | <i>IX</i>  | <i>S</i>   | <i>IS</i>  |
|-----------|----------|------------|------------|------------|
| <i>X</i>  | Conflict | Conflict   | Conflict   | Conflict   |
| <i>IX</i> | Conflict | Compatible | Conflict   | Compatible |
| <i>S</i>  | Conflict | Conflict   | Compatible | Compatible |
| <i>IS</i> | Conflict | Compatible | Compatible | Compatible |

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause *deadlock*, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of *IX* and *IS* locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and *InnoDB monitor* output:

```
TABLE LOCK table `test`.`t` trx id 10080 lock mode IX
```

## Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE`; prevents any other transaction from inserting, updating, or deleting rows where the value of *t.c1* is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, *InnoDB* creates a hidden clustered index and uses this index for record locking. See [Section 14.11.2.1, “Clustered and Secondary Indexes”](#).

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and *InnoDB monitor* output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc      ;;
 1: len 6; hex 00000000274f; asc    'O';
 2: len 7; hex b60000019d0110; asc      ;;
```

## Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE`; prevents other transactions from inserting a value of 15 into column *t.c1*, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in [InnoDB](#) are “purely inhibitive”, which means they only stop other transactions from inserting to the gap. They do not prevent different transactions from taking gap locks on the same gap. Thus, a gap X-lock has the same effect as a gap S-lock.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to [READ COMMITTED](#) or enable the [innodb\\_locks\\_unsafe\\_for\\_binlog](#) system variable. Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the [READ COMMITTED](#) isolation level or enabling [innodb\\_locks\\_unsafe\\_for\\_binlog](#). Record locks for nonmatching rows are released after MySQL has evaluated the [WHERE](#) condition. For [UPDATE](#) statements, [InnoDB](#) does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the [WHERE](#) condition of the [UPDATE](#).

## Next-Key Locks

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

[InnoDB](#) performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record [R](#) in an index, another session cannot insert a new index record in the gap immediately before [R](#) in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, InnoDB operates in `REPEATABLE READ` transaction isolation level and with the `innodb_locks_unsafe_for_binlog` system variable disabled. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see [Section 14.8.4, “Phantom Rows”](#)).

Transaction data for a next-key lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
 0: len 8; hex 73757072656d756d; asc supremum;;

Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc      ;;
 1: len 6; hex 00000000274f; asc    'O';
 2: len 7; hex b60000019d0110; asc      ;;
```

## Insert Intention Locks

An insert intention lock is a type of gap lock set by `INSERT` operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);

mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
| id   |
+-----+
| 102  |
+-----+
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 80000066; asc    f;;
 1: len 6; hex 000000002215; asc    "  ;;
 2: len 7; hex 9000000172011c; asc    r  ;;...
```

## AUTO-INC Locks

An [AUTO-INC](#) lock is a special table-level lock taken by transactions inserting into tables with [AUTO\\_INCREMENT](#) columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The [innodb\\_autoinc\\_lock\\_mode](#) configuration option controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see [Section 14.11.1.5, “AUTO\\_INCREMENT Handling in InnoDB”](#).

## 14.8.2 InnoDB Transaction Model

In the [InnoDB](#) transaction model, the goal is to combine the best properties of a [multi-versioning](#) database with traditional two-phase locking. [InnoDB](#) performs locking at the row level and runs queries as nonlocking [consistent reads](#) by default, in the style of Oracle. The lock information in [InnoDB](#) is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in [InnoDB](#) tables, or any random subset of the rows, without causing [InnoDB](#) memory exhaustion.

### 14.8.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym [ACID](#); the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

[InnoDB](#) offers all four transaction isolation levels described by the SQL:1992 standard: [READ UNCOMMITTED](#), [READ COMMITTED](#), [REPEATABLE READ](#), and [SERIALIZABLE](#). The default isolation level for [InnoDB](#) is [REPEATABLE READ](#).

A user can change the isolation level for a single session or for all subsequent connections with the [SET TRANSACTION](#) statement. To set the server's default isolation level for all connections, use the [--transaction-isolation](#) option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see [Section 13.3.6, “SET TRANSACTION Syntax”](#).

[InnoDB](#) supports each of the transaction isolation levels described here using different locking strategies. You can enforce a high degree of consistency with the default [REPEATABLE READ](#) level, for operations on crucial data where ACID compliance is important. Or you can relax the consistency rules with [READ COMMITTED](#) or even [READ UNCOMMITTED](#), in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. [SERIALIZABLE](#) enforces even stricter rules than [REPEATABLE READ](#), and is used mainly in specialized situations, such as with XA transactions and for troubleshooting issues with concurrency and deadlocks.

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- [REPEATABLE READ](#)

This is the default isolation level for [InnoDB](#). [Consistent reads](#) within the same transaction read the [snapshot](#) established by the first read. This means that if you issue several plain (nonlocking) [SELECT](#) statements within the same transaction, these [SELECT](#) statements are consistent also with respect to each other. See [Section 14.8.2.3, “Consistent Nonlocking Reads”](#).

For **locking reads** (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE`, and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

- For a unique index with a unique search condition, **InnoDB** locks only the index record found, not the **gap** before it.
- For other search conditions, **InnoDB** locks the index range scanned, using **gap locks** or **next-key locks** to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see [Section 14.8.1, “InnoDB Locking”](#).
- `READ COMMITTED`

Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see [Section 14.8.2.3, “Consistent Nonlocking Reads”](#).

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE` statements, and `DELETE` statements, **InnoDB** locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

Because gap locking is disabled, phantom problems may occur, as other sessions can insert new rows into the gaps. For information about phantoms, see [Section 14.8.4, “Phantom Rows”](#).

If you use `READ COMMITTED`, you *must* use row-based binary logging.

Using `READ COMMITTED` has additional effects:

- For `UPDATE` or `DELETE` statements, **InnoDB** holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For `UPDATE` statements, if a row is already locked, **InnoDB** performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time **InnoDB** either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 14.11.2.1, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an `UPDATE` using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an `UPDATE` by executing these statements following those of the first client:

```
SET autocommit = 0;
```

```
UPDATE t SET b = 4 WHERE b = 2;
```

As InnoDB executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If InnoDB does not modify the row, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default `REPEATABLE READ` isolation level, the first `UPDATE` acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `READ COMMITTED` is used instead, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, InnoDB does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

The effects of using the `READ COMMITTED` isolation level are the same as enabling the `innodb_locks_unsafe_for_binlog` configuration option, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`.

- `READ UNCOMMITTED`

`SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a “dirty read.” Otherwise, this isolation level works like `READ COMMITTED`.

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

### 14.8.2.2 autocommit, Commit, and Rollback

In InnoDB, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 14.23.4, “InnoDB Error Handling”](#).

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all InnoDB locks that were set during the current transaction.

### Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of `DML` statements and commit them or roll them back all together.

To use multiple-statement [transactions](#), switch `autocommit` off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave `autocommit` on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a))
-> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
```

```

mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a     | b       |
+-----+-----+
| 10    | Heikki  |
+-----+-----+
1 row in set (0.00 sec)
mysql>

```

### Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

#### 14.8.2.3 Consistent Nonlocking Reads

A **consistent read** means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction **isolation level** is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

#### Note

The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to `DML` statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued

from another concurrent [REPEATABLE READ](#) transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
-- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz';
-- Deletes several rows recently committed by other transaction.

SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
-- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
-- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another [SELECT](#) or [START TRANSACTION WITH CONSISTENT SNAPSHOT](#).

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

|      | Session A         | Session B                    |
|------|-------------------|------------------------------|
| time | SET autocommit=0; | SET autocommit=0;            |
|      | SELECT * FROM t;  |                              |
|      | empty set         |                              |
|      |                   | INSERT INTO t VALUES (1, 2); |
|      |                   |                              |
| v    | SELECT * FROM t;  |                              |
|      | empty set         | COMMIT;                      |
|      |                   |                              |
|      | SELECT * FROM t;  |                              |
|      | empty set         |                              |
|      | COMMIT;           |                              |
|      | SELECT * FROM t;  |                              |
|      | -----             |                              |
|      | 1   2             |                              |
|      | -----             |                              |

If you want to see the “freshest” state of the database, use either the [READ COMMITTED](#) isolation level or a [locking read](#):

```
SELECT * FROM t LOCK IN SHARE MODE;
```

With [READ COMMITTED](#) isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With [LOCK IN SHARE MODE](#), a locking read occurs instead: A [SELECT](#) blocks until the transaction containing the freshest rows ends (see [Section 14.8.2.4](#), “[Locking Reads](#)”).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over [DROP TABLE](#), because MySQL cannot use a table that has been dropped and [InnoDB](#) destroys the table.

- Consistent read does not work over `ALTER TABLE`, because that statement makes a temporary copy of the original table and deletes the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken.

The type of read varies for selects in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `LOCK IN SHARE MODE`:

- By default, InnoDB uses stronger locks and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To use a consistent read in such cases, enable the `innodb_locks_unsafe_for_binlog` option and set the isolation level of the transaction to `READ UNCOMMITTED`, `READ COMMITTED`, or `REPEATABLE READ` (that is, anything other than `SERIALIZABLE`). In this case, no locks are set on rows read from the selected table.

### 14.8.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of [locking reads](#) that offer extra safety:

- `SELECT ... LOCK IN SHARE MODE`

Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

- `SELECT ... FOR UPDATE`

For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an `UPDATE` statement for those rows. Other transactions are blocked from updating those rows, from doing `SELECT ... LOCK IN SHARE MODE`, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying [undo logs](#) on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by `LOCK IN SHARE MODE` and `FOR UPDATE` queries are released when the transaction is committed or rolled back.

#### Note

Locking of rows for update using `SELECT FOR UPDATE` only applies when autocommit is disabled (either by beginning transaction with `START TRANSACTION` or by setting `autocommit` to 0. If autocommit is enabled, the rows matching the specification are not locked.

### Locking Read Examples

Suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table `PARENT` and verify that the parent row exists. Can you safely insert the child row to table `CHILD`? No, because some other session could delete the parent row in the moment between your `SELECT` and your `INSERT`, without you being aware of it.

To avoid this potential issue, perform the `SELECT` using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the `LOCK IN SHARE MODE` query returns the parent 'Jones', you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the `PARENT` table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

### 14.8.3 Locks Set by Different SQL Statements in InnoDB

A [locking read](#), an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. `InnoDB` does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally [next-key locks](#) that also block inserts into the “gap” immediately before the record. However, [gap locking](#) can be disabled explicitly, which causes next-key locking not to be used. For more information, see [Section 14.8.1, “InnoDB Locking”](#). The transaction isolation level also can affect which locks are set; see [Section 14.8.2.1, “Transaction Isolation Levels”](#).

If a secondary index is used in a search and index record locks to be set are exclusive, `InnoDB` also retrieves the corresponding clustered index records and sets locks on them.

Differences between shared and exclusive locks are described in [Section 14.8.1, “InnoDB Locking”](#).

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

For `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the `WHERE` clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a `UNION`, scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

InnoDB sets specific types of locks as follows.

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `SELECT ... FROM ... FOR UPDATE` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

For index records the search encounters, `SELECT ... FROM ... FOR UPDATE` blocks other sessions from doing `SELECT ... FROM ... LOCK IN SHARE MODE` or from reading in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view.

- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- When `UPDATE` modifies a clustered index record, implicit locks are taken on affected secondary index records. The `UPDATE` operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an **InnoDB** table **t1** has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;  
INSERT INTO t1 VALUES(1);
```

Session 2:

```
START TRANSACTION;  
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;  
INSERT INTO t1 VALUES(1);
```

Session 1:

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;  
DELETE FROM t1 WHERE i = 1;
```

Session 2:

```
START TRANSACTION;  
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;  
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `INSERT ... ON DUPLICATE KEY UPDATE` differs from a simple `INSERT` in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.
- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record lock (without a gap lock) on each row inserted into `T`. If the transaction isolation level is `READ COMMITTED`, or `innodb_locks_unsafe_for_binlog` is enabled and the transaction isolation level is not `SERIALIZABLE`, InnoDB does the search on `S` as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from `S`. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement must be executed in exactly the same way it was done originally.

`CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, InnoDB sets shared next-key locks on rows from table `s`.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 14.8.2, “InnoDB Transaction Model”](#).

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above InnoDB knows about row-level locks.

Otherwise, InnoDB's automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 14.8.5.2, “Deadlock Detection and Rollback”](#). See also [Section 14.11.1.7, “Limits on InnoDB Tables”](#).

## 14.8.4 Phantom Rows

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by InnoDB include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in [Section 14.8.1, “InnoDB Locking”](#). This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

## 14.8.5 Deadlocks in InnoDB

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as `UPDATE` or `SELECT ... FOR UPDATE`), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see [Section 14.8.5.1, “An InnoDB Deadlock Example”](#).

To reduce the possibility of deadlocks, use transactions rather than `LOCK TABLES` statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of

operations (such as `SELECT ... FOR UPDATE`) in each transaction; create indexes on the columns used in `SELECT ... FOR UPDATE` and `UPDATE ... WHERE` statements. The possibility of deadlocks is not affected by the isolation level, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see [Section 14.8.5.3, “How to Minimize and Handle Deadlocks”](#).

If a deadlock does occur, InnoDB detects the condition and rolls back one of the transactions (the victim). Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To see the last deadlock in an InnoDB user transaction, use the `SHOW ENGINE INNODB STATUS` command. If frequent deadlocks highlight a problem with transaction structure or application error handling, run with the `innodb_print_all_deadlocks` setting enabled to print information about all deadlocks to the `mysqld` error log. For more information about how deadlocks are automatically detected and handled, see [Section 14.8.5.2, “Deadlock Detection and Rollback”](#).

### 14.8.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an `S` lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+-----+
| i     |
+-----+
|      1 |
+-----+
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an `X` lock. The lock cannot be granted because it is incompatible with the `S` lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an `X` lock to delete the row. However, that lock request cannot be granted because client B already has a request for an `X` lock and is waiting for client A to release its `S` lock. Nor can the `S` lock held by A be upgraded to an `X` lock because of the prior request by B for an `X` lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock;  
try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

### 14.8.5.2 Deadlock Detection and Rollback

InnoDB automatically detects transaction [deadlocks](#) and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction rolls back.

If the `LATEST DETECTED DEADLOCK` section of InnoDB Monitor output includes a message stating, “TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION,” this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see [Section 14.8.5, “Deadlocks in InnoDB”](#).

### 14.8.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in [Section 14.8.5.2, “Deadlock Detection and Rollback”](#). It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

[Deadlocks](#) are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue the `SHOW ENGINE INNODB STATUS` command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.
- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` configuration option. Information about each deadlock, not just the latest one, is recorded in the MySQL [error log](#). Disable this option when you are finished debugging.

- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Keep transactions small and short in duration to make them less prone to collision.
- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.
- If you use **locking reads** (`SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

## 14.9 InnoDB Configuration

This section provides configuration information and procedures for InnoDB initialization, startup, and various components and features of the InnoDB storage engine. For information about optimizing database operations for InnoDB tables, see [Section 8.5, “Optimizing for InnoDB Tables”](#).

### 14.9.1 InnoDB Startup Configuration

The first decisions to make about InnoDB configuration involve the configuration of data files, log files, and memory buffers. It is recommended that you define data file, log file, and page size configuration before

creating the [InnoDB](#) instance. Modifying data file or log file configuration after the [InnoDB](#) instance is created may involve a non-trivial procedure.

In addition to these topics, this section provides information about specifying [InnoDB](#) options in a configuration file, viewing [InnoDB](#) initialization information, and important storage considerations.

- [Specifying Options in a MySQL Configuration File](#)
- [Viewing InnoDB Initialization Information](#)
- [Important Storage Considerations](#)
- [System Tablespace Data File Configuration](#)
- [InnoDB Log File Configuration](#)
- [InnoDB Memory Configuration](#)

## Specifying Options in a MySQL Configuration File

Because MySQL uses data file and log file configuration settings to initialize the [InnoDB](#) instance, it is recommended that you define these settings in a configuration file that MySQL reads at startup, prior to initializing [InnoDB](#) for the first time. [InnoDB](#) is initialized when the MySQL server is started, and the first initialization of [InnoDB](#) normally occurs the first time you start the MySQL server.

You can place [InnoDB](#) options in the `[mysqld]` group of any option file that your server reads when it starts. The locations of MySQL option files are described in [Section 4.2.6, “Using Option Files”](#).

To make sure that `mysqld` reads options only from a specific file, use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_configuration_file
```

## Viewing InnoDB Initialization Information

To view [InnoDB](#) initialization information during startup, start `mysqld` from a command prompt. When `mysqld` is started from a command prompt, initialization information is printed to the console.

For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.5\bin`, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --console
```

On Unix-like systems, `mysqld` is located in the `bin` directory of your MySQL installation:

```
sell> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information [InnoDB](#) printed during the startup process.

For information about starting MySQL using other methods, see [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).

## Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

- In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. For example, you can place system tablespace data files and log files on different disks. You can also use raw disk partitions (raw devices) for InnoDB data files, which may speed up I/O. See [Section 14.10.3, “Using Raw Disk Partitions for the System Tablespace”](#).
- InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On OS X 10.3 and higher, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.  
  
On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**
- With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see [Section 14.15.1, “InnoDB Disk I/O”](#).
- Before using NFS with InnoDB, review potential issues outlined in [Using NFS with MySQL](#).

## System Tablespace Data File Configuration

System tablespace data files are configured using the `innodb_data_file_path` and `innodb_data_home_dir` configuration options.

The `innodb_data_file_path` configuration option is used to configure the InnoDB system tablespace data files. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (;) characters:

```
innodb_data_file_path=datafile_spec1[:datafile_spec2]...
```

For example, the following setting explicitly creates a minimally sized system tablespace:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend
```

This setting configures a single 12MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using `K`, `M`, or `G` suffix letters to indicate units of KB, MB, or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the file name, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` and `max` attributes can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 64MB at a time by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. For tablespace reconfiguration instructions, see [Section 14.10.1, “Resizing the InnoDB System Tablespace”](#).

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance, because exceeding the maximum size causes a fatal error, possibly including a crash. The following configuration permits `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default (`datadir`). To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to create two files named `ibdata1` and `ibdata2` in a directory named `myibdata`, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

#### Note

A trailing slash is required when specifying a value for `innodb_data_home_dir`.

InnoDB does not create directories, so make sure that the `myibdata` directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name. If the `innodb_data_home_dir` option is not specified in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/path/to/myibdata/ibdata1:50M:/path/to/myibdata/ibdata2:50M:autoextend
```

## InnoDB Log File Configuration

By default, [InnoDB](#) creates two 5MB log files in the MySQL data directory ([datadir](#)) named [ib\\_logfile0](#) and [ib\\_logfile1](#).

The following options can be used to modify the default configuration:

- [innodb\\_log\\_group\\_home\\_dir](#) defines directory path to the [InnoDB](#) log files (the redo logs). If this option is not configured, [InnoDB](#) log files are created in the MySQL data directory ([datadir](#)).

You might use this option to place [InnoDB](#) log files in a different physical storage location than [InnoDB](#) data files to avoid potential I/O resource conflicts. For example:

```
[mysqld]
innodb_log_group_home_dir = /dr3/iblogs
```

### Note

[InnoDB](#) does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS [mkdir](#) command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create log files.

- [innodb\\_log\\_files\\_in\\_group](#) defines the number of log files in the log group. The default and recommended value is 2.
- [innodb\\_log\\_file\\_size](#) defines the size in bytes of each log file in the log group. The combined size of log files ([innodb\\_log\\_file\\_size](#) \* [innodb\\_log\\_files\\_in\\_group](#)) cannot exceed a maximum value that is slightly less than 4GB. A pair of 2047 MB log files, for example, approaches the limit but does not exceed it. The default log file size is 5MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. For additional information, see [Section 8.5.3, “Optimizing InnoDB Redo Logging”](#).

## InnoDB Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for [InnoDB](#), always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use [MyISAM](#) tables, consider the amount of memory allocated for the key buffer ([key\\_buffer\\_size](#)). For an overview of MySQL buffers and caches, see [Section 8.12.4.1, “How MySQL Uses Memory”](#).

Buffers specific to [InnoDB](#) are configured using the following parameters:

- [innodb\\_buffer\\_pool\\_size](#) defines size of the buffer pool, which is the memory area that holds cached data for [InnoDB](#) tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that [innodb\\_buffer\\_pool\\_size](#) is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For

additional guidance, see [Section 8.12.4.1, “How MySQL Uses Memory”](#). For information about how to configure InnoDB buffer pool size, see [Configuring InnoDB Buffer Pool Size](#). Buffer pool size can be configured at startup.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the by `innodb_buffer_pool_instances` option. By default, InnoDB creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see [Section 14.9.2.2, “Configuring Multiple Buffer Pool Instances”](#).

- `innodb_additional_mem_pool_size` defines size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.
- `innodb_log_buffer_size` defines the size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default size is 8MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. `innodb_log_buffer_size` can be configured at startup. For related information, see [Section 8.5.3, “Optimizing InnoDB Redo Logging”](#).

### Warning

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. `glibc` may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the memory allocated to the `mysqld` process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see [Section 8.12.4.1, “How MySQL Uses Memory”](#).

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size` + `read_buffer_size` additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool and additional memory pool. See [Section 8.12.4.2, “Enabling Large Page Support”](#).

## 14.9.2 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the InnoDB buffer pool.

### 14.9.2.1 The InnoDB Buffer Pool

InnoDB maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the InnoDB buffer pool works, and taking advantage of it to keep frequently accessed data in

memory, is an important aspect of MySQL tuning. For information about how the [InnoDB](#) buffer pool works, see [InnoDB Buffer Pool LRU Algorithm](#).

You can configure the various aspects of the [InnoDB](#) buffer pool to improve performance.

- Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more [InnoDB](#) acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. Buffer pool size is configured using the [innodb\\_buffer\\_pool\\_size](#) configuration option.
- With 64-bit systems with large memory sizes, you can split the buffer pool into multiple parts, to minimize contention for the memory structures among concurrent operations. For details, see [Section 14.9.2.2, “Configuring Multiple Buffer Pool Instances”](#).
- You can keep frequently accessed data in memory despite sudden spikes of activity for operations such as backups or reporting. For details, see [Section 14.9.2.3, “Making the Buffer Pool Scan Resistant”](#).
- You can control when and how [InnoDB](#) performs read-ahead requests to prefetch pages into the buffer pool asynchronously, in anticipation that the pages will be needed soon. For details, see [Section 14.9.2.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- You can control when background flushing of dirty pages occurs and whether or not [InnoDB](#) dynamically adjusts the rate of flushing based on workload. For details, see [Section 14.9.2.5, “Configuring InnoDB Buffer Pool Flushing”](#).

## InnoDB Buffer Pool LRU Algorithm

[InnoDB](#) manages the buffer pool as a list, using a variation of the least recently used (LRU) algorithm. When room is needed to add a new page to the pool, [InnoDB](#) evicts the least recently used page and adds the new page to the middle of the list. This “midpoint insertion strategy” treats the list as two sublists:

- At the head, a sublist of “new” (or “young”) pages that were accessed recently.
- At the tail, a sublist of “old” pages that were accessed less recently.

This algorithm keeps pages that are heavily used by queries in the new sublist. The old sublist contains less-used pages; these pages are candidates for [eviction](#).

The LRU algorithm operates as follows by default:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When [InnoDB](#) reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read in because it is required for a user-specified operation such as an SQL query, or as part of a [read-ahead](#) operation performed automatically by [InnoDB](#).
- Accessing a page in the old sublist makes it “young”, moving it to the head of the buffer pool (the head of the new sublist). If the page was read in because it was required, the first access occurs immediately and the page is made young. If the page was read in due to read-ahead, the first access does not occur immediately (and might not occur at all before the page is evicted).
- As the database operates, pages in the buffer pool that are not accessed “age” by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old

sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused for long enough reaches the tail of the old sublist and is evicted.

By default, pages read by queries immediately move into the new sublist, meaning they stay in the buffer pool longer. A table scan (such as performed for a `mysqldump` operation, or a `SELECT` statement with no `WHERE` clause) can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and then accessed only once move to the head of the new list. These situations can push frequently used pages to the old sublist, where they become subject to eviction. For information about optimizing this behavior, see [Section 14.9.2.3, “Making the Buffer Pool Scan Resistant”](#), and [Section 14.9.2.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

InnoDB Standard Monitor output contains several fields in the `BUFFER POOL AND MEMORY` section that pertain to operation of the buffer pool LRU algorithm. For details, see [Section 14.9.2.6, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

## InnoDB Buffer Pool Configuration Options

Several configuration options affect different aspects of the InnoDB buffer pool.

- `innodb_buffer_pool_size`

Specifies the size of the buffer pool. If the buffer pool is small and you have sufficient memory, making the buffer pool larger can improve performance by reducing the amount of disk I/O needed as queries access InnoDB tables.

- `innodb_buffer_pool_instances`

Divides the buffer pool into a user-specified number of separate regions, each with its own LRU list and related data structures, to reduce contention during concurrent memory read and write operations. This option only takes effect when you set `innodb_buffer_pool_size` to a value of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1 gigabyte. See [Section 14.9.2.2, “Configuring Multiple Buffer Pool Instances”](#) for more information.

- `innodb_old_blocks_pct`

Specifies the approximate percentage of the buffer pool that InnoDB uses for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). See [Section 14.9.2.3, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_old_blocks_time`

Specifies how long in milliseconds (ms) a page inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. If the value is 0, a page inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, pages remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes pages to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

Setting `innodb_old_blocks_time` greater than 0 prevents one-time table scans from flooding the new sublist with pages used only for the scan. Rows in a page read in for a scan are accessed many times in rapid succession, but the page is unused after that. If `innodb_old_blocks_time` is set to a value greater than time to process the page, the page remains in the “old” sublist and ages to the tail of the list to be evicted quickly. This way, pages used only for a one-time scan do not act to the detriment of heavily used pages in the new sublist.

`innodb_old_blocks_time` can be set at runtime, so you can change it temporarily while performing operations such as table scans and dumps:

```
SET GLOBAL innodb_old_blocks_time = 1000;  
... perform queries that scan tables ...  
SET GLOBAL innodb_old_blocks_time = 0;
```

This strategy does not apply if your intent is to “warm up” the buffer pool by filling it with a table's content. For example, benchmark tests often perform a table or index scan at server startup, because that data would normally be in the buffer pool after a period of normal use. In this case, leave `innodb_old_blocks_time` set to 0, at least until the warmup phase is complete.

See [Section 14.9.2.3, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_read_ahead_threshold`

Controls the sensitivity of linear [read-ahead](#) that [InnoDB](#) uses to prefetch pages into the buffer pool.

See [Section 14.9.2.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_random_read_ahead`

Enables random [read-ahead](#) technique for prefetching pages into the buffer pool. Random read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. `innodb_random_read_ahead` is disabled by default.

See [Section 14.9.2.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_adaptive_flushing`

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the buffer pool based on workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default.

See [Section 14.9.2.5, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_max_dirty_pages_pct`

[InnoDB](#) tries to [flush](#) data from the buffer pool so that the percentage of [dirty pages](#) does not exceed this value. Specify an integer in the range from 0 to 99. The default value is 75.

See [Section 14.9.2.5, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

### 14.9.2.2 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a [buffer pool](#) size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the [InnoDB](#) buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages

its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

### 14.9.2.3 Making the Buffer Pool Scan Resistant

Rather than using a strict LRU algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the buffer pool and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as read-ahead and full table scans bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is 3/8 from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the LRU list, and “age out” sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the InnoDB buffer pool and specifics about the LRU algorithm, see [Section 14.9.2.1, “The InnoDB Buffer Pool”](#).

You can control the insertion point in the LRU list and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of 3/8. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 0, corresponding to the original behavior of moving a page to the most-recently used end of the buffer pool list when it is first accessed in the buffer pool. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` are dynamic, global and can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` command. Changing the setting requires the `SUPER` privilege.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see [Section 14.9.2.6, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

#### 14.9.2.4 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A **read-ahead** request is an I/O request to prefetch multiple pages in the **buffer pool** asynchronously, in anticipation that these pages will be needed soon. The requests bring in all the pages in one **extent**. **InnoDB** uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when **InnoDB** performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, **InnoDB** would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read in the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive **InnoDB** is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, **InnoDB** initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, **InnoDB** triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, **InnoDB** triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL **configuration file**, or change it dynamically with the `SET GLOBAL` command, which requires the **SUPER** privilege.

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, **InnoDB** asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to **ON**.

Random read-ahead functionality was removed from the **InnoDB Plugin** (version 1.0.4) and was therefore not included in MySQL 5.5.0 when **InnoDB Plugin** became the “built-in” version of **InnoDB**. Random read-ahead was reintroduced in MySQL 5.1.59 and 5.5.16 and higher along with the `innodb_random_read_ahead` configuration option, which is disabled by default. To enable this feature, set the configuration variable `innodb_random_read_ahead` to **ON**.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_read_ahead`
- `Innodb_buffer_pool_read_ahead_evicted`

- `Innodb_buffer_pool_read_ahead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#) and [Section 8.12.2, “Optimizing Disk I/O”](#).

### 14.9.2.5 Configuring InnoDB Buffer Pool Flushing

InnoDB performs certain tasks in the background, including [flushing](#) of [dirty pages](#) (those pages that have been changed but are not yet written to the database files) from the [buffer pool](#), a task performed by the [master thread](#). InnoDB aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool exceeds `innodb_max_dirty_pages_pct`.

InnoDB uses an algorithm to estimate the required rate of flushing, based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that buffer flush activity keeps up with the need to keep the buffer pool “clean”. Automatically adjusting the rate of flushing can help to avoid sudden dips in throughput, when excessive buffer pool flushing limits the I/O capacity available for ordinary read and write activity.

InnoDB uses its log files in a circular fashion. Before reusing a portion of a log file, InnoDB flushes to disk all dirty buffer pool pages whose redo entries are contained in that portion of the log file, a process known as a [sharp checkpoint](#). If a workload is write-intensive, it generates a lot of redo information, all written to the log file. If all available space in the log files is used up, a sharp checkpoint occurs, causing a temporary reduction in throughput. This situation can happen even if `innodb_max_dirty_pages_pct` is not reached.

InnoDB uses a heuristic-based algorithm to avoid such a scenario, by measuring the number of dirty pages in the buffer pool and the rate at which redo is being generated. Based on these numbers, InnoDB decides how many dirty pages to flush from the buffer pool each second. This self-adapting algorithm is able to deal with sudden changes in workload.

Internal benchmarking has shown that this algorithm not only maintains throughput over time, but can also improve overall throughput significantly.

Because adaptive flushing can significantly affect the I/O pattern of a workload, the `innodb_adaptive_flushing` configuration parameter lets you turn off this feature. The default value for `innodb_adaptive_flushing` is `ON`, enabling the adaptive flushing algorithm. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

For more information about InnoDB I/O performance, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

### 14.9.2.6 Monitoring the Buffer Pool Using the InnoDB Standard Monitor

InnoDB Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics that pertain to operation of the InnoDB buffer pool. Buffer pool metrics are located in the `BUFFER POOL AND MEMORY` section of InnoDB Standard Monitor output and appear similar to the following:

```
-----
BUFFER POOL AND MEMORY
-----
Total memory allocated 2217738240; in additional pool allocated 0
Dictionary memory allocated 121719
Buffer pool size      131072

The following table describes [InnoDB](#) buffer pool metrics reported by the [InnoDB](#) Standard Monitor.

#### Note

Per second averages provided in [InnoDB](#) Standard Monitor output are based on the elapsed time since [InnoDB](#) Standard Monitor output was last printed.

**Table 14.2 InnoDB Buffer Pool Metrics**

| Name                        | Description  |
|-----------------------------|--|
| Total memory allocated      | The total memory allocated for the buffer pool in bytes.   |
| additional pool allocated   | The total memory allocated for the additional pool in bytes.   |
| Dictionary memory allocated | The total memory allocated for the <a href="#">InnoDB</a> data dictionary in bytes.  |
| Buffer pool size            | The total size in pages allocated to the buffer pool.  |
| Free buffers                | The total size in pages of the buffer pool free list.  |
| Database pages              | The total size in pages of the buffer pool LRU list.   |
| Old database pages          | The total size in pages of the buffer pool old LRU sublist.  |
| Modified db pages           | The current number of pages modified in the buffer pool.   |
| Pending reads               | The number of buffer pool pages waiting to be read in to the buffer pool.  |
| Pending writes LRU          | The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list.  |
| Pending writes flush list   | The number of buffer pool pages to be flushed during checkpointing.  |
| Pending writes single page  | The number of pending independent page writes within the buffer pool.  |
| Pages made young            | The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of “new” pages).  |
| Pages made not young        | The total number of pages not made young in the buffer pool LRU list (pages that have remained in the “old” sublist without being made young).                                       |
| youngs/s                    | The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information.     |
| non-youngs/s                | The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information. |

| Name                         | Description   |
|------------------------------|---|
| Pages read                   | The total number of pages read from the buffer pool.  |
| Pages created                | The total number of pages created within the buffer pool.   |
| Pages written                | The total number of pages written from the buffer pool.   |
| reads/s                      | The per second average number of buffer pool page reads per second.   |
| creates/s                    | The per second average number of buffer pool pages created per second.  |
| writes/s                     | The per second average number of buffer pool page writes per second.  |
| Buffer pool hit rate         | The buffer pool page hit rate for pages read from the buffer pool memory vs from disk storage.  |
| young-making rate            | The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information.     |
| not (young-making rate)      | The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information. |
| Pages read ahead             | The per second average of read ahead operations.  |
| Pages evicted without access | The per second average of the pages evicted without being accessed from the buffer pool.  |
| Random read ahead            | The per second average of random read ahead operations.   |
| LRU len                      | The total size in pages of the buffer pool LRU list.  |
| unzip_LRU len                | The total size in pages of the buffer pool unzip_LRU list.  |
| I/O sum                      | The total number of buffer pool LRU list pages accessed, for the last 50 seconds.   |
| I/O cur                      | The total number of buffer pool LRU list pages accessed.  |
| I/O unzip sum                | The total number of buffer pool unzip_LRU list pages accessed.  |
| I/O unzip cur                | The total number of buffer pool unzip_LRU list pages accessed.  |

**Notes:**

- The [young/s](#) metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you see very low [young/s](#) values when there are no large scans occurring, you might need to reduce the delay time or increase the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger, so pages in that sublist take longer to move to the tail and to be evicted. This increases the likelihood that the pages will be accessed again and be made young.
- The [non-young/s](#) metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you do not see a lot of [non-young/s](#) when you are doing large table scans (and lots of [young/s](#)), increase the delay value.
- The [young-making](#) rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist. The [young-making](#) rate and [not](#) rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.

- `not (young-making rate)` is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by `innodb_old_blocks_time` not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist.

InnoDB buffer pool [server status variables](#) and the `INNODB_BUFFER_POOL_STATS` table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information about the `INNODB_BUFFER_POOL_STATS` table, see [Example 14.6, “Querying the INNODB\\_BUFFER\\_POOL\\_STATS Table”](#).

### 14.9.3 Configuring the Memory Allocator for InnoDB

When InnoDB was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, InnoDB implemented its own memory allocator in the `mem` subsystem. This allocator is guarded by a single mutex, which may become a [bottleneck](#). InnoDB also implements a wrapper interface around the system allocator (`malloc` and `free`) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. These new memory allocators perform better and are more scalable than they were in the past. Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, InnoDB-specific memory allocator.

You can control whether InnoDB uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter `innodb_use_sys_malloc` in the MySQL option file (`my.cnf` or `my.ini`). If set to `ON` or `1` (the default), InnoDB uses the `malloc` and `free` functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the InnoDB memory allocator, set `innodb_use_sys_malloc` to `0`.

#### Note

When the InnoDB memory allocator is disabled, InnoDB ignores the value of the parameter `innodb_additional_mem_pool_size`. The InnoDB memory allocator uses an additional memory pool for satisfying allocation requests without having to fall back to the system memory allocator. When the InnoDB memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable `LD_PRELOAD` or `LD_LIBRARY_PATH` point to the dynamic library that implements the allocator. On other systems, some relinking may be necessary. Please refer to the documentation of the memory allocator library of your choice.

Since InnoDB cannot track all memory use when the system memory allocator is used (`innodb_use_sys_malloc` is `ON`), the section “BUFFER POOL AND MEMORY” in the output of the `SHOW ENGINE INNODB STATUS` command only includes the buffer pool statistics in the “Total memory allocated”. Any memory allocated using the `mem` subsystem or using `ut_malloc` is excluded.

For more information about the performance implications of InnoDB memory usage, see [Section 8.10, “Buffering and Caching”](#).

## 14.9.4 Configuring InnoDB Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. InnoDB has a `change buffer` that caches changes to secondary index entries when the relevant `page` is not in the `buffer pool`, thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded to the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a `slow shutdown`.

Because it can result in fewer disk reads and writes, the change buffer feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working set fits entirely within the buffer, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which InnoDB performs change buffering using the `innodb_change_buffering` configuration parameter. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. In MySQL 5.5 and higher, the default `innodb_change_buffering` value is changed from `inserts` to `all`.

Permitted `innodb_change_buffering` values include:

- `all`

The default value: buffer inserts, delete-marking operations, and purges.

- `none`

Do not buffer any operations.

- `inserts`

Buffer insert operations.

- `deletes`

Buffer delete-marking operations.

- `changes`

Buffer both inserts and delete-marking operations.

- `purges`

Buffer the physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege. Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

For related information, see [Section 14.7.2, “Change Buffer”](#).

## 14.9.5 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system [threads](#) to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up reduce the need to limit the number of concurrently executing threads inside InnoDB.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter [innodb\\_thread\\_concurrency](#). Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter [innodb\\_thread\\_sleep\\_delay](#), before being placed into the queue.

The default value for [innodb\\_thread\\_concurrency](#) and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of [innodb\\_thread\\_concurrency](#) is 0, so that by default there is no limit on the number of concurrently executing threads, as shown in [Table 14.3, “Changes to innodb\\_thread\\_concurrency”](#).

**Table 14.3 Changes to innodb\_thread\_concurrency**

| InnoDB Version         | MySQL Version             | Default value | Default limit of concurrent threads | Value to allow unlimited threads |
|------------------------|---------------------------|---------------|-------------------------------------|----------------------------------|
| Built-in               | Earlier than 5.1.11       | 20            | No limit                            | 20 or higher                     |
| Built-in               | 5.1.11 and newer          | 8             | 8                                   | 0                                |
| InnoDB before 1.0.3    | (corresponding to Plugin) | 8             | 8                                   | 0                                |
| InnoDB 1.0.3 and newer | (corresponding to Plugin) | 0             | No limit                            | 0                                |

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if [innodb\\_thread\\_concurrency](#) is 0, the value of [innodb\\_thread\\_sleep\\_delay](#) is ignored.

When there is a limit on the number of threads (when [innodb\\_thread\\_concurrency](#) is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a *single SQL statement* to enter InnoDB without observing the limit set by [innodb\\_thread\\_concurrency](#). Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe [innodb\\_thread\\_concurrency](#). Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and [innodb\\_thread\\_concurrency](#) is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to

enter [InnoDB](#), tickets are assigned again. The number of tickets assigned is specified by the global option [innodb\\_concurrency\\_tickets](#), which is 500 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as [innodb\\_use\\_sys\\_malloc](#) and [innodb\\_adaptive\\_hash\\_index](#).

For general performance information about MySQL thread handling, see [Section 8.12.5.1, “How MySQL Uses Threads for Client Connections”](#).

## 14.9.6 Configuring the Number of Background InnoDB I/O Threads

[InnoDB](#) uses background [threads](#) to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the [innodb\\_read\\_io\\_threads](#) and [innodb\\_write\\_io\\_threads](#) configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file ([my.cnf](#) or [my.ini](#)); you cannot change values dynamically. The default value for these parameters is 4 and permissible values range from 1–64.

These parameters replace [innodb\\_file\\_io\\_threads](#) from earlier versions of MySQL. If you try to set a value for this obsolete parameter, a warning is written to the log file and the value is ignored. This parameter only applied to Windows platforms. (On non-Windows platforms, there was only one thread each for read and write.)

The purpose of these configuration options to make [InnoDB](#) more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is [read-ahead](#) requests. [InnoDB](#) tries to balance the load of incoming requests in such way that most background threads share work equally. [InnoDB](#) also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than 64 × [innodb\\_read\\_io\\_threads](#) pending read requests in [SHOW ENGINE INNODB STATUS](#) output, you might improve performance by increasing the value of [innodb\\_read\\_io\\_threads](#).

On Linux systems, [InnoDB](#) uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages, which changes the way that [InnoDB](#) background threads service these types of I/O requests. For more information, see [Section 14.9.7, “Using Asynchronous I/O on Linux”](#).

For more information about [InnoDB](#) I/O performance, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

## 14.9.7 Using Asynchronous I/O on Linux

[InnoDB](#) uses the asynchronous I/O subsystem (native AIO) on Linux to perform readahead and write requests for data file pages. This behavior is controlled by the [innodb\\_use\\_native\\_aio](#) configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, [InnoDB](#) uses synchronous I/O only. Historically, [InnoDB](#) only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the [libaio](#) library.

With synchronous I/O, query threads queue I/O requests, and [InnoDB](#) background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the [InnoDB](#) background thread that is handling the request calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel

is  $n$ , where  $n$  is the number of InnoDB background threads. The number of InnoDB background threads is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See [Section 14.9.6, “Configuring the Number of Background InnoDB I/O Threads”](#).

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. InnoDB background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output. The increase in parallel processing when using native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support asynchronous I/O on `tmpfs`.

## 14.9.8 Configuring the InnoDB Master Thread I/O Rate

The `master thread` in InnoDB is a thread that performs various tasks in the background. Most of these tasks are I/O related, such as flushing dirty pages from the buffer pool or writing changes from the insert buffer to the appropriate secondary indexes. The master thread attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the free I/O bandwidth available and tune its activities to take advantage of this free capacity. Historically, InnoDB has used a hard coded value of 100 IOPs (input/output operations per second) as the total I/O capacity of the server.

The parameter `innodb_io_capacity` indicates the overall I/O capacity available to InnoDB. This parameter should be set to approximately the number of I/O operations that the system can perform per second. The value depends on your system configuration. When `innodb_io_capacity` is set, the master threads estimates the I/O bandwidth available for background tasks based on the set value. Setting the value to `100` reverts to the old behavior.

You can set the value of `innodb_io_capacity` to any number 100 or greater. The default value is `200`, reflecting that the performance of typical modern I/O devices is higher than in the early days of MySQL. Typically, values around the previous default of 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and SSDs benefit from higher values.

The `innodb_io_capacity` setting is a total limit for all buffer pool instances. When dirty pages are flushed, the `innodb_io_capacity` limit is divided equally among buffer pool instances. For more information, see the `innodb_io_capacity` system variable description.

You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

For more information about InnoDB I/O performance, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

## 14.9.9 Configuring Spin Lock Polling

Many InnoDB [mutexes](#) and [rw-locks](#) are reserved for a short time. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a while before sleeping. If the mutex or rw-lock becomes available during this polling period, the thread can continue immediately, in the same time slice. However, too-frequent polling by multiple threads of a shared object can cause “cache ping pong”, different processors invalidating portions of each others' cache. InnoDB minimizes this issue by waiting a random time between subsequent polls. The delay is implemented as a busy loop.

You can control the maximum delay between testing a mutex or rw-lock using the parameter [innodb\\_spin\\_wait\\_delay](#). The duration of the delay loop depends on the C compiler and the target processor. (In the 100MHz Pentium era, the unit of delay was one microsecond.) On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting [innodb\\_spin\\_wait\\_delay=0](#). On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The default value of [innodb\\_spin\\_wait\\_delay](#) is 6. The spin wait delay is a dynamic, global parameter that you can specify in the MySQL option file ([my.cnf](#) or [my.ini](#)) or change at runtime with the command [SET GLOBAL innodb\\_spin\\_wait\\_delay=delay](#), where *delay* is the desired maximum delay. Changing the setting requires the [SUPER](#) privilege.

For performance considerations for InnoDB locking operations, see [Section 8.11, “Optimizing Locking Operations”](#).

## 14.9.10 Configuring InnoDB Purge Scheduling

Starting in MySQL 5.5, the [purge](#) operations (a type of garbage collection) that InnoDB performs automatically can be done in a separate thread rather than as part of the [master thread](#). This change improves scalability by allowing the main database operations to run independently from maintenance work happening in the background.

To enable this feature, set the configuration option [innodb\\_purge\\_threads](#) to 1, as opposed to the default of 0, which combines the purge operation into the master thread. [innodb\\_purge\\_threads](#) is a non-dynamic configuration option, which means it cannot be configured at runtime.

You might not notice a significant speedup, because the purge thread might encounter new types of contention; the single purge thread really lays the groundwork for further tuning and possibly multiple purge threads in the future. There is another new configuration option, [innodb\\_purge\\_batch\\_size](#) with a default value of 20 and maximum value of 5000. This option is mainly intended for experimentation and tuning of purge operations, and should not be interesting to typical users.

For more information about InnoDB I/O performance, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

## 14.9.11 Configuring Optimizer Statistics for InnoDB

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. Certain operations cause InnoDB to sample random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).) These operations include the [ANALYZE TABLE](#) statement, the [SHOW TABLE STATUS](#) statement, and accessing the table for the first time after a restart.

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can now change the number of sampled pages using the parameter [innodb\\_stats\\_sample\\_pages](#). Previously, the number of sampled pages was always 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in [joins](#). Unnecessary [full table scans](#) for such tables can be a substantial performance issue.

You can set the global parameter `innodb_stats_sample_pages`, at runtime. The default value for this parameter is 8, preserving the same behavior as in past releases.

#### Note

The value of `innodb_stats_sample_pages` affects the index sampling for *all* tables and indexes. There are the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in very inaccurate estimates of cardinality.
- Increasing the `innodb_stats_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a big slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.
- The optimizer might choose very different query plans based on different estimates of index selectivity.

To disable the cardinality estimation for metadata statements such as `SHOW TABLE STATUS` or `SHOW INDEX`, or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables, execute the statement `SET GLOBAL innodb_stats_on_metadata=OFF`. The ability to set this option dynamically is also relatively new.

All InnoDB tables are opened, and the statistics are re-estimated for all associated indexes, when the `mysql` client starts with the `--auto-rehash` setting on (the default). To improve the start up time of the `mysql` client, you can turn auto-rehash off using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

Whatever value of `innodb_stats_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again. The more accurate statistics calculated by `ANALYZE` running with a high value of `innodb_stats_sample_pages` can be wiped away later.

Although it is not possible to specify the sample size on a per-table basis, smaller tables generally require fewer index samples than larger tables do. If your database has many large tables, consider using a higher value for `innodb_stats_sample_pages` than if you have mostly smaller tables.

### 14.9.11.1 Estimating ANALYZE TABLE Complexity for InnoDB Tables

`ANALYZE TABLE` complexity for InnoDB tables is dependent on:

- The number of pages sampled, as defined by `innodb_stats_sample_pages`.
- The number of indexed columns in a table
- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating `ANALYZE TABLE` complexity would be:

`innodb_stats_sample_pages` \* number of indexed columns in a table \* number of partitions

Typically, the greater the resulting value, the greater the execution time for `ANALYZE TABLE`.

For more information about the `innodb_stats_sample_pages` configuration parameter, see [Section 14.9.11, “Configuring Optimizer Statistics for InnoDB”](#).

## 14.10 InnoDB Tablespaces

This section covers topics related to [InnoDB](#) tablespaces.

### 14.10.1 Resizing the InnoDB System Tablespace

This section describes how to increase or decrease the size of the [InnoDB](#) system tablespace.

#### Increasing the Size of the InnoDB System Tablespace

The easiest way to increase the size of the [InnoDB](#) system tablespace is to configure it from the beginning to be auto-extending. Specify the [autoextend](#) attribute for the last data file in the tablespace definition. Then [InnoDB](#) increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the [innodb\\_autoextend\\_increment](#) system variable, which is measured in megabytes.

You can expand the system tablespace by a defined amount by adding another data file:

1. Shut down the MySQL server.
2. If the previous last data file is defined with the keyword [autoextend](#), change its definition to use a fixed size, based on how large it has actually grown. Check the size of the data file, round it down to the closest multiple of 1024 × 1024 bytes (= 1MB), and specify this rounded size explicitly in [innodb\\_data\\_file\\_path](#).
3. Add a new data file to the end of [innodb\\_data\\_file\\_path](#), optionally making that file auto-extending. Only the last data file in the [innodb\\_data\\_file\\_path](#) can be specified as auto-extending.
4. Start the MySQL server again.

For example, this tablespace has just one auto-extending data file [ibdata1](#):

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to use a fixed size and adding a new auto-extending data file:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:988M:/disk2/ibdata2:50M:autoextend
```

When you add a new data file to the system tablespace configuration, make sure that the filename does not refer to an existing file. [InnoDB](#) creates and initializes the file when you restart the server.

#### Decreasing the Size of the InnoDB System Tablespace

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use [mysqldump](#) to dump all your [InnoDB](#) tables.
2. Stop the server.
3. Remove all the existing tablespace files, including the [ibdata](#) and [ib\\_log](#) files. If you want to keep a backup copy of the information, then copy all the [ib\\*](#) files to another location before the removing the files in your MySQL installation.

4. Remove any `.frm` files for InnoDB tables.
5. Configure a new tablespace.
6. Restart the server.
7. Import the dump files.

## 14.10.2 Changing the Number or Size of InnoDB Redo Log Files

To change the number or the size of your InnoDB redo log files, perform the following steps:

1. If `innodb_fast_shutdown` is set to 2, set `innodb_fast_shutdown` to 1:

```
mysql> SET GLOBAL innodb_fast_shutdown = 1;
```

2. After ensuring that `innodb_fast_shutdown` is not set to 2, stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the log).
3. Copy the old log files into a safe place in case something went wrong during the shutdown and you need them to recover the tablespace.
4. Delete the old log files from the log file directory.
5. Edit `my.cnf` to change the log file configuration.
6. Start the MySQL server again. `mysqld` sees that no InnoDB log files exist at startup and creates new ones.

## 14.10.3 Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the InnoDB system tablespace. This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the `mysql` user, the partition must be readable and writeable by `mysql`. If you run the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writeable by `root`.

The procedures described below involve option file modification. For additional information, see [Section 4.2.6, “Using Option Files”](#).

### Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]  
innodb_data_home_dir=  
innodb_data_file_path=/dev/hdd1:3Gnewraw:/dev/hdd2:2Gnewraw
```

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB

reinitializes the partition and your changes are lost. (As a safety measure [InnoDB](#) prevents users from modifying data when any partition with [newraw](#) is specified.)

3. After [InnoDB](#) has initialized the new partition, stop the server, change [newraw](#) in the data file specification to [raw](#):

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Graw:/dev/hdd2:2Graw
```

4. Restart the server. [InnoDB](#) now permits changes to be made.

## Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the [innodb\\_data\\_file\\_path](#) setting differs slightly on Windows.

1. When you create a new data file, specify the keyword [newraw](#) immediately after the data file size for the [innodb\\_data\\_file\\_path](#) option:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. [InnoDB](#) notices the [newraw](#) keyword and initializes the new partition.
3. After [InnoDB](#) has initialized the new partition, stop the server, change [newraw](#) in the data file specification to [raw](#):

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Graw
```

4. Restart the server. [InnoDB](#) now permits changes to be made.

## 14.10.4 InnoDB File-Per-Table Tablespaces

By default, all [InnoDB](#) tables and indexes are stored in the [system tablespace](#). As an alternative, you can store each [InnoDB](#) table and associated indexes in its own data file. This feature is called “file-per-table tablespaces” because each table has its own tablespace, and each tablespace has its own [.ibd](#) data file. This feature is controlled by the [innodb\\_file\\_per\\_table](#) configuration option.

### Advantages of File-Per-Table Tablespaces

- You can reclaim disk space when truncating or dropping a table stored in a file-per-table tablespace. Truncating or dropping tables stored in the shared [system tablespace](#) creates free space internally in the system tablespace data files ([ibdata files](#)) which can only be used for new [InnoDB](#) data.

Similarly, a table-copying [ALTER TABLE](#) operation on table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. The additional space required for the table-copying [ALTER TABLE](#) operation is not released back to the operating system as it is for file-per-table tablespaces.

- The [TRUNCATE TABLE](#) operation is faster when run on tables stored in file-per-table tablespaces.

- You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes.
- You can run `OPTIMIZE TABLE` to compact or recreate a file-per-table tablespace. When you run an `OPTIMIZE TABLE`, InnoDB creates a new `.ibd` file with a temporary name, using only the space required to store actual data. When the optimization is complete, InnoDB removes the old `.ibd` file and replaces it with the new one. If the previous `.ibd` file grew significantly but the actual data only accounted for a portion of its size, running `OPTIMIZE TABLE` can reclaim the unused space.
- You can move individual InnoDB tables rather than entire databases.
- Tables created in file-per-table tablespaces use the Barracuda file format. The Barracuda file format enables features such as `compressed` and `dynamic` row formats. Tables created in the system tablespace cannot use these features. To take advantage of these features for an existing table, enable the `innodb_file_per_table` setting and run `ALTER TABLE t ENGINE=INNODB` to place the table in a file-per-table tablespace. Before converting tables, refer to [Section 14.11.1.4, “Converting Tables from MyISAM to InnoDB”](#).
- You can enable more efficient storage for tables with large `BLOB` or `TEXT` columns using the `dynamic row format`.
- File-per-table tablespaces may improve chances for a successful recovery and save time when a corruption occurs, when a server cannot be restarted, or when backup and binary logs are unavailable.
- You can back up or restore individual tables quickly using the MySQL Enterprise Backup product, without interrupting the use of other InnoDB tables. This is beneficial if you have tables that require backup less frequently or on a different backup schedule. See [Partial Backup and Restore Options](#) for details.
- File-per-table tablespaces are convenient for per-table status reporting when copying or backing up tables.
- You can monitor table size at a file system level, without accessing MySQL.
- Common Linux file systems do not permit concurrent writes to a single file when `innodb_flush_method` is set to `O_DIRECT`. As a result, there are possible performance improvements when using `innodb_file_per_table` in conjunction with `innodb_flush_method`.
- The system tablespace stores the InnoDB data dictionary and undo logs, and has a 64TB size limit. By comparison, each file-per-table tablespace has a 64TB size limit, which provides room for growth. See [Section 14.11.1.7, “Limits on InnoDB Tables”](#) for related information.

## Potential Disadvantages of File-Per-Table Tablespaces

- With file-per-table tablespaces, each table may have unused space, which can only be utilized by rows of the same table. This could lead to wasted space if not properly managed.
- `fsync` operations must run on each open table rather than on a single file. Because there is a separate `fsync` operation for each file, write operations on multiple tables cannot be combined into a single I/O operation. This may require InnoDB to perform a higher total number of `fsync` operations.
- `mysqld` must keep one open file handle per table, which may impact performance if you have numerous tables in file-per-table tablespaces.
- More file descriptors are used.
- If backward compatibility with MySQL 5.1 is a concern, be aware that enabling `innodb_file_per_table` means that an `ALTER TABLE` operation can move an InnoDB table from

the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (`ALTER OFFLINE`).

For example, when restructuring the clustered index for an InnoDB table, the table is re-created using the current setting for `innodb_file_per_table`. This behavior does not apply when adding or dropping InnoDB secondary indexes. When a secondary index is created without rebuilding the table, the index is stored in the same file as the table data, regardless of the current `innodb_file_per_table` setting.

- If many tables are growing there is potential for more fragmentation which can impede `DROP TABLE` and table scan performance. However, when fragmentation is managed, having files in their own tablespace can improve performance.
- The buffer pool is scanned when dropping a file-per-table tablespace, which can take several seconds for buffer pools that are tens of gigabytes in size. The scan is performed with a broad internal lock, which may delay other operations. Tables in the system tablespace are not affected.
- The `innodb_autoextend_increment` variable, which defines increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

## Enabling and Disabling File-Per-Table Tablespaces

To enable file-per-table tablespaces, start the server with the `--innodb_file_per_table` option. For example, add a line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table=1
```

With `innodb_file_per_table` enabled, InnoDB stores each newly created table into its own `tbl_name.ibd` file in the database directory where the table belongs. This is similar to what the MyISAM storage engine does, but MyISAM divides the table into a `tbl_name.MYD` data file and an `tbl_name.MYI` index file. For InnoDB, the data and the indexes are stored together in the `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, newly created InnoDB tables are created inside the shared tablespace files again.

To move a table from the system tablespace to its own tablespace, change the `innodb_file_per_table` setting and rebuild the table:

```
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE table_name ENGINE=InnoDB;
```

### Note

InnoDB requires the shared tablespace to store its internal data dictionary and undo logs. The `.ibd` files alone are not sufficient for InnoDB to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new InnoDB data, but is not reclaimed for use by the operating system. When moving large InnoDB tables out of the system tablespace, where disk space is limited, you might prefer to turn on `innodb_file_per_table` and then recreate the entire instance using the `mysqldump` command.

## Portability Considerations for .ibd Files

You cannot freely move `.ibd` files between database directories as you can with `MyISAM` table files. The table definition stored in the `InnoDB` shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.
2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

3. Copy the backup `.ibd` file to the proper database directory.
4. Issue this `ALTER TABLE` statement to tell `InnoDB` to use the new `.ibd` file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged change buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of `InnoDB` is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the `InnoDB` installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

### 14.10.4.1 Enabling and Disabling File-Per-Table Tablespaces

To make file-per-table tablespaces the default for a MySQL server, start the server with the `--innodb_file_per_table` command-line option, or add this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

You can also issue the command while the server is running:

```
SET GLOBAL innodb_file_per_table=1;
```

With `innodb-file-per-table` enabled, InnoDB stores each newly created table in its own `tbl_name.ibd` file in the appropriate database directory. Unlike the `MyISAM` storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files for indexes and data, InnoDB stores the data and the indexes together in a single `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove `innodb_file_per_table` from your startup options and restart the server, or turn it off with the `SET GLOBAL` command, InnoDB creates any new tables inside the system tablespace.

You can always read and write any InnoDB tables, regardless of the file-per-table setting.

To move a table from the system tablespace to its own tablespace, change the `innodb_file_per_table` setting and rebuild the table:

```
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE table_name ENGINE=InnoDB;
```

#### Note

InnoDB always needs the system tablespace because it puts its internal [data dictionary](#) and [undo logs](#) there. The `.ibd` files are not sufficient for InnoDB to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new InnoDB data, but is not reclaimed for use by the operating system. When moving large InnoDB tables out of the system tablespace, where disk space is limited, you might prefer to turn on `innodb_file_per_table` and then recreate the entire instance using the `mysqldump` command.

## 14.11 InnoDB Tables and Indexes

This section covers topics related to InnoDB tables and indexes.

### 14.11.1 InnoDB Tables

This section covers topics related to InnoDB tables.

#### 14.11.1.1 Creating InnoDB Tables

To create an InnoDB table, use the `CREATE TABLE` statement.

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

You do not need to specify the `ENGINE=InnoDB` clause if InnoDB is defined as the default storage engine, which it is by default. To check the default storage engine, issue the following statement:

```
mysql> SELECT @@default_storage_engine;
+-----+
| @@default_storage_engine |
+-----+
| InnoDB                   |
+-----+
```

+-----+  
You might still use `ENGINE=InnoDB` clause if you plan to use `mysqldump` or replication to replay the `CREATE TABLE` statement on a server where the default storage engine is not `InnoDB`.

An `InnoDB` table and its indexes can be created in the `system tablespace` or in a `file-per-table` tablespace. When `innodb_file_per_table` is enabled, an `InnoDB` table is implicitly created in an individual file-per-table tablespace. Conversely, when `innodb_file_per_table` is disabled, an `InnoDB` table is implicitly created in the `InnoDB` system tablespace.

When you create an `InnoDB` table, MySQL creates a `.frm` file in the database directory under the MySQL data directory. For more information about `.frm` files, see [InnoDB Tables and .frm Files](#). For a table created in a file-per-table tablespace, MySQL also creates an `.ibd` tablespace file in the database directory. A table created in the `InnoDB` system tablespace is created in an existing `ibdata file`, which resides in the MySQL data directory.

Internally, `InnoDB` adds an entry for each table to the `InnoDB` data dictionary. The entry includes the database name. For example, if table `t1` is created in the `test` database, the data dictionary entry for the database name is `'test/t1'`. This means you can create a table of the same name (`t1`) in a different database, and the table names do not collide inside `InnoDB`.

## InnoDB Tables and .frm Files

MySQL stores data dictionary information for tables in `.frm` files in database directories. Unlike other MySQL storage engines, `InnoDB` also encodes information about the table in its own internal data dictionary inside the system tablespace. When MySQL drops a table or a database, it deletes one or more `.frm` files as well as the corresponding entries inside the `InnoDB` data dictionary. You cannot move `InnoDB` tables between databases simply by moving the `.frm` files. For information about moving `InnoDB` tables, see [Section 14.11.1.3, “Moving or Copying InnoDB Tables”](#).

## InnoDB Tables and Row Formats

The default `row format` of an `InnoDB` table is `Compact`. Although this row format is fine for basic experimentation, consider using the `Dynamic` or `Compressed` row format to take advantage of `InnoDB` features such as table compression and efficient off-page storage of long column values. Using these row formats requires that `innodb_file_per_table` is enabled and that `innodb_file_format` is set to `Barracuda`:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=barracuda;
CREATE TABLE t3 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=DYNAMIC;
CREATE TABLE t4 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=COMPRESSED;
```

For more information about `InnoDB` row formats, see [Section 14.14, “InnoDB Row Storage and Row Formats”](#). For how to determine the row format of an `InnoDB` table and the physical characteristics of `InnoDB` row formats, see [Section 14.11.1.2, “The Physical Row Structure of an InnoDB Table”](#).

## InnoDB Tables and Primary Keys

Always define a `primary key` for an `InnoDB` table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.
- Rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on (`firstname`, `lastname`) because more than one person can have the same name, some people have blank last names, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an [auto-increment](#) column so that ascending values are filled in automatically as rows are inserted:

```
-- The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));

-- The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

Although the table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the `CREATE TABLE` statement. If you create the table, load data, and then run `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table.

## Viewing InnoDB Table Properties

To view the properties of an [InnoDB](#) table, issue a `SHOW TABLE STATUS` statement:

```
mysql> SHOW TABLE STATUS FROM test LIKE 't%' \G;
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 0
      Data_free: 41943040
      Auto_increment: NULL
      Create_time: 2015-03-16 16:42:17
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
1 row in set (0.00 sec)
```

For information about `SHOW TABLE STATUS` output, see [Section 13.7.5.37, “SHOW TABLE STATUS Syntax”](#).

### 14.11.1.2 The Physical Row Structure of an InnoDB Table

The physical row structure of an [InnoDB](#) table depends on the row format specified when the table is created. If a row format is not specified, the default row format is used. The default [InnoDB](#) row format is `COMPACT`. When `innodb_file_per_table` is enabled and `innodb_file_format` is set to `Barracuda`, you can use `DYNAMIC` and `COMPRESSED` row formats. For more information, see [Section 14.14, “InnoDB Row Storage and Row Formats”](#).

The following sections describe the characteristics of [InnoDB](#) row formats.

- [Determining the Row Format of an InnoDB Table](#)
- [Redundant Row Format Characteristics](#)

- [COMPACT Row Format Characteristics](#)
- [DYNAMIC and COMPRESSED Row Format Characteristics](#)

For more information about [InnoDB](#) row formats, see [Section 14.14, “InnoDB Row Storage and Row Formats”](#).

## Determining the Row Format of an InnoDB Table

To check the row format of an [InnoDB](#) table, use `SHOW TABLE STATUS`. For example:

```
mysql> SHOW TABLE STATUS IN test1\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2014-10-31 16:02:01
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

## Redundant Row Format Characteristics

The [REDUNDANT](#) format is available to retain compatibility with older versions of MySQL.

Rows in [InnoDB](#) tables that use [REDUNDANT](#) row format have the following characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.
- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, [InnoDB](#) stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. [InnoDB](#) does not truncate trailing spaces from [VARCHAR](#) columns.
- [InnoDB](#) encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.
- An SQL `NULL` value reserves one or two bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length

column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for `NULL` values enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.

## COMPACT Row Format Characteristics

The `COMPACT` row format decreases row storage space by about 20% compared to the `REDUNDANT` format at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, `COMPACT` format is likely to be faster. If the workload is a rare case that is limited by CPU speed, compact format might be slower.

Rows in `InnoDB` tables that use `COMPACT` row format have the following characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The variable-length part of the record header contains a bit vector for indicating `NULL` columns. If the number of columns in the index that can be `NULL` is  $N$ , the bit vector occupies  $\text{CEILING}(N/8)$  bytes. (For example, if there are anywhere from 9 to 15 columns that can be `NULL`, the bit vector uses two bytes.) Columns that are `NULL` do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are `NOT NULL` and have a fixed length, the record header has no variable-length part.
- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.
- The record header is followed by the data contents of the non-`NULL` columns.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.
- Internally, for nonvariable-length character sets, `InnoDB` stores fixed-length character columns such as `CHAR(10)` in a fixed-length format.

`InnoDB` does not truncate trailing spaces from `VARCHAR` columns.

- Internally, for variable-length character sets such as `utf8mb3` and `utf8mb4`, `InnoDB` attempts to store `CHAR(N)` in  $N$  bytes by trimming trailing spaces. If the byte length of a `CHAR(N)` column value exceeds  $N$  bytes, `InnoDB` trims trailing spaces to a minimum of the column value byte length. The maximum length of a `CHAR(N)` column is the maximum character byte length  $\times N$ .

`InnoDB` reserves a minimum of  $N$  bytes for `CHAR(N)`. Reserving the minimum space  $N$  in many cases enables column updates to be done in place without causing fragmentation of the index page. By comparison, for `ROW_FORMAT=REDUNDANT`, `CHAR(N)` columns occupy the maximum character byte length  $\times N$ .

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

`ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPRESSED` handle `CHAR` storage in the same way as `ROW_FORMAT=COMPACT`.

## DYNAMIC and COMPRESSED Row Format Characteristics

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format. For information about these row formats, see [Section 14.14.3, “DYNAMIC and COMPRESSED Row Formats”](#).

### 14.11.1.3 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all InnoDB tables to a different server or instance. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replication slave server; you might copy individual tables to another instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Techniques for moving or copying InnoDB tables include:

- [Copying Data Files \(Cold Backup Method\)](#)
- [Export and Import \(mysqldump\)](#)

### Copying Data Files (Cold Backup Method)

You can move an InnoDB database simply by copying all the relevant files listed under "Cold Backups" in [Section 14.21.1, “InnoDB Backup”](#).

Like MyISAM data files, InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files.

### Export and Import (mysqldump)

You can use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

One way to increase the performance of this method is to switch off `autocommit` mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

### 14.11.1.4 Converting Tables from MyISAM to InnoDB

If you have MyISAM tables that you want to convert to InnoDB for better reliability and scalability, review the following guidelines and tips before converting.

- [Adjusting Memory Usage for MyISAM and InnoDB](#)
- [Handling Too-Long Or Too-Short Transactions](#)
- [Handling Deadlocks](#)
- [Planning the Storage Layout](#)
- [Converting an Existing Table](#)
- [Cloning the Structure of a Table](#)
- [Transferring Existing Data](#)
- [Storage Requirements](#)
- [Defining a PRIMARY KEY for Each Table](#)
- [Application Performance Considerations](#)
- [Understanding Files Associated with InnoDB Tables](#)

## Adjusting Memory Usage for MyISAM and InnoDB

As you transition away from `MyISAM` tables, lower the value of the `key_buffer_size` configuration option to free memory no longer needed for caching results. Increase the value of the `innodb_buffer_pool_size` configuration option, which performs a similar role of allocating cache memory for `InnoDB` tables. The `InnoDB` buffer pool caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see [Section 8.12.4.1, “How MySQL Uses Memory”](#).

On a busy server, run benchmarks with the query cache turned off. The `InnoDB` buffer pool provides similar benefits, so the query cache might be tying up memory unnecessarily. For information about the query cache, see [Section 8.10.3, “The MySQL Query Cache”](#).

## Handling Too-Long Or Too-Short Transactions

Because `MyISAM` tables do not support [transactions](#), you might not have paid much attention to the `autocommit` configuration option and the `COMMIT` and `ROLLBACK` statements. These keywords are important to allow multiple sessions to read and write `InnoDB` tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a `mysql` session for interactive experiments, always `COMMIT` (to finalize the changes) or `ROLLBACK` (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.
- Make sure that any error handlers in your application also `ROLLBACK` incomplete changes or `COMMIT` completed changes.
- `ROLLBACK` is a relatively expensive operation, because `INSERT`, `UPDATE`, and `DELETE` operations are written to `InnoDB` tables prior to the `COMMIT`, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.
- When loading large volumes of data with a sequence of `INSERT` statements, periodically `COMMIT` the results to avoid having transactions that last for hours. In typical load operations for data warehousing,

if something goes wrong, you truncate the table (using `TRUNCATE TABLE`) and start over from the beginning rather than doing a `ROLLBACK`.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each `COMMIT`, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on InnoDB tables, you should use the setting `autocommit=0`. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive `INSERT`, `UPDATE`, or `DELETE` statements. From a safety perspective, this allows you to issue a `ROLLBACK` statement to recover lost or garbled data if you make a mistake on the `mysql` command line, or in an exception handler in your application.
- The time when `autocommit=1` is suitable for InnoDB tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to `COMMIT` or `ROLLBACK`, and InnoDB can automatically optimize the read-only workload.
- If you make a series of related changes, finalize all the changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.
- Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

## Handling Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. Despite the scary-sounding name, a **deadlock** is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. MySQL immediately detects this condition and cancels (rolls back) the “smaller” transaction, allowing the other to proceed.

Your applications do need error-handling logic to restart a transaction that is forcibly cancelled like this. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions.

For more information, see [Section 14.8.5, “Deadlocks in InnoDB”](#).

## Planning the Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table` and `innodb_file_format` configuration options, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, new InnoDB tables are implicitly created in `file-per-table` tablespaces. In contrast

with the [InnoDB](#) system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support the [Barracuda](#) file format and associated features such as table compression and efficient off-page storage for long variable-length columns. For more information, see [Section 14.10.4, “InnoDB File-Per-Table Tablespaces”](#).

## Converting an Existing Table

To convert a non-[InnoDB](#) table to use [InnoDB](#) use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

### Important

Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the [InnoDB](#) type. This is an unsupported operation. The system tables must always be of the [MyISAM](#) type.

## Cloning the Structure of a Table

You might make an [InnoDB](#) table that is a clone of a [MyISAM](#) table, rather than using `ALTER TABLE` to perform conversion, to test the old and new table side-by-side before switching.

Create an empty [InnoDB](#) table with identical column and index definitions. Use `SHOW CREATE TABLE table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

## Transferring Existing Data

To transfer a large volume of data into an empty [InnoDB](#) table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the [InnoDB](#) table after inserting the data. Historically, creating new secondary indexes was a slow operation for [InnoDB](#), but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have [UNIQUE](#) constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because [InnoDB](#) can use its [change buffer](#) to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
  WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the [InnoDB](#) buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the size of [InnoDB](#) log files.

## Storage Requirements

If you intend to make several temporary copies of your data in InnoDB tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the `innodb_file_per_table` configuration option is enabled (the default), newly created InnoDB tables are implicitly created in file-per-table tablespaces.

Whether you convert the MyISAM table directly or create a cloned InnoDB table, make sure that you have sufficient disk space to hold both the old and new tables during the process. **InnoDB tables require more disk space than MyISAM tables.** If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 14.23.2, “Forcing InnoDB Recovery”](#).

## Defining a PRIMARY KEY for Each Table

The `PRIMARY KEY` clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

- Declare a `PRIMARY KEY` for each table. Typically, it is the most important column that you refer to in `WHERE` clauses when looking up a single row.
- Declare the `PRIMARY KEY` clause in the original `CREATE TABLE` statement, rather than adding it later through an `ALTER TABLE` statement.
- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.
- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.
- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a [primary key](#) to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any [secondary indexes](#), because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the [buffer pool](#), speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a `VARCHAR`, consider adding a new unsigned `AUTO_INCREMENT` column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as `UNIQUE NOT NULL` to enforce the same constraints as the `PRIMARY KEY` clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of

employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the `PRIMARY KEY` clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

## Application Performance Considerations

The reliability and scalability features of `InnoDB` require more disk storage than equivalent `MyISAM` tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for `join` queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned `INT` column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see [Section 11.2.1, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#).

## Understanding Files Associated with InnoDB Tables

`InnoDB` files require more care and planning than `MyISAM` files do.

- You must not delete the `ibdata` files that represent the `InnoDB` system tablespace.
- Methods of moving or copying `InnoDB` tables to a different server are described in [Section 14.11.1.3, “Moving or Copying InnoDB Tables”](#).

### 14.11.1.5 AUTO\_INCREMENT Handling in InnoDB

`InnoDB` provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with `AUTO_INCREMENT` columns. To use the `AUTO_INCREMENT` mechanism with an `InnoDB` table, an `AUTO_INCREMENT` column must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section describes the behavior of `AUTO_INCREMENT` lock modes, usage implications for different `AUTO_INCREMENT` lock mode settings, and how `InnoDB` initializes the `AUTO_INCREMENT` counter.

- [InnoDB AUTO\\_INCREMENT Lock Modes](#)
- [InnoDB AUTO\\_INCREMENT Lock Mode Usage Implications](#)
- [InnoDB AUTO\\_INCREMENT Counter Initialization](#)

## InnoDB AUTO\_INCREMENT Lock Modes

This section describes the behavior of `AUTO_INCREMENT` lock modes used to generate auto-increment values, and how each lock mode affects replication. Auto-increment lock modes are configured at startup using the `innodb_autoinc_lock_mode` configuration parameter.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- “INSERT-like” statements

All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. InnoDB assigns new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` configuration parameter. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively.

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` configuration parameter was introduced in MySQL 5.1. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

In this lock mode, all “INSERT-like” statements obtain a special table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
```

```
c1 INT(11) NOT NULL AUTO_INCREMENT,
c2 VARCHAR(10) DEFAULT NULL,
PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

InnoDB cannot tell in advance how many rows are retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement is consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 is either be smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results are the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the `consecutive` lock mode, InnoDB can avoid using table-level `AUTO-INC` locks for “simple insert” statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the `interleaved` lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time. If the source table of the bulk insert operation is different from the target table, the `AUTO-INC` lock on the target table is taken after a shared lock is taken on the first row selected from the source table. If the source and target of the bulk insert operation are the same table, the `AUTO-INC` lock is taken after shared locks are taken on all selected rows.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level `AUTO-INC` locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, *not* until the

statement completes. No table-level `AUTO-INC` lock is used unless an `AUTO-INC` lock is held by another transaction. If another transaction holds an `AUTO-INC` lock, a “simple insert” waits for the `AUTO-INC` lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. There is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “`INSERT`-like” statements use the table-level `AUTO-INC` lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “`INSERT`-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there are no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

## InnoDB `AUTO_INCREMENT` Lock Mode Usage Implications

- Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “`INSERT`-like” statement is completed, and whether or not the containing

transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an `AUTO_INCREMENT` column of a table.

- Specifying NULL or 0 for the `AUTO_INCREMENT` column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the `AUTO_INCREMENT` column in an `INSERT`, InnoDB treats the row as if the value was not specified and generates a new value for it.

- Assigning a negative value to the `AUTO_INCREMENT` column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if you assign a negative value to the `AUTO_INCREMENT` column.

- If the `AUTO_INCREMENT` value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level `AUTO-INC` lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “`INSERT`-like” statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100.

```
mysql> CREATE TABLE t1 (
-> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> c2 CHAR(1)
-> ) ENGINE = INNODB;

mysql> INSERT INTO t1 VALUES(1,'a'),(101,'b'),(5,'c'),(102,'d');
```

Now, consider the following “mixed-mode insert” statement:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 (“traditional”), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1   | c2   |
+-----+-----+
| 1    | a    |
| 101  | b    |
| 5    | c    |
| 102  | d    |
```

```
+-----+-----+
```

The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “[INSERT-like](#)” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows are also:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 1 | a |
| 101 | b |
| 5 | c |
| 102 | d |
+-----+-----+
```

However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “[INSERT-like](#)” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 1 | a |
| x | b |
| 5 | c |
| y | d |
+-----+-----+
```

The values of `x` and `y` are unique and larger than any previously generated rows. However, the specific values of `x` and `y` depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement generates a duplicate-key error 23000 (`Can't write; duplicate key in table`) because 5 is allocated for the row `(NULL, 'b')` and insertion of the row `(5, 'c')` fails.

- Modifying `AUTO_INCREMENT` column values in the middle of a sequence of [INSERT](#) statements

In all lock modes (0, 1, and 2), modifying an `AUTO_INCREMENT` column value in the middle of a sequence of [INSERT](#) statements could lead to “Duplicate entry” errors. For example, if you perform an [UPDATE](#) operation that changes an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, subsequent [INSERT](#) operations that do not specify an unused auto-increment value could encounter “Duplicate entry” errors. This behavior is demonstrated in the following example.

```
mysql> CREATE TABLE t1 (
-> c1 INT NOT NULL AUTO_INCREMENT,
```

```

-> PRIMARY KEY (c1)
-> ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 1 |
| 2 |
| 3 |
+-----+

mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 2 |
| 3 |
| 4 |
+-----+

mysql> INSERT INTO t1 VALUES(0);
ERROR 1062 (23000): Duplicate entry '4' for key 'PRIMARY'

```

## InnoDB AUTO\_INCREMENT Counter Initialization

This section describes how [InnoDB](#) initializes [AUTO\\_INCREMENT](#) counters.

If you specify an [AUTO\\_INCREMENT](#) column for an [InnoDB](#) table, the table handle in the [InnoDB](#) data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

To initialize an auto-increment counter after a server restart, [InnoDB](#) executes the equivalent of the following statement on the first insert into a table containing an [AUTO\\_INCREMENT](#) column.

```
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

[InnoDB](#) increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by 1. This default can be overridden by the [auto\\_increment\\_increment](#) configuration setting.

If the table is empty, [InnoDB](#) uses the value 1. This default can be overridden by the [auto\\_increment\\_offset](#) configuration setting.

If a [SHOW TABLE STATUS](#) statement examines the table before the auto-increment counter is initialized, [InnoDB](#) initializes but does not increment the value. The value is stored for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction. [InnoDB](#) follows the same procedure for initializing the auto-increment counter for a newly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an [AUTO\\_INCREMENT](#) column, [InnoDB](#) increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is greater than the current counter value, the counter is set to the specified column value.

InnoDB uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, InnoDB reinitializes the counter for each table for the first INSERT to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with InnoDB tables to set the initial counter value or alter the current counter value.

#### 14.11.1.6 InnoDB and FOREIGN KEY Constraints

How the InnoDB storage engine handles foreign key constraints is described under the following topics in this section:

- [Foreign Key Definitions](#)
- [Referential Actions](#)
- [Foreign Key Usage and Error Information](#)

For foreign key usage information and examples, see [Section 13.1.17.6, “Using FOREIGN KEY Constraints”](#).

#### Foreign Key Definitions

Foreign key definitions for InnoDB tables are subject to the following conditions:

- InnoDB permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- InnoDB does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned InnoDB table may contain foreign key references or columns referenced by foreign keys.
- InnoDB allows a foreign key constraint to reference a non-unique key. *This is an InnoDB extension to standard SQL.*

#### Referential Actions

Referential actions for foreign keys of InnoDB tables are subject to the following conditions:

- While `SET DEFAULT` is allowed by the MySQL Server, it is rejected as invalid by InnoDB. `CREATE TABLE` and `ALTER TABLE` statements using this clause are not allowed for InnoDB tables.
- If there are several rows in the parent table that have the same referenced key value, InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, InnoDB does not permit the deletion of any of those parent rows.
- InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.

- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, [InnoDB](#) checks [UNIQUE](#) and [FOREIGN KEY](#) constraints row-by-row. When performing foreign key checks, [InnoDB](#) sets shared row-level locks on child or parent records it has to look at. [InnoDB](#) checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until [InnoDB](#) implements deferred constraint checking, some things are impossible, such as deleting a record that refers to itself using a foreign key.

## Foreign Key Usage and Error Information

You can obtain general information about foreign keys and their usage from querying the [INFORMATION\\_SCHEMA.KEY\\_COLUMN\\_USAGE](#) table.

In addition to [SHOW ERRORS](#), in the event of a foreign key error involving [InnoDB](#) tables (usually Error 150 in the MySQL Server), you can obtain a detailed explanation of the most recent [InnoDB](#) foreign key error by checking the output of [SHOW ENGINE INNODB STATUS](#).

### 14.11.1.7 Limits on InnoDB Tables

Limits on [InnoDB](#) tables are described under the following topics in this section:

- [Maximums and Minimums](#)
- [Restrictions on InnoDB Tables](#)
- [Locking and Transactions](#)

#### Warning

Do *not* convert MySQL system tables in the [mysql](#) database from [MyISAM](#) to [InnoDB](#) tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them by reinitializing the data directory (see [Section 2.10.1, “Initializing the Data Directory”](#)).

#### Warning

Before using NFS with [InnoDB](#), review potential issues outlined in [Using NFS with MySQL](#).

## Maximums and Minimums

- A table can contain a maximum of 1000 columns.
- A table can contain a maximum of 64 [secondary indexes](#).
- By default, the index key prefix length limit is 767 bytes. See [Section 13.1.13, “CREATE INDEX Syntax”](#). For example, you might hit this limit with a [column prefix](#) index of more than 255 characters on a [TEXT](#) or [VARCHAR](#) column, assuming a [utf8mb3](#) character set and the maximum of 3 bytes for each character. When the [innodb\\_large\\_prefix](#) configuration option is enabled, the index key prefix length limit is raised to 3072 bytes for [InnoDB](#) tables that use [DYNAMIC](#) or [COMPRESSED](#) row format.

If you specify an index key prefix length that exceeds the limit, the length is silently reduced to the maximum length.

When [innodb\\_large\\_prefix](#) is enabled, attempting to create an index key prefix with a length greater than 3072 bytes for a [DYNAMIC](#) or [COMPRESSED](#) table causes an [ER\\_INDEX\\_COLUMN\\_TOO\\_LONG](#) error.

The limits that apply to index key prefixes also apply to full-column index keys.

- A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

```
ERROR 1070 (42000): Too many key parts specified; max 16 parts allowed
```

- The maximum row length, except for variable-length columns ([VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#)), is slightly less than half of a page. That is, the maximum row length is about 8000 bytes. [LONGBLOB](#) and [LONGTEXT](#) columns must be less than 4GB, and the total row length, including [BLOB](#) and [TEXT](#) columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 14.15.2, “File Space Management”](#).

The row size for [BLOB](#) columns that are chosen for external off-page storage should not exceed 10% of the combined [redo log](#) file size. If the row size exceeds 10% of the combined redo log file size, [InnoDB](#) could overwrite the most recent checkpoint which may result in lost data during crash recovery. (Bug#69477).

- Although [InnoDB](#) supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- On some older operating systems, files must be less than 2GB. This is not a limitation of [InnoDB](#) itself, but if you require a large tablespace, configure it using several smaller data files rather than one large data file.
- The combined size of the [InnoDB](#) log files must be less than 4GB.
- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size is four billion pages (64TB). This is also the maximum size for a table.
- The default page size in [InnoDB](#) is 16KB.

Changing the page size is not a supported operation and there is no guarantee that [InnoDB](#) functions normally with a page size other than 16KB. Problems compiling or running [InnoDB](#) may occur. In particular, [ROW\\_FORMAT=COMPRESSED](#) in the [Barracuda](#) file format assumes that the page size is at most 16KB and uses 14-bit pointers.

A version of [InnoDB](#) built for one page size cannot use data files or log files from a version built for a different page size. This limitation could affect restore or downgrade operations using data from MySQL 5.6, which does support page sizes other than 16KB.

- [InnoDB](#) tables do not support [FULLTEXT](#) indexes.
- [InnoDB](#) tables support spatial data types, but not indexes on them.

## Restrictions on InnoDB Tables

- [ANALYZE TABLE](#) determines index cardinality (as displayed in the [Cardinality](#) column of [SHOW INDEX](#) output) by performing [random dives](#) on each of the index trees and updating index cardinality

estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can change the number of random dives by modifying the `innodb_stats_sample_pages` system variable.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See [Section B.5.5, “Optimizer-Related Issues”](#).

- If statements or transactions are running on a table, and `ANALYZE TABLE` is run on the same table followed by a second `ANALYZE TABLE` operation, the second `ANALYZE TABLE` operation is blocked until the statements or transactions are completed. This behavior occurs because `ANALYZE TABLE` marks the currently loaded table definition as obsolete when `ANALYZE TABLE` is finished running. New statements or transactions (including a second `ANALYZE TABLE` statement) must load the new table definition into the table cache, which cannot occur until currently running statements or transactions are completed and the old table definition is purged. Loading multiple concurrent table definitions is not supported.
- `SHOW TABLE STATUS` does not give accurate [statistics](#) on InnoDB tables except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

To process a `SELECT COUNT(*)` statement, InnoDB scans an index of the table, which takes some time if the index is not entirely in the buffer pool. For a faster count, you can create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, `SHOW TABLE STATUS` can be used.

InnoDB handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.
- An `AUTO_INCREMENT` column `ai_col` must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.
- InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column while initializing a previously specified `AUTO_INCREMENT` column on a table.

With `innodb_autoinc_lock_mode=0`, InnoDB uses a special `AUTO-INC` table lock mode where the lock is obtained and held to the end of the current SQL statement while accessing the auto-increment counter. Other clients cannot insert into the table while the `AUTO-INC` table lock is held. The same behavior occurs for “bulk inserts” with `innodb_autoinc_lock_mode=1`. Table-level `AUTO-INC` locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See [Section 14.11.1.5, “AUTO\\_INCREMENT Handling in InnoDB”](#).

- When you restart the MySQL server, [InnoDB](#) may reuse an old value that was generated for an [AUTO\\_INCREMENT](#) column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an [AUTO\\_INCREMENT](#) integer column runs out of values, a subsequent [INSERT](#) operation returns a duplicate-key error. This is general MySQL behavior, similar to how [MyISAM](#) works.
- [DELETE FROM tbl\\_name](#) does not regenerate the table but instead deletes all rows, one by one.
- Under some conditions, [TRUNCATE tbl\\_name](#) for an [InnoDB](#) table is mapped to [DELETE FROM tbl\\_name](#). See [Section 13.1.33, “TRUNCATE TABLE Syntax”](#).
- Cascaded foreign key actions do not activate triggers.
- You cannot create a table with a column name that matches the name of an internal [InnoDB](#) column (including [DB\\_ROW\\_ID](#), [DB\\_TRX\\_ID](#), [DB\\_ROLL\\_PTR](#), and [DB\\_MIX\\_ID](#)). This restriction applies to use of the names in any letter case.

```
mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;  
ERROR 1166 (42000): Incorrect column name 'db_row_id'
```

## Locking and Transactions

- [LOCK TABLES](#) acquires two locks on each table if [innodb\\_table\\_locks=1](#) (the default). In addition to a table lock on the MySQL layer, it also acquires an [InnoDB](#) table lock. Versions of MySQL before 4.1.2 did not acquire [InnoDB](#) table locks; the old behavior can be selected by setting [innodb\\_table\\_locks=0](#). If no [InnoDB](#) table lock is acquired, [LOCK TABLES](#) completes even if some records of the tables are being locked by other transactions.

As of MySQL 5.5.3, [innodb\\_table\\_locks=0](#) has no effect for tables locked explicitly with [LOCK TABLES ... WRITE](#). It still has an effect for tables locked for read or write by [LOCK TABLES ... WRITE](#) implicitly (for example, through triggers) or by [LOCK TABLES ... READ](#).

- All [InnoDB](#) locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke [LOCK TABLES](#) on [InnoDB](#) tables in [autocommit=1](#) mode because the acquired [InnoDB](#) table locks would be released immediately.
- You cannot lock additional tables in the middle of a transaction because [LOCK TABLES](#) performs an implicit [COMMIT](#) and [UNLOCK TABLES](#).
- The limit of 1023 concurrent data-modifying transactions has been raised in MySQL 5.5 and above. The limit is now 128 \* 1023 concurrent transactions that generate undo records. You can remove any workarounds that require changing the proper structure of your transactions, such as committing more frequently.

## 14.11.2 InnoDB Indexes

This section covers topics related to [InnoDB](#) indexes.

### 14.11.2.1 Clustered and Secondary Indexes

Every [InnoDB](#) table has a special index called the [clustered index](#) where the data for the rows is stored. Typically, the clustered index is synonymous with the [primary key](#). To get the best performance from queries, inserts, and other database operations, you must understand how [InnoDB](#) uses the clustered index to optimize the most common lookup and DML operations for each table.

- When you define a [PRIMARY KEY](#) on your table, [InnoDB](#) uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new [auto-increment](#) column, whose values are filled in automatically.
- If you do not define a [PRIMARY KEY](#) for your table, MySQL locates the first [UNIQUE](#) index where all the key columns are [NOT NULL](#) and [InnoDB](#) uses it as the clustered index.
- If the table has no [PRIMARY KEY](#) or suitable [UNIQUE](#) index, [InnoDB](#) internally generates a hidden clustered index on a synthetic column containing row ID values. The rows are ordered by the ID that [InnoDB](#) assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

## How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record. (For example, [MyISAM](#) uses one file for data rows and another for index records.)

## How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as [secondary indexes](#). In [InnoDB](#), each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. [InnoDB](#) uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For guidelines to take advantage of [InnoDB](#) clustered and secondary indexes, see [Section 8.3](#), “[Optimization and Indexes](#)”.

### 14.11.2.2 The Physical Structure of an InnoDB Index

All [InnoDB](#) indexes are [B-trees](#) where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB.

When new records are inserted into an [InnoDB clustered index](#), [InnoDB](#) tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the [fill factor](#) of an index page drops below 1/2, [InnoDB](#) tries to contract the index tree to free the page.

Changing the [InnoDB](#) page size is not a supported operation and there is no guarantee that [InnoDB](#) functions normally with a page size other than 16KB. Problems compiling or running [InnoDB](#) may occur. In particular, [ROW\\_FORMAT=COMPRESSED](#) in the Barracuda file format assumes that the page size is at most 16KB and uses 14-bit pointers.

An instance using a particular [InnoDB](#) page size cannot use data files or log files from an instance that uses a different page size.

## 14.12 InnoDB Table Compression

By using the SQL syntax and [InnoDB](#) configuration options for [compression](#), you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with [secondary indexes](#), because index data is compressed also. Compression can be especially important for [SSD](#) storage devices, because they tend to have lower capacity than [HDD](#) devices.

## 14.12.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are [disk-bound](#). Data [compression](#) enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with `ROW_FORMAT=COMPRESSED` can use a smaller [page size](#) on disk than the usual 16KB default. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The page size is specified through the `KEY_BLOCK_SIZE` parameter. The different page size means the table must be in its own `.ibd` file rather than in the [system tablespace](#), which requires enabling the `innodb_file_per_table` option. The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates a 16KB page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

## 14.12.2 Enabling Compression for a Table

Before creating a compressed table, make sure the `innodb_file_per_table` configuration option is enabled, and `innodb_file_format` is set to `Barracuda`. You can set these parameters in the MySQL [configuration file](#) `my.cnf` or `my.ini`, or with the `SET` statement without shutting down the MySQL server.

To enable compression for a table, you use the clauses `ROW_FORMAT=COMPRESSED`, `KEY_BLOCK_SIZE`, or both in a `CREATE TABLE` or `ALTER TABLE` statement.

To create a compressed table, you might use statements like these:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
(c1 INT PRIMARY KEY)
ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
```

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the default compressed page size of 8KB is used.
- If you specify `KEY_BLOCK_SIZE`, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic [workload](#).

- For additional performance-related configuration options, see [Section 14.12.3, “Tuning Compression for InnoDB Tables”](#).

The default uncompressed size of InnoDB data [pages](#) is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the `.ibd` file of the table. The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.

Setting `KEY_BLOCK_SIZE=16` typically does not result in much compression, since the normal InnoDB [page size](#) is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer [overflow pages](#) as described in [Section 14.12.5, “How Compression Works for InnoDB Tables”](#).

All indexes of a table (including the [clustered index](#)) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax, and are ignored if they are specified (although you see them in the output of the `SHOW CREATE TABLE` statement).

## Restrictions on Compressed Tables

Because MySQL versions prior to 5.1 cannot process compressed tables, using compression requires specifying the configuration parameter `innodb_file_format=Barracuda`, to avoid accidentally introducing compatibility issues.

Table compression is also not available for the InnoDB [system tablespace](#). The system tablespace (space 0, the `ibdata*` files) can contain user data, but it also contains internal system information, and therefore is never compressed. Thus, compression applies only to tables (and indexes) stored in their own tablespaces, that is, created with the `innodb_file_per_table` option enabled.

Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

## 14.12.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in [InnoDB Data Storage and Compression](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a [data warehouse](#) (primarily queries) or an [OLTP](#) system (mix of queries and [DML](#)).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive [compression failures](#) at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see [Section 14.12.4, “Monitoring InnoDB Table Compression at Runtime”](#) for ways to verify the effectiveness of those choices under real-world conditions.

## When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

## Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in [CHAR](#), [VARCHAR](#), [TEXT](#) or [BLOB](#) columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) [page size](#). It might be that the [primary key](#) (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in [Section 14.14.3, “DYNAMIC and COMPRESSED Row Formats”](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as [gzip](#) or WinZip) on a copy of the [.ibd file](#) for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the [page size](#), 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) and look at the size of the resulting [.ibd file](#). For example:

```
use test;
set global innodb_file_per_table=1;
set global innodb_file_format=Barracuda;
set global autocommit=0;

-- Create an uncompressed table with a million or two rows.
create table big_table as select * from information_schema.columns;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;
alter table big_table add id int unsigned not null primary key auto_increment;
```

```
show create table big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

create table key_block_size_4 like big_table;
alter table key_block_size_4 key_block_size=4 row_format=compressed;

insert into key_block_size_4 select * from big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw----  1 cirrus  staff  310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw----  1 cirrus  staff  83886080 Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular [workload](#), use a MySQL instance with no other compressed tables and run queries against the [INFORMATION\\_SCHEMA.INNODB\\_CMP](#) table. For example, you examine the ratio of successful compression operations to overall compression operations. (In the [INNODB\\_CMP](#) table, compare [COMPRESS\\_OPS](#) to [COMPRESS\\_OPS\\_OK](#). See [INNODB\\_CMP](#) for more information.) If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.

## Compression and Application and Schema Design

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

## Compressing in the Database

The InnoDB table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as [LIKE](#), and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

## Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

## Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some

data (and store it in uncompressed InnoDB tables) and allow InnoDB to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

## Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that InnoDB maintains for compressed data. If the updates predominantly change non-indexed columns or those containing [BLOBs](#) or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are [INSERTs](#) that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since InnoDB can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, [DELETE](#) operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

## Configuration Characteristics and Compression

Reading and writing database [pages](#) from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, InnoDB often uses an additional 16K in the [buffer pool](#) for an uncompressed copy of the page. The adaptive LRU algorithm in the InnoDB storage engine attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the InnoDB buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

## Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Compression of B-Tree Pages](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the [B-tree](#) nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, [KEY\\_BLOCK\\_SIZE=8](#) is usually a safe choice.

## 14.12.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from [Section 14.12.3, “Tuning Compression for InnoDB Tables”](#), and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the [Information Schema](#) tables described in [Example 14.1, “Using the Compression Information Schema Tables”](#). These tables reflect the internal use of memory and the rates of compression used overall.

The [INNODB\\_CMP](#) table reports information about compression activity for each compressed page size ([KEY\\_BLOCK\\_SIZE](#)) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since InnoDB must split [B-tree](#) nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the [INNODB\\_CMP](#) tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the InnoDB buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster CPUs, or those with more cores, can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the InnoDB buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of [INSERT](#), [UPDATE](#) and [DELETE](#) operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations ([COMPRESS\\_OPS\\_OK](#)) is a high percentage of the total number of compression operations ([COMPRESS\\_OPS](#)), then the system is likely performing well. If the ratio is low, then InnoDB is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase [KEY\\_BLOCK\\_SIZE](#) for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 14.12.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about [compression](#) for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

#### Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written

to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

InnoDB implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the `.ibd` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization.

## InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long [VARCHAR](#), [BLOB](#), or [TEXT](#) columns, as explained in the following sections.

## Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique InnoDB uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, InnoDB attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

Generally, InnoDB requires that each B-tree page can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit in uncompressed

form, in the per-page modification log. Starting with InnoDB storage engine version 1.0.2, and if `innodb_strict_mode` is `ON`, the InnoDB storage engine checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` is `OFF`, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

## Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

### Note

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of InnoDB use the [Antelope](#) file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, InnoDB applies the `zlib` compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

Using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form.

## Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes. To access the data in a page, InnoDB reads the compressed page from disk if it is not already in the [buffer pool](#), then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, InnoDB may [evict](#) from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

InnoDB keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that [hot](#) (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an [I/O-bound](#) or [CPU-bound](#) manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

## Compression and the InnoDB Redo Log Files

Before a compressed page is written to a [data file](#), MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for [crash recovery](#), even in the unlikely case that the [zlib](#) library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of [log files](#), or a need for more frequent [checkpoints](#), can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Note that compressed tables use a different file format for the redo log and the per-table tablespaces than in MySQL 5.1 and earlier. The [MySQL Enterprise Backup](#) product supports this latest [Barracuda](#) file format for compressed InnoDB tables.

## 14.12.6 SQL Compression Syntax Warnings and Errors

Specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if the Barracuda file format is not enabled. You can view them with the `SHOW WARNINGS` statement.

| Level   | Code | Message  |
|---------|------|--|
| Warning | 1478 | <code>InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.</code>        |
| Warning | 1478 | <code>InnoDB: KEY_BLOCK_SIZE requires innodb_file_format=1</code>          |
| Warning | 1478 | <code>InnoDB: ignoring KEY_BLOCK_SIZE=4.</code>                            |
| Warning | 1478 | <code>InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table.</code> |
| Warning | 1478 | <code>InnoDB: assuming ROW_FORMAT=COMPACT.</code>                          |

Notes:

- By default, these messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.
- When `innodb_strict_mode` is enabled, MySQL generates an error, not a warning, for these cases. The table is not created if the current configuration does not permit using compressed tables.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters `innodb_file_format` and `innodb_file_per_table`.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

| Level   | Code | Message   |
|---------|------|---|
| Warning | 1478 | InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED. |

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 14.4, “`ROW_FORMAT` and `KEY_BLOCK_SIZE` Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

**Table 14.4 `ROW_FORMAT` and `KEY_BLOCK_SIZE` Options**

| Option                             | Usage Notes   | Description   |
|------------------------------------|---|---|
| <code>ROW_FORMAT=REDUNDANT</code>  | Storage format used prior to MySQL 5.0.3                      | Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility  |
| <code>ROW_FORMAT=COMPACT</code>    | Default storage format since MySQL 5.0.3                      | Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page |
| <code>ROW_FORMAT=DYNAMIC</code>    | Available only with <code>innodb_file_format=Barracuda</code> | Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)     |
| <code>ROW_FORMAT=COMPRESSED</code> | Available only with <code>innodb_file_format=Barracuda</code> | Compresses the table and indexes using zlib to default compressed page size of 8K bytes   |
| <code>KEY_BLOCK_SIZE=n</code>      | Available only with <code>innodb_file_format=Barracuda</code> | Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code>                            |

Table 14.5, “`CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, InnoDB creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;

ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.      |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-----+-----+-----+
```

Table 14.5 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

| Syntax  | Warning or Error Condition   | Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code> |
|---|--|--|
| <code>ROW_FORMAT=REDUNDANT</code>   | None   | <code>REDUNDANT</code>   |
| <code>ROW_FORMAT=COMPACT</code>   | None   | <code>COMPACT</code>   |
| <code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified                     | Ignored unless both <code>innodb_file_format=Barracuda</code> and <code>innodb_file_per_table</code> are enabled | <code>COMPACT</code>   |
| Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)   | <code>KEY_BLOCK_SIZE</code> is ignored   | the specified row format, or <code>COMPACT</code> by default                   |
| <code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified  | None; <code>KEY_BLOCK_SIZE</code> specified is used, not the 8K default  | <code>COMPRESSED</code>  |
| <code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code> row format        | <code>KEY_BLOCK_SIZE</code> is ignored   | <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code>          |
| <code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code> , <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code> | Ignored if recognized by the MySQL parser. Otherwise, an error is issued.  | <code>COMPACT</code> or N/A  |

When `innodb_strict_mode` is `ON`, the InnoDB storage engine rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

Note that it is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

## 14.13 InnoDB File-Format Management

As InnoDB evolves, data file formats that are not compatible with prior versions of InnoDB are sometimes required to support new features. To help manage compatibility in upgrade and downgrade situations, and systems that run different versions of MySQL, InnoDB uses named file formats. InnoDB currently supports two named file formats, [Antelope](#) and [Barracuda](#).

- [Antelope](#) is the original [InnoDB](#) file format, which previously did not have a name. It supports [COMPACT](#) and [REDUNDANT](#) row formats for [InnoDB](#) tables and is the default file format in MySQL 5.5 to ensure maximum compatibility with earlier MySQL versions that do not support the Barracuda file format.
- [Barracuda](#) is the newest file format. It supports all [InnoDB](#) row formats including the newer [COMPRESSED](#) and [DYNAMIC](#) row formats. The features associated with [COMPRESSED](#) and [DYNAMIC](#) row formats include compressed tables and efficient storage of off-page columns. See [Section 14.14, “InnoDB Row Storage and Row Formats”](#).

This section discusses enabling [InnoDB](#) file formats, verifying compatibility of different file formats between MySQL releases, identifying the file format in use, and downgrading the file format.

## 14.13.1 Enabling File Formats

The `innodb_file_format` configuration option enables an [InnoDB](#) file format for [file-per-table](#) tablespaces.

[Antelope](#) is the default `innodb_file_format`.

To preclude the use of features supported by the Barracuda file that make your database inaccessible to the built-in [InnoDB](#) in MySQL 5.1 and prior releases, set `innodb_file_format` to [Antelope](#). Alternatively, you can disable `innodb_file_per_table` to have new tables created in the [system tablespace](#). The system tablespace is stored in the original Antelope file format.

You can set the value of `innodb_file_format` on the command line when you start `mysqld`, or in the option file (`my.cnf` on Unix, `my.ini` on Windows). You can also change it dynamically with a `SET GLOBAL` statement.

```
SET GLOBAL innodb_file_format=Barracuda;
```

Although Oracle recommends using the Barracuda format for new tables where practical, in MySQL 5.5 the default file format is [Antelope](#), for maximum compatibility with replication configurations containing earlier MySQL releases.

## 14.13.2 Verifying File Format Compatibility

InnoDB incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an old release of the MySQL server on InnoDB data files that use a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

### Backward Compatibility

You only need to consider backward file format compatibility when using a recent version of InnoDB (the InnoDB Plugin, or MySQL 5.5 and higher with InnoDB) alongside an older version (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with an older version of InnoDB without risk of crashes, hangs, wrong results or corruptions. MySQL 5.5 and higher with InnoDB includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with a prior version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to the earlier Antelope file format is to copy the data to a new table, in a tablespace that uses the earlier format. This can be done with the [ALTER TABLE](#) statement, as described in [Section 14.13.4, “Downgrading the File Format”](#).

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the [SHOW TABLE STATUS](#) command or querying the table [INFORMATION\\_SCHEMA.TABLES](#). If the [Row\\_format](#) of the table is reported as 'Compressed' or 'Dynamic', the tablespace containing the table uses the Barracuda format. Otherwise, it uses the prior InnoDB file format, Antelope.

## Internal Details

Every InnoDB file-per-table tablespace (represented by a \*.ibd file) is labeled with a file format identifier. The system tablespace (represented by the ibdata files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with [ROW\\_FORMAT=DYNAMIC](#), updates the file header of the corresponding file-per-table .ibd file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support the Barracuda file format. To protect against anomalous behavior, InnoDB version 5.0.21 and later performs a compatibility check when the table is opened. (In many cases, the [ALTER TABLE](#) statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in [Section 14.16, “InnoDB Fast Index Creation”](#).)

## Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more [ibdata](#) files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
- Zero or more single-table tablespaces (also called “file per table” files, named \*.ibd files).
- InnoDB log files; usually two, [ib\\_logfile0](#) and [ib\\_logfile1](#). Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding .frm files that contain metadata about InnoDB tables. The .frm files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

### 14.13.2.1 Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., [innodb\\_fast\\_shutdown](#) is greater than zero), there may be on-disk data structures

(such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check`, which is `ON` by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is `ON`, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a
file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` is useful (with future releases) if you manually “downgrade” all of the tables in an ib-file set (as described in [Section 14.4, “Downgrading the InnoDB Storage Engine”](#)). You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a new file format that is not supported by the software you are using. If you set the configuration parameter `innodb_file_format_check` to `OFF`, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a
file format that this version doesn't support
```

#### Note

This is a dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was a crash or “fast shutdown”. You should only set `innodb_file_format_check` to `OFF` if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs.

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in [Section 14.13.2.2, “Compatibility Check When a Table Is Opened”](#). Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the latest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

### 14.13.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses a specific file format, even if the file format is supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses a supported format.

Versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in [Section 14.13.3, “Identifying the File Format in Use”](#).

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a newer file format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to `OFF`), the table-level checking described in this section still applies.

Users are *strongly* urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It is possible to “downgrade” such tables to the Antelope format with the procedure described in [Section 14.13.4, “Downgrading the File Format”](#).

### 14.13.3 Identifying the File Format in Use

If you enable a different file format using the `innodb_file_format` configuration option, the change only applies to newly created tables. Also, when you create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required to support the table's features. For example, if you enable the `Barracuda` file format, and create a new table that does not use the Dynamic or Compressed row format, the new tablespace that contains the table is tagged as using the `Antelope` file format.

It is easy to identify the file format used by a given table. The table uses the `Antelope` file format if the row format reported by `SHOW TABLE STATUS` is either `Compact` or `Redundant`. The table uses the

[Barracuda](#) file format if the row format reported by `SHOW TABLE STATUS` is either [Compressed](#) or [Dynamic](#).

```
mysql> SHOW TABLE STATUS\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2014-11-03 13:32:10
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

### 14.13.4 Downgrading the File Format

Each InnoDB tablespace file (with a name matching `*.ibd`) is tagged with the file format used to create its table and indexes. The way to downgrade the tablespace is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the command:

```
ALTER TABLE t ROW_FORMAT=COMPACT;
```

on each table that you want to downgrade. The [COMPACT](#) row format uses the file format Antelope. It was introduced in MySQL 5.0.3.

## 14.14 InnoDB Row Storage and Row Formats

This section discusses how InnoDB features such as table [compression](#) and off-page storage of long variable-length column values are controlled by the `ROW_FORMAT` clause of the `CREATE TABLE` statement. It also discusses considerations for choosing the right row format, and compatibility of row formats between MySQL releases.

### 14.14.1 Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk [page](#), queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into [pages](#). The pages that make up each table are arranged in a tree data structure called a [B-tree index](#). Table data and [secondary indexes](#) both use this type of structure. The B-tree index that represents an entire table is known as the [clustered index](#), which is organized according to the [primary key](#) columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as [BLOB](#) and [VARCHAR](#) that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#). We call

such columns [off-page columns](#). The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The [Barracuda](#) file format provides a new option ([KEY\\_BLOCK\\_SIZE](#)) to control how much column data is stored in the clustered index, and how much is placed on overflow pages.

The following sections describe how to configure the row format of [InnoDB](#) tables to control how variable-length columns values are stored. Row format configuration also determines the availability of the [table compression](#) feature.

## 14.14.2 Specifying the Row Format for a Table

You specify the row format for a table with the [ROW\\_FORMAT](#) clause of the [CREATE TABLE](#) and [ALTER TABLE](#) statements. For example:

```
CREATE TABLE t1 (f1 int unsigned) ROW_FORMAT=DYNAMIC ENGINE=INNODB;
```

[InnoDB](#) [ROW\\_FORMAT](#) options include [COMPACT](#), [REDUNDANT](#), [DYNAMIC](#), and [COMPRESSED](#). For [InnoDB](#) tables, rows are stored in [COMPACT](#) format ([ROW\\_FORMAT=COMPACT](#)) by default. Refer to the [CREATE TABLE](#) documentation for additional information about the [ROW\\_FORMAT](#) table option.

The physical row structure of an [InnoDB](#) table is dependant on the row format. See [Section 14.11.1.2, “The Physical Row Structure of an InnoDB Table”](#) for more information.

## 14.14.3 DYNAMIC and COMPRESSED Row Formats

This section discusses the [DYNAMIC](#) and [COMPRESSED](#) row formats for [InnoDB](#) tables. To create tables that use these row formats, [innodb\\_file\\_format](#) must be set to [Barracuda](#), and [innodb\\_file\\_per\\_table](#) must be enabled. (The [Barracuda](#) file format also allows the [COMPACT](#) and [REDUNDANT](#) row formats.)

When a table is created with [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPRESSED](#), [InnoDB](#) can store long variable-length column values (for [VARCHAR](#), [VARBINARY](#), and [BLOB](#) and [TEXT](#) types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. [InnoDB](#) also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields. For example, a [CHAR\(255\)](#) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with [utf8mb4](#).

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, [InnoDB](#) chooses the longest columns for off-page storage until the clustered index record fits on the [B-tree](#) page. [TEXT](#) and [BLOB](#) columns that are less than or equal to 40 bytes are always stored in-line.

The [DYNAMIC](#) row format maintains the efficiency of storing the entire row in the index node if it fits (as do the [COMPACT](#) and [REDUNDANT](#) formats), but this new format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The [DYNAMIC](#) format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With [DYNAMIC](#) format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The [COMPRESSED](#) row format uses similar internal details for off-page storage as the [DYNAMIC](#) row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the [COMPRESSED](#) row format, the option [KEY\\_BLOCK\\_SIZE](#) controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the [COMPRESSED](#) row format, see [Section 14.12, “InnoDB Table Compression”](#).

`ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPRESSED` are variations of `ROW_FORMAT=COMPACT` and therefore handle `CHAR` storage in the same way as `ROW_FORMAT=COMPACT`. For more information, see [Section 14.11.1.2, “The Physical Row Structure of an InnoDB Table”](#).

## 14.14.4 COMPACT and REDUNDANT Row Formats

Early versions of `InnoDB` used an unnamed file format (now called `Antelope`) for database files. With that file format, tables are defined with `ROW_FORMAT=COMPACT` or `ROW_FORMAT=REDUNDANT`. With these row formats, `InnoDB` stores up to the first 768 bytes of variable-length columns (`VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) in the index record within the `B-tree` node, with the remainder stored on the overflow pages. `InnoDB` also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

With the `Antelope` file format, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the B-tree node. This works well for relatively short `BLOBS`, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause B-tree nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

To preserve compatibility with prior versions of `InnoDB`, `InnoDB` tables created in MySQL 5.5 default to the `COMPACT` row format rather than the newer `DYNAMIC` row format. See [Section 14.14.3, “DYNAMIC and COMPRESSED Row Formats”](#) for more information.

For information about the physical row structure of tables that use the `REDUNDANT` or `COMPACT` row format, see [Section 14.11.1.2, “The Physical Row Structure of an InnoDB Table”](#).

## 14.15 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The `ACID` design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, `InnoDB` tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a [fast shutdown](#).

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as `InnoDB` tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

### 14.15.1 InnoDB Disk I/O

`InnoDB` uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, `InnoDB` uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, `InnoDB` still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

## Read-Ahead

If [InnoDB](#) can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in [InnoDB](#):

- In sequential read-ahead, if [InnoDB](#) notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if [InnoDB](#) notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see [Section 14.9.2.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

## Doublewrite Buffer

[InnoDB](#) uses a novel file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default (`innodb_doublewrite=ON`). It adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, [InnoDB](#) first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does [InnoDB](#) write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write (causing a [torn page](#) condition), [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during recovery.

## 14.15.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the [InnoDB system tablespace](#). The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, [InnoDB](#) allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option, which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by [InnoDB](#) within the system tablespace.

## Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of size 1MB (64 consecutive pages). The “files” inside a tablespace are called [segments](#) in [InnoDB](#). (These segments are different from the [rollback segment](#), which actually contains many tablespace segments.)

When a segment grows inside the tablespace, [InnoDB](#) allocates the first 32 pages to it one at a time. After that, [InnoDB](#) starts to allocate whole extents to the segment. [InnoDB](#) can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in [InnoDB](#). One is for nonleaf nodes of the [B-tree](#), the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an [InnoDB](#) tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a [SHOW TABLE STATUS](#) statement, [InnoDB](#) reports the extents that are definitely free in the tablespace. [InnoDB](#) always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, [InnoDB](#) contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the [purge](#) operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 14.6, “InnoDB Multi-Versioning”](#).)

To see information about the tablespace, use the Tablespace Monitor. See [Section 14.20, “InnoDB Monitors”](#).

## How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page. For example, the maximum row length is slightly less than 8KB for the 16KB [InnoDB](#) page size.

If a row does not exceed the half page limit, all of it is stored locally within the page. If a row exceeds the half page limit, [variable-length columns](#) are chosen for external off-page storage until the row fits within half a page. External off-page storage for variable-length columns differs by row format:

- *COMPACT and REDUNDANT Row Formats*

When a variable-length column is chosen for external off-page storage, [InnoDB](#) stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See [Section 14.14.4, “COMPACT and REDUNDANT Row Formats”](#).

- *DYNAMIC and COMPRESSED Row Formats*

When a variable-length column is chosen for external off-page storage, [InnoDB](#) stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See [Section 14.14.3, “DYNAMIC and COMPRESSED Row Formats”](#).

[LONGBLOB](#) and [LONGTEXT](#) columns must be less than 4GB, and the total row length, including [BLOB](#) and [TEXT](#) columns, must be less than 4GB.

## 14.15.3 InnoDB Checkpoints

Making your [log files](#) very large may reduce disk I/O during [checkpointing](#). It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

## How Checkpoint Processing Works

[InnoDB](#) implements a [checkpoint](#) mechanism known as [fuzzy checkpointing](#). [InnoDB](#) flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During [crash recovery](#), [InnoDB](#) looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then [InnoDB](#) scans the log files forward from the checkpoint, applying the logged modifications to the database.

[InnoDB](#) writes to its log files on a rotating basis. It also writes checkpoint information to the first log file at each checkpoint. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case [InnoDB](#) has to do a recovery. This means that when [InnoDB](#) starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that [InnoDB](#) is going to reuse. In other words, [InnoDB](#) must create a checkpoint and this often involves flushing of modified database pages to disk.

## 14.15.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All [InnoDB](#) data and indexes are stored in [B-trees](#), and their [fill factor](#) may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” [ALTER TABLE](#) operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

Another way to perform a defragmentation operation is to use [mysqldump](#) to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the [InnoDB](#) filesystem management algorithm guarantees that fragmentation in the index does not occur.

## 14.15.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when [truncating](#) an [InnoDB](#) table, the table must be stored in its own [.ibd](#) file. For a table to be stored in its own [.ibd](#) file, [innodb\\_file\\_per\\_table](#) must be enabled when the table is created. Additionally, there cannot be a [foreign key](#) constraint between the table being truncated and other tables, otherwise the [TRUNCATE TABLE](#) operation fails. This is a change from previous behavior, which would transform the [TRUNCATE](#) operation to a [DELETE](#) operation that removes all rows and triggers [ON DELETE](#) operations on child tables. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new [.ibd](#) file (previous versions of [InnoDB](#) would keep the existing [.ibd](#) file), and the freed space is returned to the operating system. This is in contrast to truncating [InnoDB](#) tables that are stored within the [InnoDB system tablespace](#) (tables created when [innodb\\_file\\_per\\_table=OFF](#)), where only [InnoDB](#) can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that [physical backups](#) can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) leaves blocks of unused space in the system tablespace.

## 14.16 InnoDB Fast Index Creation

In MySQL 5.5 and higher, or in MySQL 5.1 with the InnoDB Plugin, creating and dropping [secondary indexes](#) does not copy the contents of the entire table, making this operation much more efficient than with prior releases.

### 14.16.1 Overview of Fast Index Creation

With MySQL 5.5 and higher, or MySQL 5.1 with the InnoDB Plugin, creating and dropping [secondary indexes](#) for InnoDB tables is much faster than before. Historically, adding or dropping an index on a table with existing data could be very slow. The `CREATE INDEX` and `DROP INDEX` statements worked by creating a new, empty table defined with the requested set of indexes, then copying the existing rows to the new table one-by-one, updating the indexes as the rows are inserted. After all rows from the original table were copied, the old table was dropped and the copy was renamed with the name of the original table.

The performance speedup for fast index creation applies to secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a [clustered index](#) organized based on the [primary key](#), forming what some database systems call an “index-organized table”. Because the table structure is so closely tied to the primary key, redefining the primary key still requires copying the data.

This new mechanism also means that you can generally speed the overall process of creating and loading an indexed table by creating the table with only the clustered index, and adding the secondary indexes after the data is loaded.

Although no syntax changes are required in the `CREATE INDEX` or `DROP INDEX` commands, some factors affect the performance, space usage, and semantics of this operation (see [Section 14.16.6, “Limitations of Fast Index Creation”](#)).

### 14.16.2 Examples of Fast Index Creation

It is possible to create multiple indexes on a table with one `ALTER TABLE` statement. This is relatively efficient, because the clustered index of the table needs to be scanned only once (although the data is sorted separately for each new index). For example:

```
CREATE TABLE T1(A INT PRIMARY KEY, B INT, C CHAR(1)) ENGINE=InnoDB;  
INSERT INTO T1 VALUES (1,2,'a'), (2,3,'b'), (3,2,'c'), (4,3,'d'), (5,2,'e');  
COMMIT;  
ALTER TABLE T1 ADD INDEX (B), ADD UNIQUE INDEX (C);
```

The above statements create table `T1` with the clustered index (primary key) on column `A`, insert several rows, and then build two new indexes on columns `B` and `C`. If there were many rows inserted into `T1` before the `ALTER TABLE` statement, this approach is much more efficient than creating all the secondary indexes before loading the data.

You can also create the indexes one at a time, but then the clustered index of the table is scanned (as well as sorted) once for each `CREATE INDEX` statement. Thus, the following statements are not as efficient as the `ALTER TABLE` statement above, even though neither requires recreating the clustered index for table `T1`.

```
CREATE INDEX B ON T1 (B);  
CREATE UNIQUE INDEX C ON T1 (C);
```

Dropping InnoDB secondary indexes also does not require any copying of table data. You can equally quickly drop multiple indexes with a single `ALTER TABLE` statement or multiple `DROP INDEX` statements:

```
ALTER TABLE T1 DROP INDEX B, DROP INDEX C;
```

or:

```
DROP INDEX B ON T1;  
DROP INDEX C ON T1;
```

Restructuring the clustered index in InnoDB always requires copying the data in the table. For example, if you create a table without a primary key, InnoDB chooses one for you, which may be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. Defining a `PRIMARY KEY` later causes the data to be copied, as in the following example:

```
CREATE TABLE T2 (A INT, B INT) ENGINE=InnoDB;  
INSERT INTO T2 VALUES (NULL, 1);  
ALTER TABLE T2 ADD PRIMARY KEY (B);
```

When you create a `UNIQUE` or `PRIMARY KEY` index, InnoDB must do some extra work. For `UNIQUE` indexes, InnoDB checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, InnoDB also checks that none of the `PRIMARY KEY` columns contains a `NULL`. It is best to define the primary key when you create a table, so you need not rebuild the table later.

### 14.16.3 Implementation Details of Fast Index Creation

InnoDB has two types of indexes: the clustered index and secondary indexes. Since the clustered index contains the data values in its B-tree nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal InnoDB system tables and the MySQL data dictionary tables are updated to reflect the fact that the index no longer exists. InnoDB returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, InnoDB scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

### 14.16.4 Concurrency Considerations for Fast Index Creation

While an InnoDB secondary index is being created or dropped, the table is locked in shared mode. Any writes to the table are blocked, but the data in the table can be read. When you alter the clustered index of a table, the table is locked in exclusive mode, because the data must be copied. Thus, during the creation of a new clustered index, all operations on the table are blocked.

A `CREATE INDEX` or `ALTER TABLE` statement for an InnoDB table always waits for currently executing transactions that are accessing the table to commit or roll back. `ALTER TABLE` statements that redefine an InnoDB primary key wait for all `SELECT` statements that access the table to complete, or their containing transactions to commit. No transactions whose execution spans the creation of the index can be accessing the table, because the original table is dropped when the clustered index is restructured.

Once a `CREATE INDEX` or `ALTER TABLE` statement that creates an InnoDB secondary index begins executing, queries can access the table for read access, but cannot update the table. If an `ALTER TABLE` statement is changing the clustered index for an InnoDB table, all queries wait until the operation completes.

A newly-created InnoDB secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement begins to execute. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

Because a newly-created index contains only information about data current at the time the index was created, queries that need to see data that was deleted or changed before the index was created cannot use the index. The only queries that could be affected by this limitation are those executing in transactions that began before the creation of the index was begun. For such queries, unpredictable results could occur. Newer queries can use the index.

### 14.16.5 How Crash Recovery Works with Fast Index Creation

Although no data is lost if the server crashes while an `ALTER TABLE` statement is executing, the [crash recovery](#) process is different for [clustered indexes](#) and [secondary indexes](#).

If the server crashes while creating an InnoDB secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes. In the following discussion, we use the word table and clustered index interchangeably.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario. Contact MySQL support.

### 14.16.6 Limitations of Fast Index Creation

Take the following considerations into account when creating or dropping InnoDB indexes:

- During index creation, files are written to the temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the value of the `--tmpdir` configuration variable). Each temporary file is large enough to hold one column that makes up the new index, and each one is removed as soon as it is merged into the final index.

- An `ALTER TABLE` statement that contains `DROP INDEX` and `ADD INDEX` clauses that both name the same index uses a table copy, not Fast Index Creation.
- The table is copied, rather than using Fast Index Creation when you create an index on a `TEMPORARY TABLE`. This has been reported as MySQL Bug #39833.
- To avoid consistency issues between the InnoDB data dictionary and the MySQL data dictionary, the table is copied, rather than using Fast Index Creation when you use the `ALTER TABLE ... RENAME COLUMN` syntax.
- The statement `ALTER IGNORE TABLE t ADD UNIQUE INDEX` does not delete duplicate rows. This has been reported as MySQL Bug #40344. The `IGNORE` keyword is ignored. If any duplicate rows exist, the operation fails with the following error message:

```
ERROR 23000: Duplicate entry '347' for key 'pl'
```

- As noted above, a newly-created index contains only information about data current at the time the index was created. Therefore, you should not run queries in a transaction that might use a secondary index that did not exist at the beginning of the transaction. There is no way for InnoDB to access “old” data that is consistent with the rest of the data read by the transaction. See the discussion of locking in [Section 14.16.4, “Concurrency Considerations for Fast Index Creation”](#).

Prior to InnoDB storage engine 1.0.4, unexpected results could occur if a query attempts to use an index created after the start of the transaction containing the query. If an old transaction attempts to access a “too new” index, InnoDB storage engine 1.0.4 and later reports an error:

```
ERROR HY000: Table definition has changed, please retry transaction
```

As the error message suggests, committing (or rolling back) the transaction, and restarting it, cures the problem.

- InnoDB storage engine 1.0.2 introduces some improvements in error handling when users attempt to drop indexes. See [Section B.3, “Server Error Codes and Messages”](#) for information related to errors [1025](#), [1553](#), and [1173](#).
- MySQL 5.5 does not support efficient creation or dropping of `FOREIGN KEY` constraints. Therefore, if you use `ALTER TABLE` to add or remove a `REFERENCES` constraint, the child table is copied, rather than using Fast Index Creation.
- `OPTIMIZE TABLE` for an InnoDB table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. This operation does not use fast index creation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key.

## 14.17 InnoDB Startup Options and System Variables

This section describes the InnoDB-related command options and system variables.

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable InnoDB checksums, you can use `--innodb_checksums` or `--skip-innodb_checksums` on the command line, or `innodb_checksums` or `skip-innodb_checksums` in an option file.
- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.

- Many system variables can be changed at runtime (see [Section 5.1.6.2, “Dynamic System Variables”](#)).
- For information about [GLOBAL](#) and [SESSION](#) variable scope modifiers, refer to the [SET](#) statement documentation.
- Certain options control the locations and layout of the [InnoDB](#) data files. [Section 14.9.1, “InnoDB Startup Configuration”](#) explains how to use these options.
- Some options, which you might not use initially, help tune [InnoDB](#) performance characteristics based on machine capacity and your database [workload](#).
- For more information on specifying options and system variables, see [Section 4.2.3, “Specifying Program Options”](#).

**Table 14.6 InnoDB Option/Variable Reference**

| Name  | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|---|----------|-------------|------------|------------|-----------|---------|
| <a href="#">foreign_key_checks</a>                    |          |             | Yes        |            | Varies    | Yes     |
| <a href="#">have_innodb</a>                           |          |             | Yes        |            | Global    | No      |
| <a href="#">ignore-builtin-innodb</a>                 | Yes      | Yes         |            |            | Global    | No      |
| - Variable:<br><a href="#">ignore_builtin_innodb</a>  |          |             | Yes        |            | Global    | No      |
| <a href="#">innodb</a>                                | Yes      | Yes         |            |            |           |         |

## InnoDB Command Options

- `--ignore-builtin-innodb`

|                            |                                      |                                       |
|----------------------------|--------------------------------------|---------------------------------------|
| <b>Deprecated</b>          | 5.5.22                               |                                       |
| <b>Command-Line Format</b> | <code>--ignore-builtin-innodb</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                          | <a href="#">ignore_builtin_innodb</a> |
|                            | <b>Variable Scope</b>                | Global                                |
|                            | <b>Dynamic Variable</b>              | No                                    |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                               |

In MySQL 5.1, this option caused the server to behave as if the built-in [InnoDB](#) were not present, which enabled the [InnoDB Plugin](#) to be used instead. In MySQL 5.5, [InnoDB](#) is the default storage engine and [InnoDB Plugin](#) is not used, so this option has no effect. As of MySQL 5.5.22, it is deprecated and its use results in a warning.

- `--innodb[=value]`

|                            |                               |                    |
|----------------------------|-------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--innodb[=value]</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                   | enumeration        |
|                            | <b>Default</b>                | <a href="#">ON</a> |

## InnoDB System Variables

|  |                     |       |
|--|---------------------|-------|
|  | <b>Valid Values</b> | OFF   |
|  |                     | ON    |
|  |                     | FORCE |

Controls loading of the [InnoDB](#) storage engine, if the server was compiled with [InnoDB](#) support. This option has a tristate format, with possible values of [OFF](#), [ON](#), or [FORCE](#). See [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

To disable [InnoDB](#), use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is [InnoDB](#), the server does not start unless you also use `--default-storage-engine` to set the default to some other engine.

- `--innodb-status-file`

|                            |                                   |                     |
|----------------------------|-----------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--innodb-status-file</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean             |
|                            | <b>Default</b>                    | <a href="#">OFF</a> |

Controls whether [InnoDB](#) creates a file named `innodb_status.pid` in the MySQL data directory. If enabled, [InnoDB](#) periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

By default, the file is not created. To create it, start `mysqld` with the `--innodb-status-file=1` option. The file is deleted during normal shutdown.

- `--skip-innodb`

Disable the [InnoDB](#) storage engine. See the description of `--innodb`.

## InnoDB System Variables

- `ignore_built_innodb`

|                            |                                      |                                     |
|----------------------------|--------------------------------------|-------------------------------------|
| <b>Deprecated</b>          | 5.5.22                               |                                     |
| <b>Command-Line Format</b> | <code>--ignore-builtin-innodb</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                          | <a href="#">ignore_built_innodb</a> |
|                            | <b>Variable Scope</b>                | Global                              |
|                            | <b>Dynamic Variable</b>              | No                                  |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                             |

See the description of `--ignore-builtin-innodb` under “InnoDB Command Options” earlier in this section.

- `innodb_adaptive_flushing`

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb-adaptive-flushing=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                               | <a href="#">innodb_adaptive_flushing</a> |
|                            | <b>Variable Scope</b>                     | Global<br>1808                           |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | ON      |

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the [InnoDB buffer pool](#) based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See [Section 14.9.2.5, “Configuring InnoDB Buffer Pool Flushing”](#) for more information. For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_adaptive\\_hash\\_index](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb-adaptive-hash-index=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                 | <a href="#">innodb_adaptive_hash_index</a> |
|                            | <b>Variable Scope</b>                       | Global                                     |
|                            | <b>Dynamic Variable</b>                     | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                                    |
|                            | <b>Default</b>                              | ON   |

Whether the [InnoDB adaptive hash index](#) is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable [adaptive hash indexing](#) to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See [Section 14.7.3, “Adaptive Hash Index”](#) for details.

This variable is enabled by default. As of MySQL 5.5, You can modify this parameter using the [SET GLOBAL](#) statement, without restarting the server. Changing the setting requires the [SUPER](#) privilege. You can also use `--skip-innodb_adaptive_hash_index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- [innodb\\_additional\\_mem\\_pool\\_size](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--innodb-additional-mem-pool-size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                      | <a href="#">innodb_additional_mem_pool_size</a> |
|                            | <b>Variable Scope</b>                            | Global  |
|                            | <b>Dynamic Variable</b>                          | No  |
| <b>Permitted Values</b>    | <b>Type</b>                                      | integer   |
|                            | <b>Default</b>                                   | <a href="#">8388608</a>                         |
|                            | <b>Min Value</b>                                 | <a href="#">2097152</a>                         |

|  |                  |            |
|--|------------------|------------|
|  | <b>Max Value</b> | 4294967295 |
|--|------------------|------------|

The size in bytes of a memory pool InnoDB uses to store [data dictionary](#) information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

This variable relates to the InnoDB internal memory allocator, which is unused if [innodb\\_use\\_sys\\_malloc](#) is enabled. For more information, see [Section 14.9.3, “Configuring the Memory Allocator for InnoDB”](#).

- [innodb\\_autoextend\\_increment](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--innodb-autoextend-increment=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                  | <a href="#">innodb_autoextend_increment</a> |
|                            | <b>Variable Scope</b>                        | Global                                      |
|                            | <b>Dynamic Variable</b>                      | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                  | integer                                     |
|                            | <b>Default</b>                               | 8   |
|                            | <b>Min Value</b>                             | 1   |
|                            | <b>Max Value</b>                             | 1000  |

The increment size (in megabytes) for extending the size of an auto-extending [system tablespace](#) file when it becomes full. The default value is 8. For related information, see [System Tablespace Data File Configuration](#), and [Section 14.10.1, “Resizing the InnoDB System Tablespace”](#).

The [innodb\\_autoextend\\_increment](#) setting does not affect [file-per-table](#) tablespace files. These files are auto-extending regardless of the [innodb\\_autoextend\\_increment](#) setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- [innodb\\_autoinc\\_lock\\_mode](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb-autoinc-lock-mode=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                               | <a href="#">innodb_autoinc_lock_mode</a> |
|                            | <b>Variable Scope</b>                     | Global                                   |
|                            | <b>Dynamic Variable</b>                   | No                                       |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                                  |
|                            | <b>Default</b>                            | 1  |
|                            | <b>Valid Values</b>                       | 0  |
|                            |   | 1  |
|                            |   | 2  |

The [lock mode](#) to use for generating [auto-increment](#) values. Permissible values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved”, respectively. The default setting is 1 (“consecutive”). For the characteristics of each lock mode, see [InnoDB AUTO\\_INCREMENT Lock Modes](#).

- [innodb\\_buffer\\_pool\\_instances](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.5.4   |  |
| <b>Command-Line Format</b> | <code>--innodb-buffer-pool-instances=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                   | <a href="#">innodb_buffer_pool_instances</a> |
|                            | <b>Variable Scope</b>                         | Global                                       |
|                            | <b>Dynamic Variable</b>                       | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                   | integer                                      |
|                            | <b>Default</b>                                | <a href="#">1</a>                            |
|                            | <b>Min Value</b>                              | <a href="#">1</a>                            |
|                            | <b>Max Value</b>                              | <a href="#">64</a>                           |

The number of regions that the [InnoDB](#) buffer pool is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

This option only takes effect when setting [innodb\\_buffer\\_pool\\_size](#) to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of [innodb\\_buffer\\_pool\\_instances](#) and [innodb\\_buffer\\_pool\\_size](#) so that each buffer pool instance is at least 1GB.

- [innodb\\_buffer\\_pool\\_size](#)

|  |  |   |
|--|--|---|
| <b>Command-Line Format</b>                 | <code>--innodb-buffer-pool-size=#</code> |   |
| <b>System Variable</b>                     | <b>Name</b>                              | <a href="#">innodb_buffer_pool_size</a> |
|  | <b>Variable Scope</b>                    | Global                                  |
|  | <b>Dynamic Variable</b>                  | No                                      |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                              | integer                                 |
|  | <b>Default</b>                           | <a href="#">134217728</a>               |
|  | <b>Min Value</b>                         | <a href="#">5242880</a>                 |
|  | <b>Max Value</b>                         | <a href="#">2**32-1</a>                 |

|  |                  |           |
|--|------------------|-----------|
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer   |
|  | <b>Default</b>   | 134217728 |
|  | <b>Min Value</b> | 5242880   |
|  | <b>Max Value</b> | 2**64-1   |

The size in bytes of the [buffer pool](#), the memory area where [InnoDB](#) caches table and index data. The default value is 128MB. The maximum value depends on the CPU architecture; the maximum is 4294967295 ( $2^{32}-1$ ) on 32-bit systems and 18446744073709551615 ( $2^{64}-1$ ) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting [innodb\\_buffer\\_pool\\_instances](#) to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- [InnoDB](#) reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant.
- [innodb\\_change\\_buffering](#)

|                                    |  |  |
|------------------------------------|--|--|
| <b>Command-Line Format</b>         | <code>--innodb-change-buffering=#</code> |  |
| <b>System Variable</b>             | <b>Name</b>                              | <a href="#">innodb_change_buffering</a>                                    |
|                                    | <b>Variable Scope</b>                    | Global   |
|                                    | <b>Dynamic Variable</b>                  | Yes  |

|                                    | <b>Default</b>                           | <a href="#">inserts</a>  |
|                                    | <b>Valid Values</b>                      | <a href="#">inserts</a><br><a href="#">none</a>                            |
| <b>Permitted Values</b> (>= 5.5.4) | <b>Type</b>                              | enumeration  |
|                                    | <b>Default</b>                           | <a href="#">all</a>  |
|                                    | <b>Valid Values</b>                      | <a href="#">none</a><br><a href="#">inserts</a><br><a href="#">deletes</a> |

|  |                         |
|--|-------------------------|
|  | <a href="#">changes</a> |
|  | <a href="#">purges</a>  |
|  | <a href="#">all</a>     |

Whether [InnoDB](#) performs [change buffering](#), an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table.

**Table 14.7 Permitted Values for `innodb_change_buffering`**

| Value                   | Description  |
|-------------------------|--|
| <a href="#">none</a>    | Do not buffer any operations.  |
| <a href="#">inserts</a> | Buffer insert operations.  |
| <a href="#">deletes</a> | Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation. |
| <a href="#">changes</a> | Buffer inserts and delete-marking operations.  |
| <a href="#">purges</a>  | Buffer the physical deletion operations that happen in the background.   |
| <a href="#">all</a>     | The default. Buffer inserts, delete-marking operations, and purges.  |

For more information, see [Section 14.7.2, “Change Buffer”](#), and [Section 14.9.4, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_change\\_buffering\\_debug](#)

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <a href="#">--innodb-change-buffering-debug=#</a> |   |
| <b>System Variable</b>     | <b>Name</b>                                       | <a href="#">innodb_change_buffering_debug</a> |
|                            | <b>Variable Scope</b>                             | Global  |
|                            | <b>Dynamic Variable</b>                           | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                       | integer                                       |
|                            | <b>Default</b>                                    | 0   |
|                            | <b>Max Value</b>                                  | 2   |

Sets a debug flag for [InnoDB](#) change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes a crash at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the [WITH\\_DEBUG CMake](#) option.

- [innodb\\_checksums](#)

|                            |                                    |                                  |
|----------------------------|------------------------------------|----------------------------------|
| <b>Command-Line Format</b> | <a href="#">--innodb-checksums</a> |                                  |
| <b>System Variable</b>     | <b>Name</b>                        | <a href="#">innodb_checksums</a> |
|                            | <b>Variable Scope</b>              | Global                           |
|                            | <b>Dynamic Variable</b>            | No                               |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | ON      |

InnoDB can use checksum validation on all pages read from disk to ensure extra fault tolerance against broken hardware or data files. This validation is enabled by default. Under specialized circumstances (such as when running benchmarks) this safety feature can be disabled with `--skip-innodb-checksums`.

- `innodb_commit_concurrency`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb-commit-concurrency=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_commit_concurrency</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |
|                            | <b>Default</b>                             | 0                                      |
|                            | <b>Min Value</b>                           | 0                                      |
|                            | <b>Max Value</b>                           | 1000                                   |

The number of `threads` that can `commit` at the same time. A value of 0 (the default) permits any number of `transactions` to commit simultaneously.

The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- `innodb_concurrency_tickets`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb-concurrency-tickets=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>innodb_concurrency_tickets</code> |
|                            | <b>Variable Scope</b>                       | Global                                  |
|                            | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                 | integer                                 |
|                            | <b>Default</b>                              | 500                                     |
|                            | <b>Min Value</b>                            | 1                                       |
|                            | <b>Max Value</b>                            | 4294967295                              |

Determines the number of `threads` that can enter InnoDB concurrently. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is permitted to enter InnoDB, it is given a number of “tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used

up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter [InnoDB](#). The default value is 500.

With a small [innodb\\_concurrency\\_tickets](#) value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small [innodb\\_concurrency\\_tickets](#) value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large [innodb\\_concurrency\\_tickets](#) value, large transactions spend less time waiting for a position at the end of the queue (controlled by [innodb\\_thread\\_concurrency](#)) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large [innodb\\_concurrency\\_tickets](#) value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a non-zero [innodb\\_thread\\_concurrency](#) value, you may need to adjust the [innodb\\_concurrency\\_tickets](#) value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the `INFORMATION_SCHEMA.INNODB_TRX` table.

For more information, see [Section 14.9.5, “Configuring Thread Concurrency for InnoDB”](#).

- [innodb\\_data\\_file\\_path](#)

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-data-file-path=name</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <a href="#">innodb_data_file_path</a> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | No                                    |
| <b>Permitted Values</b>    | <b>Type</b>                               | string                                |
|                            | <b>Default</b>                            | <code>ibdata1:10M:autoextend</code>   |

Defines the path and file size for individual [InnoDB system tablespace data files](#). The full directory path for system tablespace data files is formed by concatenating path defined by [innodb\\_data\\_home\\_dir](#) and [innodb\\_data\\_file\\_path](#). File sizes are specified KB, MB or GB (1024MB) by appending [K](#), [M](#) or [G](#) to the size value. If specifying the data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 10MB. If you do not specify [innodb\\_data\\_file\\_path](#), the default behavior is to create a single auto-extending data file, slightly larger than 10MB, named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also [use raw disk partitions as data files](#). For more information about configuring system tablespace data files, see [Section 14.9.1, “InnoDB Startup Configuration”](#).

- [innodb\\_data\\_home\\_dir](#)

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-data-home-dir=dir_name</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                                  | <a href="#">innodb_data_home_dir</a> |

|                         |                         |                |
|-------------------------|-------------------------|----------------|
|                         | <b>Variable Scope</b>   | Global         |
|                         | <b>Dynamic Variable</b> | No             |
| <b>Permitted Values</b> | <b>Type</b>             | directory name |

The common part of the directory path for [InnoDB system tablespace](#) data files. This setting does not affect the location of [file-per-table](#) tablespaces when [innodb\\_file\\_per\\_table](#) is enabled. The default value is the MySQL [data](#) directory. If you specify the value as an empty string, you can specify an absolute file paths for [innodb\\_data\\_file\\_path](#).

A trailing slash is required when specifying a value for [innodb\\_data\\_home\\_dir](#). For example:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
```

For related information, see [Section 14.9.1, “InnoDB Startup Configuration”](#).

- [innodb\\_doublewrite](#)

|                            |                                      |                                    |
|----------------------------|--------------------------------------|------------------------------------|
| <b>Command-Line Format</b> | <a href="#">--innodb-doublewrite</a> |                                    |
| <b>System Variable</b>     | <b>Name</b>                          | <a href="#">innodb_doublewrite</a> |
|                            | <b>Variable Scope</b>                | Global                             |
|                            | <b>Dynamic Variable</b>              | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                            |
|                            | <b>Default</b>                       | <a href="#">ON</a>                 |

When enabled (the default), [InnoDB](#) stores all data twice, first to the [doublewrite buffer](#), and then to the actual [data files](#). This variable can be turned off with [--skip-innodb\\_doublewrite](#) for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

For related information, see [Section 14.7.7, “Doublewrite Buffer”](#).

- [innodb\\_fast\\_shutdown](#)

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <a href="#">--innodb-fast-shutdown[=#]</a> |                                      |
| <b>System Variable</b>     | <b>Name</b>                                | <a href="#">innodb_fast_shutdown</a> |
|                            | <b>Variable Scope</b>                      | Global                               |
|                            | <b>Dynamic Variable</b>                    | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                              |
|                            | <b>Default</b>                             | <a href="#">1</a>                    |
|                            | <b>Valid Values</b>                        | <a href="#">0</a>                    |
|                            |  | <a href="#">1</a>                    |
|                            |  | <a href="#">2</a>                    |

The [InnoDB shutdown](#) mode. If the value is 0, [InnoDB](#) does a [slow shutdown](#), a full [purge](#) and a change buffer merge before shutting down. If the value is 1 (the default), [InnoDB](#) skips these operations at shutdown, a process known as a [fast shutdown](#). If the value is 2, [InnoDB](#) flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the [crash recovery](#) operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- `innodb_file_format`

|                                       |                                     |                                 |
|---------------------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b>            | <code>--innodb-file-format=#</code> |                                 |
| <b>System Variable</b>                | <b>Name</b>                         | <code>innodb_file_format</code> |
|                                       | <b>Variable Scope</b>               | Global                          |
|                                       | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values (&lt;= 5.5.6)</b> | <b>Type</b>                         | string                          |
|                                       | <b>Default</b>                      | <a href="#">Barracuda</a>       |
|                                       | <b>Valid Values</b>                 | <a href="#">Antelope</a>        |
|                                       |                                     | <a href="#">Barracuda</a>       |
| <b>Permitted Values (&gt;= 5.5.7)</b> | <b>Type</b>                         | string                          |
|                                       | <b>Default</b>                      | <a href="#">Antelope</a>        |
|                                       | <b>Valid Values</b>                 | <a href="#">Antelope</a>        |
|                                       |                                     | <a href="#">Barracuda</a>       |

Enables an [InnoDB](#) file format for [file-per-table](#) tablespaces. Supported file formats are [Antelope](#) and [Barracuda](#). [Antelope](#) is the original [InnoDB](#) file format, which supports [REDUNDANT](#) and [COMPACT](#) row formats for [InnoDB](#) tables. [Barracuda](#) is the newer file format, which supports [COMPRESSED](#) and [DYNAMIC](#) row formats.

[COMPRESSED](#) and [DYNAMIC](#) row formats enable important storage features for [InnoDB](#) tables. See [Section 14.14, “InnoDB Row Storage and Row Formats”](#).

To create tables that use [COMPRESSED](#) or [DYNAMIC](#) row format, the [Barracuda](#) file format and `innodb_file_per_table` must be enabled.

Changing the `innodb_file_format` setting does not affect the file format of existing [InnoDB](#) tablespace files.

For more information, see [Section 14.13, “InnoDB File-Format Management”](#).

- `innodb_file_format_check`

|                            |   |
|----------------------------|---|
| <b>Command-Line Format</b> | <code>--innodb-file-format-check=#</code> |
|----------------------------|---|

|  |                         |  |
|--|-------------------------|--|
| <b>System Variable</b> (<= 5.5.4)            | <b>Name</b>             | <a href="#">innodb_file_format_check</a> |
|  | <b>Variable Scope</b>   | Global                                   |
|  | <b>Dynamic Variable</b> | Yes                                      |
| <b>System Variable</b> (>= 5.5.5)            | <b>Name</b>             | <a href="#">innodb_file_format_check</a> |
|  | <b>Variable Scope</b>   | Global                                   |

| <b>Permitted Values</b> (5.5.0)              | <b>Type</b>             | string                                   |
|  | <b>Default</b>          | <a href="#">Antelope</a>                 |
| <b>Permitted Values</b> (>= 5.5.1, <= 5.5.4) | <b>Type</b>             | string                                   |
|  | <b>Default</b>          | <a href="#">Barracuda</a>                |
| <b>Permitted Values</b> (>= 5.5.5)           | <b>Type</b>             | boolean                                  |
|  | <b>Default</b>          | <a href="#">ON</a>                       |

As of MySQL 5.5.5, this variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the [file format](#) tag in the [system tablespace](#) (for example, [Antelope](#) or [Barracuda](#)). If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of [innodb\\_file\\_format\\_max](#) to the file format tag.

Before MySQL 5.5.5, this variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the file format tag in the shared tablespace. If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of [innodb\\_file\\_format\\_check](#) to the file format tag, which is the value seen at runtime.

#### Note

Despite the default value sometimes being displayed as [ON](#) or [OFF](#), always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line string.

For more information, see [Section 14.13.2.1, “Compatibility Check When InnoDB Is Started”](#).

- [innodb\\_file\\_format\\_max](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.5.5                                      |  |

|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | string                                 |
|                            | <b>Default</b>                             | <a href="#">Antelope</a>               |

|  |                     |           |
|--|---------------------|-----------|
|  | <b>Valid Values</b> | Antelope  |
|  |                     | Barracuda |

At server startup, InnoDB sets the value of this variable to the `file format` tag in the `system tablespace` (for example, `Antelope` or `Barracuda`). If the server creates or opens a table with a “higher” file format, it sets the value of `innodb_file_format_max` to that format.

For related information, see [Section 14.13, “InnoDB File-Format Management”](#).

- `innodb_file_per_table`

|                                       |                                      |                                    |
|---------------------------------------|--------------------------------------|------------------------------------|
| <b>Command-Line Format</b>            | <code>--innodb-file-per-table</code> |                                    |
| <b>System Variable</b>                | <b>Name</b>                          | <code>innodb_file_per_table</code> |
|                                       | <b>Variable Scope</b>                | Global                             |
|                                       | <b>Dynamic Variable</b>              | Yes                                |
| <b>Permitted Values (&lt;= 5.5.6)</b> | <b>Type</b>                          | boolean                            |
|                                       | <b>Default</b>                       | ON                                 |
| <b>Permitted Values (&gt;= 5.5.7)</b> | <b>Type</b>                          | boolean                            |
|                                       | <b>Default</b>                       | OFF                                |

When `innodb_file_per_table` is disabled, InnoDB stores the data for tables and indexes in the `ibdata files` that make up the `system tablespace`. This setting reduces the performance overhead of file system operations for operations such as `DROP TABLE` or `TRUNCATE TABLE`. It is most appropriate for a server environment where entire storage devices are devoted to MySQL data. Because the system tablespace never shrinks, and is shared across all databases in an `instance`, avoid loading huge amounts of temporary data on a space-constrained system when `innodb_file_per_table` is disabled. Set up a separate instance in such cases, so that you can drop the entire instance to reclaim the space.

When `innodb_file_per_table` is enabled, InnoDB stores data and indexes for each newly created table in a separate `.ibd file` instead of the system tablespace. The storage for these tables is reclaimed when the tables are dropped or truncated. This setting enables InnoDB features such as `table compression`. See [Section 14.10.4, “InnoDB File-Per-Table Tablespaces”](#) for more information.

Enabling `innodb_file_per_table` also means that an `ALTER TABLE` operation moves an InnoDB table from the system tablespace to an individual `.ibd file` in cases where `ALTER TABLE` rebuilds the table (`ALTER OFFLINE`).

`innodb_file_per_table` is dynamic and can be set `ON` or `OFF` using `SET GLOBAL`.

Dynamically changing the value requires the `SUPER` privilege and immediately affects the operation of all connections.

- `innodb_flush_log_at_trx_commit`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb-flush-log-at-trx-commit[=#]</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                       | <code>innodb_flush_log_at_trx_commit</code> |
|                            | <b>Variable Scope</b>                             | Global                                      |

|                         |                         |             |
|-------------------------|-------------------------|-------------|
|                         | <b>Dynamic Variable</b> | Yes         |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration |
|                         | <b>Default</b>          | 1           |
|                         | <b>Valid Values</b>     | 0           |
|                         |                         | 1           |
|                         |                         | 2           |

Controls the balance between strict [ACID](#) compliance for [commit](#) operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose up to a second of transactions in a crash.

- The default value of 1 is required for full ACID compliance. With this value, the contents of the [InnoDB log buffer](#) are written out to the [log file](#) at each transaction commit and the log file is [flushed](#) to disk.
- With a value of 0, the contents of the [InnoDB log buffer](#) are written to the log file approximately once per second and the log file is flushed to disk. No writes from the log buffer to the log file are performed at transaction commit. Once-per-second flushing is not guaranteed to happen every second due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions with any [mysqld](#) process crash.
- With a value of 2, the contents of the [InnoDB log buffer](#) are written to the log file after each transaction commit and the log file is flushed to disk approximately once per second. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions in an operating system crash or a power outage.
- [InnoDB crash recovery](#) works regardless of the value. Transactions are either applied entirely or erased entirely.

For the greatest possible durability and consistency in a replication setup using [InnoDB](#) with transactions, use [innodb\\_flush\\_log\\_at\\_trx\\_commit=1](#) and [sync\\_binlog=1](#) in your master server [my.cnf](#) file.

### Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell [mysqld](#) that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the setting 1, and in the worst case, a power outage can corrupt [InnoDB](#) data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- [innodb\\_flush\\_method](#)

|                            |  |                                     |
|----------------------------|--|-------------------------------------|
| <b>Command-Line Format</b> | <a href="#">--innodb-flush-method=name</a> |                                     |

|                            | <b>Variable Scope</b>                      | Global                              |

|                                   | Dynamic Variable    | No               |
|-----------------------------------|---------------------|------------------|
| <b>Permitted Values</b> (Unix)    | <b>Type</b>         | string           |
|                                   | <b>Default</b>      | NULL             |
|                                   | <b>Valid Values</b> | fsync            |
|                                   |                     | littlesync       |
|                                   |                     | nosync           |
|                                   |                     | O_DSYNC          |
|                                   |                     | O_DIRECT         |
| <b>Permitted Values</b> (Windows) | <b>Type</b>         | string           |
|                                   | <b>Default</b>      | NULL             |
|                                   | <b>Valid Values</b> | async_unbuffered |
|                                   |                     | normal           |
|                                   |                     | unbuffered       |

Defines the method used to **flush** data to **InnoDB data files** and **log files**, which can affect I/O throughput.

If `innodb_flush_method` is set to `NULL` on a Unix-like system, the `fsync` option is used by default. If `innodb_flush_method` is set to `NULL` on Windows, the `async_unbuffered` option is used by default.

The `innodb_flush_method` options for Unix-like systems include:

- **fsync**: InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.
- **O\_DSYNC**: InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- **littlesync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **nosync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **O\_DIRECT**: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.

The `innodb_flush_method` options for Windows systems include:

- **async\_unbuffered**: InnoDB uses Windows asynchronous I/O and non-buffered I/O. `async_unbuffered` is the default setting on Windows systems.
- **normal**: InnoDB uses simulated asynchronous I/O and buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **unbuffered**: InnoDB uses simulated asynchronous I/O and non-buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `InnoDB_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

Prior to MySQL 5.1.24, the default `innodb_flush_method` option was named `fdatasync`. When `fdatasync` was specified, InnoDB used the `fsync()` system call to flush both the data and log files. To avoid confusing the `fdatasync` option name with the `fdatasync()` system call, the option name was changed to `fsync` in MySQL 5.1.24.

- `innodb_force_load_corrupted`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.5.18                                     |  |
| <b>Command-Line Format</b> | <code>--innodb-force-load-corrupted</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_force_load_corrupted</code> |
|                            | <b>Variable Scope</b>                      | Global                                   |
|                            | <b>Dynamic Variable</b>                    | No                                       |
| <b>Permitted Values</b>    | <b>Type</b>                                | boolean                                  |
|                            | <b>Default</b>                             | <code>OFF</code>                         |

Permits InnoDB to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

- `innodb_force_recovery`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-force-recovery=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>innodb_force_recovery</code> |
|                            | <b>Variable Scope</b>                  | Global                             |
|                            | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                            | integer                            |
|                            | <b>Default</b>                         | 0                                  |
|                            | <b>Min Value</b>                       | 0                                  |
|                            | <b>Max Value</b>                       | 6                                  |

The [crash recovery](#) mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about [innodb\\_force\\_recovery](#), see [Section 14.23.2, “Forcing InnoDB Recovery”](#).

### Warning

Only set this variable to a value greater than 0 in an emergency situation so that you can start [InnoDB](#) and dump your tables. As a safety measure, [InnoDB](#) prevents [INSERT](#), [UPDATE](#), or [DELETE](#) operations when [innodb\\_force\\_recovery](#) is greater than 0.

- [innodb\\_io\\_capacity](#)

|  | <b>Min Value</b>                    | <a href="#">100</a>                |
|  | <b>Max Value</b>                    | $2^{64}-1$                         |

The [innodb\\_io\\_capacity](#) parameter sets an upper limit on I/O activity performed by [InnoDB](#) background tasks, such as [flushing](#) pages from the [buffer pool](#) and merging data from the [change buffer](#).

The [innodb\\_io\\_capacity](#) limit is a total limit for all buffer pool instances. When dirty pages are flushed, the limit is divided equally among buffer pool instances.

[innodb\\_io\\_capacity](#) should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly for caching to provide a significant benefit.

The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes.

In general, you can increase the value as a function of the number of drives used for [InnoDB](#) I/O. For example, you can increase the value on systems that use multiple disks or solid-state disks (SSD).

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to the former default of 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that can perform about 100 IOPS.

Although you can specify a very high value such as one million, in practice such large values have little if any benefit. Generally, a value of 20000 or higher is not recommended unless you have proven that lower values are insufficient for your workload.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

You can set `innodb_io_capacity` in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically using a `SET GLOBAL` statement, which requires the `SUPER` privilege.

See [Section 14.9.8, “Configuring the InnoDB Master Thread I/O Rate”](#) for more information. For general information about InnoDB I/O performance, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- `innodb_large_prefix`

|                            |                                    |                                  |
|----------------------------|------------------------------------|----------------------------------|
| <b>Introduced</b>          | 5.5.14                             |                                  |
| <b>Command-Line Format</b> | <code>--innodb-large-prefix</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                        | <code>innodb_large_prefix</code> |
|                            | <b>Variable Scope</b>              | Global                           |
|                            | <b>Dynamic Variable</b>            | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                        | boolean                          |
|                            | <b>Default</b>                     | <code>OFF</code>                 |

Enable this option to allow index key prefixes longer than 767 bytes (up to 3072 bytes), for InnoDB tables that use `DYNAMIC` or `COMPRESSED` row format. (Creating such tables also requires the option values `innodb_file_format=barracuda` and `innodb_file_per_table=true`.) See [Section 14.11.1.7, “Limits on InnoDB Tables”](#) for maximums associated with index key prefixes under various settings.

For tables that use `REDUNDANT` or `COMPACT` row format, this option does not affect the permitted index key prefix length. When this setting is enabled, attempting to create an index prefix with a key length greater than 3072 for a `REDUNDANT` or `COMPACT` table causes an `ER_INDEX_COLUMN_TOO_LONG` error.

- `innodb_limit_optimistic_insert_debug`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb-limit-optimistic-insert-debug=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_limit_optimistic_insert_debug</code> |
|                            | <b>Variable Scope</b>                                 | Global  |
|                            | <b>Dynamic Variable</b>                               | Yes   |

|                         |                  |            |
|-------------------------|------------------|------------|
| <b>Permitted Values</b> | <b>Type</b>      | integer    |
|                         | <b>Default</b>   | 0          |
|                         | <b>Min Value</b> | 0          |
|                         | <b>Max Value</b> | $2^{32}-1$ |

Limits the number of records per [B-tree](#) page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_lock_wait_timeout`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-lock-wait-timeout=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_lock_wait_timeout</code> |
|                            | <b>Variable Scope</b>                     | Global, Session                       |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 50                                    |
|                            | <b>Min Value</b>                          | 1                                     |
|                            | <b>Max Value</b>                          | 1073741824                            |

The length of time in seconds an [InnoDB transaction](#) waits for a [row lock](#) before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another [InnoDB](#) transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is [rolled back](#) (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 14.23.4, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or [OLTP](#) systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to [InnoDB](#) row locks only. A MySQL [table lock](#) does not happen inside [InnoDB](#) and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to [deadlocks](#), because [InnoDB](#) detects them immediately and rolls back one of the deadlocked transactions. See [Section 14.8.5.2, “Deadlock Detection and Rollback”](#).

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires the [SUPER](#) privilege and affects the operation

of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_locks_unsafe_for_binlog`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb-locks-unsafe-for-binlog</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                   | <code>innodb_locks_unsafe_for_binlog</code> |
|                            | <b>Variable Scope</b>                         | Global                                      |
|                            | <b>Dynamic Variable</b>                       | No  |
| <b>Permitted Values</b>    | <b>Type</b>                                   | boolean                                     |
|                            | <b>Default</b>                                | <code>OFF</code>                            |

This variable affects how InnoDB uses gap locking for searches and index scans. Normally, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the gap before the index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order. See [Section 14.8.1, “InnoDB Locking”](#).

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effects of enabling `innodb_locks_unsafe_for_binlog` are the same as setting the transaction isolation level to `READ COMMITTED`, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For more information about the effect of isolation level on gap locking, see [Section 14.8.2.1, “Transaction Isolation Levels”](#).

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where the `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, `InnoDB` does not guarantee serializability. Therefore, if `innodb_locks_unsafe_for_binlog` is enabled, `InnoDB` guarantees at most an isolation level of `READ COMMITTED`. (Conflict serializability is still guaranteed.) For more information about phantoms, see [Section 14.8.4, “Phantom Rows”](#).

Enabling `innodb_locks_unsafe_for_binlog` has additional effects:

- For `UPDATE` or `DELETE` statements, `InnoDB` holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For `UPDATE` statements, if a row is already locked, `InnoDB` performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time `InnoDB` either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 14.11.2.1, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an `UPDATE` using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an `UPDATE` by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As `InnoDB` executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If `InnoDB` does not modify the row and `innodb_locks_unsafe_for_binlog` is enabled, it releases the lock. Otherwise, `InnoDB` retains the lock until the end of the transaction. This affects transaction processing as follows.

If `innodb_locks_unsafe_for_binlog` is disabled, the first `UPDATE` acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because the first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `innodb_locks_unsafe_for_binlog` is enabled, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, InnoDB does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

- `innodb_log_buffer_size`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-log-buffer-size=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_log_buffer_size</code> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | No                                  |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                             |
|                            | <b>Default</b>                          | 8388608                             |
|                            | <b>Min Value</b>                        | 262144                              |
|                            | <b>Max Value</b>                        | 4294967295                          |

The size in bytes of the buffer that InnoDB uses to write to the [log files](#) on disk. The default value is 8MB. A large [log buffer](#) enables large [transactions](#) to run without the need to write the log to disk before the transactions [commit](#). Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For related information, see [InnoDB Memory Configuration](#), and [Section 8.5.3, “Optimizing InnoDB Redo Logging”](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- `innodb_log_file_size`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-log-file-size=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>innodb_log_file_size</code> |

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>Permitted Values</b> | <b>Variable Scope</b>   | Global                                       |
|                         | <b>Dynamic Variable</b> | No   |
|                         | <b>Type</b>             | integer                                      |
|                         | <b>Default</b>          | 5242880                                      |
|                         | <b>Min Value</b>        | 1048576                                      |
|                         | <b>Max Value</b>        | 4GB / <code>innodb_log_files_in_group</code> |

The size in bytes of each [log file](#) in a [log group](#). The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 4GB. A pair of 2047 MB log files, for example, approaches the limit but does not exceed it. The default value is 5MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in the buffer pool, saving disk I/O. Larger log files also make [crash recovery](#) slower, although improvements to recovery performance in MySQL 5.5 and higher make the log file size less of a consideration.

For related information, see [InnoDB Log File Configuration](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- `innodb_log_files_in_group`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb-log-files-in-group=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_log_files_in_group</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |
|                            | <b>Default</b>                             | 2                                      |
|                            | <b>Min Value</b>                           | 2                                      |
|                            | <b>Max Value</b>                           | 100                                    |

The number of [log files](#) in the [log group](#). InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of the files is specified by `innodb_log_group_home_dir`.

For related information, see [InnoDB Log File Configuration](#).

- `innodb_log_group_home_dir`

|                            |   |
|----------------------------|---|
| <b>Command-Line Format</b> | <code>--innodb-log-group-home-dir=dir_name</code> |
|----------------------------|---|

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">innodb_log_group_home_dir</a> |
|                         | <b>Variable Scope</b>   | Global                                    |
|                         | <b>Dynamic Variable</b> | No  |
| <b>Permitted Values</b> | <b>Type</b>             | directory name                            |

The directory path to the [InnoDB redo log](#) files, whose number is specified by [innodb\\_log\\_files\\_in\\_group](#). If you do not specify any [InnoDB](#) log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Log file size is given by the [innodb\\_log\\_file\\_size](#) system variable.

For related information, see [InnoDB Log File Configuration](#).

- [innodb\\_max\\_dirty\\_pages\\_pct](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb-max-dirty-pages-pct=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                 | <a href="#">innodb_max_dirty_pages_pct</a> |
|                            | <b>Variable Scope</b>                       | Global                                     |
|                            | <b>Dynamic Variable</b>                     | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                 | numeric                                    |
|                            | <b>Default</b>                              | <a href="#">75</a>                         |
|                            | <b>Min Value</b>                            | <a href="#">0</a>                          |
|                            | <b>Max Value</b>                            | <a href="#">99</a>                         |

[InnoDB](#) tries to [flush](#) data from the [buffer pool](#) so that the percentage of [dirty pages](#) does not exceed this value. Specify an integer in the range from 0 to 99. The default value is 75.

For additional information about this variable, see [Section 14.9.2.5, “Configuring InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_max\\_purge\\_lag](#)

|                            |                                       |                                      |
|----------------------------|---------------------------------------|--------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-max-purge-lag=#</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                           | <a href="#">innodb_max_purge_lag</a> |
|                            | <b>Variable Scope</b>                 | Global                               |
|                            | <b>Dynamic Variable</b>               | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                              |
|                            | <b>Default</b>                        | <a href="#">0</a>                    |
|                            | <b>Min Value</b>                      | <a href="#">0</a>                    |

|  |                  |            |
|--|------------------|------------|
|  | <b>Max Value</b> | 4294967295 |
|--|------------------|------------|

Controls how to delay [INSERT](#), [UPDATE](#), and [DELETE](#) operations when [purge](#) operations are lagging (see [Section 14.6, “InnoDB Multi-Versioning”](#)). The default value is 0 (no delays).

The [InnoDB](#) transaction system maintains a list of transactions that have index records delete-marked by [UPDATE](#) or [DELETE](#) operations. The length of the list represents the [purge\\_lag](#) value. When [purge\\_lag](#) exceeds [innodb\\_max\\_purge\\_lag](#), [INSERT](#), [UPDATE](#), and [DELETE](#) operations are delayed by  $((\text{purge\_lag}/\text{innodb\_max\_purge\_lag}) \times 10) - 5$  milliseconds. The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old [consistent read](#) view that could see the rows to be purged.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged [InnoDB](#) table rows.

The lag value is displayed as the history list length in the [TRANSACTIONS](#) section of [InnoDB Monitor output](#). For example, if the output includes the following lines, the lag value is 20:

```
-----
TRANSACTIONS
-----
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_mirrored\\_log\\_groups](#)

Has no effect.

- [innodb\\_old\\_blocks\\_pct](#)

|                            |  |                                       |
|----------------------------|--|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-old-blocks-pct=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                            | <a href="#">innodb_old_blocks_pct</a> |
|                            | <b>Variable Scope</b>                  | Global                                |
|                            | <b>Dynamic Variable</b>                | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                            | integer                               |
|                            | <b>Default</b>                         | 37                                    |
|                            | <b>Min Value</b>                       | 5                                     |
|                            | <b>Max Value</b>                       | 95                                    |

Specifies the approximate percentage of the [InnoDB buffer pool](#) used for the old block [sublist](#). The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool).

For more information, see [Section 14.9.2.3, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the [LRU](#) algorithm, and [eviction](#) policies, see [Section 14.9.2.1, “The InnoDB Buffer Pool”](#).

- `innodb_old_blocks_time`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-old-blocks-time=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_old_blocks_time</code> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                             |
|                            | <b>Default</b>                          | 0                                   |
|                            | <b>Min Value</b>                        | 0                                   |
|                            | <b>Max Value</b>                        | $2^{32}-1$                          |

Non-zero values protect against the [buffer pool](#) being filled by data that is referenced only for a brief period, such as during a [full table scan](#). Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

This configuration option is often used in combination with `innodb_old_blocks_pct`. For more information, see [Section 14.9.2.3, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the [LRU](#) algorithm, and [eviction](#) policies, see [Section 14.9.2.1, “The InnoDB Buffer Pool”](#).

- `innodb_open_files`

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-open-files=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                        | <code>innodb_open_files</code> |
|                            | <b>Variable Scope</b>              | Global                         |
|                            | <b>Dynamic Variable</b>            | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                        | integer                        |
|                            | <b>Default</b>                     | 300                            |
|                            | <b>Min Value</b>                   | 10                             |
|                            | <b>Max Value</b>                   | 4294967295                     |

This configuration option is only relevant if you use multiple [InnoDB tablespaces](#). It specifies the maximum number of `.ibd` files that MySQL can keep open at one time. The minimum value is 10. The default value is 300.

The file descriptors used for `.ibd` files are for InnoDB tables only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache.

- `innodb_print_all_deadlocks`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.5.30                                      |   |
| <b>Command-Line Format</b> | <code>--innodb-print-all-deadlocks=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>innodb_print_all_deadlocks</code> |
|                            | <b>Variable Scope</b>                       | Global                                  |
|                            | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                                 |
|                            | <b>Default</b>                              | <code>OFF</code>                        |

When this option is enabled, information about all [deadlocks](#) in InnoDB user transactions is recorded in the [mysqld error log](#). Otherwise, you see information about only the last deadlock, using the `SHOW ENGINE INNODB STATUS` command. An occasional InnoDB deadlock is not necessarily an issue, because InnoDB detects the condition immediately and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are occurring if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue [DML](#) or `SELECT ... FOR UPDATE` statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

For related information, see [Section 14.8.5, “Deadlocks in InnoDB”](#).

- `innodb_purge_batch_size`

|                                       |  |                                      |
|---------------------------------------|--|--------------------------------------|
| <b>Introduced</b>                     | 5.5.4                                    |                                      |
| <b>Command-Line Format</b>            | <code>--innodb-purge-batch-size=#</code> |                                      |
| <b>System Variable</b>                | <b>Name</b>                              | <code>innodb_purge_batch_size</code> |
|                                       | <b>Variable Scope</b>                    | Global                               |
|                                       | <b>Dynamic Variable</b>                  | Yes                                  |
| <b>Permitted Values (&gt;= 5.5.4)</b> | <b>Type</b>                              | integer                              |
|                                       | <b>Default</b>                           | <code>20</code>                      |
|                                       | <b>Min Value</b>                         | <code>1</code>                       |
|                                       | <b>Max Value</b>                         | <code>5000</code>                    |

Defines the number of undo log pages that purge parses and processes in one batch from the [history list](#). The `innodb_purge_batch_size` option also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The `innodb_purge_batch_size` option is intended for advanced performance tuning in combination with the `innodb_purge_threads` setting. Most MySQL users need not change `innodb_purge_batch_size` from its default value.

For related information, see [Section 14.9.10, “Configuring InnoDB Purge Scheduling”](#).

- `innodb_purge_threads`

|                                       |                                       |                                   |
|---------------------------------------|---------------------------------------|-----------------------------------|
| <b>Introduced</b>                     | 5.5.4                                 |                                   |
| <b>Command-Line Format</b>            | <code>--innodb-purge-threads=#</code> |                                   |
| <b>System Variable</b>                | <b>Name</b>                           | <code>innodb_purge_threads</code> |
|                                       | <b>Variable Scope</b>                 | Global                            |
|                                       | <b>Dynamic Variable</b>               | No                                |
| <b>Permitted Values (&gt;= 5.5.4)</b> | <b>Type</b>                           | integer                           |
|                                       | <b>Default</b>                        | 0                                 |
|                                       | <b>Min Value</b>                      | 0                                 |
|                                       | <b>Max Value</b>                      | 1                                 |

The number of background threads devoted to the [InnoDB purge](#) operation. Currently, can only be 0 (the default) or 1. The default value of 0 signifies that the purge operation is performed as part of the [master thread](#). Running the purge operation in its own thread can reduce internal contention within [InnoDB](#), improving scalability. Currently, the performance gain might be minimal because the background thread might encounter different kinds of contention than before. This feature primarily lays the groundwork for future performance work.

For related information, see [Section 14.9.10, “Configuring InnoDB Purge Scheduling”](#).

- `innodb_random_read_ahead`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Introduced</b>          | 5.5.16                                    |                                       |
| <b>Command-Line Format</b> | <code>--innodb-random-read-ahead=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_random_read_ahead</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | boolean                               |
|                            | <b>Default</b>                            | <code>OFF</code>                      |

Enables the random [read-ahead](#) technique for optimizing [InnoDB I/O](#). Random read-ahead functionality was removed from the [InnoDB Plugin](#) (version 1.0.4) and was therefore not included in MySQL 5.5.0 when [InnoDB Plugin](#) became the “built-in” version of [InnoDB](#). Random read-ahead was reintroduced in MySQL 5.1.59 and 5.5.16 and higher along with the `innodb_random_read_ahead` configuration option, which is disabled by default.

For details about performance considerations for different types of read-ahead requests, see [Section 14.9.2.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_ahead_threshold`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb-read-ahead-threshold=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_read_ahead_threshold</code> |
|                            | <b>Variable Scope</b>                        | Global                                   |
|                            | <b>Dynamic Variable</b>                      | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                  | integer                                  |
|                            | <b>Default</b>                               | 56                                       |
|                            | <b>Min Value</b>                             | 0  |
|                            | <b>Max Value</b>                             | 64                                       |

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#). If InnoDB reads at least `innodb_read_ahead_threshold` pages sequentially from an [extent](#) (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. The default is 56: InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the `innodb_read_ahead_threshold` setting. As of MySQL 5.5, `SHOW ENGINE INNODB STATUS` output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables, which report the number of pages brought into the [buffer pool](#) by read-ahead requests, and the number of such pages [evicted](#) from the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

`SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the [BUFFER POOL AND MEMORY](#) section of the `SHOW ENGINE INNODB STATUS` output.

For more information, see [Section 14.9.2.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_io_threads`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-read-io-threads=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_read_io_threads</code> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | No                                  |

|                  |           |         |
|------------------|-----------|---------|
| Permitted Values | Type      | integer |
|                  | Default   | 4       |
|                  | Min Value | 1       |
|                  | Max Value | 64      |

The number of I/O threads for read operations in [InnoDB](#). Its counterpart for write threads is [innodb\\_write\\_io\\_threads](#). For more information, see [Section 14.9.6, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for [innodb\\_read\\_io\\_threads](#), [innodb\\_write\\_io\\_threads](#), and the Linux [aio-max-nr](#) setting can exceed system limits. Ideally, increase the [aio-max-nr](#) setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

- [innodb\\_replication\\_delay](#)

|                     |   |  |
|---------------------|---|--|
| Command-Line Format | <code>--innodb-replication-delay=#</code> |  |
| System Variable     | Name                                      | <a href="#">innodb_replication_delay</a> |
|                     | Variable Scope                            | Global                                   |
|                     | Dynamic Variable                          | Yes                                      |
| Permitted Values    | Type                                      | integer                                  |
|                     | Default                                   | 0  |
|                     | Min Value                                 | 0  |
|                     | Max Value                                 | 4294967295                               |

The replication thread delay (in ms) on a slave server if [innodb\\_thread\\_concurrency](#) is reached.

- [innodb\\_rollback\\_on\\_timeout](#)

|                     |   |  |
|---------------------|---|--|
| Command-Line Format | <code>--innodb-rollback-on-timeout</code> |  |
| System Variable     | Name                                      | <a href="#">innodb_rollback_on_timeout</a> |
|                     | Variable Scope                            | Global                                     |
|                     | Dynamic Variable                          | No   |
| Permitted Values    | Type                                      | boolean                                    |
|                     | Default                                   | <a href="#">OFF</a>                        |

InnoDB **rolls back** only the last statement on a transaction timeout by default. If `--innodb_rollback_on_timeout` is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction (the same behavior as in MySQL 4.1).

#### Note

If the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

For more information, see [Section 14.23.4, “InnoDB Error Handling”](#).

- `innodb_rollback_segments`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Introduced</b>          | 5.5.11                                    |                                       |
| <b>Command-Line Format</b> | <code>--innodb-rollback-segments=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_rollback_segments</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 128                                   |
|                            | <b>Min Value</b>                          | 1                                     |
|                            | <b>Max Value</b>                          | 128                                   |

Defines how many of the **rollback segments** in the **system tablespace** are used for InnoDB transactions. You might reduce this value from its default of 128 if a smaller number of rollback segments performs better for your workload.

- `innodb_spin_wait_delay`

|  |   |                                     |
|--|---|-------------------------------------|
| <b>Command-Line Format</b>                 | <code>--innodb-spin-wait-delay=#</code> |                                     |
| <b>System Variable</b>                     | <b>Name</b>                             | <code>innodb_spin_wait_delay</code> |
|  | <b>Variable Scope</b>                   | Global                              |
|  | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 6                                   |
|  | <b>Min Value</b>                        | 0                                   |
|  | <b>Max Value</b>                        | $2^{32}-1$                          |

|  |                  |            |
|--|------------------|------------|
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer    |
|  | <b>Default</b>   | 6          |
|  | <b>Min Value</b> | 0          |
|  | <b>Max Value</b> | $2^{64}-1$ |

The maximum delay between polls for a [spin](#) lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. For more information, see [Section 14.9.9, “Configuring Spin Lock Polling”](#).

- [innodb\\_stats\\_method](#)

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Introduced</b>          | 5.5.10                                  |                                     |
| <b>Command-Line Format</b> | <code>--innodb-stats-method=name</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <a href="#">innodb_stats_method</a> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                             | enumeration                         |
|                            | <b>Default</b>                          | <a href="#">nulls_equal</a>         |
|                            | <b>Valid Values</b>                     | <a href="#">nulls_equal</a>         |
|                            |   | <a href="#">nulls_unequal</a>       |
|                            |   | <a href="#">nulls_ignored</a>       |

How the server treats [NULL](#) values when collecting [statistics](#) about the distribution of index values for [InnoDB](#) tables. Permitted values are [nulls\\_equal](#), [nulls\\_unequal](#), and [nulls\\_ignored](#). For [nulls\\_equal](#), all [NULL](#) index values are considered equal and form a single value group with a size equal to the number of [NULL](#) values. For [nulls\\_unequal](#), [NULL](#) values are considered unequal, and each [NULL](#) forms a distinct value group of size 1. For [nulls\\_ignored](#), [NULL](#) values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- [innodb\\_stats\\_on\\_metadata](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.5.4                                   |  |
| <b>Command-Line Format</b> | <code>--innodb-stats-on-metadata</code> |  |
| <b>System Variable</b>     | <b>Name</b>                             | <a href="#">innodb_stats_on_metadata</a> |
|                            | <b>Variable Scope</b>                   | Global                                   |
|                            | <b>Dynamic Variable</b>                 | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                             | boolean                                  |
|                            | <b>Default</b>                          | <a href="#">ON</a>                       |

When this option is enabled (the default), InnoDB updates [statistics](#) when metadata statements such as `SHOW TABLE STATUS` or `SHOW INDEX` are run, or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Disabling this variable can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of [execution plans](#) for queries that involve InnoDB tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing the setting requires the `SUPER` privilege and immediately affects the operation of all connections.

- `innodb_stats_sample_pages`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb-stats-sample-pages=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_stats_sample_pages</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |
|                            | <b>Default</b>                             | 8                                      |
|                            | <b>Min Value</b>                           | 1                                      |
|                            | <b>Max Value</b>                           | $2^{64}-1$                             |

The number of index pages to sample for index distribution [statistics](#) such as are calculated by `ANALYZE TABLE`. The default value is 8. For more information, see [Section 14.9.11, “Configuring Optimizer Statistics for InnoDB”](#).

Setting a high value for `innodb_stats_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see [Section 14.9.11.1, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

- `innodb_strict_mode`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-strict-mode=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>innodb_strict_mode</code> |
|                            | <b>Variable Scope</b>               | Global, Session                 |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | boolean                         |
|                            | <b>Default</b>                      | <code>OFF</code>                |

When `innodb_strict_mode` is enabled, InnoDB returns errors rather than warnings for certain conditions.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is enabled, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE` and `CREATE INDEX` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is disabled, InnoDB ignores conflicting clauses and creates the table or index with only a warning in the message log. The resulting table might have different characteristics than intended, such as lack of compression support when attempting to create a compressed table. When `innodb_strict_mode` is enabled, such problems generate an immediate error and the table or index is not created.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL [configuration file](#). You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where *mode* is either `ON` or `OFF`. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

- `innodb_support_xa`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-support-xa</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>innodb_support_xa</code> |
|                            | <b>Variable Scope</b>            | Global, Session                |
|                            | <b>Dynamic Variable</b>          | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | <code>TRUE</code>              |

Enables InnoDB support for two-phase commit in [XA](#) transactions, causing an extra disk flush for transaction preparation. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you disable `innodb_support_xa`, transactions can be written to the binary log in a different order than the live database is committing them, which can produce different data when the binary log is replayed in disaster recovery or on a replication slave. Do not disable `innodb_support_xa` on a replication master server unless you have an unusual setup where only one thread is able to change data.

For a server that is accepting data changes from only one thread, it is safe and recommended to disable this option to improve performance for InnoDB tables. For example, you can turn it off on replication slaves where only the replication SQL thread is changing data.

You can also disable this option if you do not need it for safe binary logging or replication, and you also do not use an external XA transaction manager.

- `innodb_sync_spin_loops`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-sync-spin-loops=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_sync_spin_loops</code> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                             |
|                            | <b>Default</b>                          | 30                                  |
|                            | <b>Min Value</b>                        | 0                                   |
|                            | <b>Max Value</b>                        | 4294967295                          |

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended.

- `innodb_table_locks`

|                            |                                   |                                 |
|----------------------------|-----------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-table-locks</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                       | <code>innodb_table_locks</code> |
|                            | <b>Variable Scope</b>             | Global, Session                 |
|                            | <b>Dynamic Variable</b>           | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean                         |
|                            | <b>Default</b>                    | TRUE                            |

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

As of MySQL 5.5.3, `innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It still has an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

For related information, see [Section 14.8, “InnoDB Locking and Transaction Model”](#).

- `innodb_thread_concurrency`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb-thread-concurrency=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_thread_concurrency</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |

|  |                  |      |
|--|------------------|------|
|  | <b>Default</b>   | 0    |
|  | <b>Min Value</b> | 0    |
|  | <b>Max Value</b> | 1000 |

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable (InnoDB uses operating system threads to process user transactions). Once the number of threads reaches this limit, additional threads are placed into a wait state within a “First In, First Out” (FIFO) queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The range of this variable is 0 to 1000. A value of 0 (the default) is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking enables InnoDB to create as many threads as it needs. A value of 0 also disables the `queries inside InnoDB` and `queries in queue counters` in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

Consider setting this variable if your MySQL instance shares CPU resources with other applications, or if your workload or number of concurrent users is growing. The correct setting depends on workload, computing environment, and the version of MySQL that you are running. You will need to test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which allows you to experiment with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is less than 64, set `innodb_thread_concurrency=0`.
- If your workload is consistently heavy or occasionally spikes, start by setting `innodb_thread_concurrency=128` and then lowering the value to 96, 80, 64, and so on, until you find the number of threads that provides the best performance. For example, suppose your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or even 200. You find that performance is stable at 80 concurrent users but starts to show a regression above this number. In this case, you would set `innodb_thread_concurrency=80` to avoid impacting performance.
- If you do not want InnoDB to use more than a certain number of vCPUs for user threads (20 vCPUs, for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance results). If your goal is to isolate MySQL from other applications, you may consider binding the `mysqld` process exclusively to the vCPUs. Be aware, however, that exclusive binding could result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you might bind the `mysqld` process to the vCPUs but also allow other applications to use some or all of the vCPUs.

#### Note

From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of vCPU time to a given application while other critical process *are not* running, and scale that value back to 40% when other critical processes *are* running.

- `innodb_thread_concurrency` values that are too high can cause performance regression due to increased contention on system internals and resources.

- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of vCPUs.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

For related information, see [Section 14.9.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_thread_sleep_delay`

|   |  |  |
|---|--|--|
| <b>Command-Line Format</b>                                | <code>--innodb-thread-sleep-delay=#</code> |  |
| <b>System Variable</b>                                    | <b>Name</b>                                | <code>innodb_thread_sleep_delay</code> |
|   | <b>Variable Scope</b>                      | Global                                 |
|   | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b> ( $\geq$ 5.5.37)                  | <b>Type</b>                                | integer                                |
|   | <b>Default</b>                             | 10000                                  |
|   | <b>Min Value</b>                           | 0                                      |
|   | <b>Max Value</b>                           | 1000000                                |
| <b>Permitted Values</b> (32-bit platforms, $\leq$ 5.5.36) | <b>Type</b>                                | integer                                |
|   | <b>Default</b>                             | 10000                                  |
|   | <b>Min Value</b>                           | 0                                      |
|   | <b>Max Value</b>                           | 4294967295                             |
| <b>Permitted Values</b> (64-bit platforms, $\leq$ 5.5.36) | <b>Type</b>                                | integer                                |
|   | <b>Default</b>                             | 10000                                  |
|   | <b>Min Value</b>                           | 0                                      |
|   | <b>Max Value</b>                           | 18446744073709551615                   |

Defines how long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is 10000. A value of 0 disables sleep.

For more information, see [Section 14.9.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_use_native_aio`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Introduced</b>          | 5.5.4                                  |                                    |
| <b>Command-Line Format</b> | <code>--innodb-use-native-aio=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>innodb_use_native_aio</code> |
|                            | <b>Variable Scope</b>                  | Global                             |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | ON      |

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

As of MySQL 5.5, the [asynchronous I/O](#) capability that [InnoDB](#) has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in [SHOW ENGINE INNODB STATUS\G](#) output.

Running with a large number of [InnoDB](#) I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents [InnoDB](#) from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if [InnoDB](#) detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support AIO on `tmpfs`.

For more information, see [Section 14.9.7, “Using Asynchronous I/O on Linux”](#).

- [innodb\\_trx\\_purge\\_view\\_update\\_only\\_debug](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--innodb-trx-purge-view-update-only-debug=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>  | <a href="#">innodb_trx_purge_view_update_only_debug</a> |
|                            | <b>Variable Scope</b>                                    | Global  |
|                            | <b>Dynamic Variable</b>                                  | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean   |
|                            | <b>Default</b>   | OFF   |

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the [WITH\\_DEBUG CMake](#) option.

- [innodb\\_trx\\_rseg\\_n\\_slots\\_debug](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--innodb-trx-rseg-n-slots-debug=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                    | <a href="#">innodb_trx_rseg_n_slots_debug</a> |
|                            | <b>Variable Scope</b>                          | Global  |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 0       |
|                         | <b>Max Value</b>        | 1024    |

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function that looks for free slots for undo log segments. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_use_sys_malloc`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-use-sys-malloc=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>innodb_use_sys_malloc</code> |
|                            | <b>Variable Scope</b>                  | Global                             |
|                            | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                            | boolean                            |
|                            | <b>Default</b>                         | ON                                 |

Enables the operating system memory allocator. If disabled, InnoDB uses its own allocator. The default value is `ON`. For more information, see [Section 14.9.3, “Configuring the Memory Allocator for InnoDB”](#).

- `innodb_version`

The InnoDB version number. Starting in MySQL 5.5.30, separate version numbering for InnoDB is discontinued and this value is the same the `version` number of the server.

- `innodb_write_io_threads`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-write-io-threads=#</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                              | <code>innodb_write_io_threads</code> |
|                            | <b>Variable Scope</b>                    | Global                               |
|                            | <b>Dynamic Variable</b>                  | No                                   |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer                              |
|                            | <b>Default</b>                           | 4                                    |
|                            | <b>Min Value</b>                         | 1                                    |
|                            | <b>Max Value</b>                         | 64                                   |

The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. For more information, see [Section 14.9.6, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

**Note**

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

Also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see [Section 8.5.7, “Optimizing InnoDB Disk I/O”](#).

## 14.18 InnoDB INFORMATION\_SCHEMA Tables

This section provides information and usage examples for `InnoDB INFORMATION_SCHEMA` tables.

`InnoDB INFORMATION_SCHEMA` tables provide metadata, status information, and statistics about various aspects of the `InnoDB` storage engine. You can view a list of `InnoDB INFORMATION_SCHEMA` tables by issuing a `SHOW TABLES` statement on the `INFORMATION_SCHEMA` database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see [Section 21.28, “InnoDB INFORMATION\\_SCHEMA Tables”](#). For general information regarding the `MySQL INFORMATION_SCHEMA` database, see [Chapter 21, INFORMATION\\_SCHEMA Tables](#).

The `InnoDB INFORMATION_SCHEMA` tables are themselves plugins to the MySQL server. To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table. Use `INSTALL PLUGIN` syntax to install an `INFORMATION_SCHEMA` table plugin. If `INFORMATION_SCHEMA` table plugins are installed, but the `InnoDB` storage engine plugin is not installed, the tables appear empty.

### 14.18.1 InnoDB INFORMATION\_SCHEMA Tables about Compression

There are two pairs of `InnoDB INFORMATION_SCHEMA` tables about compression that can provide insight into how well compression is working overall:

- `INNODB_CMP` and `INNODB_CMP_RESET` contain information about the number of compression operations and the amount of time spent performing compression.
- `INNODB_CMPMEM` and `INNODB_CMP_RESET` contain information about the way memory is allocated for compression.

#### 14.18.1.1 INNODB\_CMP and INNODB\_CMP\_RESET

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information about operations related to compressed tables, which are described in [Section 14.12, “InnoDB Table Compression”](#). The `PAGE_SIZE` column reports the compressed [page size](#).

These two tables have identical contents, but reading from `INNODB_CMP_RESET` resets the statistics on compression and uncompression operations. For example, if you archive the output of `INNODB_CMP_RESET` every 60 minutes, you see the statistics for each hourly period. If you monitor the output of `INNODB_CMP` (making sure never to read `INNODB_CMP_RESET`), you see the cumulated statistics since `InnoDB` was started.

For the table definition, see [Section 21.28.4](#), “The INFORMATION\_SCHEMA INNODB\_CMP and INNODB\_CMP\_RESET Tables”.

### 14.18.1.2 INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information about compressed pages that reside in the buffer pool. Please consult [Section 14.12](#), “InnoDB Table Compression” for further information on compressed tables and the use of the buffer pool. The `INNODB_CMP` and `INNODB_CMP_RESET` tables should provide more useful statistics on compression.

#### Internal Details

InnoDB uses a [buddy allocator](#) system to manage memory allocated to [pages of various sizes](#), from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables have identical contents, but reading from `INNODB_CMPMEM_RESET` resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of `INNODB_CMPMEM_RESET`, it would show the hourly statistics. If you never read `INNODB_CMPMEM_RESET` and monitored the output of `INNODB_CMPMEM` instead, it would show the cumulated statistics since InnoDB was started.

For the table definition, see [Section 21.28.5](#), “The INFORMATION\_SCHEMA INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET Tables”.

### 14.18.1.3 Using the Compression Information Schema Tables

#### Example 14.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 14.12](#), “InnoDB Table Compression”, `INNODB_CMP`, and `INNODB_CMPMEM`).

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMP` under a light [workload](#). The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

| page size | compress ops | compress ops ok | compress time | uncompress ops | uncompress time |
|-----------|--------------|-----------------|---------------|----------------|-----------------|
| 1024      | 0            | 0               | 0             | 0              | 0               |
| 2048      | 0            | 0               | 0             | 0              | 0               |
| 4096      | 0            | 0               | 0             | 0              | 0               |
| 8192      | 1048         | 921             | 0             | 61             | 0               |
| 16384     | 0            | 0               | 0             | 0              | 0               |

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the buffer pool.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light [workload](#). Some memory is unusable due to fragmentation of the InnoDB memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

| page size | pages used | pages free | relocation ops | relocation time |
|-----------|------------|------------|----------------|-----------------|
| 1024      | 0          | 0          | 0              | 0               |
| 2048      | 0          | 1          | 0              | 0               |
| 4096      | 0          | 1          | 0              | 0               |
| 8192      | 6169       | 0          | 5              | 0               |
| 16384     | 0          | 0          | 0              | 0               |

## 14.18.2 InnoDB INFORMATION\_SCHEMA Transaction and Locking Information

Three [InnoDB INFORMATION\\_SCHEMA](#) tables enable you to monitor transactions and diagnose potential locking problems:

- [INNODB\\_TRX](#): Contains information about every transaction currently executing inside [InnoDB](#), including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.
- [INNODB\\_LOCKS](#): Each transaction in [InnoDB](#) that is waiting for another transaction to release a lock ([INNODB\\_TRX.TRX\\_STATE](#) is [LOCK\\_WAIT](#)) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock that blocks a transaction is always held in a mode incompatible with the mode of requested lock (read vs. write, shared vs. exclusive). The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, [INNODB\\_LOCKS](#) contains one row that describes each lock the transaction has requested, and for which it is waiting. [INNODB\\_LOCKS](#) also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock ([INNODB\\_TRX.TRX\\_STATE](#) is [RUNNING](#), [LOCK\\_WAIT](#), [ROLLING\\_BACK](#) or [COMMITTING](#)).
- [INNODB\\_LOCK\\_WAITS](#): This table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The [REQUESTED\\_LOCK\\_ID](#) value refers to the lock requested by a transaction, and the [BLOCKING\\_LOCK\\_ID](#) value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in [INNODB\\_LOCK\\_WAITS](#) have the same value for [REQUESTED\\_LOCK\\_ID](#) and different values for [BLOCKING\\_LOCK\\_ID](#).

For more information about the preceding tables, see [Section 21.28.8, “The INFORMATION\\_SCHEMA INNODB\\_TRX Table”](#), [Section 21.28.6, “The INFORMATION\\_SCHEMA INNODB\\_LOCKS Table”](#), and [Section 21.28.7, “The INFORMATION\\_SCHEMA INNODB\\_LOCK\\_WAITS Table”](#).

### 14.18.2.1 Using InnoDB Transaction and Locking Information

#### Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about [InnoDB](#) transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see [Section 14.18.2, “InnoDB INFORMATION\\_SCHEMA Transaction and Locking Information”](#).)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- Session A:

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- Session B:

```
SELECT b FROM t FOR UPDATE;
```

- Session C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```
SELECT
  r.trx_id waiting_trx_id,
  r.trx_mysql_thread_id waiting_thread,
  r.trx_query waiting_query,
  b.trx_id blocking_trx_id,
  b.trx_mysql_thread_id blocking_thread,
  b.trx_query blocking_query
FROM   information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b
  ON b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r
  ON r.trx_id = w.requesting_trx_id;
```

| waiting<br>trx id | waiting<br>thread | waiting query                 | blocking<br>trx id | blocking<br>thread | blocking query                |
|-------------------|-------------------|-------------------------------|--------------------|--------------------|-------------------------------|
| A4                | 6                 | SELECT b FROM t FOR<br>UPDATE | A3                 | 5                  | SELECT SLEEP(100)             |
| A5                | 7                 | SELECT c FROM t FOR<br>UPDATE | A3                 | 5                  | SELECT SLEEP(100)             |
| A5                | 7                 | SELECT c FROM t FOR<br>UPDATE | A4                 | 6                  | SELECT b FROM t FOR<br>UPDATE |

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id [A4](#), thread [6](#)) and Session C (trx id [A5](#), thread [7](#)) are both waiting for Session A (trx id [A3](#), thread [5](#)).
- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the tables [INNODB\\_TRX](#), [INNODB\\_LOCKS](#), and [INNODB\\_LOCK\\_WAITS](#).

The following table shows some sample contents of [INFORMATION\\_SCHEMA.INNODB\\_TRX](#).

| trx<br>id | trx<br>state | trx started            | trx<br>requested<br>lock id | trx wait started       | trx<br>weight | trx mysql<br>thread id | trx query                     |
|-----------|--------------|------------------------|-----------------------------|------------------------|---------------|------------------------|-------------------------------|
| A3        | RUN-<br>NING | 2008-01-15<br>16:44:54 | NULL                        | NULL                   | 2             | 5                      | SELECT<br>SLEEP(100)          |
| A4        | LOCK<br>WAIT | 2008-01-15<br>16:45:09 | A4:1:3:2                    | 2008-01-15<br>16:45:09 | 2             | 6                      | SELECT b FROM t<br>FOR UPDATE |

| trx id | trx state    | trx started            | trx requested lock id | trx wait started       | trx weight | trx mysql thread id | trx query                     |
|--------|--------------|------------------------|-----------------------|------------------------|------------|---------------------|-------------------------------|
| A5     | LOCK<br>WAIT | 2008-01-15<br>16:45:14 | A5:1:3:2              | 2008-01-15<br>16:45:14 | 2          | 7                   | SELECT c FROM t<br>FOR UPDATE |

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCKS`.

| lock id  | lock trx id | lock mode | lock type | lock table | lock index | lock data |
|----------|-------------|-----------|-----------|------------|------------|-----------|
| A3:1:3:2 | A3          | X         | RECORD    | test.t     | PRIMARY    | 0x0200    |
| A4:1:3:2 | A4          | X         | RECORD    | test.t     | PRIMARY    | 0x0200    |
| A5:1:3:2 | A5          | X         | RECORD    | test.t     | PRIMARY    | 0x0200    |

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCK_WAITS`.

| requesting trx id | requested lock id | blocking trx id | blocking lock id |
|-------------------|-------------------|-----------------|------------------|
| A4                | A4:1:3:2          | A3              | A3:1:3:2         |
| A5                | A5:1:3:2          | A3              | A3:1:3:2         |
| A5                | A5:1:3:2          | A4              | A4:1:3:2         |

## Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal `InnoDB` locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given `InnoDB` transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the `INFORMATION_SCHEMA` tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables show that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D`, and `77B` to commit.
- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.
- Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.
- Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.
- Transaction `77A` is running, currently executing `SELECT`.
- Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.
- Transaction `E55` (executing an `INSERT`) is waiting for transaction `19C` to commit.
- Transaction `19C` is running, currently executing an `INSERT`.

### Note

There may be inconsistencies between queries shown in the `INFORMATION_SCHEMA.PROCESSLIST` and `INNODB_TRX` tables. For an explanation, see [Section 14.18.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

The following table shows the contents of `INFORMATION_SCHEMA.PROCESSLIST` for a system running a heavy [workload](#).

| ID  | USER | HOST      | DB   | COMMAND | TIME | STATE     | INFO                      |
|-----|------|-----------|------|---------|------|-----------|---------------------------|
| 384 | root | localhost | test | Query   | 10   | update    | INSERT INTO t2 VALUES ... |
| 257 | root | localhost | test | Query   | 3    | update    | INSERT INTO t2 VALUES ... |
| 130 | root | localhost | test | Query   | 0    | update    | INSERT INTO t2 VALUES ... |
| 61  | root | localhost | test | Query   | 1    | update    | INSERT INTO t2 VALUES ... |
| 8   | root | localhost | test | Query   | 1    | update    | INSERT INTO t2 VALUES ... |
| 4   | root | localhost | test | Query   | 0    | preparing | SELECT * FROM PROCESSLIST |
| 2   | root | localhost | test | Sleep   | 566  |           | NULL                      |

### 14.18.2.2 InnoDB Lock and Lock-Wait Information

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for

a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA.INNODB_TRX` table indicates transaction state values.)

The `INNODB_LOCKS` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The `INNODB_LOCK_WAITS` table shows which locks already held by a transaction are blocking locks requested by other transactions.

### 14.18.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

The data exposed by the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading joins between the transaction and locking tables, InnoDB collects the required transaction and locking information into an intermediate buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time “snapshot”. If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you join any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the `PROCESS` privilege are allowed to `SELECT` from them.

As described previously, the data that fills the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`) is fetched automatically and saved to an intermediate buffer that provides a “point-in-time” snapshot. The data across all three tables is consistent when queried from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. The data from the `PROCESSLIST` table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. `INNODB_TRX` may reference rows that are not present in `PROCESSLIST` or the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` may differ from the one in `PROCESSLIST.INFO`.

### 14.18.3 InnoDB INFORMATION\_SCHEMA Buffer Pool Tables

The InnoDB `INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the InnoDB buffer pool. The tables were introduced in MySQL 5.6.2 and later backported to MySQL 5.5 (in MySQL 5.5.28) and MySQL 5.1 (in MySQL 5.1.66).

The InnoDB `INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%) |
+-----+
| INNODB_BUFFER_PAGE_LRU                        |
| INNODB_BUFFER_PAGE                           |
| INNODB_BUFFER_POOL_STATS                     |
+-----+
```

## Table Overview

- **INNODB\_BUFFER\_PAGE**: Holds information about each page in the **InnoDB** buffer pool.
- **INNODB\_BUFFER\_PAGE\_LRU**: Holds information about the pages in the **InnoDB** buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The **INNODB\_BUFFER\_PAGE\_LRU** table has the same columns as the **INNODB\_BUFFER\_PAGE** table, except that the **INNODB\_BUFFER\_PAGE\_LRU** table has an **LRU\_POSITION** column instead of a **BLOCK\_ID** column.
- **INNODB\_BUFFER\_POOL\_STATS**: Provides buffer pool status information. Much of the same information is provided by **SHOW ENGINE INNODB STATUS** output, or may be obtained using **InnoDB** buffer pool server status variables.

### Warning

Querying the **INNODB\_BUFFER\_PAGE** table or **INNODB\_BUFFER\_PAGE\_LRU** table can introduce significant performance overhead. Do not query these tables on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

### Example 14.2 Querying System Data in the INNODB\_BUFFER\_PAGE Table

This query provides an approximate count of pages that contain system data by excluding pages where the **TABLE\_NAME** value is either **NULL** or includes a slash / or period . in the table name, which indicates a user-defined table.

```
SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| COUNT(*) |
+-----+
|      381 |
+-----+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
  ) AS system_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ROUND((system_pages/total_pages) * 100)
  ) AS system_page_percentage;
+-----+-----+-----+
| system_pages | total_pages | system_page_percentage |
```

|     |      |   |
|-----|------|---|
| 381 | 8192 | 5 |
|-----|------|---|

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

| PAGE_TYPE         |
|-------------------|
| IBUF_BITMAP       |
| SYSTEM            |
| INDEX             |
| UNDO_LOG          |
| FILE_SPACE_HEADER |
| UNKNOWN           |
| INODE             |
| EXTENT_DESCRIPTOR |

### Example 14.3 Querying User Data in the INNODB\_BUFFER\_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is `NOT NULL`.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL;
```

| COUNT(*) |
|----------|
| 7811     |

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```
mysql> SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
) AS user_pages,
(
SELECT COUNT(*)
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((user_pages/total_pages) * 100)
) AS user_page_percentage;
```

| user_pages | total_pages | user_page_percentage |
|------------|-------------|----------------------|
| 7811       | 8192        | 95                   |

This query identifies user-defined tables with pages in the buffer pool:

```
mysql> SELECT DISTINCT TABLE_NAME
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL
AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0);
```

| TABLE_NAME         |
|--------------------|
| employees/salaries |

```
| employees/employees |
+-----+
```

#### Example 14.4 Querying Index Data in the INNODB\_BUFFER\_PAGE Table

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, 16384, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)' FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = 'employees/salaries';
+-----+-----+-----+
| INDEX_NAME | Pages | Total Data (MB) |
+-----+-----+-----+
| emp_no     | 1244  | 19              |
+-----+-----+-----+
```

This query returns the number of pages and total data size of pages for all indexes defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, 16384, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = 'employees/salaries'
GROUP BY INDEX_NAME;
+-----+-----+-----+
| INDEX_NAME | Pages | Total Data (MB) |
+-----+-----+-----+
| emp_no     | 1244  | 19              |
| PRIMARY    | 6086  | 95              |
+-----+-----+-----+
```

#### Example 14.5 Querying LRU\_POSITION Data in the INNODB\_BUFFER\_PAGE\_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the `employees.employees` table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME='employees/employees' AND LRU_POSITION < 3072;
+-----+
| COUNT(LRU_POSITION) |
+-----+
| 481                  |
+-----+
```

#### Example 14.6 Querying the INNODB\_BUFFER\_POOL\_STATS Table

The `INNODB_BUFFER_POOL_STATS` table provides information similar to `SHOW ENGINE INNODB STATUS` and InnoDB buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
***** 1. row *****
      POOL_ID: 0
     POOL_SIZE: 8192
    FREE_BUFFERS: 1
   DATABASE_PAGES: 7942
  OLD_DATABASE_PAGES: 2911
```

```

MODIFIED_DATABASE_PAGES: 0
PENDING_DECOMPRESS: 0
PENDING_READS: 0
PENDING_FLUSH_LRU: 0
PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 8358
PAGES_NOT_MADE_YOUNG: 0
PAGES_MADE_YOUNG_RATE: 0
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 7045
NUMBER_PAGES_CREATED: 12382
NUMBER_PAGES_WRITTEN: 15790
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITTEN_RATE: 0
NUMBER_PAGES_GET: 28731589
HIT_RATE: 0
YOUNG_MAKE_PER_THOUSAND_GETS: 0
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 2934
NUMBER_READ_AHEAD_EVICTED: 23
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0

```

For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see [Section 14.20.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

```

mysql> SHOW ENGINE INNODB STATUS \G
...
-----
BUFFER POOL AND MEMORY
-----
Total memory allocated 137363456; in additional pool allocated 0
Dictionary memory allocated 71426
Buffer pool size      8192
Free buffers          1
Database pages        7942
Old database pages    2911
Modified db pages     0
Pending reads         0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 8358, not young 0
0.00 youngs/s, 0.00 non-youngs/s
Pages read 7045, created 12382, written 15790
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 7942, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...

```

For status variable descriptions, see [Section 5.1.7, “Server Status Variables”](#).

```

mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_pages_data | 7942 |
| Innodb_buffer_pool_bytes_data | 130121728 |
+-----+-----+

```

|                                       |          |
|---------------------------------------|----------|
| InnoDB_buffer_pool_pages_dirty        | 0        |
| InnoDB_buffer_pool_bytes_dirty        | 0        |
| InnoDB_buffer_pool_pages_flushed      | 15790    |
| InnoDB_buffer_pool_pages_free         | 1        |
| InnoDB_buffer_pool_pages_misc         | 249      |

## 14.19 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to [InnoDB](#) integration with Performance Schema. For comprehensive Performance Schema documentation, see [Chapter 22, MySQL Performance Schema](#).

Starting with InnoDB 1.1 with MySQL 5.5, you can profile certain internal [InnoDB](#) operations using the MySQL [Performance Schema feature](#). This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine [InnoDB](#) performance:

- You must be running MySQL 5.5 or higher with the Performance Schema feature available and enabled, as described in [Section 22.2, “Performance Schema Build Configuration”](#), and [Section 22.3, “Performance Schema Startup Configuration”](#). Since the Performance Schema feature introduces some performance overhead, you should use it on a test or development system rather than on a production system.
- You must be running InnoDB 1.1 or higher.
- You must be generally familiar with how to use the [Performance Schema feature](#). For example, you should know how enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see [Section 22.1, “Performance Schema Quick Start”](#).
- You should be familiar with Performance Schema instruments that are available for [InnoDB](#). To view [InnoDB](#)-related instruments, you can query the `setup_instruments` table for instrument names that contain 'innodb'.

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE '%innodb%';
```

| NAME   | ENABLED | TIMED |
|--|---------|-------|
| wait/synch/mutex/innodb/commit_cond_mutex        | YES     | YES   |
| wait/synch/mutex/innodb/innobase_share_mutex     | YES     | YES   |
| wait/synch/mutex/innodb/prepare_commit_mutex     | YES     | YES   |
| wait/synch/mutex/innodb/autoinc_mutex            | YES     | YES   |
| wait/synch/mutex/innodb/btr_search_enabled_mutex | YES     | YES   |
| wait/synch/mutex/innodb/buf_pool_mutex           | YES     | YES   |
| wait/synch/mutex/innodb/buf_pool_zip_mutex       | YES     | YES   |
| wait/synch/mutex/innodb/cache_last_read_mutex    | YES     | YES   |
| wait/synch/mutex/innodb/dict_foreign_err_mutex   | YES     | YES   |
| wait/synch/mutex/innodb/dict_sys_mutex           | YES     | YES   |
| wait/synch/mutex/innodb/file_format_max_mutex    | YES     | YES   |
| ...  |         |       |
| wait/synch/rwlock/innodb/btr_search_latch        | YES     | YES   |

|  |     |     |
|--|-----|-----|
| wait/synch/rwlock/innodb/dict_operation_lock | YES | YES |
| wait/synch/rwlock/innodb/file_space_latch    | YES | YES |
| wait/synch/rwlock/innodb/checkpoint_lock     | YES | YES |
| wait/synch/rwlock/innodb/trx_i_s_cache_lock  | YES | YES |
| wait/synch/rwlock/innodb/trx_purge_latch     | YES | YES |
| wait/synch/rwlock/innodb/index_tree_rw_lock  | YES | YES |
| wait/synch/rwlock/innodb/dict_table_stats    | YES | YES |
| wait/synch/cond/innodb/commit_cond           | YES | YES |
| wait/io/file/innodb/innodb_data_file         | YES | YES |
| wait/io/file/innodb/innodb_log_file          | YES | YES |
| wait/io/file/innodb/innodb_temp_file         | YES | YES |

-----+-----+-----

46 rows in set (0.00 sec)

For additional information about the instrumented [InnoDB](#) objects, you can query Performance Schema [instances tables](#), which provide additional information about instrumented objects. Instance tables relevant to [InnoDB](#) include:

- The [mutex\\_instances](#) table
- The [rwlock\\_instances](#) table
- The [cond\\_instances](#) table
- The [file\\_instances](#) table

#### Note

Mutexes and RW-locks related to the [InnoDB](#) buffer pool are not included in this coverage; the same applies to the output of the [SHOW ENGINE INNODB MUTEX](#) command.

For example, to view information about instrumented [InnoDB](#) file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```
mysql> SELECT * FROM file_instances WHERE EVENT_NAME LIKE '%innodb%'\G
***** 1. row *****
FILE_NAME: /path/to/mysql-5.5/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 1
***** 2. row *****
FILE_NAME: /path/to/mysql-5.5/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 1
***** 3. row *****
FILE_NAME: /path/to/mysql-5.5/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 1
```

- You should be familiar with [performance\\_schema](#) tables that store [InnoDB](#) event data. Tables relevant to [InnoDB](#)-related events include:
  - The [Wait Event](#) tables, which store wait events.
  - The [Summary](#) tables, which provide aggregated information for terminated events over time. Summary tables include [file I/O summary tables](#), which aggregate information about I/O operations.

If you are only interested in [InnoDB](#)-related objects, use the clause [WHERE EVENT\\_NAME LIKE '%innodb%'](#) or [WHERE NAME LIKE '%innodb%'](#) (as required) when querying these tables.

## 14.19.1 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For [InnoDB](#) mutexes that are instrumented, mutex waits can be monitored using [Performance Schema](#). Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to view [InnoDB](#) mutex wait instruments, how to verify that associated consumers are enabled, and how to query wait event data. It is assumed that Performance Schema was enabled at server startup. For information about enabling Performance Schema, see [Section 22.1, “Performance Schema Quick Start”](#).

1. To view available [InnoDB](#) mutex wait instruments, query the Performance Schema `setup_instruments` table, as shown below. Instruments are enabled by default.

```
mysql> SELECT * FROM performance_schema.setup_instruments
      -> WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

| NAME  | ENABLED | TIMED |
|---|---------|-------|
| wait/synch/mutex/innodb/commit_cond_mutex             | YES     | YES   |
| wait/synch/mutex/innodb/innobase_share_mutex          | YES     | YES   |
| wait/synch/mutex/innodb/prepare_commit_mutex          | YES     | YES   |
| wait/synch/mutex/innodb/autoinc_mutex                 | YES     | YES   |
| wait/synch/mutex/innodb/btr_search_enabled_mutex      | YES     | YES   |
| wait/synch/mutex/innodb/buf_pool_mutex                | YES     | YES   |
| wait/synch/mutex/innodb/buf_pool_zip_mutex            | YES     | YES   |
| wait/synch/mutex/innodb/cache_last_read_mutex         | YES     | YES   |
| wait/synch/mutex/innodb/dict_foreign_err_mutex        | YES     | YES   |
| wait/synch/mutex/innodb/dict_sys_mutex                | YES     | YES   |
| wait/synch/mutex/innodb/file_format_max_mutex         | YES     | YES   |
| wait/synch/mutex/innodb/fil_system_mutex              | YES     | YES   |
| wait/synch/mutex/innodb/flush_list_mutex              | YES     | YES   |
| wait/synch/mutex/innodb/log_flush_order_mutex         | YES     | YES   |
| wait/synch/mutex/innodb/hash_table_mutex              | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_bitmap_mutex             | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_mutex                    | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex | YES     | YES   |
| wait/synch/mutex/innodb/kernel_mutex                  | YES     | YES   |
| wait/synch/mutex/innodb/log_sys_mutex                 | YES     | YES   |
| wait/synch/mutex/innodb/mem_pool_mutex                | YES     | YES   |
| wait/synch/mutex/innodb/mutex_list_mutex              | YES     | YES   |
| wait/synch/mutex/innodb/purge_sys_bh_mutex            | YES     | YES   |
| wait/synch/mutex/innodb/recv_sys_mutex                | YES     | YES   |
| wait/synch/mutex/innodb/rseg_mutex                    | YES     | YES   |
| wait/synch/mutex/innodb/rw_lock_list_mutex            | YES     | YES   |
| wait/synch/mutex/innodb/rw_lock_mutex                 | YES     | YES   |
| wait/synch/mutex/innodb/srv_dict_tmpfile_mutex        | YES     | YES   |
| wait/synch/mutex/innodb/srv_innodb_monitor_mutex      | YES     | YES   |
| wait/synch/mutex/innodb/srv_misc_tmpfile_mutex        | YES     | YES   |
| wait/synch/mutex/innodb/srv_monitor_file_mutex        | YES     | YES   |
| wait/synch/mutex/innodb/syn_arr_mutex                 | YES     | YES   |
| wait/synch/mutex/innodb/trx_doublewrite_mutex         | YES     | YES   |
| wait/synch/mutex/innodb/trx_undo_mutex                | YES     | YES   |

```
34 rows in set (0.00 sec)
```

2. Verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled by default.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

| NAME   | ENABLED |
|--|---------|
| events_waits_current                         | YES     |
| events_waits_history                         | YES     |
| events_waits_history_long                    | YES     |
| events_waits_summary_by_thread_by_event_name | YES     |
| events_waits_summary_by_event_name           | YES     |
| events_waits_summary_by_instance             | YES     |
| file_summary_by_event_name                   | YES     |
| file_summary_by_instance                     | YES     |

8 rows in set (0.00 sec)

- Run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
-> --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

- Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

The number of summarized wait events.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed wait events.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed wait events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed wait events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
-> FROM performance_schema.events_waits_summary_global_by_event_name
-> WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
-> ORDER BY COUNT_STAR DESC;
```

| EVENT_NAME | COUNT_STAR | SUM_TIMER_WAIT_MS |
|------------|------------|-------------------|
|------------|------------|-------------------|

|   |        |           |
|---|--------|-----------|
| wait/synch/mutex/innodb/buf_pool_mutex                | 154477 | 6258.6407 |
| wait/synch/mutex/innodb/kernel_mutex                  | 54294  | 1747.1980 |
| wait/synch/mutex/innodb/log_sys_mutex                 | 40578  | 3167.6126 |
| wait/synch/mutex/innodb/dict_sys_mutex                | 34261  | 26.4183   |
| wait/synch/mutex/innodb/log_flush_order_mutex         | 24463  | 0.5867    |
| wait/synch/mutex/innodb/rseg_mutex                    | 18204  | 0.4750    |
| wait/synch/mutex/innodb/flush_list_mutex              | 15949  | 0.7182    |
| wait/synch/mutex/innodb/mutex_list_mutex              | 10439  | 0.2299    |
| wait/synch/mutex/innodb/file_system_mutex             | 9815   | 0.5027    |
| wait/synch/mutex/innodb/rw_lock_list_mutex            | 8292   | 0.1763    |
| wait/synch/mutex/innodb/trx_undo_mutex                | 6070   | 0.2339    |
| wait/synch/mutex/innodb/innobase_share_mutex          | 1994   | 0.0761    |
| wait/synch/mutex/innodb/file_format_max_mutex         | 1007   | 0.0245    |
| wait/synch/mutex/innodb/trx_doublewrite_mutex         | 387    | 0.0214    |
| wait/synch/mutex/innodb/recv_sys_mutex                | 186    | 0.0047    |
| wait/synch/mutex/innodb/ibuf_mutex                    | 121    | 0.0030    |
| wait/synch/mutex/innodb/purge_sys_bh_mutex            | 99     | 0.0033    |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex | 40     | 0.0011    |
| wait/synch/mutex/innodb/srv_innodb_monitor_mutex      | 3      | 0.0003    |

19 rows in set (0.00 sec)

**Note**

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the [events\\_waits\\_summary\\_global\\_by\\_event\\_name](#) table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

## 14.20 InnoDB Monitors

[InnoDB](#) monitors provide information about the [InnoDB](#) internal state. This information is useful for performance tuning.

### 14.20.1 InnoDB Monitor Types

There are four types of [InnoDB](#) monitors:

- The standard [InnoDB](#) Monitor displays the following types of information:
  - Work done by the main background thread
  - Semaphore waits
  - Data about the most recent foreign key and deadlock errors
  - Lock waits for transactions
  - Table and record locks held by active transactions
  - Pending I/O operations and related statistics
  - Insert buffer and adaptive hash index statistics
  - Redo log data
  - Buffer pool statistics

- Row operation data
- The [InnoDB Lock Monitor](#) prints additional lock information as part of the standard [InnoDB Monitor](#) output.
- The [InnoDB Tablespace Monitor](#) prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures.
- The [InnoDB Table Monitor](#) prints the contents of the [InnoDB](#) internal data dictionary.

For additional information about [InnoDB](#) table and tablespace monitors, see [Mark Leith: InnoDB Table and Tablespace Monitors](#).

## 14.20.2 Enabling InnoDB Monitors

When you enable [InnoDB](#) monitors for periodic output, [InnoDB](#) writes the output to the [mysqld](#) server standard error output ([stderr](#)). In this case, no output is sent to clients. When switched on, [InnoDB](#) monitors print data about every 15 seconds. Server output usually is directed to the error log (see [Section 5.4.2, “The Error Log”](#)). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

[InnoDB](#) sends diagnostic output to [stderr](#) or to files rather than to [stdout](#) or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. [InnoDB](#) removes the file when the server is shut down normally. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, examine them to see if they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is only created if the `innodb-status-file` configuration option is enabled. It is disabled by default.

[InnoDB](#) monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if you enable monitor output by creating the associated table, your error log may become quite large if you forget to remove the table later.

### Note

To assist with troubleshooting, [InnoDB](#) temporarily enables standard [InnoDB](#) Monitor output under certain conditions. For more information, see [Section 14.23, “InnoDB Troubleshooting”](#).

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
=====
141016 15:41:44 INNODB MONITOR OUTPUT
=====
```

The header for the standard [InnoDB](#) Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

Enabling an [InnoDB](#) monitor for periodic output involves using a `CREATE TABLE` statement to create a specially named [InnoDB](#) table that is associated with the monitor. For example, to enable the standard [InnoDB](#) Monitor, you would create an [InnoDB](#) table named `innodb_monitor`.

Using `CREATE TABLE` syntax is just a way to pass a command to the [InnoDB](#) engine through MySQL's SQL parser. The only things that matter are the table name and that it be an [InnoDB](#) table. The structure of the table is not relevant. If you shut down the server, the monitor does not restart automatically when

you restart the server. Drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor.

The `PROCESS` privilege is required to start or stop the `InnoDB` monitors.

### Enabling the Standard InnoDB Monitor

To enable the standard `InnoDB` Monitor for periodic output, create the `innodb_monitor` table:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To disable the standard `InnoDB` Monitor, drop the table:

```
DROP TABLE innodb_monitor;
```

### Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard `InnoDB` Monitor for periodic output, you can obtain standard `InnoDB` Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes `InnoDB` Lock Monitor data if the `InnoDB` Lock Monitor is enabled.

### Enabling the InnoDB Lock Monitor

To enable the `InnoDB` Lock Monitor for periodic output, create the `innodb_lock_monitor` table:

```
CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;
```

To disable the `InnoDB` Lock Monitor, drop the table:

```
DROP TABLE innodb_lock_monitor;
```

### Enabling the InnoDB Tablespace Monitor

To enable the `InnoDB` Tablespace Monitor for periodic output, create the `innodb_tablespace_monitor` table:

```
CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;
```

To disable the standard `InnoDB` Tablespace Monitor, drop the table:

```
DROP TABLE innodb_tablespace_monitor;
```

### Enabling the InnoDB Table Monitor

To enable the `InnoDB` Table Monitor for periodic output, create the `innodb_table_monitor` table:

```
CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;
```

To disable the `InnoDB` Table Monitor, drop the table:

```
DROP TABLE innodb_table_monitor;
```

### 14.20.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to server standard error output (`stderr`).

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
  Type: InnoDB
  Name:
  Status:
=====
141016 15:41:44 INNODB MONITOR OUTPUT

END OF INNODB MONITOR OUTPUT
=====

```

## Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the [Metrics](#) chapter in the [Oracle Enterprise Manager for MySQL Database User's Guide](#).

- [Status](#)

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time [InnoDB](#) Monitor output was printed.

- [BACKGROUND THREAD](#)

The `srv_master_thread` line shows work done by the main background thread.

- [SEMAPHORES](#)

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside [InnoDB](#). Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

- [LATEST FOREIGN KEY ERROR](#)

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

- [LATEST DETECTED DEADLOCK](#)

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction [InnoDB](#) decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 14.8.1, “InnoDB Locking”](#).

- [TRANSACTIONS](#)

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

- [FILE I/O](#)

This section provides information about threads that [InnoDB](#) uses to perform various types of I/O. The first few of these are dedicated to general [InnoDB](#) processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 14.17, “InnoDB Startup Options and System Variables”](#).

- [INSERT BUFFER AND ADAPTIVE HASH INDEX](#)

This section shows the status of the [InnoDB](#) insert buffer (also referred to as the [change buffer](#)) and the adaptive hash index.

For related information, see [Section 14.7.2, “Change Buffer”](#), and [Section 14.7.3, “Adaptive Hash Index”](#).

- [LOG](#)

This section displays information about the [InnoDB](#) log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which [InnoDB](#) last took a checkpoint. (See [Section 14.15.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

- [BUFFER POOL AND MEMORY](#)

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see [Section 14.9.2.6, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#). For additional information about the operation of the buffer pool, see [Section 14.9.2.1, “The InnoDB Buffer Pool”](#).

- [ROW OPERATIONS](#)

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

In MySQL 5.5, output from the standard [InnoDB Monitor](#) includes additional sections compared to the output for previous versions. For details, see [Diagnostic and Monitoring Capabilities](#).

## 14.20.4 InnoDB Tablespace Monitor Output

The [InnoDB Tablespace Monitor](#) prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. The Tablespace Monitor does not describe file-per-table tablespaces created with the `innodb_file_per_table` option.

Example [InnoDB Tablespace Monitor](#) output:

```
=====
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT

NUMBER of file segments: 73
Validating tablespace
Validation ok
-----
END OF INNODB TABLESPACE MONITOR OUTPUT
=====
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

In this example using the default [page size](#), the tablespace consists of database pages that are 16KB each. The pages are grouped into [extents](#) of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- [id](#)

The tablespace ID. A value of 0 refers to the shared tablespace.

- [size](#)

The current tablespace size in pages.

- [free limit](#)

The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.

- [free extents](#)

The number of free extents.

- [not full frag extents](#), [used pages](#)

The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.

- [full frag extents](#)

The number of completely full fragment extents.

- [first seg id not used](#)

The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0: pages 0
```

Segment information includes these values:

- [id](#)

The segment ID.

- [space](#), [page](#)

The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. InnoDB uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (`id`, `res`, and so forth) are derived from information in the inode.

- `res`

The number of pages allocated (reserved) for the segment.

- `used`

The number of allocated pages in use by the segment.

- `full ext`

The number of extents allocated for the segment that are completely used.

- `fragm pages`

The number of initial pages that have been allocated to the segment.

- `free extents`

The number of extents allocated for the segment that are completely unused.

- `not full extents`

The number of extents allocated for the segment that are partially used.

- `pages`

The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and InnoDB allocates the first pages for it one at a time, up to 32 pages (this is the `fragm pages` value). After that, InnoDB allocates complete extents. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
```

It is possible for a segment that has extents allocated to it to have a `fragm pages` value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

## 14.20.5 InnoDB Table Monitor Output

The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

The output contains one section per table. The `SYS_FOREIGN` and `SYS_FOREIGN_COLS` sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created InnoDB table. Suppose that the following two tables have been created in the `test` database:

```

CREATE TABLE parent
(
  par_id      INT NOT NULL,
  fname       CHAR(20),
  lname       CHAR(20),
  PRIMARY KEY (par_id),
  UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id      INT NOT NULL,
  child_id    INT NOT NULL,
  name        VARCHAR(40),
  birth       DATE,
  weight      DECIMAL(10,2),
  misc_info   VARCHAR(255),
  last_update TIMESTAMP,
  PRIMARY KEY (par_id, child_id),
  INDEX (name),
  FOREIGN KEY (par_id) REFERENCES parent (par_id)
    ON DELETE CASCADE
    ON UPDATE CASCADE
) ENGINE = INNODB;

```

Then the Table Monitor output will look something like this (reformatted slightly):

```

=====

END OF INNODB TABLE MONITOR OUTPUT
=====

```

For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in *db\_name/tbl\_name* format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The **COLUMNS** part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as **DB\_ROW\_ID** (row ID), **DB\_TRX\_ID** (transaction ID), and **DB\_ROLL\_PTR** (a pointer to the rollback/undo data).

- **DATA\_xxx**

These symbols indicate the data type. There may be multiple **DATA\_xxx** symbols for a given column.

- **prtype**

The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the [innobase/include/data0type.h](#) source file.

- **len**

The column length in bytes.

Each **INDEX** part of the table section provides the name and characteristics of one table index:

- `name`

The index name. If the name is `PRIMARY`, the index is a primary key. If the name is `GEN_CLUST_INDEX`, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-`NULL` unique index. See [Section 14.11.2.1, "Clustered and Secondary Indexes"](#).

- `id`

The index ID.

- `fields`

The number of fields in the index, as a value in `m/n` format:

- `m` is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.
- `n` is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.

- `uniq`

The number of leading fields that are enough to determine index values uniquely.

- `type`

The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a `type` value of 3. An index with a `type` value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.

- `root page`

The index root page number.

- `appr. key vals`

The approximate index cardinality.

- `leaf pages`

The approximate number of leaf pages in the index.

- `size pages`

The approximate total number of pages in the index.

- `FIELDS`

The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal `DB_ROW_ID` (row ID) field. `DB_TRX_ID` and `DB_ROLL_PTR` are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the `FOREIGN KEY` definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

## 14.21 InnoDB Backup and Recovery

This section covers topics related to [InnoDB](#) backup and recovery.

- For information about backup techniques applicable to [InnoDB](#), see [Section 14.21.1, “InnoDB Backup”](#).
- For information about point-in-time recovery, recovery from disk failure or corruption, and how [InnoDB](#) performs crash recovery, see [Section 14.21.2, “InnoDB Recovery”](#).

### 14.21.1 InnoDB Backup

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: [hot backup](#) with MySQL Enterprise Backup; [cold backup](#) by copying files while the MySQL server is shut down; [logical backup](#) with `mysqldump` for smaller data volumes or to record the structure of schema objects. Hot and cold backups are [physical backups](#) that copy actual data files, which can be used directly by the `mysql` server for faster restore.

#### Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including [InnoDB](#) tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying [InnoDB](#) tables, reads and writes to [InnoDB](#) can continue. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see [Section 25.2, “MySQL Enterprise Backup Overview”](#).

#### Cold Backups

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by [InnoDB](#) to manage its tables. Use the following procedure:

1. Perform a [slow shutdown](#) of the MySQL server and make sure that it stops without errors.
2. Copy all [InnoDB](#) data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all the `.frm` files for [InnoDB](#) tables to a safe place.
4. Copy all [InnoDB](#) log files (`ib_logfile` files) to a safe place.
5. Copy your `my.cnf` configuration file or files to a safe place.

#### Logical Backups Using `mysqldump`

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See [Section 7.3.1, “Establishing a Backup Policy”](#).

Replication works with [InnoDB](#) tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See [Section 14.22, “InnoDB and MySQL Replication”](#).

## 14.21.2 InnoDB Recovery

This section describes [InnoDB](#) recovery. Topics include:

- [Point-in-Time Recovery](#)
- [Recovery from Data Corruption or Disk Failure](#)
- [InnoDB Crash Recovery](#)

### Point-in-Time Recovery

To recover an [InnoDB](#) database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

### Recovery from Data Corruption or Disk Failure

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using [mysqlbinlog](#) and [mysql](#) to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the [CHECK TABLE](#) statement to check whether a table is corrupt, although [CHECK TABLE](#) naturally cannot detect every possible kind of corruption. You can use the Tablespace Monitor to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of [InnoDB](#) consistency problems, see [Section 14.23.2, “Forcing InnoDB Recovery”](#) for steps to start the instance in recovery mode, which permits you to dump the data.

### InnoDB Crash Recovery

To recover from a MySQL server crash, the only requirement is to restart the MySQL server. [InnoDB](#) automatically checks the logs and performs a roll-forward of the database to the present. [InnoDB](#) automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, [mysqld](#) displays output similar to this:

```
InnoDB: Log scan progressed past the checkpoint lsn 452854464
InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
InnoDB: Doing recovery: scanned up to log sequence number 457028695
InnoDB: 1 transaction(s) which must be rolled back or cleaned up
InnoDB: in total 990682 row operations to undo
InnoDB: Trx id counter is 500
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Progress in percents: 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21
22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45
46 47 48 49 50 51 52 53 54 55 56 57 58 59 60 61 62 63 64 65 66 67 68 69
70 71 72 73 74 75 76 77 78 79 80 81 82 83 84 85 86 87 88 89 90 91 92 93
```

```
94 95 96 97 98 99
InnoDB: Apply batch completed
InnoDB: Waiting for the background threads to start
InnoDB: Starting in background the rollback of uncommitted transactions
InnoDB: Rolling back trx with id 3B1, 990682 rows to undo
...
InnoDB: 5.5.55 started; log sequence number 457028695
...
./mysqld: ready for connections.
```

The [InnoDB crash recovery](#) process consists of several steps:

- [Redo log](#) application

Redo log application is the first step and is performed during initialization, before accepting any connections. If all changes are flushed from the [buffer pool](#) to the [tablespaces](#) ([ibdata\\*](#) and [\\*.ibd](#) files) at the time of the shutdown or crash, redo log application is skipped. [InnoDB](#) also skips redo log application if redo log files are missing at startup.

Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with [innodb\\_fast\\_shutdown](#) set to [0](#) or [1](#).

- [Roll back](#) of incomplete [transactions](#)

Incomplete transactions are any transactions that were active at the time of crash or [fast shutdown](#). The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start [InnoDB](#) with an [innodb\\_force\\_recovery](#) setting of [3](#) or greater. See [Section 14.23.2, “Forcing InnoDB Recovery”](#).

- [Change buffer](#) merge

Applying changes from the change buffer (part of the [system tablespace](#)) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- [Purge](#)

Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, [InnoDB](#) attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, [InnoDB](#) rolls back transactions that were not committed or in [XA PREPARE](#) state when the server crashed. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted [InnoDB](#) data, MySQL might refuse to start. In this case, see [Section 14.23.2, “Forcing InnoDB Recovery”](#).

For information about the binary log and [InnoDB](#) crash recovery, see [Section 5.4.4, “The Binary Log”](#).

## 14.22 InnoDB and MySQL Replication

MySQL replication works for [InnoDB](#) tables as it does for [MyISAM](#) tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an [InnoDB](#) table on the master to a [MyISAM](#) table on the slave. For more information see, [Section 17.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).

For information about setting up a new slave for a master, see [Section 17.1.1.8, “Setting Up Replication with Existing Data”](#). To make a new slave without taking down the master or an existing slave, use the [MySQL Enterprise Backup](#) product.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

**Replication and CASCADE.** Cascading actions for [InnoDB](#) tables on the master are replicated on the slave *only* if the tables sharing the foreign key relation use [InnoDB](#) on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the master using the following [CREATE TABLE](#) statements:

```
CREATE TABLE fc1 (
  i INT PRIMARY KEY,
  j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
  m INT PRIMARY KEY,
  n INT,
  FOREIGN KEY ni (n) REFERENCES fc1 (i)
    ON DELETE CASCADE
) ENGINE = InnoDB;
```

Suppose that the slave does not have [InnoDB](#) support enabled. If this is the case, then the tables on the slave are created, but they use the [MyISAM](#) storage engine, and the [FOREIGN KEY](#) option is ignored. Now we insert some rows into the tables on the master:

```
master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

At this point, on both the master and the slave, table [fc1](#) contains 2 rows, and table [fc2](#) contains 3 rows, as shown here:

```
master> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)
```

```

master> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+-----+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+-----+
3 rows in set (0.00 sec)

```

Now suppose that you perform the following `DELETE` statement on the master:

```

master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```

master> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 2 | 2 |
+-----+
1 row in set (0.00 sec)

```

However, the cascade does not propagate on the slave because on the slave the `DELETE` for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```

slave> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+-----+
3 rows in set (0.00 sec)

```

This difference is due to the fact that the cascading deletes are handled internally by the [InnoDB](#) storage engine, which means that none of the changes are logged.

## 14.23 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 5.4.2, “The Error Log”](#)). [Section B.3, “Server Error Codes and Messages”](#) provides troubleshooting information for some of the common InnoDB-specific errors that you may encounter.
- If the failure is related to a [deadlock](#), run with the `innodb_print_all_deadlocks` option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see [Section 14.8.5, “Deadlocks in InnoDB”](#).
- Issues relating to the InnoDB data dictionary include failed `CREATE TABLE` statements (orphan table files), inability to open InnoDB files, and `system cannot find the path specified` errors. For information about these sorts of problems and errors, see [Section 14.23.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Enable the InnoDB Monitors to obtain information about a problem (see [Section 14.20, “InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of InnoDB. If the problem is with locks, enable the Lock Monitor. If the problem is in creation of tables or other data dictionary operations, enable the Table Monitor to print the contents of the InnoDB internal data dictionary. To see tablespace information enable the Tablespace Monitor.

InnoDB temporarily enables standard InnoDB Monitor output under the following conditions:

- A long semaphore wait
- InnoDB cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

## 14.23.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for InnoDB I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

### Initialization Problems

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, delete all files created by InnoDB: all `ibdata` files and all `ib_logfile` files. If you already created some InnoDB tables, also delete the corresponding `.frm` files for these tables, and any `.ibd` files if you are using multiple tablespaces, from the MySQL database directories. Then try the InnoDB database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

### Runtime Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the [InnoDB](#) data file directory and the [InnoDB](#) log directory exist.
- Make sure `mysqld` has access rights to create files in those directories.
- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

## 14.23.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM tbl_name` statements or [InnoDB](#) background operations to crash or assert, or even cause [InnoDB](#) roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the [InnoDB](#) storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

### Warning

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start [InnoDB](#) and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on separate physical copy of your database. When forcing [InnoDB](#) recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into [B-trees](#) and other database structures.

As a safety measure, [InnoDB](#) prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

Lets the server run even if it detects a corrupt [page](#). Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (SRV\_FORCE\_NO\_BACKGROUND)

Prevents the [master thread](#) and any [purge threads](#) from running. If a crash would occur during the [purge](#) operation, this recovery value prevents it.

- 3 (SRV\_FORCE\_NO\_TRX\_UNDO)

Does not run transaction [rollbacks](#) after [crash recovery](#).

- 4 (SRV\_FORCE\_NO\_IBUF\_MERGE)

Prevents [insert buffer](#) merge operations. If they would cause a crash, does not do them. Does not calculate table [statistics](#). This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes.

- 5 (SRV\_FORCE\_NO\_UNDO\_LOG\_SCAN)

Does not look at [undo logs](#) when starting the database: [InnoDB](#) treats even incomplete transactions as committed. This value can permanently corrupt data files.

- 6 (SRV\_FORCE\_NO\_LOG\_REDO)

Does not do the [redo log](#) roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

You can [SELECT](#) from tables to dump them, or [DROP](#) or [CREATE](#) tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or [ALTER TABLE](#): kill the `mysqld` process and set [innodb\\_force\\_recovery](#) to 3 to bring the database up without the rollback, then [DROP](#) the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an [ORDER BY primary\\_key DESC](#) clause might be able to dump the portion of the table after the corrupted part.

If a high [innodb\\_force\\_recovery](#) value is required to start [InnoDB](#), there may be corrupted data structures that could cause complex queries (queries containing [WHERE](#), [ORDER BY](#), or other clauses) to fail. In this case, you may only be able to run basic [SELECT \\* FROM t](#) queries.

## 14.23.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored both in the [.frm](#) files, and in the [InnoDB data dictionary](#). If you move [.frm](#) files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting [InnoDB](#), see [Section 14.23.2, “Forcing InnoDB Recovery”](#) for information about manual recovery.

### CREATE TABLE Failure Due to Orphan Table

A symptom of an out-of-sync data dictionary is that a [CREATE TABLE](#) statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the [InnoDB](#) internal data dictionary, you have an orphan table inside the [InnoDB](#) tablespace files that has no corresponding [.frm](#) file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphan table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

## Cannot Open File Error

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open an InnoDB file:

```
ERROR 1016: Can't open file: 'child2.ibd'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphan `.frm` file without a corresponding table inside InnoDB. You can drop the orphan `.frm` file by deleting it manually.

## Orphan Temporary Tables

If MySQL exits in the middle of an `ALTER TABLE` operation, you may be left with an orphan temporary table that takes up space on your system. This section describes how to identify and remove orphan temporary tables.

Orphan temporary table names begin with an `#sql-` prefix (e.g., `#sql-540_3`). The accompanying `.frm` file has the same base name as the orphan temporary table.

### Note

If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan temporary table (it must have the same columns and indexes) and must be placed in the database directory of the orphan temporary table.

To identify orphan temporary tables on your system, you can view [Table Monitor](#) output. Look for table names that begin with `#sql`. If the original table resides in a [file-per-table](#) tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan temporary table should be visible in the database directory.

To remove an orphan temporary table, drop the table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-540_3`;
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as “#”.

## Tablespace Does Not Exist

With `innodb_file_per_table` enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,  
InnoDB: but tablespace with that id or name does not exist. Have  
InnoDB: you deleted or moved .ibd files?  
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE  
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the  
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.
2. Issue `DROP TABLE` for the original table. That should successfully drop the table and InnoDB should print a warning to the error log that the `.ibd` file was missing.

## 14.23.4 InnoDB Error Handling

The following items describe how InnoDB performs error handling. InnoDB sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a `tablespace`, a MySQL `Table is full` error occurs and InnoDB rolls back the SQL statement.
- A transaction `deadlock` causes InnoDB to `roll back` the entire `transaction`. Retry the whole transaction when this happens.

A lock wait timeout causes InnoDB to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.

- Other errors are mostly detected by the MySQL layer of code (above the [InnoDB](#) storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit [ROLLBACK](#) SQL statement, [SHOW PROCESSLIST](#) displays [Rolling back](#) in the [State](#) column for the relevant connection.

---

Storage engines are MySQL components that handle the SQL operations for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle nontransaction-safe tables. [InnoDB](#) is the default storage engine as of MySQL 5.5.5 (The [CREATE TABLE](#) statement in MySQL 5.5 creates [InnoDB](#) tables by default.)

MySQL uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the [SHOW ENGINES](#) statement. The value in the [Support](#) column indicates whether an engine can be used. A value of [YES](#), [NO](#), or [DEFAULT](#) indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
      XA: NO
  Savepoints: NO
***** 2. row *****
  Engine: InnoDB
```

```
Support: DEFAULT
Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
XA: YES
Savepoints: YES
***** 3. row *****
Engine: MRG_MYISAM
Support: YES
Comment: Collection of identical MyISAM tables
Transactions: NO
XA: NO
Savepoints: NO
***** 4. row *****
Engine: BLACKHOLE
Support: YES
Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
XA: NO
Savepoints: NO
***** 5. row *****
Engine: MyISAM
Support: YES
Comment: MyISAM storage engine
Transactions: NO
XA: NO
Savepoints: NO
...
```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default [InnoDB](#) storage engine or the [NDB](#) storage engine which are covered in [Chapter 14, The InnoDB Storage Engine](#) and [Chapter 18, MySQL NDB Cluster 7.2](#). For advanced users, this chapter also contains a description of the pluggable storage engine architecture (see [Section 15.2, “Overview of MySQL Storage Engine Architecture”](#)).

For information about storage engine support offered in commercial MySQL Server binaries, see [MySQL Enterprise Server 5.5](#), on the MySQL Web site. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to some commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 5.5 FAQ: Storage Engines”](#).

## MySQL 5.5 Supported Storage Engines

- **InnoDB**: The default storage engine as of MySQL 5.5.5. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints. For more information about [InnoDB](#), see [Chapter 14, The InnoDB Storage Engine](#).
- **MyISAM**: The MySQL storage engine that is used the most in Web, data warehousing, and other application environments. [MyISAM](#) is supported in all MySQL configurations, and is the default storage engine prior to MySQL 5.5.5.
- **Memory**: Stores all data in RAM for extremely fast access in environments that require quick lookups of reference and other like data. This engine was formerly known as the [HEAP](#) engine.
- **Merge**: Enables a MySQL DBA or developer to logically group a series of identical [MyISAM](#) tables and reference them as one object. Good for VLDB environments such as data warehousing.

- **Archive:** Provides the perfect solution for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- **Federated:** Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- **NDB** (also known as **NDBCLUSTER**)—This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.

#### Note

The **NDB** storage engine is not supported in standard MySQL 5.5 releases. Currently supported NDB Cluster releases include MySQL NDB Cluster 7.0 and MySQL NDB Cluster 7.1, which are based on MySQL 5.1, and MySQL NDB Cluster 7.2, which is based on MySQL 5.5. While based on MySQL Server, these releases also contain support for **NDB**.

- **CSV:** The CSV storage engine stores data in text files using comma-separated values format. You can use the CSV engine to easily exchange data between other software and applications that can import and export in CSV format.
- **Blackhole:** The Blackhole storage engine accepts but does not store data and retrievals always return an empty set. The functionality can be used in distributed database design where data is automatically replicated, but not stored locally.
- **Example:** The Example storage engine is “stub” engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

It is important to remember that you are not restricted to using the same storage engine for an entire server or schema: you can use a different storage engine for each table in your schema.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. To use the pluggable storage architecture effectively, it is good to have an idea of the advantages and disadvantages of the various storage engines. The following table provides an overview of some storage engines provided with MySQL:

**Table 15.1 Storage Engines Feature Summary**

| Feature                      | MyISAM | Memory | InnoDB           | Archive | NDB   |
|------------------------------|--------|--------|------------------|---------|-------|
| Storage limits               | 256TB  | RAM    | 64TB             | None    | 384EB |
| Transactions                 | No     | No     | Yes              | No      | Yes   |
| Locking granularity          | Table  | Table  | Row              | Row     | Row   |
| MVCC                         | No     | No     | Yes              | No      | No    |
| Geospatial data type support | Yes    | No     | Yes              | Yes     | Yes   |
| Geospatial indexing support  | Yes    | No     | Yes <sup>a</sup> | No      | No    |

| Feature                                      | MyISAM           | Memory | InnoDB           | Archive | NDB              |
|--|------------------|--------|------------------|---------|------------------|
| B-tree indexes                               | Yes              | Yes    | Yes              | No      | No               |
| T-tree indexes                               | No               | No     | No               | No      | Yes              |
| Hash indexes                                 | No               | Yes    | No <sup>b</sup>  | No      | Yes              |
| Full-text search indexes                     | Yes              | No     | Yes <sup>c</sup> | No      | No               |
| Clustered indexes                            | No               | No     | Yes              | No      | No               |
| Data caches                                  | No               | N/A    | Yes              | No      | Yes              |
| Index caches                                 | Yes              | N/A    | Yes              | No      | Yes              |
| Compressed data                              | Yes <sup>d</sup> | No     | Yes <sup>e</sup> | Yes     | No               |
| Encrypted data <sup>f</sup>                  | Yes              | Yes    | Yes              | Yes     | Yes              |
| Cluster database support                     | No               | No     | No               | No      | Yes              |
| Replication support <sup>g</sup>             | Yes              | Yes    | Yes              | Yes     | Yes              |
| Foreign key support                          | No               | No     | Yes              | No      | Yes <sup>h</sup> |
| Backup / point-in-time recovery <sup>i</sup> | Yes              | Yes    | Yes              | Yes     | Yes              |
| Query cache support                          | Yes              | Yes    | Yes              | Yes     | Yes              |
| Update statistics for data dictionary        | Yes              | Yes    | Yes              | Yes     | Yes              |

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and later.

<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and later.

<sup>d</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>e</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>f</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

<sup>g</sup>Implemented in the server, rather than in the storage engine.

<sup>h</sup>Support for foreign keys is available in MySQL Cluster NDB 7.3 and later.

<sup>i</sup>Implemented in the server, rather than in the storage engine.

## 15.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an [ENGINE](#) table option to the [CREATE TABLE](#) statement:

```
-- ENGINE=INNODB not needed as of 5.5.5 unless you have set a
-- different default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

If you omit the [ENGINE](#) option, the default storage engine is used. The default engine is [InnoDB](#) as of MySQL 5.5.5 ([MyISAM](#) before 5.5.5). You can specify the default engine by using the [--default-storage-engine](#) server startup option, or by setting the [default-storage-engine](#) option in the [my.cnf](#) configuration file.

You can set the default storage engine to be used during the current session by setting the [default\\_storage\\_engine](#) variable:

```
SET default_storage_engine=MYISAM;
```

When MySQL is installed on Windows using the MySQL Configuration Wizard, the [InnoDB](#) or [MyISAM](#) storage engine can be selected as the default. See [Section 2.3.6.5, “The Database Usage Dialog”](#).

To convert a table from one storage engine to another, use an [ALTER TABLE](#) statement that indicates the new engine:

```
ALTER TABLE t ENGINE = MYISAM;
```

See [Section 13.1.17, “CREATE TABLE Syntax”](#), and [Section 13.1.7, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only nontransactional storage engines for greater speed.)

This automatic substitution of the default storage engine for unavailable engines can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed. To prevent this from happening if the desired engine is unavailable, enable the [NO\\_ENGINE\\_SUBSTITUTION](#) SQL mode. In this case, an error occurs instead of a warning and the table is not created or altered if the desired engine is unavailable. See [Section 5.1.8, “Server SQL Modes”](#).

For new tables, MySQL always creates an [.frm](#) file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the [.frm](#) file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

A database may contain tables of different types. That is, tables need not all be created with the same storage engine.

## 15.2 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

### 15.2.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

#### Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

#### Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

## 15.2.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

## 15.3 The MyISAM Storage Engine

Before MySQL 5.5.5, [MyISAM](#) is the default storage engine. (The default was changed to [InnoDB](#) in MySQL 5.5.5.) [MyISAM](#) is based on the older (and no longer available) [ISAM](#) storage engine but has many useful extensions.

**Table 15.2 [MyISAM](#) Storage Engine Features**

|                       |       |                     |    |                            |       |
|-----------------------|-------|---------------------|----|----------------------------|-------|
| <b>Storage limits</b> | 256TB | <b>Transactions</b> | No | <b>Locking granularity</b> | Table |
|-----------------------|-------|---------------------|----|----------------------------|-------|

|  |     |  |                  |  |     |
|--|-----|--|------------------|--|-----|
| <b>MVCC</b>  | No  | <b>Geospatial data type support</b>    | Yes              | <b>Geospatial indexing support</b>           | Yes |
| <b>B-tree indexes</b>                              | Yes | <b>T-tree indexes</b>                  | No               | <b>Hash indexes</b>                          | No  |
| <b>Full-text search indexes</b>                    | Yes | <b>Clustered indexes</b>               | No               | <b>Data caches</b>                           | No  |
| <b>Index caches</b>                                | Yes | <b>Compressed data</b>                 | Yes <sup>a</sup> | <b>Encrypted data<sup>b</sup></b>            | Yes |

<sup>a</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>b</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

<sup>d</sup>Implemented in the server, rather than in the storage engine.

Each [MyISAM](#) table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` ([MYData](#)) extension. The index file has an `.MYI` ([MYIndex](#)) extension.

To specify explicitly that you want a [MyISAM](#) table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

As of MySQL 5.5.5, it is normally necessary to use `ENGINE` to specify the [MyISAM](#) storage engine because [InnoDB](#) is the default engine. Before 5.5.5, this is unnecessary because [MyISAM](#) is the default engine unless the default has been changed. To ensure that [MyISAM](#) is used in situations where the default might have been changed, include the `ENGINE` option explicitly.

You can check or repair [MyISAM](#) tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress [MyISAM](#) tables with `myisampack` to take up much less space. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), and [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

[MyISAM](#) tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of  $(2^{32})^2$  (1.844E+19) rows in a [MyISAM](#) table.
- The maximum number of indexes per [MyISAM](#) table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one `AUTO_INCREMENT` column per table is supported. `MyISAM` automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 8.11.3, “Concurrent Inserts”](#).
- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 13.1.17, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Section 10.1, “Character Set Support”](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover-options` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

- A forum dedicated to the [MyISAM](http://forums.mysql.com/list.php?21) storage engine is available at <http://forums.mysql.com/list.php?21>.

### 15.3.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of [MyISAM](#) tables. For additional information, see [Section 5.1.4, “Server Command Options”](#).

**Table 15.3** [MyISAM](#) Option/Variable Reference

| Name  | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|---|----------|-------------|------------|------------|-----------|---------|
| <a href="#">bulk_insert_buffer_size</a>               | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">concurrent_insert</a>                     | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">delay-key-write</a>                       | Yes      | Yes         |            |            | Global    | Yes     |
| - Variable:<br><a href="#">delay_key_write</a>        |          |             | Yes        |            | Global    | Yes     |
| <a href="#">have_rtree_keys</a>                       |          |             | Yes        |            | Global    | No      |
| <a href="#">key_buffer_size</a>                       | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">log-isam</a>                              | Yes      | Yes         |            |            |           |         |
| <a href="#">myisam-block-size</a>                     | Yes      | Yes         |            |            |           |         |
| <a href="#">myisam_data_pointer_size</a>              | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">myisam_max_sort_size</a>                  | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">myisam_mmap_size</a>                      | Yes      | Yes         | Yes        |            | Global    | No      |
| <a href="#">myisam-recover</a>                        | Yes      | Yes         |            |            |           |         |
| - Variable:<br><a href="#">myisam_recover_options</a> |          |             |            |            |           |         |
| <a href="#">myisam-recover-options</a>                | Yes      | Yes         |            |            |           |         |
| - Variable:<br><a href="#">myisam_recover_options</a> |          |             |            |            |           |         |
| <a href="#">myisam_recover_options</a>                |          |             | Yes        |            | Global    | No      |
| <a href="#">myisam_repair_threads</a>                 | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_sort_buffer_size</a>               | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_stats_method</a>                   | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_use_mmap</a>                       | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">skip-concurrent-insert</a>                | Yes      | Yes         |            |            |           |         |
| - Variable:<br><a href="#">concurrent_insert</a>      |          |             |            |            |           |         |
| <a href="#">tmp_table_size</a>                        | Yes      | Yes         | Yes        |            | Both      | Yes     |

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed [MyISAM](#) tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any [MyISAM](#) table.

**Note**

If you do this, you should not access [MyISAM](#) tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of [MyISAM](#) tables. For additional information, see [Section 5.1.5, “Server System Variables”](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization.

**Note**

This is a limit *per thread*!

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a [MyISAM](#) table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

## 15.3.2 Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as  $(key\_length + 4) / 0.67$ , summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 15.3.3 MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 13.1.17, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed `MyISAM` tables using `myisamchk --unpack`; see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

### 15.3.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for `MyISAM` tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three `MyISAM` storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format `MyISAM` file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. `MyISAM` table indexes can always be reconstructed based on the data rows.

#### Note

Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.
- The expected row length in bytes for static-sized rows is calculated using the following expression:

```
row length = 1
             + (sum of column lengths)
             + (number of NULL columns + delete_flag + 7) / 8
             + (number of variable-length columns)
```

`delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

### 15.3.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a `MyISAM` table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.

- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```

3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8

```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 15.3.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

#### Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For

example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

### 15.3.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

#### 15.3.4.1 Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), [Section 13.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 24.5, “Debugging and Porting MySQL”](#).

#### 15.3.4.2 Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

## 15.4 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

**Table 15.4** `MEMORY` Storage Engine Features

|  |     |  |     |  |       |
|--|-----|--|-----|--|-------|
| <b>Storage limits</b>                              | RAM | <b>Transactions</b>                    | No  | <b>Locking granularity</b>                   | Table |
| <b>MVCC</b>  | No  | <b>Geospatial data type support</b>    | No  | <b>Geospatial indexing support</b>           | No    |
| <b>B-tree indexes</b>                              | Yes | <b>T-tree indexes</b>                  | No  | <b>Hash indexes</b>                          | Yes   |
| <b>Full-text search indexes</b>                    | No  | <b>Clustered indexes</b>               | No  | <b>Data caches</b>                           | N/A   |
| <b>Index caches</b>                                | N/A | <b>Compressed data</b>                 | No  | <b>Encrypted data<sup>a</sup></b>            | Yes   |
| <b>Cluster database support</b>                    | No  | <b>Replication support<sup>b</sup></b> | Yes | <b>Foreign key support</b>                   | No    |
| <b>Backup / point-in-time recovery<sup>c</sup></b> | Yes | <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes   |

<sup>a</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

**When to Use MEMORY or NDB Cluster.** Developers looking to deploy applications that use the [MEMORY](#) storage engine for important, highly available, or frequently updated data should consider whether NDB Cluster is a better choice. A typical use case for the [MEMORY](#) engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in [MEMORY](#) tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

NDB Cluster offers the same features as the [MEMORY](#) engine with higher performance levels, and provides additional features not available with [MEMORY](#):

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including [BLOB](#) and [TEXT](#)) not supported by [MEMORY](#).

## Performance Characteristics

[MEMORY](#) performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for [MEMORY](#) tables, they are not necessarily faster than [InnoDB](#) tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of [MEMORY](#) tables from multiple sessions.

Depending on the kinds of queries performed on a [MEMORY](#) table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

## Physical Characteristics of MEMORY Tables

The [MEMORY](#) storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of `.frm`.

[MEMORY](#) tables have the following characteristics:

- Space for [MEMORY](#) tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. [MEMORY](#) tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- [MEMORY](#) tables use a fixed-length row-storage format. Variable-length types such as [VARCHAR](#) are stored using a fixed length.
- [MEMORY](#) tables cannot contain [BLOB](#) or [TEXT](#) columns.
- [MEMORY](#) includes support for [AUTO\\_INCREMENT](#) columns.
- Non-[TEMPORARY MEMORY](#) tables are shared among all clients, just like any other non-[TEMPORARY](#) table.

## DDL Operations for MEMORY Tables

To create a [MEMORY](#) table, specify the clause [ENGINE=MEMORY](#) on the [CREATE TABLE](#) statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, [MEMORY](#) tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in [MEMORY](#) tables are lost. The tables themselves continue to exist because their definitions are stored in [.frm](#) files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a [MEMORY](#) table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
->     SELECT ip,SUM(downloads) AS down
->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of [MEMORY](#) tables is limited by the [max\\_heap\\_table\\_size](#) system variable, which has a default value of 16MB. To enforce different size limits for [MEMORY](#) tables, change the value of this variable. The value in effect for [CREATE TABLE](#), or a subsequent [ALTER TABLE](#) or [TRUNCATE TABLE](#), is the value used for the life of the table. A server restart also sets the maximum size of existing [MEMORY](#) tables to the global [max\\_heap\\_table\\_size](#) value. You can set the size for individual tables as described later in this section.

## Indexes

The [MEMORY](#) storage engine supports both [HASH](#) and [BTREE](#) indexes. You can specify one or the other for a given index by adding a [USING](#) clause as shown here:

```
CREATE TABLE lookup
(id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

[MEMORY](#) tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a [MEMORY](#) table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a [BTREE](#) index to avoid this problem.

[MEMORY](#) tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain [NULL](#) values.

## User-Created and Temporary Tables

[MEMORY](#) table contents are stored in memory, which is a property that [MEMORY](#) tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that [MEMORY](#) tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).
- User-created [MEMORY](#) tables are never converted to disk tables.

## Loading Data

To populate a [MEMORY](#) table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.1.4, “Server Command Options”](#), and [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

For loading data into [MEMORY](#) tables accessed by other sessions concurrently, [MEMORY](#) supports [INSERT DELAYED](#). See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#).

## MEMORY Tables and Replication

A server's [MEMORY](#) tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave [MEMORY](#) tables, when a [MEMORY](#) table is used on a master for the first time since it was started, a `DELETE` statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the [MEMORY](#) table on the master at startup.

## Managing Memory Use

The server needs sufficient memory to maintain all [MEMORY](#) tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a [MEMORY](#) table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a [MEMORY](#) table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a [MEMORY](#) table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

## Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

## 15.5 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
```

```
Records: 2  Duplicates: 0  Warnings: 0
```

```
mysql> SELECT * FROM test;
```

```
+-----+-----+
| i      | c          |
+-----+-----+
|      1 | record one |
|      2 | record two |
+-----+-----+
2 rows in set (0.00 sec)
```

Creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

## 15.5.1 Repairing and Checking CSV Tables

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
```

```
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check   | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
```

```
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check   | error    | Corrupt  |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
```

```
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check   | warning  | Table is marked as crashed |
| test.csvtest | check   | status   | OK       |
+-----+-----+-----+-----+
```

```
+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use [REPAIR](#), this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+
| test.csvtest | repair | status   | OK       |
+-----+
1 row in set (0.02 sec)
```

### Warning

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

## 15.5.2 CSV Limitations

The [CSV](#) storage engine does not support indexing.

Partitioning is not supported for tables using the [CSV](#) storage engine.

All tables that you create using the [CSV](#) storage engine must have the [NOT NULL](#) attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

## 15.6 The ARCHIVE Storage Engine

The [ARCHIVE](#) storage engine is used for storing large amounts of data without indexes in a very small footprint.

**Table 15.5 [ARCHIVE](#) Storage Engine Features**

|  |      |  |     |  |     |
|--|------|--|-----|--|-----|
| <b>Storage limits</b>                              | None | <b>Transactions</b>                    | No  | <b>Locking granularity</b>                   | Row |
| <b>MVCC</b>  | No   | <b>Geospatial data type support</b>    | Yes | <b>Geospatial indexing support</b>           | No  |
| <b>B-tree indexes</b>                              | No   | <b>T-tree indexes</b>                  | No  | <b>Hash indexes</b>                          | No  |
| <b>Full-text search indexes</b>                    | No   | <b>Clustered indexes</b>               | No  | <b>Data caches</b>                           | No  |
| <b>Index caches</b>                                | No   | <b>Compressed data</b>                 | Yes | <b>Encrypted data<sup>a</sup></b>            | Yes |
| <b>Cluster database support</b>                    | No   | <b>Replication support<sup>b</sup></b> | Yes | <b>Foreign key support</b>                   | No  |
| <b>Backup / point-in-time recovery<sup>c</sup></b> | Yes  | <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes |

<sup>a</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

The [ARCHIVE](#) storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke [CMake](#) with the [-DWITH\\_ARCHIVE\\_STORAGE\\_ENGINE](#) option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with the `SHOW ENGINES` statement.

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 11.5.1, “Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

The `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

`ARCHIVE` does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading.

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#).
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#), [Section 13.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 13.7.5.37, “SHOW TABLE STATUS Syntax”](#).

## Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

## 15.7 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the [BLACKHOLE](#) storage engine if you build MySQL from source, invoke [CMake](#) with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the [BLACKHOLE](#) engine, look in the `sql` directory of a MySQL source distribution.

When you create a [BLACKHOLE](#) table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The [BLACKHOLE](#) storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the [BLACKHOLE](#) storage engine is available with the `SHOW ENGINES` statement.

Inserts into a [BLACKHOLE](#) table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is [BLACKHOLE](#), depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

### Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

### Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section [Section 17.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the [BLACKHOLE](#) engine. This is carried out in a way similar to how master table filtering is achieved - by using the [BLACKHOLE](#) engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

## 15.8 The MERGE Storage Engine

The [MERGE](#) storage engine, also known as the [MRG\\_MyISAM](#) engine, is a collection of identical [MyISAM](#) tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge [MyISAM](#) tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the [MyISAM](#) tables can be compressed with [myisampack](#). See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as [AVG\\_ROW\\_LENGTH](#), [MAX\\_ROWS](#), or [PACK\\_KEYS](#) do not matter.

An alternative to a [MERGE](#) table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the [MyISAM](#) storage engine. For more information, see [Chapter 19, Partitioning](#).

When you create a [MERGE](#) table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the underlying [MyISAM](#) tables that should be used as one. The tables do not have to be in the same database as the [MERGE](#) table.

You can use [SELECT](#), [DELETE](#), [UPDATE](#), and [INSERT](#) on [MERGE](#) tables. You must have [SELECT](#), [DELETE](#), and [UPDATE](#) privileges on the [MyISAM](#) tables that you map to a [MERGE](#) table.

### Note

The use of [MERGE](#) tables entails the following security issue: If a user has access to [MyISAM](#) table *t*, that user can create a [MERGE](#) table *m* that accesses *t*. However, if the user's privileges on *t* are subsequently revoked, the user can continue to access *t* by doing so through *m*.

Use of [DROP TABLE](#) with a [MERGE](#) table drops only the [MERGE](#) specification. The underlying tables are not affected.

To create a [MERGE](#) table, you must specify a [UNION=\(list-of-tables\)](#) option that indicates which [MyISAM](#) tables to use. You can optionally specify an [INSERT\\_METHOD](#) option to control how inserts into the [MERGE](#) table take place. Use a value of [FIRST](#) or [LAST](#) to cause inserts to be made in the first or last underlying table, respectively. If you specify no [INSERT\\_METHOD](#) option or if you specify it with a value of [NO](#), inserts into the [MERGE](#) table are not permitted and attempts to do so result in an error.

The following example shows how to create a [MERGE](#) table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+-----+
| a | message |
+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+-----+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.
- The column order in the underlying table and the `MERGE` table must match.
- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the `MERGE` table must be equal.

- The column length in the underlying table and the `MERGE` table must be equal.
- The column of the underlying table and the `MERGE` table can be `NULL`.
- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
  - Check whether index parts can be `NULL`.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

## Additional Resources

- A forum dedicated to the `MERGE` storage engine is available at <http://forums.mysql.com/list.php?93>.

### 15.8.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.
- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap.

(You must still specify the index definitions when you create a [MERGE](#) table, even though no indexes are created.)

- If you have a set of tables from which you create a large table on demand, you can instead create a [MERGE](#) table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each [MyISAM](#) table is bound by this limit, but a collection of [MyISAM](#) tables is not.
- You can create an alias or synonym for a [MyISAM](#) table by defining a [MERGE](#) table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of [MERGE](#) tables are:

- You can use only identical [MyISAM](#) tables for a [MERGE](#) table.
- Some [MyISAM](#) features are unavailable in [MERGE](#) tables. For example, you cannot create [FULLTEXT](#) indexes on [MERGE](#) tables. (You can create [FULLTEXT](#) indexes on the underlying [MyISAM](#) tables, but you cannot search the [MERGE](#) table with a full-text search.)
- If the [MERGE](#) table is nontemporary, all underlying [MyISAM](#) tables must be nontemporary. If the [MERGE](#) table is temporary, the [MyISAM](#) tables can be any mix of temporary and nontemporary.
- [MERGE](#) tables use more file descriptors than [MyISAM](#) tables. If 10 clients are using a [MERGE](#) table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the [MERGE](#) storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the [MERGE](#) storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes [MERGE](#) indexes much slower on [eq\\_ref](#) searches, but not much slower on [ref](#) searches. For more information about [eq\\_ref](#) and [ref](#), see [Section 13.8.2, “EXPLAIN Syntax”](#).

## 15.8.2 MERGE Table Problems

The following are known problems with [MERGE](#) tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child [MyISAM](#) tables.

From versions 5.1.23, [MERGE](#) children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the [MyISAM](#) tables corrupted them.

- If you use [ALTER TABLE](#) to change a [MERGE](#) table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying [MyISAM](#) tables are copied into the altered table, which then uses the specified storage engine.
- The [INSERT\\_METHOD](#) table option for a [MERGE](#) table indicates which underlying [MyISAM](#) table to use for inserts into the [MERGE](#) table. However, use of the [AUTO\\_INCREMENT](#) table option for that [MyISAM](#) table has no effect for inserts into the [MERGE](#) table until at least one row has been inserted directly into the [MyISAM](#) table.
- A [MERGE](#) table cannot maintain uniqueness constraints over the entire table. When you perform an [INSERT](#), the data goes into the first or last [MyISAM](#) table (as determined by the [INSERT\\_METHOD](#)

option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.

- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.
- The definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.
- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.
- The maximum number of rows in a `MERGE` table is  $2^{64}$  (~1.844E+19; the same as for a `MyISAM` table). It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.
- The `MERGE` storage engine does not support `INSERT DELAYED` statements.

- Use of underlying [MyISAM](#) tables of differing row formats with a parent [MERGE](#) table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary [MERGE](#) table when [LOCK TABLES](#) is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;  
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;  
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary [MERGE](#) table.

- You cannot create a [MERGE](#) table with [CREATE ... SELECT](#), neither as a temporary [MERGE](#) table, nor as a nontemporary [MERGE](#) table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: *tbl\_name* is not [BASE TABLE](#).

- In some cases, differing [PACK\\_KEYS](#) table option values among the [MERGE](#) and underlying tables cause unexpected results if the underlying tables contain [CHAR](#) or [BINARY](#) columns. As a workaround, use [ALTER TABLE](#) to ensure that all involved tables have the same [PACK\\_KEYS](#) value. (Bug #50646)

## 15.9 The FEDERATED Storage Engine

The [FEDERATED](#) storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local [FEDERATED](#) table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the [FEDERATED](#) storage engine if you build MySQL from source, invoke [CMake](#) with the [-DWITH\\_FEDERATED\\_STORAGE\\_ENGINE](#) option.

The [FEDERATED](#) storage engine is not enabled by default in the running server; to enable [FEDERATED](#), you must start the MySQL server binary using the [--federated](#) option.

To examine the source for the [FEDERATED](#) engine, look in the [storage/federated](#) directory of a MySQL source distribution.

### 15.9.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as [MyISAM](#), [CSV](#) or [InnoDB](#)), the table consists of the table definition and the associated data. When you create a [FEDERATED](#) table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A [FEDERATED](#) table consists of two elements:

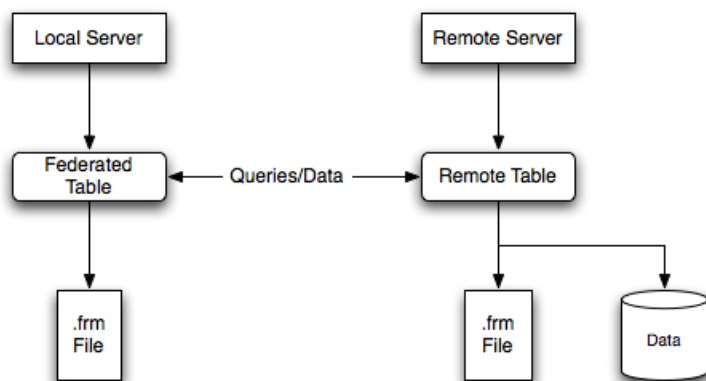

- A *remote server* with a database table, which in turn consists of the table definition (stored in the [.frm](#) file) and the associated table. The table type of the remote table may be any type supported by the remote [mysqld](#) server, including [MyISAM](#) or [InnoDB](#).
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the [.frm](#) file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a [FEDERATED](#) table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote

server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a **FEDERATED** table setup is shown in [Figure 15.1, “FEDERATED Table Structure”](#).

**Figure 15.1 FEDERATED Table Structure**

When a client issues an SQL statement that refers to a **FEDERATED** table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the **FEDERATED** table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the **FEDERATED** engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

## 15.9.2 How to Create FEDERATED Tables

To create a **FEDERATED** table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
```

```

    other INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;

```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

### Important

When you create the local table it *must* have an identical field definition to the remote table.

### Note

You can improve the performance of a [FEDERATED](#) table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the [WHERE](#) clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

## 15.9.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the [CONNECTION](#) string after the engine type in a [CREATE TABLE](#) statement. For example:

```

CREATE TABLE federated_table (
    id INT(20) NOT NULL AUTO_INCREMENT,
    name VARCHAR(32) NOT NULL DEFAULT '',
    other INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';

```

### Note

[CONNECTION](#) replaces the [COMMENT](#) used in some previous versions of MySQL.

The [CONNECTION](#) string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server [remote\\_host](#), using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```

scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name

```

Where:

- *scheme*: A recognized connection protocol. Only `mysql` is supported as the *scheme* value at this point.
- *user\_name*: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- *password*: (Optional) The corresponding password for *user\_name*.
- *host\_name*: The host name or IP address of the remote server.
- *port\_num*: (Optional) The port number for the remote server. The default is 3306.
- *db\_name*: The name of the database holding the remote table.
- *tbl\_name*: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'  
CONNECTION='mysql://username@hostname/database/tablename'  
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 15.9.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER  
server_name  
FOREIGN DATA WRAPPER wrapper_name  
OPTIONS (option [, option] ...)
```

The *server\_name* is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink  
FOREIGN DATA WRAPPER mysql  
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (  
  id      INT(20) NOT NULL AUTO_INCREMENT,  
  name    VARCHAR(32) NOT NULL DEFAULT '',  
  other   INT(20) NOT NULL DEFAULT '0',  
  PRIMARY KEY (id),  
  INDEX name (name),  
  INDEX other_key (other)  
)  
ENGINE=FEDERATED  
DEFAULT CHARSET=latin1  
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see [Section 13.1.16, “CREATE SERVER Syntax”](#).

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

| Description       | CONNECTION string      | CREATE SERVER option      | mysql.servers column  |
|-------------------|------------------------|---------------------------|-----------------------|
| Connection scheme | <code>scheme</code>    | <code>wrapper_name</code> | <code>Wrapper</code>  |
| Remote user       | <code>user_name</code> | <code>USER</code>         | <code>Username</code> |
| Remote password   | <code>password</code>  | <code>PASSWORD</code>     | <code>Password</code> |
| Remote host       | <code>host_name</code> | <code>HOST</code>         | <code>Host</code>     |
| Remote port       | <code>port_num</code>  | <code>PORT</code>         | <code>Port</code>     |
| Remote database   | <code>db_name</code>   | <code>DATABASE</code>     | <code>Db</code>       |

### 15.9.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns will fail. The following definition in `MyISAM` is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the **FEDERATED** engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses **SELECT**, **INSERT**, **UPDATE**, and **DELETE**, but not **HANDLER**.
- The **FEDERATED** storage engine supports **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE TABLE**, and indexes. It does not support **ALTER TABLE**, or any Data Definition Language statements that directly affect the structure of the table, other than **DROP TABLE**. The current implementation does not use prepared statements.
- **FEDERATED** accepts **INSERT ... ON DUPLICATE KEY UPDATE** statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a **FEDERATED** table when performing bulk inserts (for example, on a **INSERT INTO ... SELECT ...** statement) is slower than with other table types because each selected row is treated as an individual **INSERT** statement on the **FEDERATED** table.
- Transactions are not supported.
- **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
  - Bulk-insert handling does not occur for **INSERT ... ON DUPLICATE KEY UPDATE**.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a **CONNECTION** string, you cannot use an '@' character in the password. You can get round this limitation by using the **CREATE SERVER** statement to create a server connection.
- The **insert\_id** and **timestamp** options are not propagated to the data provider.
- Any **DROP TABLE** statement issued against a **FEDERATED** table drops only the local table, not the remote table.
- **FEDERATED** tables do not work with the query cache.
- User-defined partitioning is not supported for **FEDERATED** tables.

## 15.9.4 FEDERATED Storage Engine Resources

The following additional resources are available for the **FEDERATED** storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

## 15.10 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

## 15.11 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [MySQL Internals: Writing a Custom Storage Engine](#).

Data is the currency of today's web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. **Availability** refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. [Scalability](#) refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: [Chapter 17, Replication](#).
- MySQL Fabric. Learn more: [MySQL Fabric](#).
- MySQL Cluster. Learn more: [Chapter 18, MySQL NDB Cluster 7.2](#).
- Oracle MySQL Cloud Service. [Learn more about MySQL Cloud Service](#).
- Oracle Clusterware Agent for MySQL. [Learn more about Oracle Clusterware](#).

- MySQL with Solaris Cluster. [Learn more about Solaris Cluster.](#)

Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

**Figure 16.1 Tradeoffs: Cost and Complexity versus Availability**

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

**Table 16.1 Feature Comparison of MySQL HA Solutions**

| Requirement         | MySQL Replication   | MySQL Cluster  |
|---------------------|---|--|
| <b>Availability</b> |   |  |
| Platform Support    | All Supported by MySQL Server ( <a href="http://www.mysql.com/">http://www.mysql.com/</a> ) | All Supported by MySQL Cluster ( <a href="http://www.mysql.com/support/supportedplatforms/cluster.html">http://www.mysql.com/support/supportedplatforms/cluster.html</a> ) |

| Requirement                                  | MySQL Replication  | MySQL Cluster                          |
|--|--|--|
|  | <a href="#">support/supportedplatforms/database.html</a> ) |  |
| Automated IP Failover                        | No   | Depends on Connector and Configuration |
| Automated Database Failover                  | No   | Yes                                    |
| Automatic Data Resynchronization             | No   | Yes                                    |
| Typical Failover Time                        | User / Script Dependent                                    | 1 Second and Less                      |
| Synchronous Replication                      | No, Asynchronous and Semisynchronous                       | Yes                                    |
| Shared Storage                               | No, Distributed  | No, Distributed                        |
| Geographic redundancy support                | Yes  | Yes, via MySQL Replication             |
| Update Schema On-Line                        | No   | Yes                                    |
| <b>Scalability</b>                           |  |  |
| Number of Nodes                              | One Master, Multiple Slaves                                | 255                                    |
| Built-in Load Balancing                      | Reads, via MySQL Replication                               | Yes, Reads and Writes                  |
| Supports Read-Intensive Workloads            | Yes  | Yes                                    |
| Supports Write-Intensive Workloads           | Yes, via Application-Level Sharding                        | Yes, via Auto-Sharding                 |
| Scale On-Line (add nodes, repartition, etc.) | No   | Yes                                    |

## 16.1 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as [Chapter 17, Replication](#).

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at [/scratchpool](#):

```

Filesystem                size      used   avail capacity  Mounted on
/dev/dsk/c0d0s0           4.6G    3.7G    886M     82%      /
/devices                   0K         0K       0K       0%      /devices
ctfs                       0K         0K       0K       0%      /system/contract
proc                       0K         0K       0K       0%      /proc
mnttab                     0K         0K       0K       0%      /etc/mnttab
swap                      1.4G    892K    1.4G       1%      /etc/svc/volatile
objfs                      0K         0K       0K       0%      /system/object
/usr/lib/libc/libc_hwcapi.so.1
                           4.6G    3.7G    886M     82%      /lib/libc.so.1
fd                         0K         0K       0K       0%      /dev/fd
swap                      1.4G     40K    1.4G       1%      /tmp

```

|                 |      |      |      |    |              |
|-----------------|------|------|------|----|--------------|
| swap            | 1.4G | 28K  | 1.4G | 1% | /var/run     |
| /dev/dsk/c0d0s7 | 26G  | 913M | 25G  | 4% | /export/home |
| scratchpool     | 16G  | 24K  | 16G  | 1% | /scratchpool |

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x  31 root    bin           50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root    bin           5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root    sys           16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000    1000         40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1    0      -    24.5K  -
scratchpool@snap2    0      -    24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

## 16.1.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x  6 root    root      7 Nov  8 09:13 ./
drwxr-xr-x 29 root    root      34 Nov  9 07:06 ../
drwxr-xr-x 31 root    bin       50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root    bin       5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root    sys      16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000   1000     40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

## 16.1.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send/ zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

## 16.1.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On `MyISAM` tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

## 16.2 Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see [Section 16.2.2, “Using `memcached`”](#)

Benefits of using `memcached` include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.
- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.
- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information is not in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 16.2, “`memcached` Architecture Overview”](#).

**Figure 16.2** `memcached` Architecture Overview

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.

## 16.2.1 Installing `memcached`

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

### Installing `memcached` from a Binary Distribution

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

#### Note

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

### Building `memcached` from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached Web site](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you might specify to the `configure`:

- `--prefix`

To specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see [Section 16.2.2.8, “memcached Thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 16.2.2.6, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

## 16.2.2 Using `memcached`

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

### Note

You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211

- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

### 16.2.2.1 `memcached` Command-Line Options

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

#### Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
kthr    memory              page            disk              faults              cpu
r  b  w   swap free  re  mf pi po fr de sr sl s2 -- --  in  sy  cs us sy id
0  0  0  5170504 3450392 2   7   2  0  0  0  4  0  0  0  0  296  54 199  0  0 100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

**Note**

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- `-s socket`

Specify a Unix socket to listen on.

If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

Specify the number of threads to use when processing incoming requests.

By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

**Note**

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

Print the help message and exit.

- `-i`

Print the `memcached` and `libevent` license.

- `-I mem`

Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- `-b`

Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

Save the process ID of the `memcached` instance into `file`.

- `-f`

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see [Section 16.2.2.9, “memcached Logs”](#).

- `-n bytes`

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

Disable the use of compare and swap (CAS) operations.

This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see [Section 16.2.4, “Getting memcached Statistics”](#)). The default is the colon (`:`). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in `memcached` 1.4.0.

### 16.2.2.2 `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must be capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.
- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.
- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 16.2.2.5, “memcached Hashing/Distribution Types”](#).

### 16.2.2.3 Using Namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieved from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

**Note**

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

**16.2.2.4 Data Expiry**

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 16.2.4, “Getting `memcached` Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

**16.2.2.5 `memcached` Hashing/Distribution Types**

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];  
$value = hash('myid');  
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 ( $7009 \% 3 = 1$ ), and store or retrieve the key and value with that server.

**Note**

This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in [Figure 16.3, “memcached Hash Selection”](#).

**Figure 16.3** `memcached` Hash Selection

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).
- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

**Note**

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

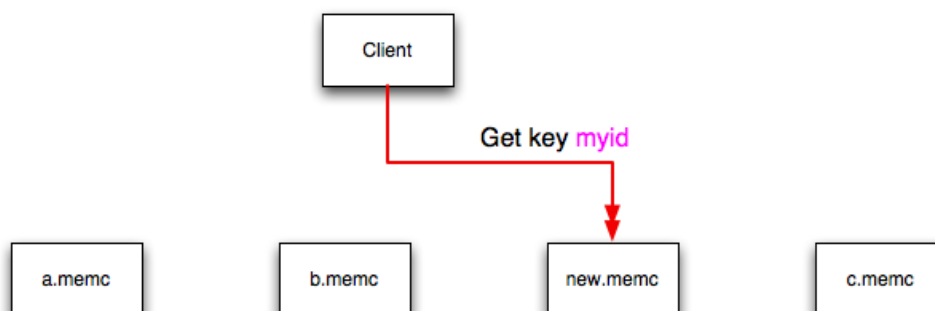

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

- A new `memcached` instance has been added to the list of available instances
- A `memcached` instance has been removed from the list of available instances
- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

**Figure 16.4** `memcached` Hash Selection with New `memcached` instance

This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can

add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

### 16.2.2.6 Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see [Section 16.2.1, "Installing `memcached`"](#).

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid`: The connection ID.

- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid`: The connection ID.

- `conn-create(ptr)`

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:

- `ptr`: A pointer to the connection. object
- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr`: A pointer to the connection object.
- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid`: The connection ID.
- `threadid`: The thread ID.
- `slabs-allocate(size, slabclass, slabsize, ptr)`

Allocate memory from the slab allocator.

Arguments:

- `size`: The requested size.
- `slabclass`: The allocation is fulfilled in this class.
- `slabsize`: The size of each item in this class.
- `ptr`: A pointer to allocated memory.
- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `size`: The requested size.
- `slabclass`: The class that failed to fulfill the request.
- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space.

Arguments:

- `slabclass`: The class that needs more memory.
- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `slabclass`: The class that failed to grab more memory.
- `slabs-free(size, slabclass, ptr)`

Release memory.

Arguments:

- `size`: The amount of memory to release, in bytes.
- `slabclass`: The class the memory belongs to.
- `ptr`: A pointer to the memory to release.
- `assoc-find(key, depth)`

Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

Arguments:

- `key`: The key searched for.
- `depth`: The depth in the list of hash table.
- `assoc-insert(key, nokeys)`

Fired when a new item has been inserted.

Arguments:

- `key`: The key just inserted.
- `nokeys`: The total number of keys currently being stored, including the key for which insert was called.
- `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key`: The key just deleted.
- `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.
- `item-link(key, size)`

Fired when an item is being linked in the cache.

Arguments:

- `key`: The items key.
- `size`: The size of the data.

- `item-unlink(key, size)`  
Fired when an item is being deleted.  
Arguments:
  - `key`: The items key.
  - `size`: The size of the data.
- `item-remove(key, size)`  
Fired when the refcount for an item is reduced.  
Arguments:
  - `key`: The item's key.
  - `size`: The size of the data.
- `item-update(key, size)`  
Fired when the "last referenced" time is updated.  
Arguments:
  - `key`: The item's key.
  - `size`: The size of the data.
- `item-replace(oldkey, oldsize, newkey, newsize)`  
Fired when an item is being replaced with another item.  
Arguments:
  - `oldkey`: The key of the item to replace.
  - `oldsize`: The size of the old item.
  - `newkey`: The key of the new item.
  - `newsize`: The size of the new item.
- `process-command-start(connid, request, size)`  
Fired when the processing of a command starts.  
Arguments:
  - `connid`: The connection ID.
  - `request`: The incoming request.
  - `size`: The size of the request.
- `process-command-end(connid, response, size)`  
Fired when the processing of a command is done.

Arguments:

- `connid`: The connection ID.
- `response`: The response to send back to the client.
- `size`: The size of the response.
- `command-get(connid, key, size)`

Fired for a `get` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `command-gets(connid, key, size, casid)`

Fired for a `gets` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The casid for the item.
- `command-add(connid, key, size)`

Fired for a `add` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).
- `command-set(connid, key, size)`

Fired for a `set` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-replace(connid, key, size)`

Fired for a `replace` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-prepend(connid, key, size)`

Fired for a `prepend` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-append(connid, key, size)`

Fired for a `append` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-cas(connid, key, size, casid)`

Fired for a `cas` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The cas ID requested.

- `command-incr(connid, key, val)`

Fired for `incr` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.

- `val`: The new value.
- `command-decr(connid, key, val)`  
Fired for `decr` command.  
Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `val`: The new value.
- `command-delete(connid, key, exptime)`  
Fired for a `delete` command.  
Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `exptime`: The expiry time.

### 16.2.2.7 Memory Allocation within `memcached`

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

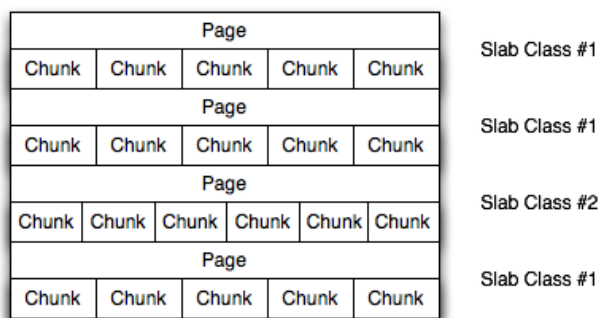

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 16.5, “Memory Allocation in `memcached`”](#).

**Figure 16.5 Memory Allocation in `memcached`**

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for  $104 \times 1.25$ , or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 16.2.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

### 16.2.2.8 `memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

### 16.2.2.9 `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

The lowest verbosity level shows you:

- Errors and warnings
- Transient errors
- Protocol and socket errors, including exhausting available connections
- Each registered client connection, including the socket descriptor number and the protocol used.

For example:

```
32: Client using the ascii protocol
33: Client using the ascii protocol
```

The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```
<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d
```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
```

```

slab class 1: chunk size      80 perslab 13107
slab class 2: chunk size     104 perslab 10082
slab class 3: chunk size     136 perslab  7710
slab class 4: chunk size     176 perslab  5957
slab class 5: chunk size     224 perslab  4681
slab class 6: chunk size     280 perslab  3744
slab class 7: chunk size     352 perslab  2978
slab class 8: chunk size     440 perslab  2383
slab class 9: chunk size     552 perslab  1899
slab class 10: chunk size    696 perslab  1506
slab class 11: chunk size    872 perslab  1202
slab class 12: chunk size   1096 perslab   956
slab class 13: chunk size   1376 perslab   762
slab class 14: chunk size   1720 perslab   609
slab class 15: chunk size   2152 perslab   487
slab class 16: chunk size   2696 perslab   388
slab class 17: chunk size   3376 perslab   310
slab class 18: chunk size   4224 perslab   248
slab class 19: chunk size   5280 perslab   198
slab class 20: chunk size   6600 perslab   158
slab class 21: chunk size   8256 perslab   127
slab class 22: chunk size  10320 perslab   101
slab class 23: chunk size  12904 perslab    81
slab class 24: chunk size  16136 perslab    64
slab class 25: chunk size  20176 perslab    51
slab class 26: chunk size  25224 perslab    41
slab class 27: chunk size  31536 perslab    33
slab class 28: chunk size  39424 perslab    26
slab class 29: chunk size  49280 perslab    21
slab class 30: chunk size  61600 perslab    17
slab class 31: chunk size  77000 perslab    13
slab class 32: chunk size  96256 perslab    10
slab class 33: chunk size 120320 perslab     8
slab class 34: chunk size 150400 perslab     6
slab class 35: chunk size 188000 perslab     5
slab class 36: chunk size 235000 perslab     4
slab class 37: chunk size 293752 perslab     3
slab class 38: chunk size 367192 perslab     2
slab class 39: chunk size 458992 perslab     2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)

```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```

shell> memcached -f 4 -m 1g -vv
slab class 1: chunk size      80 perslab 13107
slab class 2: chunk size     320 perslab  3276
slab class 3: chunk size    1280 perslab   819
slab class 4: chunk size    5120 perslab   204
slab class 5: chunk size   20480 perslab    51
slab class 6: chunk size   81920 perslab    12
slab class 7: chunk size  327680 perslab     3

```

...

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```

32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545

```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the `memcached` server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```

<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol

```

```
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

### 16.2.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

#### 16.2.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- `get(key)`: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])`: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days ( $30 \times 24 \times 60 \times 60$ ), or an absolute time (epoch) if larger than this value.
- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.
- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.
- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.
- `incr(key, value)`: Increments the item associated with the `key` by the specified `value`.

- `decr(key , value)`: Decrements the item associated with the `key` by the specified `value`.
- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

### 16.2.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the `InnoDB buffer pool` and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

#### Caution

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached` instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use `IPTables` or similar techniques to restrict access to the `memcached` ports to a select set of hosts.

You can introduce `memcached` to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using `memcached` in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 16.6, “Typical `memcached` Application Flowchart”](#).

**Figure 16.6 Typical `memcached` Application Flowchart**

### Adapting Database Best Practices to `memcached` Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a `primary key`. Because of the uniqueness requirements for `memcached` keys, make sure your database schema makes appropriate use of primary keys and `unique constraints`.

If you combine multiple column values into a single `memcached` item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to `memcached` lookups are those with a single `WHERE` clause, using an `=` or `IN` operator. For complicated `WHERE` clauses, or those using operators such as `<`, `>`, `BETWEEN`, or `LIKE`, `memcached` does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

#### 16.2.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Key stored successfully\n");
    else
        fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));

    return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
```

```
Added server successfully
Key stored successfully
```

## `libmemcached` Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

## `libmemcached` Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
memcached_server_add (memcached_st *ptr,
                     char *hostname,
                     unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
memcached_server_add_unix_socket (memcached_st *ptr,
                                 char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
    memcached_server_push (memcached_st *ptr,
                          memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
    memcached_server_list_append (memcached_server_st *ptr,
                                char *hostname,
                                unsigned int port,
                                memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

## libmemcached Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```
memcached_return
    memcached_set (memcached_st *ptr,
                  const char *key,
                  size_t key_length,
                  const char *value,
                  size_t value_length,
                  time_t expiration,
                  uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see [Controlling libmemcached Behaviors](#).

This table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

| libmemcached Function   | Equivalent Core Function  |
|---|---|
| <code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>   | Generic <code>set()</code> operation.   |
| <code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>   | Generic <code>add()</code> function.  |
| <code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Generic <code>replace()</code> .  |
| <code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .  |
| <code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>  | Appends the specified <code>value</code> after the current value of the specified <code>key</code> .  |
| <code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>                                      | Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.                        |
| <code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server.       |
| <code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the generic <code>add()</code> , but has the option of an additional master key that can be used to identify an individual server.       |
| <code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.   |
| <code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the <code>memcached_prepend()</code> , but has the option of an additional master key that can be used to identify an individual server. |
| <code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>  | Similar to the <code>memcached_append()</code> , but has the option of an additional master key that can be used to identify an individual server.  |
| <code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the <code>memcached_cas()</code> , but has the option of an additional master key that can be used to identify an individual server.     |

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
```

```
const char *master_key,
size_t master_key_length,
const char *key,
size_t key_length,
const char *value,
size_t value_length,
time_t expiration,
uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

## `libmemcached` Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                    const char *key, size_t key_length,
                    size_t *value_length,
                    uint32_t *flags,
                    memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
               char **keys, size_t *key_length,
               unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                     const char *key, size_t *key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
```

```

{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;

    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;

    memc = memcached_create(NULL);

    servers = memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc = memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    for(x = 0; x < 3; x++)
    {
        key_length[x] = strlen(keys[x]);
        value_length[x] = strlen(values[x]);

        rc = memcached_set(memc, keys[x], key_length[x], values[x],
                           value_length[x], (time_t)0, (uint32_t)0);
        if (rc == MEMCACHED_SUCCESS)
            fprintf(stderr, "Key %s stored successfully\n", keys[x]);
        else
            fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));
    }

    rc = memcached_mget(memc, keys, key_length, 3);

    if (rc == MEMCACHED_SUCCESS)
    {
        while ((return_value = memcached_fetch(memc, return_key, &return_key_length,
                                                &return_value_length, &flags, &rc)) != NULL)
        {
            if (rc == MEMCACHED_SUCCESS)
            {
                fprintf(stderr, "Key %s returned %s\n", return_key, return_value);
            }
        }
    }

    return 0;
}

```

Running the above application produces the following output:

```

shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green

```

## Controlling `libmemcached` Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```
memcached_return
memcached_behavior_set (memcached_st *ptr,
                        memcached_behavior flag,
                        uint64_t data);
```

To get the current behavior setting:

```
uint64_t
memcached_behavior_get (memcached_st *ptr,
                        memcached_behavior flag);
```

The following table describes `libmemcached` behavior flags.

| Behavior  | Description   |
|---|---|
| <code>MEMCACHED_BEHAVIOR_NO_BLOCK</code>        | Caused <code>libmemcached</code> to use asynchronous I/O.   |
| <code>MEMCACHED_BEHAVIOR_TCP_NODELAY</code>     | Turns on no-delay for network sockets.  |
| <code>MEMCACHED_BEHAVIOR_HASH</code>            | Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include <code>MEMCACHED_HASH_DEFAULT</code> , <code>MEMCACHED_HASH_MD5</code> , <code>MEMCACHED_HASH_CRC</code> , <code>MEMCACHED_HASH_FNV1_64</code> , <code>MEMCACHED_HASH_FNV1A_64</code> , <code>MEMCACHED_HASH_FNV1_32</code> , and <code>MEMCACHED_HASH_FNV1A_32</code> . |
| <code>MEMCACHED_BEHAVIOR_DISTRIBUTION</code>    | Changes the method of selecting the server used to store a given value. The default method is <code>MEMCACHED_DISTRIBUTION_MODULA</code> . You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> . <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> .   |
| <code>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</code>   | Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.  |
| <code>MEMCACHED_BEHAVIOR_SUPPORT_CAS</code>     | Support CAS operations. By default, this is disabled because it imposes a performance penalty.  |
| <code>MEMCACHED_BEHAVIOR_KETAMA</code>          | Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code> .  |
| <code>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</code>    | Modify the timeout value used by <code>poll()</code> . Supply a signed <code>int</code> pointer for the timeout value.  |
| <code>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</code> | Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.   |
| <code>MEMCACHED_BEHAVIOR_VERIFY_KEY</code>      | Forces <code>libmemcached</code> to verify that a specified key is valid.   |

| Behavior  | Description  |
|---|--|
| <code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code>      | If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled. |
| <code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code> | In nonblocking mode this changes the value of the timeout during socket connection.  |

### `libmemcached` Command-Line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file name as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

#### 16.2.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using [CPAN](#):

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

### Note

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

| <code>Cache::Memcached</code> Function | Equivalent Generic Method  |
|--|--|
| <code>get()</code>                     | Generic <code>get()</code> .   |
| <code>get_multi(keys)</code>           | Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs. |
| <code>set()</code>                     | Generic <code>set()</code> .   |

| Cache::Memcached Function | Equivalent Generic Method        |
|---------------------------|----------------------------------|
| <code>add()</code>        | Generic <code>add()</code> .     |
| <code>replace()</code>    | Generic <code>replace()</code> . |
| <code>delete()</code>     | Generic <code>delete()</code> .  |
| <code>incr()</code>       | Generic <code>incr()</code> .    |
| <code>decr()</code>       | Generic <code>decr()</code> .    |

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filename = shift or die "Must specify the film name\n";
my $filmkey = $filename;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
    $filmdata = load_filmdata($filename);

    if (defined($filmdata))
    {
        # Set the data into the cache, using the key

        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filename\n";
    }
}
else
{

```

```

    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmdname) = @_ ;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila', 'password');

    my ($filmdbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                    $dbh->quote($filmdname)));

    if (!defined($filmdname))
    {
        return (undef);
    }

    $filmdbase->{stars} =
    $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                    'from film_actor left join (actor) ' .
                                    'on (film_actor.actor_id = actor.actor_id) ' .
                                    ' where film_id=%s',
                                    $dbh->quote($filmdbase->{film_id})));

    return($filmdbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to [memcached](#). When calling it for a film does not exist, you get this result:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached

```

When accessing a film that has already been added to the cache:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached

```

### 16.2.3.5 Using MySQL and [memcached](#) with Python

The Python [memcache](#) module interfaces to [memcached](#) servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```

python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43

```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. When you store Python data structures as `memcached` items, they are automatically serialized (turned into string values) using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class. For example, if the `memcached` daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each `memcached` instance to use. To enable debugging, set the optional `debug` parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is `crc32`. To change the function used, set the value of `memcache.serverHashFunction` to the alternate function to use. For example:

```
from zlib import Adler32
memcache.serverHashFunction = Adler32
```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

| Python <code>memcache</code> Function                      | Equivalent Generic Function  |
|--|--|
| <code>get()</code>   | Generic <code>get()</code> .   |
| <code>get_multi(keys)</code>                               | Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs. |
| <code>set()</code>   | Generic <code>set()</code> .   |
| <code>set_multi(dict [, expiry [, key_prefix]])</code>     | Sets multiple key/value pairs from the supplied <code>dict</code> .  |
| <code>add()</code>   | Generic <code>add()</code> .   |
| <code>replace()</code>                                     | Generic <code>replace()</code> .   |
| <code>prepend(key, value [, expiry])</code>                | Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .                         |
| <code>append(key, value [, expiry])</code>                 | Appends the supplied <code>value</code> to the value of the existing <code>key</code> .                          |
| <code>delete()</code>                                      | Generic <code>delete()</code> .  |
| <code>delete_multi(keys [, expiry [, key_prefix]] )</code> | Deletes all the keys from the hash matching each string in the array <code>keys</code> .                         |
| <code>incr()</code>  | Generic <code>incr()</code> .  |
| <code>decr()</code>  | Generic <code>decr()</code> .  |

#### Note

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a [memcache](#) instance, loading the raw data from MySQL:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the [memcached](#) server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using [cPickle/pickle](#), when you load the data back from [memcached](#), you can use the object directly. In the example above, the information stored to [memcached](#) is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from [memcached](#) and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

### 16.2.3.6 Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

| Configuration option                        | Default  | Description   |
|---|----------|---|
| <code>memcache.allow_failover</code>        | 1        | Specifies whether another server in the list should be queried if the first server selected fails.  |
| <code>memcache.max_failover_attempts</code> | 20       | Specifies the number of servers to try before returning a failure.  |
| <code>memcache.chunk_size</code>            | 8192     | Defines the size of network chunks used to exchange data with the <code>memcached</code> server.  |
| <code>memcache.default_port</code>          | 11211    | Defines the default port to use when communicating with the <code>memcached</code> servers.   |
| <code>memcache.hash_strategy</code>         | standard | Specifies which hash strategy to use. Set to <code>consistent</code> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code> , an older (modula) strategy is used that potentially uses different servers for storage. |
| <code>memcache.hash_function</code>         | crc32    | Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.  |

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the `memcache` object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                        [, int $weight [, int $timeout [, int $retry_interval
```

```
[, bool $status [, callback $failure_callback
]]]]]] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php

$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table:

| PECL <code>memcache</code> Function | Generic Function                 |
|-------------------------------------|----------------------------------|
| <code>get()</code>                  | Generic <code>get()</code> .     |
| <code>set()</code>                  | Generic <code>set()</code> .     |
| <code>add()</code>                  | Generic <code>add()</code> .     |
| <code>replace()</code>              | Generic <code>replace()</code> . |
| <code>delete()</code>               | Generic <code>delete()</code> .  |
| <code>increment()</code>            | Generic <code>incr()</code> .    |
| <code>decrement()</code>            | Generic <code>decr()</code> .    |

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php

$memc = new Memcache;
$memc->addServer('localhost',11211);

if(empty($_POST['film'])) {
?>
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Simple Memcache Lookup</title>
</head>
<body>
```

```

<form method="post">
  <p><b>Film</b>: <input type="text" size="20" name="film"></p>
  <input type="submit">
</form>
<hr/>
<?php
} else {

    echo "Loading data...\n";

    $film    = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }
    } else {

        $mysqli = mysqli('localhost','sakila','password','sakila');

        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);

        if (!$result) {
            sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }

        $row = $result->fetch_assoc();

        $memc->set($row['title'], $row);

        printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8'));
    }
}
?>
</body>
</html>

```

With PHP, the connections to the [memcached](#) instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 16.2.3.7 Using MySQL and [memcached](#) with Ruby

There are a number of different modules for interfacing to [memcached](#) within Ruby. The [Ruby-MemCache](#) client library provides a native interface to [memcached](#) that does not require any external libraries, such as [libmemcached](#). You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn] y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

| Ruby <code>MemCache</code> Method | Equivalent <code>memcached</code> API Functions  |
|-----------------------------------|--|
| <code>get()</code>                | Generic <code>get()</code> .   |
| <code>get_hash(keys)</code>       | Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values. |
| <code>set()</code>                | Generic <code>set()</code> .   |
| <code>set_many(pairs)</code>      | Set the values of the keys and values in the hash <code>pairs</code> .   |
| <code>add()</code>                | Generic <code>add()</code> .   |
| <code>replace()</code>            | Generic <code>replace()</code> .   |

| Ruby <code>MemCache</code> Method | Equivalent <code>memcached</code> API Functions |
|-----------------------------------|---|
| <code>delete()</code>             | Generic <code>delete()</code> .                 |
| <code>incr()</code>               | Generic <code>incr()</code> .                   |
| <code>decr()</code>               | Generic <code>decr()</code> .                   |

### 16.2.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <https://github.com/gwhalin/Memcached-Java-Client/downloads>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {

        String[] servers =
            {
                "localhost:11211",
            };

        Integer[] weights = { 1 };

        SockIOPool pool = SockIOPool.getInstance();

        pool.setServers( servers );
        pool.setWeights( weights );
    }
}
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
```

```
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modular hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

| Java <code>com.danga.MemCached</code> Method | Equivalent Generic Method   |
|--|---|
| <code>get()</code>                           | Generic <code>get()</code> .  |
| <code>getMulti(keys)</code>                  | Get the values of multiple <code>keys</code> , returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values. |
| <code>set()</code>                           | Generic <code>set()</code> .  |
| <code>add()</code>                           | Generic <code>add()</code> .  |
| <code>replace()</code>                       | Generic <code>replace()</code> .  |
| <code>delete()</code>                        | Generic <code>delete()</code> .   |
| <code>incr()</code>                          | Generic <code>incr()</code> .   |
| <code>decr()</code>                          | Generic <code>decr()</code> .   |

### 16.2.3.9 Using the `memcached` TCP Text Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with `memcached`, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (`cas`):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- `command`: The command name.
  - `set`: Store value against key
  - `add`: Store this value against key if the key does not already exist
  - `replace`: Store this value against key if the key already exists
  - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
- `key`: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- `flags`: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- `exptime`: The expiry time, or zero for no expiry.
- `length`: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
- `casunique`: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- `noreply`: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see [Table 16.3, “memcached Protocol Responses”](#).

- **Retrieval commands:** `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 .... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key`: The key name.
- `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.
- `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- `casunique`: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands:** `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- `key`: The key name.
- `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- `noreply`: Tells the server not to reply to the command.

Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr`, `decr`

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- `key`: The key name.
- `value`: An integer to be used as the increment or decrement value.
- `noreply`: Tells the server not to reply to the command.

The response is:

- `NOT_FOUND`: The specified key could not be located.
- `value`: The new value associated with the specified key.

Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands:** `stats`

The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- `name`: The optional name of the statistics to return. If not specified, the general statistics are returned.
- `value`: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see [Section 16.2.4, “Getting `memcached` Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

**Table 16.2** `memcached` Command Reference

| Command              | Command Formats   |
|----------------------|---|
| <code>set</code>     | <code>set key flags exptime length, set key flags exptime length noreply</code>                     |
| <code>add</code>     | <code>add key flags exptime length, add key flags exptime length noreply</code>                     |
| <code>replace</code> | <code>replace key flags exptime length, replace key flags exptime length noreply</code>             |
| <code>append</code>  | <code>append key length, append key length noreply</code>   |
| <code>prepend</code> | <code>prepend key length, prepend key length noreply</code>   |
| <code>cas</code>     | <code>cas key flags exptime length casunique, cas key flags exptime length casunique noreply</code> |
| <code>get</code>     | <code>get key1 [key2 ... keyn]</code>   |
| <code>gets</code>    |   |
| <code>delete</code>  | <code>delete key, delete key noreply, delete key expiry, delete key expiry noreply</code>           |
| <code>incr</code>    | <code>incr key, incr key noreply, incr key value, incr key value noreply</code>                     |
| <code>decr</code>    | <code>decr key, decr key noreply, decr key value, decr key value noreply</code>                     |
| <code>stat</code>    | <code>stat, stat name, stat name value</code>   |

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 16.3** `memcached` Protocol Responses

| String   | Description   |
|--|---|
| <code>STORED</code>  | Value has successfully been stored.   |
| <code>NOT_STORED</code>  | The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code> ), or where the item has already been set to be deleted. |
| <code>EXISTS</code>  | When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.   |
| <code>NOT_FOUND</code>   | The item you are trying to store, update or delete does not exist or has already been deleted.  |
| <code>ERROR</code>   | You submitted a nonexistent command name.   |
| <code>CLIENT_ERROR</code><br><code>errorstring</code>                          | There was an error in the input line, the detail is contained in <code>errorstring</code> .   |
| <code>SERVER_ERROR</code><br><code>errorstring</code>                          | There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.  |
| <code>VALUE</code> <code>keys</code> <code>flags</code><br><code>length</code> | The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block are returned, of the specified <code>length</code> .  |
| <code>DELETED</code>   | The requested key was deleted from the server.  |
| <code>STAT</code> <code>name</code> <code>value</code>                         | A line of statistics data.  |

| String           | Description                     |
|------------------|---------------------------------|
| <code>END</code> | The end of the statistics data. |

## 16.2.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the [Section 16.2.4.2, “memcached Slabs Statistics”](#) and [Section 16.2.4.1, “memcached General Statistics”](#) information. For more information, see [Section 16.2.4.6, “Using memcached-tool”](#).

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
```

```
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
  'hosts' => {
    'localhost:11211' => {
      'misc' => {
        'bytes' => '2421',
        'curr_connections' => '3',
        'connection_structures' => '56',
        'pointer_size' => '32',
        'time' => '1211440166',
        'total_items' => '410956',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'evictions' => '0',
        'curr_items' => '31',
        'pid' => '23599',
        'limit_maxbytes' => '67108864',
        'uptime' => '1254',
        'rusage_user' => '9.857805',
        'cmd_get' => '838451',
        'rusage_system' => '34.096988',
        'version' => '1.2.5',
        'get_hits' => '581511',
        'bytes_read' => '46665716',
        'threads' => '1',
        'total_connections' => '3104',
        'get_misses' => '256940'
      },
      'sizes' => {
        '128' => '16',
        '64' => '15'
      }
    }
  },
  'self' => {},
  'total' => {
    'cmd_get' => 838451,
    'bytes' => 2421,
    'get_hits' => 581511,
    'connection_structures' => 56,
    'bytes_read' => 46665716,
    'total_items' => 410956,
    'total_connections' => 3104,
    'cmd_set' => 588167,
    'bytes_written' => 35715151,
    'curr_items' => 31,
    'get_misses' => 256940
  }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 16.2.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 16.2.4.2, “memcached Slabs Statistics”](#).

- Item statistics (`items`), see [Section 16.2.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 16.2.4.4, “memcached Size Statistics”](#).
- Detailed status (`detail`), see [Section 16.2.4.5, “memcached Detail Statistics”](#).

### 16.2.4.1 `memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u:32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

| Statistic                          | Data type | Description  | Version |
|------------------------------------|-----------|--|---------|
| <code>pid</code>                   | 32u       | Process ID of the <code>memcached</code> instance.                   |         |
| <code>uptime</code>                | 32u       | Uptime (in seconds) for this <code>memcached</code> instance.        |         |
| <code>time</code>                  | 32u       | Current time (as epoch).   |         |
| <code>version</code>               | string    | Version string of this instance.                                     |         |
| <code>pointer_size</code>          | string    | Size of pointers for this host specified in bits (32 or 64).         |         |
| <code>rusage_user</code>           | 32u:32u   | Total user time for this instance (seconds:microseconds).            |         |
| <code>rusage_system</code>         | 32u:32u   | Total system time for this instance (seconds:microseconds).          |         |
| <code>curr_items</code>            | 32u       | Current number of items stored by this instance.                     |         |
| <code>total_items</code>           | 32u       | Total number of items stored during the life of this instance.       |         |
| <code>bytes</code>                 | 64u       | Current number of bytes used by this server to store items.          |         |
| <code>curr_connections</code>      | 32u       | Current number of open connections.                                  |         |
| <code>total_connections</code>     | 32u       | Total number of connections opened since the server started running. |         |
| <code>connection_structures</code> | 32u       | Number of connection structures allocated by the server.             |         |
| <code>cmd_get</code>               | 64u       | Total number of retrieval requests ( <code>get</code> operations).   |         |
| <code>cmd_set</code>               | 64u       | Total number of storage requests ( <code>set</code> operations).     |         |
| <code>get_hits</code>              | 64u       | Number of keys that have been requested and found present.           |         |
| <code>get_misses</code>            | 64u       | Number of items that have been requested and not found.              |         |
| <code>delete_hits</code>           | 64u       | Number of keys that have been deleted and found present.             | 1.3.x   |
| <code>delete_misses</code>         | 64u       | Number of items that have been delete and not found.                 | 1.3.x   |

| Statistic                   | Data type | Description   | Version |
|-----------------------------|-----------|---|---------|
| <code>incr_hits</code>      | 64u       | Number of keys that have been incremented and found present.  | 1.3.x   |
| <code>incr_misses</code>    | 64u       | Number of items that have been incremented and not found.   | 1.3.x   |
| <code>decr_hits</code>      | 64u       | Number of keys that have been decremented and found present.  | 1.3.x   |
| <code>decr_misses</code>    | 64u       | Number of items that have been decremented and not found.   | 1.3.x   |
| <code>cas_hits</code>       | 64u       | Number of keys that have been compared and swapped and found present.   | 1.3.x   |
| <code>cas_misses</code>     | 64u       | Number of items that have been compared and swapped and not found.  | 1.3.x   |
| <code>cas_badvalue</code>   | 64u       | Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value. | 1.3.x   |
| <code>evictions</code>      | 64u       | Number of valid items removed from cache to free memory for new items.  |         |
| <code>bytes_read</code>     | 64u       | Total number of bytes read by this server from network.   |         |
| <code>bytes_written</code>  | 64u       | Total number of bytes sent by this server to network.   |         |
| <code>limit_maxbytes</code> | 32u       | Number of bytes this server is permitted to use for storage.  |         |
| <code>threads</code>        | 32u       | Number of worker threads requested.   |         |
| <code>conn_yields</code>    | 64u       | Number of yields for connections (related to the <code>-R</code> option).   | 1.4.0   |

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

#### 16.2.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
```

```

STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END

```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

| Statistic                    | Description   | Version |
|------------------------------|---|---------|
| <code>chunk_size</code>      | Space allocated to each chunk within this slab class.                   |         |
| <code>chunks_per_page</code> | Number of chunks within a single page for this slab class.              |         |
| <code>total_pages</code>     | Number of pages allocated to this slab class.                           |         |
| <code>total_chunks</code>    | Number of chunks allocated to the slab class.                           |         |
| <code>used_chunks</code>     | Number of chunks allocated to an item..                                 |         |
| <code>free_chunks</code>     | Number of chunks not yet allocated to items.                            |         |
| <code>free_chunks_end</code> | Number of free chunks at the end of the last allocated page.            |         |
| <code>get_hits</code>        | Number of get hits to this chunk  | 1.3.x   |
| <code>cmd_set</code>         | Number of set commands on this chunk                                    | 1.3.x   |
| <code>delete_hits</code>     | Number of delete hits to this chunk                                     | 1.3.x   |
| <code>incr_hits</code>       | Number of increment hits to this chunk                                  | 1.3.x   |
| <code>decr_hits</code>       | Number of decrement hits to this chunk                                  | 1.3.x   |
| <code>cas_hits</code>        | Number of CAS hits to this chunk  | 1.3.x   |
| <code>cas_badval</code>      | Number of CAS hits on this chunk where the existing value did not match | 1.3.x   |
| <code>mem_requested</code>   | The true amount of memory of memory requested within this chunk         | 1.4.1   |

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

| Statistic                   | Description                                     | Version |
|-----------------------------|---|---------|
| <code>active_slabs</code>   | Total number of slab classes allocated.         |         |
| <code>total_malloced</code> | Total amount of memory allocated to slab pages. |         |

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

### 16.2.4.3 `memcached` Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

| Statistic                    | Description  |       |
|------------------------------|--|-------|
| <code>number</code>          | The number of items currently stored in this slab class.   |       |
| <code>age</code>             | The age of the oldest item within the slab class, in seconds.  |       |
| <code>evicted</code>         | The number of items evicted to make way for new entries.   |       |
| <code>evicted_time</code>    | The time of the last evicted entry   |       |
| <code>evicted_nonzero</code> | The time of the last evicted non-zero entry  | 1.4.0 |
| <code>outofmemory</code>     | The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect). |       |
| <code>tailrepairs</code>     | Number of times the entries for a particular ID need repairing   |       |

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

### 16.2.4.4 `memcached` Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the

nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

### Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

## 16.2.4.5 `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the `get`, `set`, and `del` operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail off
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

#### 16.2.4.6 Using `memcached-tool`

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
```

| #  | Item_Size | Max_age | Pages | Count | Full? | Evicted | Evict_Time | OOM |
|----|-----------|---------|-------|-------|-------|---------|------------|-----|
| 1  | 80B       | 93s     | 1     | 20    | no    | 0       | 0          | 0   |
| 2  | 104B      | 93s     | 1     | 16    | no    | 0       | 0          | 0   |
| 3  | 136B      | 1335s   | 1     | 28    | no    | 0       | 0          | 0   |
| 4  | 176B      | 1335s   | 1     | 24    | no    | 0       | 0          | 0   |
| 5  | 224B      | 1335s   | 1     | 32    | no    | 0       | 0          | 0   |
| 6  | 280B      | 1335s   | 1     | 34    | no    | 0       | 0          | 0   |
| 7  | 352B      | 1335s   | 1     | 36    | no    | 0       | 0          | 0   |
| 8  | 440B      | 1335s   | 1     | 46    | no    | 0       | 0          | 0   |
| 9  | 552B      | 1335s   | 1     | 58    | no    | 0       | 0          | 0   |
| 10 | 696B      | 1335s   | 1     | 66    | no    | 0       | 0          | 0   |
| 11 | 872B      | 1335s   | 1     | 89    | no    | 0       | 0          | 0   |
| 12 | 1.1K      | 1335s   | 1     | 112   | no    | 0       | 0          | 0   |
| 13 | 1.3K      | 1335s   | 1     | 145   | no    | 0       | 0          | 0   |
| 14 | 1.7K      | 1335s   | 1     | 123   | no    | 0       | 0          | 0   |
| 15 | 2.1K      | 1335s   | 1     | 198   | no    | 0       | 0          | 0   |
| 16 | 2.6K      | 1335s   | 1     | 199   | no    | 0       | 0          | 0   |
| 17 | 3.3K      | 1335s   | 1     | 229   | no    | 0       | 0          | 0   |

| 25 | 19.7K     | 1335s   | 7     | 357   | yes   | 908     | 170        | 0   |
| 26 | 24.6K     | 1336s   | 7     | 287   | yes   | 1012    | 1          | 0   |
| 27 | 30.8K     | 1336s   | 7     | 231   | yes   | 1193    | 169        | 0   |
| 28 | 38.5K     | 1336s   | 4     | 104   | yes   | 1323    | 169        | 0   |
| 29 | 48.1K     | 1336s   | 1     | 21    | yes   | 1287    | 1          | 0   |
| 30 | 60.2K     | 1336s   | 1     | 17    | yes   | 1093    | 169        | 0   |
| 31 | 75.2K     | 1337s   | 1     | 13    | yes   | 713     | 168        | 0   |
| 32 | 94.0K     | 1337s   | 1     | 10    | yes   | 278     | 168        | 0   |
| 33 | 117.5K    | 1336s   | 1     | 3     | no    | 0       | 0          | 0   |

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
# Item_Size Max_age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0
2 104B 93s 1 16 no 0 0 0
...
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab
- `Count`: The number of items in this slab
- `Full?`: Whether the slab is fully populated
- `Evicted`: The number of objects evicted from this slab
- `Evict_Time`: The time (in seconds) since the last eviction
- `OOM`: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211 Field Value
accepting_conns 1
bytes 162
bytes_read 485
bytes_written 6820

### 16.2.5.1 Can memcached be run on a Windows environment?

No. Currently [memcached](#) is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

### 16.2.5.2 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In [memcached](#) 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile [memcached](#). You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In [memcached](#) 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. [memcached](#) is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

### 16.2.5.3 Is it true [memcached](#) will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

**16.2.5.4** Are there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with `memcached`, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

**16.2.5.5** How is an event such as a crash of one of the `memcached` servers handled by the `memcached` client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 16.2.2.5, “memcached Hashing/Distribution Types”](#).

**16.2.5.6** What is a recommended hardware configuration for a `memcached` server?

`memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. A `memcached` server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

To build and deploy a dedicated `memcached` server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

**16.2.5.7** Is `memcached` more effective for video and audio as opposed to textual read/writes?

`memcached` works equally well for all kinds of data. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` is 1MB, but can be configured to be larger by using the `-I` option in `memcached` 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using `memcached` with audio and video content, you will probably want to increase the maximum object size. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**16.2.5.8** Can `memcached` work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# `memcached` library. For more information, see <https://sourceforge.net/projects/memcacheddotnet/>.

**16.2.5.9** How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a `memcached` instance to reduce the latency. Connection pooling

would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

**16.2.5.10** How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

**16.2.5.11** How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

**16.2.5.12** Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

**16.2.5.13** Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

**16.2.5.14** What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the memcached servers, and there is no complex configuration; just add more servers to the list and let the client API and the memcached servers make the decisions.

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous by default, therefore slaves do not need to be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see [Section A.13, “MySQL 5.5 FAQ: Replication”](#).

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.

- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of NDB Cluster (see [Chapter 18, MySQL NDB Cluster 7.2](#)). In MySQL 5.5, an interface to semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. See [Section 17.3.8, “Semisynchronous Replication”](#)

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 17.1.1, “How to Set Up Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 17.1.2, “Replication Formats”](#). In MySQL 5.5, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 17.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see [Section 17.4, “Replication Notes and Tips”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see [Section 17.2, “Replication Implementation”](#).

## 17.1 Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation.

Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's `master.info` file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, [Section 17.1.1, “How to Set Up Replication”](#), deals with the configuration of the systems and provides methods for copying data between the master and slaves.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 17.1.2, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 17.1.4, “Common Replication Administration Tasks”](#).

## 17.1.1 How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See [Section 17.1.1.1, “Setting the Replication Master Configuration”](#).
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Section 17.1.1.2, “Setting the Replication Slave Configuration”](#).
- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See [Section 17.1.1.3, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see [Section 17.1.1.5, “Creating a Data Snapshot Using mysqldump”](#)) or by copying the data files directly (see [Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#)).
- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Section 17.1.1.10, “Setting the Master Configuration on the Slave”](#).

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see [Section 17.1.1.7, “Setting Up Replication with New Master and Slaves”](#).
- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see [Section 17.1.1.8, “Setting Up Replication with Existing Data”](#).
- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See [Section 17.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”](#).

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), and [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). You should also familiarize yourself with the replication startup options described in [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).

**Note**

Note that certain steps within the setup process require the [SUPER](#) privilege. If you do not have this privilege, it might not be possible to enable replication.

### 17.1.1.1 Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging *must* be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and  $(2^{32})-1$ . How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

**Note**

If you omit `server-id` (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

**Note**

For the greatest possible durability and consistency in a replication setup using [InnoDB](#) with transactions, you should use [innodb\\_flush\\_log\\_at\\_trx\\_commit=1](#) and [sync\\_binlog=1](#) in the master [my.cnf](#) file.

**Note**

Ensure that the [skip-networking](#) option is not enabled on your replication master. If networking has been disabled, your slave will not be able to communicate with the master and replication will fail.

### 17.1.1.2 Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique [server-id](#) value that differs from that of the master and from each of the other slaves. Think of [server-id](#) values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

**Note**

If you omit [server-id](#) (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

### 17.1.1.3 Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the [REPLICATION SLAVE](#) privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the [master.info](#) file (see [Section 17.2.2.2, “Slave Status Logs”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use [CREATE USER](#). To grant this account the privileges required for replication, use the [GRANT](#) statement. If you create an account solely for the purposes of replication, that account needs only the [REPLICATION SLAVE](#) privilege. For example, to set up a new user, [repl](#), that can connect for replication from any host within the [mydomain.com](#) domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%mydomain.com';
```

See [Section 13.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

#### 17.1.1.4 Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For `InnoDB` tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

#### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.000003 | 73      | test        | manual,mysql     |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ( `' '` ) and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be to synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to [Section 17.1.1.5, “Creating a Data](#)

[Snapshot Using mysqldump](#), or [Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#). The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

### 17.1.1.5 Creating a Data Snapshot Using mysqldump

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool to create a dump of all the databases you want to replicate. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

The example shown here dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually (using `FLUSH TABLES WITH READ LOCK`) prior to running `mysqldump`, then exiting or running `UNLOCK TABLES` from the second session to release the locks. You must also obtain binary log position information matching the snapshot, using `SHOW MASTER STATUS`, and use this to issue the appropriate `CHANGE MASTER TO` statement when starting the slave.

When choosing databases to include in the dump, remember that you need to filter out databases on each slave that you do not want to include in the replication process.

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

### 17.1.1.6 Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using `mysqldump` and importing the file on each slave. This technique skips the overhead of updating indexes as the `INSERT` statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 25.2, “MySQL Enterprise Backup Overview”](#) for detailed information.

Otherwise, use the `cold backup` technique to obtain a reliable binary snapshot of `InnoDB` tables: copy all data files after doing a `slow shutdown` of the MySQL Server.

To create a raw data snapshot of `MyISAM` tables, you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot

tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For `InnoDB`, all tables in all databases are stored in the `system tablespace` files, unless you have the `innodb_file_per_table` option enabled.)

You might want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The `master.info` file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

### 17.1.1.7 Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See [Section 17.1.1.1, “Setting the Replication Master Configuration”](#).
2. Start up the MySQL master.
3. Set up a user. See [Section 17.1.1.3, “Creating a User for Replication”](#).
4. Obtain the master status information. See [Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See [Section 17.1.1.2, “Setting the Replication Slave Configuration”](#).
7. Start up the MySQL slave.
8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Section 17.1.1.10, “Setting the Master Configuration on the Slave”](#).

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

### 17.1.1.8 Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See [Section 17.1.1.3, “Creating a User for Replication”](#).
2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See [Section 17.1.1.1, “Setting the Replication Master Configuration”](#).

If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see [Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#)) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see [Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

3. If your master server is already correctly configured, obtain its status (see [Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#)) and then use `mysqldump` to take a snapshot (see [Section 17.1.1.5, “Creating a Data Snapshot Using mysqldump”](#)) or take a raw snapshot of the live server using the guide in [Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).
4. Update the configuration of the slave. See [Section 17.1.1.2, “Setting the Replication Slave Configuration”](#).
5. The next step depends on how you created the snapshot of data on the master.

If you used `mysqldump`:

- a. Start the slave, using the `--skip-slave-start` option so that replication does not start.
- b. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

- a. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

- b. Start the slave, using the `--skip-slave-start` option so that replication does not start.
6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Section 17.1.1.10, “Setting the Master Configuration on the Slave”](#).
7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO`

statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

#### Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

### 17.1.1.9 Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#), for more information about these options.)

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively—if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.

If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.

- b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
  - c. Proceed with the remaining steps in this section.
3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.
  4. Start the existing slave.
  5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.
  6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

#### 17.1.1.10 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

#### Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

### 17.1.2 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard statement-based binary logging format. In older versions of MySQL (5.1.4 and earlier), binary logging and replication used this format exclusively.
- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as *row-based replication* (often abbreviated as *RBR*). In row-based replication, the master writes *events* to the binary log that indicate how individual table rows are changed.

- The server can change the binary logging format in real time according to the type of event using *mixed-format logging*.

When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

In MySQL 5.5, statement-based format is the default.

**NDB Cluster.** The default binary logging format in all MySQL NDB Cluster 7.2 releases, beginning with MySQL NDB Cluster 7.2.1, is `STATEMENT`. (This is a change from previous versions of NDB Cluster.) You should note that NDB Cluster Replication always uses row-based replication, and that the `NDB` storage engine is incompatible with statement-based replication. This means that you must manually set the format to `ROW` prior to enabling NDB Cluster Replication. See [Section 18.6.2, “General Requirements for NDB Cluster Replication”](#), for more information.

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See [Section 5.4.4.2, “Setting The Binary Log Format”](#).

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 20.7, “Binary Logging of Stored Programs”](#).

### 17.1.2.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

## Advantages of statement-based replication

- Proven technology.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

## Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**

Not all statements which modify data (such as `INSERT`, `DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:

- A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 17.4.1.12, “Replication of Invoked Features”](#), for more information.
- `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See [Section 17.4.1.16, “Replication and LIMIT”](#).
- Statements using any of the following functions cannot be replicated properly using statement-based replication:
  - `LOAD_FILE()`
  - `UUID()`, `UUID_SHORT()`
  - `USER()`
  - `FOUND_ROWS()`
  - `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)
  - `GET_LOCK()`
  - `IS_FREE_LOCK()`
  - `IS_USED_LOCK()`
  - `MASTER_POS_WAIT()`
  - `RAND()`
  - `RELEASE_LOCK()`
  - `SLEEP()`
  - `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see [Section 17.4.1.15, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using [SHOW WARNINGS](#).

- [INSERT ... SELECT](#) requires a greater number of row-level locks than with row-based replication.
- [UPDATE](#) statements that require a table scan (because no index is used in the [WHERE](#) clause) must lock a greater number of rows than with row-based replication.
- For [InnoDB](#): An [INSERT](#) statement that uses [AUTO\\_INCREMENT](#) blocks other nonconflicting [INSERT](#) statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 17.4.1.29, “Slave Errors During Replication”](#).
- Stored functions execute with the same [NOW\(\)](#) value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See [Section 17.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

### Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

The [mysql](#) database is not replicated. The [mysql](#) database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information—such as [GRANT](#), [REVOKE](#) and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as [CREATE TABLE ... SELECT](#), a [CREATE](#) statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - [INSERT ... SELECT](#)
  - [INSERT](#) statements with [AUTO\\_INCREMENT](#)

- `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

### Disadvantages of row-based replication

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

### 17.1.2.2 Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see [Section 17.1.2, “Replication Formats”](#), and [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

For information about issues specific to NDB Cluster Replication (which depends on row-based replication), see [Section 18.6.3, “Known Issues in NDB Cluster Replication”](#).

- **RBL, RBR, and temporary tables.** As noted in [Section 17.4.1.24, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format. When mixed format is in effect, “safe” statements involving temporary tables are logged using statement-based format. For more information, see [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

Beginning with MySQL 5.5.5, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS`

statement for each temporary table that still exists for a given client session when that session ends. (Bug #11760229, Bug #11762267) While this means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF EXISTS` option.

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave's copy of the table.)
- **Latency and binary log size.** Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 13.7.6.1, “BINLOG Syntax”](#)). This statement displays an event in printable form, but as a base 64-encoded string the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBL when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 5.1.5, “Server System Variables”](#).

**Note**

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with NDB Cluster, for which `IDEMPOTENT` is the default value (see [Section 18.6, “NDB Cluster Replication”](#)).

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than NDB.

- **Lack of binary log checksums.** RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#), for general information about setting up MySQL with SSL.
- **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements, a simple example of such a clause being `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` system variable for statement filtering, you must also use `--binlog_format=STATEMENT`.

In MySQL 5.5, you can do filtering based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with the statement-based and row-based logging formats.

- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact that your choice of replication format has on how they operate, see [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).
- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database may reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format.

Use of `STOP SLAVE` (or `STOP SLAVE SQL_THREAD` in MySQL 5.5.9 and later) prior to shutting down the slave MySQL server helps prevent such issues from occurring, and is always recommended regardless of the logging format or storage engines employed.

### 17.1.2.3 Determination of Safe and Unsafe Statements in Binary Logging

When speaking of the “safeness” of a statement in MySQL Replication, we are referring to whether a statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see [Section 17.4.1.13, “Replication and Floating-Point Values”](#)).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- No distinction is made in the treatment of safe and unsafe statements when the binary logging mode is `ROW`.
- If the binary logging format is `MIXED`, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- If the binary logging format is `STATEMENT`, statements flagged as being unsafe generate a warning to this effect. (Safe statements are logged normally.)

Each statement flagged as unsafe generates a warning. Formerly, in cases where a great many such statements were executed on the master, this could lead to very large error log files, sometimes even filling up an entire disk unexpectedly. To guard against this, MySQL 5.5.27 introduced a warning suppression mechanism, which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note `The last warning was repeated N times in last S seconds` is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client (MySQL clients still receive one warning for each such statement).

For more information, see [Section 17.1.2, “Replication Formats”](#).

**Statements considered unsafe.**

Statements having the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.**

These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

**Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and `LAST_INSERT_ID()`.

For more information, see [Section 17.4.1.15, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. For exceptions, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

See [Section 17.4.1.38, “Replication and Variables”](#).

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.
- **Updates a table having an `AUTO_INCREMENT` column.** Prior to MySQL 5.5.3, all such statements were always considered unsafe because the order in which the rows are updated could differ on the master and the slave. In MySQL 5.3.3 and later, these statements are unsafe only when they are executed by a trigger or stored program (Bug #50192, Bug #11758052).

An `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

For more information, see [Section 17.4.1.1, “Replication and `AUTO\_INCREMENT`”](#).

- **`INSERT DELAYED` statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.
- **`INSERT ... ON DUPLICATE KEY UPDATE` statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication beginning with MySQL 5.5.24. (Bug #11765650, Bug #58637)

- **Updates using `LIMIT`.** The order in which rows are retrieved is not specified.

See [Section 17.4.1.16, “Replication and `LIMIT`”](#).

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 17.4.1.35, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **LOAD DATA INFILE statements.** Beginning with MySQL 5.5.6, `LOAD DATA INFILE` is treated as unsafe and when `binlog_format=mixed` the statement is logged in row-based format. When `binlog_format=statement` `LOAD DATA INFILE` does not generate a warning, unlike other unsafe statements.

For additional information, see [Section 17.4.1, “Replication Features and Issues”](#).

### 17.1.3 Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

|                            |                            |                        |
|----------------------------|----------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--server-id=#</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                | <code>server_id</code> |
|                            | <b>Variable Scope</b>      | Global                 |
|                            | <b>Dynamic Variable</b>    | Yes                    |
| <b>Permitted Values</b>    | <b>Type</b>                | integer                |
|                            | <b>Default</b>             | 0                      |
|                            | <b>Min Value</b>           | 0                      |
|                            | <b>Max Value</b>           | 4294967295             |

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 17.1.3.2, “Replication Master Options and Variables”](#), and [Section 17.1.3.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id`, the default ID is 0, in which case the master refuses connections from all slaves, and slaves refuse to connect to the master. In MySQL 5.5, whether the server ID is set to 0 explicitly or the default is allowed to be used, the server sets the `server_id` system variable to 1; this is a known issue that is fixed in MySQL 5.7.

For more information, see [Section 17.1.1.2, “Setting the Replication Slave Configuration”](#).

#### 17.1.3.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 17.1 Summary of Replication options and variables in MySQL 5.5**

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| <a href="#">abort-slave-event-count</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Option used by mysql-test for debugging and testing of replication |                 |                 |
| <a href="#">Com_change_master</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Count of CHANGE MASTER TO statements                               |                 |                 |
| <a href="#">Com_show_master_status</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Count of SHOW MASTER STATUS statements                             |                 |                 |
| <a href="#">Com_show_new_master</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Count of SHOW NEW MASTER statements                                |                 |                 |
| <a href="#">Com_show_slave_hosts</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Count of SHOW SLAVE HOSTS statements                               |                 |                 |
| <a href="#">Com_show_slave_status</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Count of SHOW SLAVE STATUS statements                              |                 |                 |
| <a href="#">Com_slave_start</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Count of START SLAVE statements                                    |                 |                 |
| <a href="#">Com_slave_stop</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Count of STOP SLAVE statements                                     |                 |                 |
| <a href="#">disconnect-slave-event-count</a>                                    |                 |                 |
| Yes   | No              | No              |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| Yes  |                 | No              |
| DESCRIPTION: Option used by mysql-test for debugging and testing of replication  |                 |                 |
| <code>init_slave</code>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Statements that are executed when a slave connects to a master  |                 |                 |
| <code>log_slave_updates</code>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Tells the slave to log the updates performed by its SQL thread to its own binary log  |                 |                 |
| <code>log_slave_updates</code>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Whether the slave should log the updates performed by its SQL thread to its own binary log. Read-only; set using the --log-slave-updates server option. |                 |                 |
| <code>master-connect-retry</code>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Number of seconds the slave thread will sleep before retrying to connect to the master in case the master goes down or the connection is lost           |                 |                 |
| <code>master-host</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Master host name or IP address for replication  |                 |                 |
| <code>master-info-file</code>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: The location and name of the file that remembers the master and where the I/O replication thread is in the master's binary logs                         |                 |                 |
| <code>master-password</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: The password the slave thread will authenticate with when connecting to master  |                 |                 |
| <code>master-port</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| DESCRIPTION: The port the master is listening on   |                 |                 |
| <code>master-retry-count</code>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Number of tries the slave makes to connect to the master before giving up   |                 |                 |
| <code>master-ssl</code>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Enable the slave to connect to the master using SSL   |                 |                 |
| <code>master-ssl-ca</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Master SSL CA file; applies only if master-ssl is enabled   |                 |                 |
| <code>master-ssl-capath</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Master SSL CA path; applies only if master-ssl is enabled   |                 |                 |
| <code>master-ssl-cert</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Master SSL certificate file name; applies only if master-ssl is enabled   |                 |                 |
| <code>master-ssl-cipher</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Master SSL cipher; applies only if master-ssl is enabled  |                 |                 |
| <code>master-ssl-key</code>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Master SSL key file name; applies only if master-ssl is enabled   |                 |                 |
| <code>master-user</code>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: The user name the slave thread will use for authentication when connecting to master. The user must have FILE privilege. If the master user is not set, user test is assumed. The value in master.info will take precedence if it can be read |                 |                 |
| <code>relay-log</code>   |                 |                 |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: The location and base name to use for relay logs<br><a href="#">relay-log-index</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: The location and name to use for the file that keeps a list of the last relay logs<br><a href="#">relay-log-info-file</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: The location and name of the file that remembers where the SQL replication thread is in the relay logs<br><a href="#">relay-log-recovery</a>                      |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Enables automatic recovery of relay log files from master at startup<br><a href="#">relay_log_index</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: The name of the relay log index file<br><a href="#">relay_log_info_file</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: The name of the file in which the slave records information about the relay logs<br><a href="#">relay_log_purge</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Determines whether relay logs are purged<br><a href="#">relay_log_recovery</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Whether automatic recovery of relay log files from master at startup is enabled; must be enabled for a crash-safe slave.<br><a href="#">relay_log_space_limit</a> |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| DESCRIPTION: Maximum space to use for all relay logs  |                 |                 |
| <a href="#">replicate-do-db</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread to restrict replication to the specified database                           |                 |                 |
| <a href="#">replicate-do-table</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread to restrict replication to the specified table                              |                 |                 |
| <a href="#">replicate-ignore-db</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread not to replicate to the specified database                                  |                 |                 |
| <a href="#">replicate-ignore-table</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread not to replicate to the specified table                                     |                 |                 |
| <a href="#">replicate-rewrite-db</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Updates to a database with a different name than the original  |                 |                 |
| <a href="#">replicate-same-server-id</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: In replication, if set to 1, do not skip events having our server id                                   |                 |                 |
| <a href="#">replicate-wild-do-table</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave thread to restrict replication to the tables that match the specified wildcard pattern |                 |                 |
| <a href="#">replicate-wild-ignore-table</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave thread not to replicate to the tables that match the given wildcard pattern            |                 |                 |
| <a href="#">report-host</a>   |                 |                 |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Host name or IP of the slave to be reported to the master during slave registration<br><a href="#">report-password</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: An arbitrary password that the slave server should report to the master. Not the same as the password for the MySQL replication user account.<br><a href="#">report-port</a>        |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Port for connecting to slave reported to the master during slave registration<br><a href="#">report-user</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: An arbitrary user name that a slave server should report to the master. Not the same as the name used with the MySQL replication user account.<br><a href="#">rpl_recovery_rank</a> |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Not used; removed in later versions<br><a href="#">Rpl_semi_sync_master_clients</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of semisynchronous slaves<br><a href="#">rpl_semi_sync_master_enabled</a>  |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Whether semisynchronous replication is enabled on the master<br><a href="#">Rpl_semi_sync_master_net_avg_wait_time</a>  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The average time the master waited for a slave reply<br><a href="#">Rpl_semi_sync_master_net_wait_time</a>  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| DESCRIPTION: The total time the master waited for slave replies                |                 |                 |
| <a href="#">Rpl_semi_sync_master_net_waits</a>                                 |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The total number of times the master waited for slave replies     |                 |                 |
| <a href="#">Rpl_semi_sync_master_no_times</a>                                  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of times the master turned off semisynchronous replication |                 |                 |
| <a href="#">Rpl_semi_sync_master_no_tx</a>                                     |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of commits not acknowledged successfully                   |                 |                 |
| <a href="#">Rpl_semi_sync_master_status</a>                                    |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Whether semisynchronous replication is operational on the master  |                 |                 |
| <a href="#">Rpl_semi_sync_master_timefunc_failures</a>                         |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of times the master failed when calling time functions     |                 |                 |
| <a href="#">rpl_semi_sync_master_timeout</a>                                   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Number of milliseconds to wait for slave acknowledgment           |                 |                 |
| <a href="#">rpl_semi_sync_master_trace_level</a>                               |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: The semisynchronous replication debug trace level on the master   |                 |                 |
| <a href="#">Rpl_semi_sync_master_tx_avg_wait_time</a>                          |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The average time the master waited for each transaction           |                 |                 |
| <a href="#">Rpl_semi_sync_master_tx_wait_time</a>                              |                 |                 |
| No   | No              | Yes             |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| No  | Global          | No              |
| DESCRIPTION: The total time the master waited for transactions<br><a href="#">Rpl_semi_sync_master_tx_waits</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: The total number of times the master waited for transactions<br><a href="#">rpl_semi_sync_master_wait_no_slave</a>   |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| DESCRIPTION: Whether master waits for timeout even with no slaves<br><a href="#">Rpl_semi_sync_master_wait_pos_backtraverse</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: The total number of times the master waited for an event with binary coordinates lower than events waited for previously<br><a href="#">Rpl_semi_sync_master_wait_sessions</a> |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of sessions currently waiting for slave replies<br><a href="#">Rpl_semi_sync_master_yes_tx</a>  |                 |                 |
| No  | No              | Yes             |

| No  | Global          | No              |
| DESCRIPTION: Whether semisynchronous replication is operational on slave<br><a href="#">rpl_semi_sync_slave_trace_level</a>   |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| DESCRIPTION: The semisynchronous replication debug trace level on the slave   |                 |                 |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| <a href="#">Rpl_status</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: The status of fail-safe replication (not implemented)  |                 |                 |
| <a href="#">show-slave-auth-info</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Show user name and password in SHOW SLAVE HOSTS on this master   |                 |                 |
| <a href="#">skip-slave-start</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: If set, slave is not autostarted   |                 |                 |
| <a href="#">slave-load-tmpdir</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: The location where the slave should put its temporary files when replicating a LOAD DATA INFILE statement                |                 |                 |
| <a href="#">slave-max-allowed-packet</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet. |                 |                 |
| <a href="#">slave_net_timeout</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Number of seconds to wait for more data from a master/slave connection before aborting the read                          |                 |                 |
| <a href="#">slave-skip-errors</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Tells the slave thread to continue replication when a query returns an error from the provided list                      |                 |                 |
| <a href="#">slave_compressed_protocol</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Use compression on master/slave protocol   |                 |                 |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| <a href="#">slave_exec_mode</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Allows for switching the slave thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for NDB Cluster, where IDEMPOTENT is always used |                 |                 |
| <a href="#">Slave_heartbeat_period</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The slave's replication heartbeat interval, in seconds  |                 |                 |
| <a href="#">slave_max_allowed_packet</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.  |                 |                 |
| <a href="#">Slave_open_temp_tables</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of temporary tables that the slave SQL thread currently has open   |                 |                 |
| <a href="#">Slave_retried_transactions</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The total number of times since startup that the replication slave SQL thread has retried transactions  |                 |                 |
| <a href="#">Slave_running</a>  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The state of this server as a replication slave (slave I/O thread status)   |                 |                 |
| <a href="#">slave_transaction_retries</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping   |                 |                 |
| <a href="#">slave_type_conversions</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| DESCRIPTION: Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave. |                 |                 |
| <a href="#">sql_slave_skip_counter</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Number of events from the master that a slave server should skip. Not compatible with GTID replication.   |                 |                 |
| <a href="#">sync_binlog</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Synchronously flush binary log to disk after every #th event  |                 |                 |
| <a href="#">sync_master_info</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Synchronize master.info to disk after every #th event.  |                 |                 |
| <a href="#">sync_relay_log</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Synchronize relay log to disk after every #th event.  |                 |                 |
| <a href="#">sync_relay_log_info</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Synchronize relay.info file to disk after every #th event.  |                 |                 |

[Section 17.1.3.2, “Replication Master Options and Variables”](#), provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see [Section 17.1.3.3, “Replication Slave Options and Variables”](#).

**Table 17.2 Summary of Binary Logging options and variables in MySQL 5.5**

| Option or Variable Name                                  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| <a href="#">binlog-do-db</a>                             |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Limits binary logging to specific databases |                 |                 |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| <a href="#">binlog_format</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Specifies the format of the binary log  |                 |                 |
| <a href="#">binlog-ignore-db</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Tells the master that updates to the given database should not be logged to the binary log  |                 |                 |
| <a href="#">binlog-row-event-max-size</a>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Binary log max event size   |                 |                 |
| <a href="#">Binlog_cache_disk_use</a>  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of transactions that used a temporary file instead of the binary log cache   |                 |                 |
| <a href="#">binlog_cache_size</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Size of the cache to hold the SQL statements for the binary log during a transaction  |                 |                 |
| <a href="#">Binlog_cache_use</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of transactions that used the temporary binary log cache   |                 |                 |
| <a href="#">binlog_direct_non_transactional_updates</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using. |                 |                 |
| <a href="#">Binlog_stmt_cache_disk_use</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of nontransactional statements that used a temporary file instead of the binary log statement cache                              |                 |                 |
| <a href="#">binlog_stmt_cache_size</a>   |                 |                 |

| Option or Variable Name  |                 |                 |

| DESCRIPTION: Option used by mysql-test for debugging and testing of replication  |                 |                 |

[Section 17.1.3.4, “Binary Log Options and Variables”](#), provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see [Section 5.4.4, “The Binary Log”](#).

For information about the `sql_log_bin` and `sql_log_off` variables, see [Section 5.1.5, “Server System Variables”](#).

For a table showing *all* command-line options, system and status variables used with `mysqld`, see [Section 5.1.3, “Server Option and Variable Reference”](#).

### 17.1.3.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see [Section 17.1.3.4, “Binary Log Options and Variables”](#).

### System Variables Used on Replication Masters

The following system variables are used in controlling replication masters:

- `auto_increment_increment`

|                         |                         |                                       |
|-------------------------|-------------------------|---------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>auto_increment_increment</code> |
|                         | <b>Variable Scope</b>   | Global, Session                       |
|                         | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values</b> | <b>Type</b>             | integer                               |

|  |                  |       |
|--|------------------|-------|
|  | <b>Default</b>   | 1     |
|  | <b>Min Value</b> | 1     |
|  | <b>Max Value</b> | 65535 |

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

**Note**

`auto_increment_increment` is also supported for use with `NDB` tables.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name | Value |
+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name | Value |
+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+----+
| col |
+----+
| 1 |
| 11 |
+----+
```

```
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset   | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)
```

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset   | 5 |
+-----+-----+
2 rows in set (0.00 sec)
```

```

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)

```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 17.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `auto_increment_offset`

|                         |                         |                                    |
|-------------------------|-------------------------|------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>auto_increment_offset</code> |
|                         | <b>Variable Scope</b>   | Global, Session                    |
|                         | <b>Dynamic Variable</b> | Yes                                |
| <b>Permitted Values</b> | <b>Type</b>             | integer                            |
|                         | <b>Default</b>          | 1                                  |
|                         | <b>Min Value</b>        | 1                                  |

|  |                  |       |
|--|------------------|-------|
|  | <b>Max Value</b> | 65535 |
|--|------------------|-------|

This variable has a default value of 1. For particulars, see the description for [auto\\_increment\\_increment](#).

#### Note

[auto\\_increment\\_offset](#) is also supported for use with [NDB](#) tables.

### 17.1.3.3 Replication Slave Options and Variables

#### Startup Options for Replication Slaves

#### Obsolete Replication Slave Options

#### System Variables Used on Replication Slaves

This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the [CHANGE MASTER TO](#) statement. You can specify system variable values using [SET](#).

**Server ID.** On the master and each slave, you must use the [server-id](#) option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example [my.cnf](#) file:

```
[mysqld]
server-id=3
```

### Startup Options for Replication Slaves

The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the [CHANGE MASTER TO](#) statement. Others, such as the [--replicate-\\*](#) options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- [--abort-slave-event-count](#)

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <a href="#">--abort-slave-event-count=#</a> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                 | integer |
|                            | <b>Default</b>                              | 0       |
|                            | <b>Min Value</b>                            | 0       |

When this option is set to some positive integer [value](#) other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, [value](#) log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from [SHOW SLAVE STATUS](#) displays [Yes](#) in both the [Slave\\_IO\\_Running](#) and the [Slave\\_SQL\\_Running](#) columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--disconnect-slave-event-count=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                   | integer |
|                            | <b>Default</b>                                | 0       |

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--log-slave-updates`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--log-slave-updates</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>log_slave_updates</code> |
|                            | <b>Variable Scope</b>            | Global                         |
|                            | <b>Dynamic Variable</b>          | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | OFF                            |

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. Prior to MySQL 5.5, the server would not start when using the `--log-slave-updates` option without also starting the server with the `--log-bin` option, and would fail with an error; in MySQL 5.5, only a warning is generated. (Bug #44663) `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the master for the slave `B`, and `B` serves as the master for the slave `C`. For this to work, `B` must be both a master *and* a slave. You must start both `A` and `B` with `--log-bin` to enable binary logging, and `B` with the `--log-slave-updates` option so that updates received from `A` are logged by `B` to its binary log.

- `--log-slow-slave-statements`

|                            |  |         |
|----------------------------|--|---------|
| <b>Command-Line Format</b> | <code>--log-slow-slave-statements</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean |
|                            | <b>Default</b>                           | OFF     |

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

- `--log-warnings[=level]`

|                            |                                 |                           |
|----------------------------|---------------------------------|---------------------------|
| <b>Command-Line Format</b> | <code>--log-warnings[=#]</code> |                           |
| <b>System Variable</b>     | <b>Name</b>                     | <code>log_warnings</code> |
|                            | <b>Variable Scope</b>           | Global, Session           |
|                            |                                 | 2029                      |

|  | Dynamic Variable | Yes                  |
|--|------------------|----------------------|
| <b>Permitted Values</b> (32-bit platforms)           | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 1                    |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms, <= 5.5.2) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 1                    |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709547520 |
| <b>Permitted Values</b> (64-bit platforms, >= 5.5.3) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 1                    |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709551615 |

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled (1) by default; to disable it, use `--log-warnings=0`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-info-file=file_name`

|                            |   |                          |
|----------------------------|---|--------------------------|
| <b>Command-Line Format</b> | <code>--master-info-file=file_name</code> |                          |
| <b>Permitted Values</b>    | <b>Type</b>                               | file name                |
|                            | <b>Default</b>                            | <code>master.info</code> |

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see [Section 17.2.2.2, “Slave Status Logs”](#).

- `--master-retry-count=count`

|  |                                     |         |
|--|-------------------------------------|---------|
| <b>Command-Line Format</b>                 | <code>--master-retry-count=#</code> |         |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                         | integer |
|  | <b>Default</b>                      | 86400   |
|  | <b>Min Value</b>                    | 0       |

|  |                  |                      |
|--|------------------|----------------------|
|  | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 86400                |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709551615 |

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

- `slave-max-allowed-packet=bytes`

|                            |   |            |
|----------------------------|---|------------|
| <b>Introduced</b>          | 5.5.26                                    |            |
| <b>Command-Line Format</b> | <code>--slave-max-allowed-packet=#</code> |            |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer    |
|                            | <b>Default</b>                            | 1073741824 |
|                            | <b>Min Value</b>                          | 1024       |
|                            | <b>Max Value</b>                          | 1073741824 |

In MySQL 5.5.26 and later, this option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--max-relay-log-size=size`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--max-relay-log-size=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>max_relay_log_size</code> |
|                            | <b>Variable Scope</b>               | Global                          |
|                            | <b>Dynamic Variable</b>             | Yes                             |
|                            | <b>Permitted Values</b>             |                                 |
|                            | <b>Type</b>                         | integer                         |
|                            | <b>Default</b>                      | 0                               |

|  |                  |            |
|--|------------------|------------|
|  | <b>Min Value</b> | 0          |
|  | <b>Max Value</b> | 1073741824 |

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see [Section 17.2.2.1, “The Slave Relay Log”](#).

- `--relay-log=file_name`

|                            |                                    |                        |
|----------------------------|------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--relay-log=file_name</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                        | <code>relay_log</code> |
|                            | <b>Variable Scope</b>              | Global                 |
|                            | <b>Dynamic Variable</b>            | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                        | file name              |

The base name for the relay log. The default base name is `host_name-relay-bin`. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

Starting with MySQL 5.5.20, when the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Prior to MySQL 5.5.20, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
  - If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
  - To increase speed by using load-balancing between disks.
- `--relay-log-index=file_name`

|                            |  |                              |
|----------------------------|--|------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-index=file_name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                              | <code>relay_log_index</code> |
|                            | <b>Variable Scope</b>                    | Global                       |
|                            | <b>Dynamic Variable</b>                  | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                              | file name                    |

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

|                            |  |                             |
|----------------------------|--|-----------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-info-file=file_name</code> |                             |
| <b>Permitted Values</b>    | <b>Type</b>                                  | file name                   |
|                            | <b>Default</b>                               | <code>relay-log.info</code> |

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see [Section 17.2.2.2, “Slave Status Logs”](#).

- `--relay-log-purge={0|1}`

|                            |                                |                              |
|----------------------------|--------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-purge</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                    | <code>relay_log_purge</code> |
|                            | <b>Variable Scope</b>          | Global                       |
|                            | <b>Dynamic Variable</b>        | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                    | boolean                      |
|                            | <b>Default</b>                 | <code>TRUE</code>            |

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-recovery={0|1}`

|                            |                                   |  |
|----------------------------|-----------------------------------|--|
| <b>Command-Line Format</b> | <code>--relay-log-recovery</code> |  |
|----------------------------|-----------------------------------|--|

|                         |                |                    |
|-------------------------|----------------|--------------------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean            |
|                         | <b>Default</b> | <code>FALSE</code> |

Enables automatic relay log recovery immediately following server startup, which means that the replication slave discards all unprocessed relay logs and retrieves them from the replication master. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

- `--relay-log-space-limit=size`

|  |  |                                    |
|--|--|------------------------------------|
| <b>Command-Line Format</b>                           | <code>--relay-log-space-limit=#</code> |                                    |
| <b>System Variable</b>                               | <b>Name</b>                            | <code>relay_log_space_limit</code> |
|  | <b>Variable Scope</b>                  | Global                             |
|  | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b> (32-bit platforms)           | <b>Type</b>                            | integer                            |
|  | <b>Default</b>                         | 0                                  |
|  | <b>Min Value</b>                       | 0                                  |
|  | <b>Max Value</b>                       | 4294967295                         |
| <b>Permitted Values</b> (64-bit platforms, <= 5.5.2) | <b>Type</b>                            | integer                            |
|  | <b>Default</b>                         | 0                                  |
|  | <b>Min Value</b>                       | 0                                  |
|  | <b>Max Value</b>                       | 18446744073709547520               |
| <b>Permitted Values</b> (64-bit platforms, >= 5.5.3) | <b>Type</b>                            | integer                            |
|  | <b>Default</b>                         | 0                                  |
|  | <b>Min Value</b>                       | 0                                  |
|  | <b>Max Value</b>                       | 18446744073709551615               |

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

|                            |                                     |        |
|----------------------------|-------------------------------------|--------|
| <b>Command-Line Format</b> | <code>--replicate-do-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                         | string |

The effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

#### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

|                            |   |        |
|----------------------------|---|--------|
| <b>Command-Line Format</b> | <code>--replicate-ignore-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                             | string |

As with `--replicate-do-db`, the effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's

copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--replicate-do-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                            | string |

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--replicate-ignore-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                                | string |

Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--replicate-rewrite-db=old_name-&gt;new_name</code> |  |
|----------------------------|---|--|

| Permitted Values | Type | string |
|------------------|------|--------|
|------------------|------|--------|

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
shell> mysql --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

| Command-Line Format | <code>--replicate-same-server-id</code> |                    |
|---------------------|---|--------------------|
| Permitted Values    | Type                                    | boolean            |
|                     | Default                                 | <code>FALSE</code> |

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

| Command-Line Format | <code>--replicate-wild-do-table=name</code> |        |
|---------------------|---|--------|
| Permitted Values    | Type  | string |

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

|                            |   |        |
|----------------------------|---|--------|
| <b>Command-Line Format</b> | <code>--replicate-wild-ignore-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                                     | string |

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

|                            |                                      |                          |
|----------------------------|--------------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--report-host=host_name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                          | <code>report_host</code> |
|                            | <b>Variable Scope</b>                | Global                   |
|                            | <b>Dynamic Variable</b>              | No                       |
| <b>Permitted Values</b>    | <b>Type</b>                          | string                   |

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

|                            |                                     |                              |
|----------------------------|-------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--report-password=name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                         | <code>report_password</code> |
|                            | <b>Variable Scope</b>               | Global                       |
|                            | <b>Dynamic Variable</b>             | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                         | string                       |

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

|  |                              |                          |
|--|------------------------------|--------------------------|
| <b>Command-Line Format</b>             | <code>--report-port=#</code> |                          |
| <b>System Variable</b>                 | <b>Name</b>                  | <code>report_port</code> |
|  | <b>Variable Scope</b>        | Global                   |
|  | <b>Dynamic Variable</b>      | No                       |
| <b>Permitted Values (&lt;= 5.5.22)</b> | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 3306                     |
|  | <b>Min Value</b>             | 0                        |
|  | <b>Max Value</b>             | 65535                    |
| <b>Permitted Values (&gt;= 5.5.23)</b> | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 0                        |
|  | <b>Min Value</b>             | 0                        |
|  | <b>Max Value</b>             | 65535                    |

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

Prior to MySQL 5.5.23, the default value for this option was 3306. In MySQL 5.5.23 and later, the value shown is the port number actually used by the slave (Bug #13333431). This change also affects the default value displayed by `SHOW SLAVE HOSTS`.

- `--report-user=user_name`

|                            |                                 |                          |
|----------------------------|---------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--report-user=name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                     | <code>report_user</code> |
|                            | <b>Variable Scope</b>           | Global                   |
|                            | <b>Dynamic Variable</b>         | No                       |
| <b>Permitted Values</b>    | <b>Type</b>                     | string                   |

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info`

|                            |                                     |                    |
|----------------------------|-------------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--show-slave-auth-info</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                         | boolean            |
|                            | <b>Default</b>                      | <code>FALSE</code> |

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

|                            |                                 |                    |
|----------------------------|---------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--skip-slave-start</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                     | boolean            |
|                            | <b>Default</b>                  | <code>FALSE</code> |

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--slave-compressed-protocol</code> |  |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_compressed_protocol</code> |
|                            | <b>Variable Scope</b>                    | Global                                 |
|                            | <b>Dynamic Variable</b>                  | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean                                |
|                            | <b>Default</b>                           | <code>OFF</code>                       |

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

|                            |   |                                |
|----------------------------|---|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-load-tmpdir=dir_name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                               | <code>slave_load_tmpdir</code> |
|                            | <b>Variable Scope</b>                     | Global                         |
|                            | <b>Dynamic Variable</b>                   | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                               | directory name                 |
|                            | <b>Default</b>                            | <code>/tmp</code>              |

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-net-timeout=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                        | <code>slave_net_timeout</code> |
|                            | <b>Variable Scope</b>              | Global                         |
|                            | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                        | integer                        |
|                            | <b>Default</b>                     | <code>3600</code>              |
|                            | <b>Min Value</b>                   | <code>1</code>                 |

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

(MySQL NDB Cluster 7.2.6 and later:) `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

|                            |                                       |                                |
|----------------------------|---------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-skip-errors=name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                           | <code>slave_skip_errors</code> |

|   |                         |                       |
|---|-------------------------|-----------------------|
|   | <b>Variable Scope</b>   | Global                |
|   | <b>Dynamic Variable</b> | No                    |

|   |                         |                       |
|   | <b>Type</b>             | string                |
|   | <b>Default</b>          | OFF                   |

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

MySQL NDB Cluster 7.2.6 and later support an additional shorthand value `ddl_exist_errors` for use with the enhanced failover mechanism which is implemented beginning with that version of NDB Cluster. This value is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`. *This value is not supported by the `mysqld` binary included with the MySQL Server 5.5 distribution.* (Bug #11762277, Bug #54854) For more information, see [Section 18.6.8, “Implementing Failover with NDB Cluster Replication”](#).

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

## Obsolete Replication Slave Options

*The following options are removed in MySQL 5.5. If you attempt to start `mysqld` with any of these options in MySQL 5.5, the server aborts with an `unknown variable` error. To set the replication parameters formerly associated with these options, you must use the `CHANGE MASTER TO ...` statement (see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#)).*

The options affected are shown in this list:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

## System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

|                            |                                |                         |
|----------------------------|--------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--init-slave=name</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                    | <code>init_slave</code> |
|                            | <b>Variable Scope</b>          | Global                  |

|                         |                         |        |
|-------------------------|-------------------------|--------|
|                         | <b>Dynamic Variable</b> | Yes    |
| <b>Permitted Values</b> | <b>Type</b>             | string |

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

#### Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 13.4.2.5, “START SLAVE Syntax”](#), for more information.

- `relay_log`

|                            |                                    |                        |
|----------------------------|------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--relay-log=file_name</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                        | <code>relay_log</code> |
|                            | <b>Variable Scope</b>              | Global                 |
|                            | <b>Dynamic Variable</b>            | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                        | file name              |

The name of the relay log file.

- `relay_log_index`

|                            |                                |  |
|----------------------------|--------------------------------|--|
| <b>Command-Line Format</b> | <code>--relay-log-index</code> |  |
| <b>System Variable</b>     | <b>Name</b>                    | <code>relay_log_index</code>             |
|                            | <b>Variable Scope</b>          | Global                                   |
|                            | <b>Dynamic Variable</b>        | No                                       |
| <b>Permitted Values</b>    | <b>Type</b>                    | file name                                |
|                            | <b>Default</b>                 | <code>*host_name*-relay-bin.index</code> |

The name of the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

|                            |  |                                  |
|----------------------------|--|----------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-info-file=file_name</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>relay_log_info_file</code> |
|                            | <b>Variable Scope</b>                        | Global                           |
|                            | <b>Dynamic Variable</b>                      | No                               |
| <b>Permitted Values</b>    | <b>Type</b>                                  | file name                        |

|  |                |                             |
|--|----------------|-----------------------------|
|  | <b>Default</b> | <code>relay-log.info</code> |
|--|----------------|-----------------------------|

The name of the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `relay_log_recovery`

|                            |                                   |                                 |
|----------------------------|-----------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-recovery</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                       | <code>relay_log_recovery</code> |
|                            | <b>Variable Scope</b>             | Global                          |
|                            | <b>Dynamic Variable</b>           | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean                         |
|                            | <b>Default</b>                    | <code>FALSE</code>              |

Enables automatic relay log recovery immediately following server startup, which means that the replication slave discards all unprocessed relay logs and retrieves them from the replication master. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled). This global variable can be changed dynamically, or by starting the slave with the `--relay-log-recovery` option.

- `rpl_recovery_rank`

This variable is unused, and is removed in MySQL 5.6.

- `slave_compressed_protocol`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--slave-compressed-protocol</code> |  |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_compressed_protocol</code> |
|                            | <b>Variable Scope</b>                    | Global                                 |
|                            | <b>Dynamic Variable</b>                  | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean                                |
|                            | <b>Default</b>                           | <code>OFF</code>                       |

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_exec_mode`

|                            |                                     |                              |
|----------------------------|-------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--slave-exec-mode=mode</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                         | <code>slave_exec_mode</code> |
|                            | <b>Variable Scope</b>               | Global                       |
|                            | <b>Dynamic Variable</b>             | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                         | enumeration                  |
|                            | <b>Default</b>                      | <code>STRICT (ALL)</code>    |

|  |                     |                               |
|--|---------------------|-------------------------------|
|  | <b>Default</b>      | <code>IDEMPOTENT</code> (NDB) |
|  | <b>Valid Values</b> | <code>IDEMPOTENT</code>       |
|  |                     | <code>STRICT</code>           |

Controls how a slave thread resolves conflicts and errors during replication. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. This mode should be employed in multi-master replication, circular replication, and some other special replication scenarios. `STRICT` mode is the default, and is suitable for most other cases.

This mode is needed for multi-master replication, circular replication, and some other special replication scenarios for NDB Cluster Replication. (See [Section 18.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”](#), and [Section 18.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.) The `mysqld` supplied with NDB Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as `IDEMPOTENT`.

In MySQL Server 5.5, `STRICT` mode is the default value. This should not be changed; currently, `IDEMPOTENT` mode is supported only by NDB.

- `slave_load_tmpdir`

|                            |   |                                |
|----------------------------|---|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-load-tmpdir=dir_name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                               | <code>slave_load_tmpdir</code> |
|                            | <b>Variable Scope</b>                     | Global                         |
|                            | <b>Dynamic Variable</b>                   | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                               | directory name                 |
|                            | <b>Default</b>                            | <code>/tmp</code>              |

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_max_allowed_packet`

|                         |                         |                                       |
|-------------------------|-------------------------|---------------------------------------|
| <b>Introduced</b>       | 5.5.26                  |                                       |
| <b>System Variable</b>  | <b>Name</b>             | <code>slave_max_allowed_packet</code> |
|                         | <b>Variable Scope</b>   | Global                                |
|                         | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values</b> | <b>Type</b>             | integer                               |
|                         | <b>Default</b>          | <code>1073741824</code>               |
|                         | <b>Min Value</b>        | <code>1024</code>                     |
|                         | <b>Max Value</b>        | <code>1073741824</code>               |

In MySQL 5.5.26 and later, this variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_net_timeout`

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-net-timeout=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                        | <code>slave_net_timeout</code> |
|                            | <b>Variable Scope</b>              | Global                         |
|                            | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                        | integer                        |
|                            | <b>Default</b>                     | 3600                           |
|                            | <b>Min Value</b>                   | 1                              |

The number of seconds to wait for more data from a master/slave connection before aborting the read.

- `slave_skip_errors`

|                            |                                       |                                |
|----------------------------|---------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-skip-errors=name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                           | <code>slave_skip_errors</code> |
|                            | <b>Variable Scope</b>                 | Global                         |
|                            | <b>Dynamic Variable</b>               | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                           | string                         |
|                            | <b>Default</b>                        | OFF                            |
|                            | <b>Valid Values</b>                   | OFF                            |
|                            |                                       | [list of error codes]          |

|   |                     | ddl_exist_errors              |

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_transaction_retries`

|  |  |  |
|--|--|--|
| <b>Command-Line Format</b>                               | <code>--slave-transaction-retries=#</code> |  |

Controls the type conversion mode in effect on the slave when using row-based replication, including NDB Cluster Replication. Its value is a comma-delimited set of zero or more elements from the list: [ALL\\_LOSSY](#), [ALL\\_NON\\_LOSSY](#). Set this variable to an empty string to disallow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

This variable was added in MySQL 5.5.3.

- [sql\\_slave\\_skip\\_counter](#)

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">sql_slave_skip_counter</a> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                |

The number of events from the master that a slave server should skip.

#### Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 13.4.2.4, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

- [sync\\_master\\_info](#)

If the value of this variable is greater than 0, a replication slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. The default value is 0 (recommended in most situations), which does not force any synchronization to disk by the MySQL server; in this case, the server relies on the operating system to flush the `master.info` file's contents from time to time as for any other file.

- `sync_relay_log`

|  |                                 |                             |

|  | <b>Max Value</b> | 18446744073709551615 |

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatsync()`) after every `sync_relay_log` events are written to the relay log.

The default value of `sync_relay_log` is 0, which does no synchronizing to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

|  |                                      |                                  |
|--|--------------------------------------|----------------------------------|
| <b>Command-Line Format</b>                           | <code>--sync-relay-log-info=#</code> |                                  |
| <b>System Variable</b>                               | <b>Name</b>                          | <code>sync_relay_log_info</code> |
|  | <b>Variable Scope</b>                | Global                           |
|  | <b>Dynamic Variable</b>              | Yes                              |
| <b>Permitted Values</b> (32-bit platforms)           | <b>Type</b>                          | integer                          |
|  | <b>Default</b>                       | 0                                |
|  | <b>Min Value</b>                     | 0                                |
|  | <b>Max Value</b>                     | 4294967295                       |
| <b>Permitted Values</b> (64-bit platforms, <= 5.5.2) | <b>Type</b>                          | integer                          |
|  | <b>Default</b>                       | 0                                |
|  | <b>Min Value</b>                     | 0                                |
|  | <b>Max Value</b>                     | 18446744073709547520             |

|  |                  |                      |
|--|------------------|----------------------|
| <b>Permitted Values</b> (64-bit platforms, >= 5.5.3) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 0                    |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709551615 |

If the value of this variable is greater than 0, a replication slave synchronizes its `relay-log.info` file to disk (using `fdatasync()`) after every `sync_relay_log_info` transactions. A value of 1 is the generally the best choice. The default value of `sync_relay_log_info` is 0, which does not force any synchronization to disk by the MySQL server—in this case, the server relies on the operating system to flush the `relay-log.info` file's contents from time to time as for any other file.

### 17.1.3.4 Binary Log Options and Variables

#### Startup Options Used with Binary Logging

#### System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.4.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.4, “Server Command Options”](#), and [Section 5.1.5, “Server System Variables”](#).

### Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

|  |  |                      |
|--|--|----------------------|
| <b>Command-Line Format</b>                           | <code>--binlog-row-event-max-size=#</code> |                      |
| <b>Permitted Values</b> (32-bit platforms)           | <b>Type</b>                                | integer              |
|  | <b>Default</b>                             | 1024                 |
|  | <b>Min Value</b>                           | 256                  |
|  | <b>Max Value</b>                           | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms, <= 5.5.2) | <b>Type</b>                                | integer              |
|  | <b>Default</b>                             | 1024                 |
|  | <b>Min Value</b>                           | 256                  |
|  | <b>Max Value</b>                           | 18446744073709547520 |
| <b>Permitted Values</b> (64-bit platforms, >= 5.5.3) | <b>Type</b>                                | integer              |
|  | <b>Default</b>                             | 1024                 |
|  | <b>Min Value</b>                           | 256                  |

|  |                  |                      |
|--|------------------|----------------------|
|  | <b>Max Value</b> | 18446744073709551615 |
|--|------------------|----------------------|

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See [Section 17.1.2, “Replication Formats”](#).

- `--log-bin[=base_name]`

|                            |                         |                      |
|----------------------------|-------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--log-bin</code>  |                      |
| <b>System Variable</b>     | <b>Name</b>             | <code>log_bin</code> |
|                            | <b>Variable Scope</b>   | Global               |
|                            | <b>Dynamic Variable</b> | No                   |
| <b>Permitted Values</b>    | <b>Type</b>             | file name            |

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 5.4.4, “The Binary Log”](#).

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see [Section B.5.7, “Known Issues in MySQL”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

In MySQL 5.5.20 and later, when the server reads an entry from the index file, it checks whether the entry contains a relative path, and if it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previous to MySQL 5.5.20, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. This is a known issue; see Bug #19614 for more information.

- `--log-bin-index[=file_name]`

|                            |  |           |
|----------------------------|--|-----------|
| <b>Command-Line Format</b> | <code>--log-bin-index=file_name</code> |           |
| <b>Permitted Values</b>    | <b>Type</b>                            | file name |

The index file for binary log file names. See [Section 5.4.4, “The Binary Log”](#). If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--log-bin-trust-function-creators</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>log_bin_trust_function_creators</code> |
|                            | <b>Variable Scope</b>                          | Global                                       |
|                            | <b>Dynamic Variable</b>                        | Yes  |
|                            |  | 2054   |

|                         |                |                    |
|-------------------------|----------------|--------------------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean            |
|                         | <b>Default</b> | <code>FALSE</code> |

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 20.7, “Binary Logging of Stored Programs”](#).

- `--log-bin-use-v1-row-events[={0|1}]`

|  |  |  |
|--|--|--|
| <b>Introduced</b>                                  | 5.5.15-ndb-7.2.1                                 |  |
| <b>Command-Line Format</b>                         | <code>--log-bin-use-v1-row-events[={0 1}]</code> |  |
| <b>System Variable</b>                             | <b>Name</b>                                      | <code>log_bin_use_v1_row_events</code> |
|  | <b>Variable Scope</b>                            | Global                                 |
|  | <b>Dynamic Variable</b>                          | No                                     |
| <b>Permitted Values</b> ( $\geq$ 5.5.15-ndb-7.2.1) | <b>Type</b>                                      | boolean                                |
|  | <b>Default</b>                                   | 0                                      |

Version 2 binary log row events are used by default beginning with MySQL NDB Cluster 7.2.1; however, Version 2 events cannot be read by previous NDB Cluster releases. Setting `--log-bin-use-v1-row-events` to 1 causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

#### Note

Version 2 binary log row events are also available in MySQL NDB Cluster 7.0.27 and MySQL NDB Cluster 7.1.6 and later MySQL NDB Cluster 7.0 and 7.1 releases. However, prior to MySQL NDB Cluster 7.2.1, Version 1 events are the default (and so the default value for this option is 1 in those versions). You should keep this mind when planning upgrades for setups using NDB Cluster Replication.

`--log-bin-use-v1-row-events` is not supported in mainline MySQL Server 5.5 releases.

For more information, see [Section 18.6.11, “NDB Cluster Replication Conflict Resolution”](#).

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 17.1.3.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

|                            |                                  |        |
|----------------------------|----------------------------------|--------|
| <b>Command-Line Format</b> | <code>--binlog-do-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                      | string |

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

#### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

|                            |                                      |        |
|----------------------------|--------------------------------------|--------|
| <b>Command-Line Format</b> | <code>--binlog-ignore-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                          | string |

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Prior to MySQL 5.5.32, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.5.32 and later, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--max-binlog-dump-events=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer |
|                            | <b>Default</b>                          | 0       |

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

|                            |  |                    |
|----------------------------|--|--------------------|
| <b>Command-Line Format</b> | <code>--sporadic-binlog-dump-fail</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean            |
|                            | <b>Default</b>                           | <code>FALSE</code> |

This option is used internally by the MySQL test suite for replication testing and debugging.

## System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary

logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see [Section 5.1.5, “Server System Variables”](#).

- `binlog_cache_size`

|  |                                    |                                |
|--|------------------------------------|--------------------------------|
| <b>Command-Line Format</b>                           | <code>--binlog-cache-size=#</code> |                                |
| <b>System Variable</b>                               | <b>Name</b>                        | <code>binlog_cache_size</code> |
|  | <b>Variable Scope</b>              | Global                         |
|  | <b>Dynamic Variable</b>            | Yes                            |

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.4.4, “The Binary Log”](#).

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the size for both caches. This means that, in these MySQL versions, the total memory used for these caches is double the value set for `binlog_cache_size`.

Beginning with MySQL 5.5.9, `binlog_cache_size` sets the size for the transaction cache only, and the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_direct_non_transactional_updates`

|                            |  |
|----------------------------|--|
| <b>Introduced</b>          | 5.5.2  |
| <b>Command-Line Format</b> | <code>--binlog-direct-non-transactional-updates[=value]</code> |

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_direct_non_transactional_updates</code> |
|                         | <b>Variable Scope</b>   | Global, Session                                      |
|                         | <b>Dynamic Variable</b> | Yes  |
| <b>Permitted Values</b> | <b>Type</b>             | boolean  |
|                         | <b>Default</b>          | <code>OFF</code>                                     |

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

Beginning with MySQL 5.5.2, the `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

#### Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

Beginning with MySQL 5.5.5, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- `binlog_format`

|                            |                                     |                            |

|  |                     |                           |
|--|---------------------|---------------------------|
| <b>Permitted Values</b> ( $\geq$ 5.5.15-ndb-7.2.1, $\leq$ 5.5.30-ndb-7.2.12) | <b>Type</b>         | enumeration               |
|  | <b>Default</b>      | <a href="#">STATEMENT</a> |
|  | <b>Valid Values</b> | <a href="#">ROW</a>       |
|  |                     | <a href="#">STATEMENT</a> |
|  |                     | <a href="#">MIXED</a>     |
| <b>Permitted Values</b> ( $\geq$ 5.5.31-ndb-7.2.13)                          | <b>Type</b>         | enumeration               |
|  | <b>Default</b>      | <a href="#">MIXED</a>     |
|  | <b>Valid Values</b> | <a href="#">ROW</a>       |
|  |                     | <a href="#">STATEMENT</a> |
|  |                     | <a href="#">MIXED</a>     |

This variable sets the binary logging format, and can be any one of [STATEMENT](#), [ROW](#), or [MIXED](#). See [Section 17.1.2, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` system variable at runtime.

#### Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

In MySQL 5.5, the default format is [STATEMENT](#).

**Exception.** In MySQL NDB Cluster 7.2.1 through MySQL NDB Cluster 7.2.12, the default for this variable is [STATEMENT](#). In MySQL NDB Cluster 7.2.13 and later, when the [NDB](#) storage engine is enabled, the default is [MIXED](#). (Bug #16417224) See also [Section 18.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#), and [Section 18.6.7, “Using Two Replication Channels for NDB Cluster Replication”](#).

You must have the [SUPER](#) privilege to set either the global or session `binlog_format` value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).

When [MIXED](#) is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that [MIXED](#) always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.
- Beginning with MySQL 5.5.3, within a transaction. (Bug #47863)

Trying to switch the format in those cases results in an error.

**Note**

Prior to MySQL NDB Cluster 7.2.1, it was also not possible to change the binary logging format at runtime when the [NDBCLUSTER](#) storage engine was enabled. In MySQL NDB Cluster 7.2.1 and later, this restriction is removed.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlog_stmt_cache_size`

|  |   |                                     |

|  | <b>Min Value</b>                        | 4096                                |
|  | <b>Max Value</b>                        | 18446744073709551615                |

Beginning with MySQL 5.5.9, this variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. In MySQL 5.5.3 and later, separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large nontransactional statements during transactions, you can increase this cache size to get more performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.4.4, “The Binary Log”](#).

In MySQL 5.5.3 through 5.5.8, the size for both caches is set using `binlog_cache_size`. This means that, in these MySQL versions, the total memory used for these caches is double the value set for

`binlog_cache_size`. Beginning with MySQL 5.5.9, `binlog_cache_size` sets the size for the transaction cache only.

- `log_bin`

|                        |                         |                      |
|------------------------|-------------------------|----------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>log_bin</code> |
|                        | <b>Variable Scope</b>   | Global               |
|                        | <b>Dynamic Variable</b> | No                   |

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See [Section 5.4.4, “The Binary Log”](#).

- `log_bin_use_v1_row_events`

|  |  |  |
|--|--|--|
| <b>Introduced</b>                                  | 5.5.15-ndb-7.2.1                                 |  |
| <b>Command-Line Format</b>                         | <code>--log-bin-use-v1-row-events[={0 1}]</code> |  |
| <b>System Variable</b>                             | <b>Name</b>                                      | <code>log_bin_use_v1_row_events</code> |
|  | <b>Variable Scope</b>                            | Global                                 |
|  | <b>Dynamic Variable</b>                          | No                                     |
| <b>Permitted Values</b> ( $\geq$ 5.5.15-ndb-7.2.1) | <b>Type</b>                                      | boolean                                |
|  | <b>Default</b>                                   | 0                                      |

Shows whether Version 2 binary logging, available beginning with MySQL NDB Cluster 7.2.1, is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of NDB Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB $EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

#### Note

MySQL NDB Cluster 7.2.1 and later use Version 2 binary log row events by default (and so the default value for this variable changes to 0 in those versions). You should keep this mind when planning upgrades for setups using NDB Cluster Replication.

This variable is not supported in mainline MySQL Server 5.5.

- `log_slave_updates`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--log-slave-updates</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>log_slave_updates</code> |
|                            | <b>Variable Scope</b>            | Global                         |
|                            | <b>Dynamic Variable</b>          | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | <code>FALSE</code>             |

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).

- `max_binlog_cache_size`

|                                       |  |                                    |

|                                       | <b>Default</b>                         | <code>18446744073709551615</code>  |
|                                       | <b>Min Value</b>                       | <code>4096</code>                  |
|                                       | <b>Max Value</b>                       | <code>18446744073709551615</code>  |

If a transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

#### Note

Prior to MySQL 5.5.28, 64-bit Windows platforms truncated the stored value for this variable to 4G, even when it was set to a greater value (Bug #13961678).

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the upper limit for both caches. This means that, in these MySQL versions, the effective maximum for these caches is double the value set for `max_binlog_cache_size`.

Beginning with MySQL 5.5.9, `max_binlog_cache_size` sets the size for the transaction cache only, and the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

Also beginning with MySQL 5.5.9, the session visibility of the `max_binlog_cache_size` system variable matches that of the `binlog_cache_size` system variable: In MySQL 5.5.8 and earlier releases, a change in `max_binlog_cache_size` took immediate effect; in MySQL 5.5.9 and later, a change in `max_binlog_cache_size` takes effect only for new sessions that started after the value is changed.

- `max_binlog_size`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--max-binlog-size=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>max_binlog_size</code> |
|                            | <b>Variable Scope</b>            | Global                       |
|                            | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Default</b>                   | <code>1073741824</code>      |
|                            | <b>Min Value</b>                 | <code>4096</code>            |
|                            | <b>Max Value</b>                 | <code>1073741824</code>      |

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.5.9                                       |   |
| <b>Command-Line Format</b> | <code>--max-binlog-stmt-cache-size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>max_binlog_stmt_cache_size</code> |
|                            | <b>Variable Scope</b>                       | Global                                  |
|                            | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                 | integer                                 |

|  |                  |                      |
|--|------------------|----------------------|
|  | <b>Default</b>   | 18446744073709547520 |
|  | <b>Min Value</b> | 4096                 |
|  | <b>Max Value</b> | 18446744073709547520 |

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

#### Note

Prior to MySQL 5.5.28, 64-bit Windows platforms truncated the stored value for this variable to 4G, even when it was set to a greater value (Bug #13961678).

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the upper limit for both caches. This means that, in these MySQL versions, the effective maximum for these caches is double the value set for `max_binlog_cache_size`.

Beginning with MySQL 5.5.9, `max_binlog_stmt_cache_size` sets the size for the statement cache only, and the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `sync_binlog`

|  |                              |                          |
|--|------------------------------|--------------------------|
| <b>Command-Line Format</b>                           | <code>--sync-binlog=#</code> |                          |
| <b>System Variable</b>                               | <b>Name</b>                  | <code>sync_binlog</code> |
|  | <b>Variable Scope</b>        | Global                   |
|  | <b>Dynamic Variable</b>      | Yes                      |
| <b>Permitted Values</b> (32-bit platforms)           | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 0                        |
|  | <b>Min Value</b>             | 0                        |
|  | <b>Max Value</b>             | 4294967295               |
| <b>Permitted Values</b> (64-bit platforms, <= 5.5.2) | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 0                        |
|  | <b>Min Value</b>             | 0                        |
|  | <b>Max Value</b>             | 18446744073709547520     |
| <b>Permitted Values</b> (64-bit platforms, >= 5.5.3) | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 0                        |
|  | <b>Min Value</b>             | 0                        |

|  |                  |            |
|--|------------------|------------|
|  | <b>Max Value</b> | 4294967295 |
|--|------------------|------------|

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fsync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

## 17.1.4 Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

### 17.1.4.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: master1
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 60
      Master_Log_File: mysql-bin.000004
      Read_Master_Log_Pos: 931
      Relay_Log_File: slave1-relay-bin.000056
      Relay_Log_Pos: 950
      Relay_Master_Log_File: mysql-bin.000004
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
      Last_Errno: 0
      Last_Error:
      Skip_Counter: 0
      Exec_Master_Log_Pos: 931
      Relay_Log_Space: 1365
      Until_Condition: None
      Until_Log_File:
      Until_Log_Pos: 0
      Master_SSL_Allowed: No
      Master_SSL_CA_File:
      Master_SSL_CA_Path:
      Master_SSL_Cert:
      Master_SSL_Cipher:
      Master_SSL_Key:
      Seconds_Behind_Master: 0
      Master_SSL_Verify_Server_Cert: No
```

```

      Last_IO_Errno: 0
      Last_IO_Error:
      Last_SQL_Errno: 0
      Last_SQL_Error:
Replicate_Ignore_Server_Ids: 0

```

The key fields from the status report to examine are:

- **Slave\_IO\_State**: The current status of the slave. See [Section 8.14.6, “Replication Slave I/O Thread States”](#), and [Section 8.14.7, “Replication Slave SQL Thread States”](#), for more information.
- **Slave\_IO\_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP SLAVE**.
- **Slave\_SQL\_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.
- **Last\_IO\_Error**, **Last\_SQL\_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- **Seconds\_Behind\_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for **Seconds\_Behind\_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave\_net\_timeout** has not yet elapsed.

It is also possible that transient values for **Seconds\_Behind\_Master** may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, **Seconds\_Behind\_Master** displays 0; but when the slave I/O thread is still queuing up a new event, **Seconds\_Behind\_Master** may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute **SHOW SLAVE STATUS** several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (**Master\_Log\_file**, **Read\_Master\_Log\_Pos**): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (**Relay\_Master\_Log\_File**, **Exec\_Master\_Log\_Pos**): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- (**Relay\_Log\_File**, **Relay\_Log\_Pos**): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using **SHOW PROCESSLIST** to examine the list of running processes. Slave connections have **Binlog Dump** in the **Command** field:

```

mysql> SHOW PROCESSLIST \G;
***** 4. row *****
      Id: 10

```

```

User: root
Host: slave1:58371
db: NULL
Command: Binlog Dump
Time: 777
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL

```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```

mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
|          10 | slave1 | 3306 |          0        |          1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

#### 17.1.4.2 Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```

mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;

```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```

mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;

```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also

ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

## 17.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 17.2.1, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 8.14, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 17.2.2, “Replication Relay and Status Logs”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

### 17.2.1 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's [Binlog Dump](#) thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as [Slave\\_IO\\_running](#) in the output of `SHOW SLAVE STATUS` or as [Slave\\_running](#) in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 8.14.5, “Replication Master Thread States”](#). For slave states, see [Section 8.14.6, “Replication Slave I/O Thread States”](#), and [Section 8.14.7, “Replication Slave SQL Thread States”](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a [Binlog Dump](#) replication thread that services a connected slave. The [State](#) information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no [Binlog Dump](#) threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
  User: system user
  Host:
  db: NULL
```

```

Command: Connect
Time: 11
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 11
User: system user
Host:
db: NULL
Command: Connect
Time: 11
State: Has read all relay log; waiting for the slave I/O
      thread to update it
Info: NULL

```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section A.13, “MySQL 5.5 FAQ: Replication”](#). If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 5.1.5, “Server System Variables”](#).

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See [Section 17.1.4.1, “Checking Replication Status”](#).

## 17.2.2 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.
- The *relay log info log* holds status information about the execution point within the slave's relay log.

### 17.2.2.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an

index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 17.2.2.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. See [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log should be protected because it contains the password for connecting to the master. See [Section 6.1.2.3, “Passwords and Logging”](#).

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file and the columns displayed by `SHOW SLAVE STATUS`.

| Line in <code>master.info</code> | <code>SHOW SLAVE STATUS</code> Column                   | Description   |
|----------------------------------|---|---|
| 1                                |   | Number of lines in the file   |
| 2                                | <code>Master_Log_File</code>                            | The name of the master binary log currently being read from the master                    |
| 3                                | <code>Read_Master_Log_Pos</code>                        | The current position within the master binary log that have been read from the master     |
| 4                                | <code>Master_Host</code>                                | The host name of the master   |
| 5                                | <code>Master_User</code>                                | The user name used to connect to the master   |
| 6                                | Password (not shown by <code>SHOW SLAVE STATUS</code> ) | The password used to connect to the master  |
| 7                                | <code>Master_Port</code>                                | The network port used to connect to the master  |
| 8                                | <code>Connect_Retry</code>                              | The period (in seconds) that the slave will wait before trying to reconnect to the master |
| 9                                | <code>Master_SSL_Allowed</code>                         | Indicates whether the server supports SSL connections                                     |
| 10                               | <code>Master_SSL_CA_File</code>                         | The file used for the Certificate Authority (CA) certificate                              |
| 11                               | <code>Master_SSL_CA_Path</code>                         | The path to the Certificate Authority (CA) certificates                                   |
| 12                               | <code>Master_SSL_Cert</code>                            | The name of the SSL certificate file  |
| 13                               | <code>Master_SSL_Cipher</code>                          | The list of possible ciphers used in the handshake for the SSL connection                 |
| 14                               | <code>Master_SSL_Key</code>                             | The name of the SSL key file  |
| 15                               | <code>Master_SSL_Verify_Server_Cert</code>              | Whether to verify the server certificate  |
| 17                               | <code>Replicate_Ignore_Server_Ids</code>                | The number of server IDs to be ignored, followed by the actual server IDs                 |

The slave SQL thread updates the relay log info log. The following table shows the correspondence between the lines in the `relay-log.info` file and the columns displayed by `SHOW SLAVE STATUS`.

| Line in <code>relay-log.info</code> | <code>SHOW SLAVE STATUS</code> Column | Description   |
|-------------------------------------|---------------------------------------|---|
| 1                                   | <code>Relay_Log_File</code>           | The name of the current relay log file  |
| 2                                   | <code>Relay_Log_Pos</code>            | The current position within the relay log file; events up to this position have been executed on the slave database |
| 3                                   | <code>Relay_Master_Log_File</code>    | The name of the master binary log file from which the events in the relay log file were read                        |
| 4                                   | <code>Exec_Master_Log_Pos</code>      | The equivalent position within the master's binary log file of events that have already been executed               |

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

## 17.2.3 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).)

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 17.2.3.2, “Evaluation of Table-Level Replication Options”](#), for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options. An example of the latter that may have unintended effects is the use of `--replicate-do-db` and `--replicate-wild-do-table` together, where `--replicate-wild-do-table` uses a pattern for the database name that matches the name given for `--replicate-do-db`. Suppose a replication slave is started with `--replicate-do-db=dbx` `--replicate-wild-do-table=db%.t1`. Then, suppose that on the master, you issue the statement `CREATE DATABASE dbx`. Although you might expect it, this statement is not replicated because it does not reference a table named `t1`.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

### Note

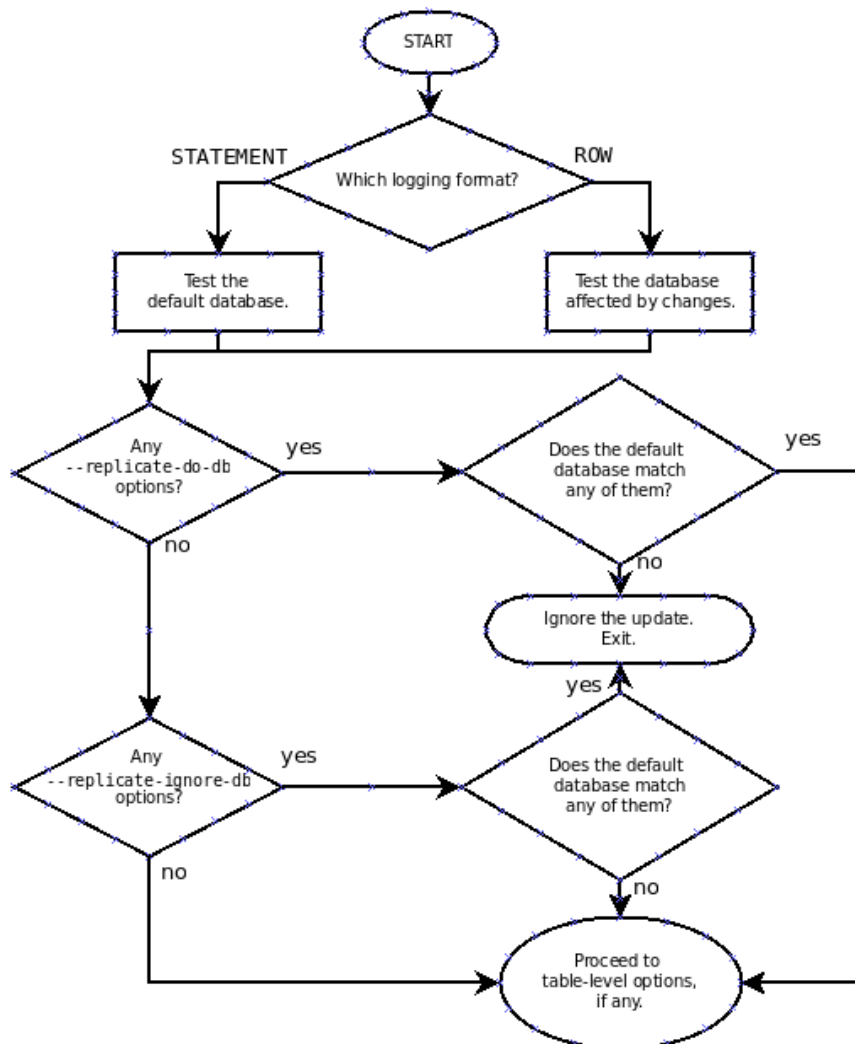

Database-level filtering options are case-sensitive on platforms supporting case sensitivity in filenames, whereas table-level filtering options are not (regardless of platform). This is true regardless of the value of the `lower_case_table_names` system variable.

### 17.2.3.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
  - **Yes.** Do any of them match the database?
  - **Yes.** Execute the statement and exit.
  - **No.** Ignore the statement and exit.
  - **No.** Continue to step 2.

2. Are there any `--replicate-ignore-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Ignore the statement and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 17.2.3.2, “Evaluation of Table-Level Replication Options”](#).

**Important**

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

**Important**

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log

statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

### 17.2.3.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

#### Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.

The following steps describe this evaluation in more detail:

1. Are there any table options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 5.
  - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 6.
  - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
  - **Yes.** Ignore the event and exit.
  - **No.** Execute the event and exit.

### 17.2.3.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

| Condition (Types of Options)                                       | Outcome  |
|--|--|
| No <code>--replicate-*</code> options at all:                      | The slave executes all events that it receives from the master.  |
| <code>--replicate-*-db</code> options, but no table options:       | The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.   |
| <code>--replicate-*-table</code> options, but no database options: | All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.   |
| A combination of database and table options:                       | The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example. |

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

## 17.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 17.3.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 17.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 17.3.3, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 17.3.4, “Replicating Different Databases to Different Slaves”](#)

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see [Section 17.3.5, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 17.3.6, “Switching Masters During Failover”](#).

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see [Section 17.3.7, “Setting Up Replication to Use Secure Connections”](#).

## 17.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 17.3.1.1, “Backing Up a Slave Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 17.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 17.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

### 17.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 17.1.4.1, "Checking Replication Status"](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 17.3.4, "Replicating Different Databases to Different Slaves"](#).

### 17.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition

to the slave's data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

### 17.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

#### Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

#### Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

### Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

## 17.3.2 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 17.3.3, “Using Replication for Scale-Out”](#)), you want to use [InnoDB](#) tables on the master to take advantage of the transactional functionality, but use [MyISAM](#) on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the [Archive](#) storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used [mysqldump](#) to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for [mysqldump](#) is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the [--skip-innodb](#) option on your slave to disable the [InnoDB](#) engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually [MyISAM](#). (This requires that the [NO\\_ENGINE\\_SUBSTITUTION](#) SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use [ALTER TABLE](#) to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an [ALTER TABLE ... ENGINE='engine\\_type'](#) for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the [default\\_storage\\_engine](#) variable is not replicated, be aware that [CREATE TABLE](#) and [ALTER TABLE](#) statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to [MyISAM](#), even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the [default\\_storage\\_engine](#) variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

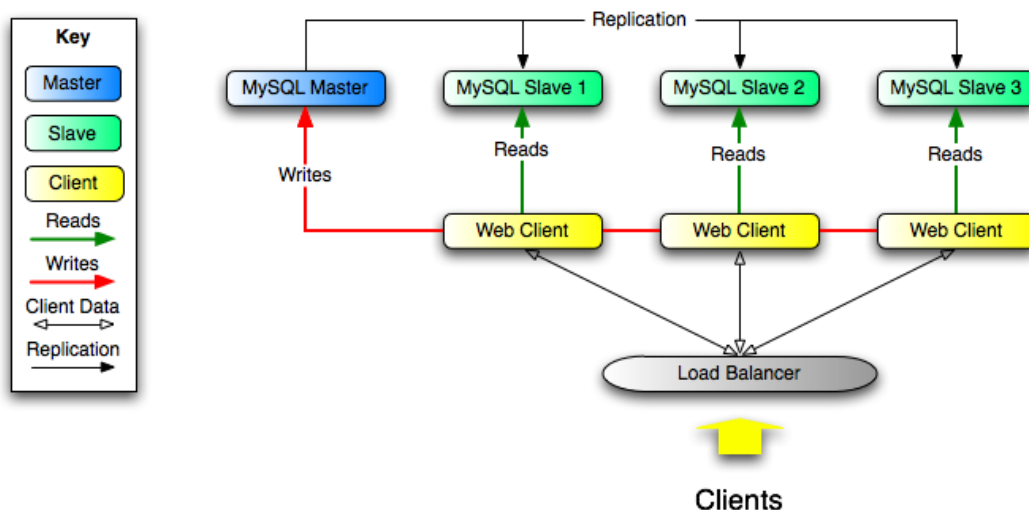

### 17.3.3 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 17.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 17.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`

- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 17.3.4 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#).

**Figure 17.2 Using Replication to Replicate Databases to Separate Replication Slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

#### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.

- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

#### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

## 17.3.5 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 17.3, “Using an Additional Replication Host to Improve Performance”](#).

**Figure 17.3 Using an Additional Replication Host to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1.

Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 17.3.4, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 17.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

## 17.3.6 Switching Masters During Failover

There is in MySQL 5.5 no official solution for providing failover between master and slaves in the event of a failure. Instead, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change master in case of failure. This section discusses some of the issues encountered when setting up failover in this fashion.

### Note

The MySQL Utilities include a `mysqlfailover` tool that provides failover capability using GTIDs, support for which requires MySQL 5.6 or later. For more information, see [mysqlfailover — Automatic replication health monitoring and failover](#), and [Replication with Global Transaction Identifiers](#).

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

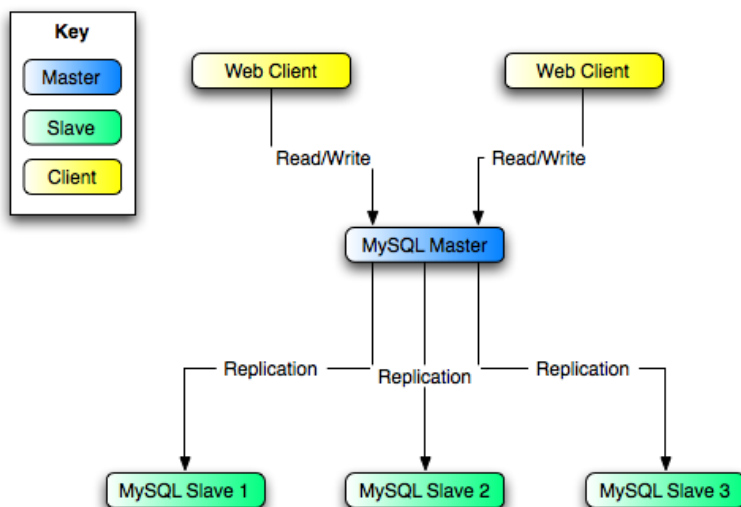

Slaves should be run with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in [Figure 17.4, “Redundancy Using Replication, Initial Structure”](#).

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start reading and executing events from the specified binary log coordinates on the new master.

In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE`; `RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in Figure 17.4, “Redundancy Using Replication, Initial Structure”.

**Figure 17.4 Redundancy Using Replication, Initial Structure**

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 17.3.3, “Using Replication for Scale-Out”.

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE`

`MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 17.5, “Redundancy Using Replication, After Master Failure”](#).

**Figure 17.5 Redundancy Using Replication, After Master Failure**

When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

## 17.3.7 Setting Up Replication to Use Secure Connections

To use a secure connection for encrypting the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support secure connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up secure connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for secure connections, see [Section 6.4.4, “Configuring MySQL to Use Secure Connections”](#).

To enable secure connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, there are two ways to specify the information required for connecting securely to the master. You can either name the slave certificate and key files in the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement:

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to connect securely:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1;
```

- To specify the certificate and key names using the `CHANGE MASTER TO` statement, append the appropriate `MASTER_SSL_xxx` options:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1,
-> MASTER_SSL_CA = 'ca_file_name',
-> MASTER_SSL_CAPATH = 'ca_directory_name',
-> MASTER_SSL_CERT = 'cert_file_name',
-> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that a secure connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce the use of secure connections during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> GRANT USAGE ON *.*
-> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

## 17.3.8 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.5 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks after the commit is done and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.

- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave after having performed a commit), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks after committing each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.
- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits after commit only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity. When a commit returns successfully, it is known that the data exists in at least two places (on the master and at least one slave). If the master commits but a crash occurs while the master is waiting for acknowledgment from a slave, it is possible that the transaction may not have reached any slave.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

### 17.3.8.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:

- `rpl_semi_sync_master_enabled`

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- `rpl_semi_sync_master_timeout`

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_xxx` system variables are described at [Section 5.1.5, “Server System Variables”](#).

- Status variables enable semisynchronous replication monitoring. Some examples:

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_xxx` status variables are described at [Section 5.1.7, “Server Status Variables”](#).

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

### 17.3.8.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.
- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working. For information on creating a master/slave relationship, see [Section 17.1.1, “How to Set Up Replication”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libbimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libbimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libbimf` from <http://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
      FROM INFORMATION_SCHEMA.PLUGINS
      WHERE PLUGIN_NAME LIKE '%semi%';
```

| PLUGIN_NAME          | PLUGIN_STATUS |
|----------------------|---------------|
| rpl_semi_sync_master | ACTIVE        |

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]  
rpl_semi_sync_slave_enabled=1
```

### 17.3.8.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

## 17.4 Replication Notes and Tips

### 17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.5 (or later), you cannot replicate to a slave that uses MySQL 5.1 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.5 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 20.7, “Binary Logging of Stored Programs”](#). For more information about row-based logging and row-based replication, see [Section 5.4.4.1, “Binary Logging Formats”](#), and [Section 17.1.2, “Replication Formats”](#).

For additional information specific to replication and [InnoDB](#), see [Section 14.22, “InnoDB and MySQL Replication”](#). For information relating to replication with NDB Cluster, see [Section 18.6, “NDB Cluster Replication”](#).

### 17.4.1.1 Replication and AUTO\_INCREMENT

Statement-based replication of [AUTO\\_INCREMENT](#), [LAST\\_INSERT\\_ID\(\)](#), and [TIMESTAMP](#) values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.5.30, [AUTO\\_INCREMENT](#) columns in tables on the slave must match the same columns on the master; that is, [AUTO\\_INCREMENT](#) columns must be replicated to [AUTO\\_INCREMENT](#) columns. (Bug #12669186)
- A statement invoking a trigger or function that causes an update to an [AUTO\\_INCREMENT](#) column is not replicated correctly using statement-based replication. In MySQL 5.5, such statements are marked as unsafe. (Bug #45677)
- An [INSERT](#) into a table that has a composite primary key that includes an [AUTO\\_INCREMENT](#) column that is not the first column of this composite key is not safe for statement-based logging or replication. Beginning with MySQL 5.5.25, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the [InnoDB](#) storage engine, since an [InnoDB](#) table with an [AUTO\\_INCREMENT](#) column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an [AUTO\\_INCREMENT](#) column to a table with [ALTER TABLE](#) might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an [AUTO\\_INCREMENT](#) number. Assuming that you want to add an [AUTO\\_INCREMENT](#) column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an [AUTO\\_INCREMENT](#) column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both master and slave, the [ORDER BY](#) clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of [CREATE TABLE ... LIKE](#): Foreign key definitions are ignored, as are the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options. If a table definition includes any of those characteristics, create `t2` using a [CREATE TABLE](#) statement that is identical to the one used to create `t1`, but with the addition of the [AUTO\\_INCREMENT](#) column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;  
ALTER TABLE t2 RENAME t1;
```

See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

### 17.4.1.2 Replication and BLACKHOLE Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. In MySQL 5.5.32 and later, a warning is logged whenever this occurs (Bug #13004581)

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

### 17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 17.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changes in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

### 17.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 17.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.5, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

### 17.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 13.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL handles the statement in a version-dependent way.

In MySQL 5.1 before 5.1.51 and in MySQL 5.5 before 5.5.6 (this is the original behavior):

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.1 as of 5.1.51:

- `STATEMENT` or `MIXED` format: The statement is logged as the equivalent pair of `CREATE TABLE` and `INSERT INTO ... SELECT` statements.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.5 as of 5.5.6:

- Nothing is inserted or logged.

These version dependencies arise due to a change in MySQL 5.5.6 in handling of `CREATE TABLE ... SELECT` not to insert rows if the destination table already exists, and a change made in MySQL 5.1.51 to preserve forward compatibility in replication of such statements from a 5.1 master to a 5.5 slave. For details, see [Section 13.1.17.5, “CREATE TABLE ... SELECT Syntax”](#).

When using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. This is due to the fact that MySQL 5.6 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement—a change in behavior from previous versions of MySQL, which permitted these statements to do so. To keep this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 5.6 (or later). (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement will fail there as well, following the upgrade, unless the statement is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events (or possibly row-update events), rather than as the entire `CREATE TABLE ... SELECT` statement.

### 17.4.1.7 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.5, the statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

### 17.4.1.8 Replication of CURRENT\_USER()

The following statements support use of the `CURRENT_USER( )` function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER( )` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When `CURRENT_USER( )` or `CURRENT_USER` is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. `CURRENT_USER( )` or `CURRENT_USER` is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`.

### 17.4.1.9 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

### 17.4.1.10 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

**Note**

Replication between tables which are partitioned differently from one another is not supported. See [Section 17.4.1.19, “Replication and Partitioning”](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

## Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

(This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  c1 INT,
  c2 INT,
  c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

**Note**

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and

the server SQL mode in effect at the time of its creation; for more information, see [Section 11.6, “Data Type Default Values”](#)).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

### Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.5.30, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the master and the slave; otherwise, updates could be applied to the wrong table on the slave. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.** Formerly, due to the fact that in row-based replication changes rather than statements are replicated, and that these changes are transmitted using formats that do not always map directly to MySQL server column data types, you could not replicate between different subtypes of the same general type (for example, from `TINYINT` to `BIGINT`, both `INT` subtypes). However, beginning with MySQL 5.5.3, MySQL Replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

**Type conversion modes (slave\_type\_conversions variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

| Mode                   | Effect  |
|------------------------|---|
| <code>ALL_LOSSY</code> | In this mode, type conversions that would mean loss of information are permitted. |

| Mode                                  | Effect   |
|---------------------------------------|--|
|                                       | This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.   |
| <code>ALL_NON_LOSSY</code>            | <p>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.</p> <p>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code>, then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code>, or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the slave to stop with an error.</p> |
| <code>ALL_LOSSY, ALL_NON_LOSSY</code> | When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.  |
| <code>[empty]</code>                  | <p>When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.</p> <p>This mode is the default.</p>   |

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For insuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $D' \geq D$  and  $(M' - D') \geq (M - D)$  are non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 12.18.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` characters of the string on the slave, where `N` is the width of the target column.

### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` bytes of the string on the slave, where `N` is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where  $M' > M$ , the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the `M` bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where  $M' < M$ , the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

**Replication type conversions in MySQL 5.5.3 and earlier.** Prior to MySQL 5.5.3, with row-based binary logging, you could not replicate between different `INT` subtypes, such as from `TINYINT` to `BIGINT`, because changes to columns of these types were represented differently from one another in the binary log when using row-based logging. (However, you could replicate from `BLOB` to `TEXT` using row-based replication because changes to `BLOB` and `TEXT` columns were represented using the same format in the binary log.)

Supported conversions for attribute promotion when using row-based replication prior to MySQL 5.5.3 are shown in the following table:

| From (Master)          | To (Slave)             |
|------------------------|------------------------|
| <code>BINARY</code>    | <code>CHAR</code>      |
| <code>BLOB</code>      | <code>TEXT</code>      |
| <code>CHAR</code>      | <code>BINARY</code>    |
| <code>DECIMAL</code>   | <code>NUMERIC</code>   |
| <code>NUMERIC</code>   | <code>DECIMAL</code>   |
| <code>TEXT</code>      | <code>BLOB</code>      |
| <code>VARBINARY</code> | <code>VARCHAR</code>   |
| <code>VARCHAR</code>   | <code>VARBINARY</code> |

### Note

In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you could replicate from a `CHAR(10)` column on the master to a column that used `BINARY(10)` or

`BINARY(25)` on the slave, but you could not replicate from a `CHAR(10)` column on the master to `BINARY(5)` column on the slave.

Any unique index (including primary keys) having a prefix must use a prefix of the same length on both master and slave; in such cases, differing prefix lengths are disallowed. It is possible to use a nonunique index whose prefix length differs between master and slave, but this can cause serious performance issues, particularly when the prefix used on the master is longer. This is due to the fact that 2 unique prefixes of a given length may no longer be unique at a shorter length; for example, the words *catalogue* and *catamount* have the 5-character prefixes *catal* and *catam*, respectively, but share the same 4-character prefix (*cata*). This can lead to queries that use such indexes executing less efficiently on the slave, when a shorter prefix is employed in the slave's definition of the same index than on the master.

For `DECIMAL` and `NUMERIC` columns, both the mantissa (*M*) and the number of decimals (*D*) must be the same size or larger on the slave as compared with the master. For example, replication from a `NUMERIC(5,4)` to a `DECIMAL(6,4)` worked, but not from a `NUMERIC(5,4)` to a `DECIMAL(5,3)`.

Prior to MySQL 5.5.3, MySQL replication did not support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

- `INT` (including `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`).

Promotion between `INT` subtypes—for example, from `SMALLINT` to `BIGINT`—was also not supported prior to MySQL 5.5.3.

- `SET` or `ENUM`.
- `FLOAT` or `DOUBLE`.
- All of the data types relating to dates, times, or both: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

#### 17.4.1.11 Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.8, “Server SQL Modes”](#).

#### 17.4.1.12 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`

- `DROP EVENT`
- `CREATE PROCEDURE`
- `DROP PROCEDURE`
- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

#### Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 21.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), and [Section 13.7.5.19, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where *event\_name* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID `master_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

### 17.4.1.13 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 12.2, “Type Conversion in Expression Evaluation”](#), and [Section B.5.4.8, “Problems with Floating-Point Values”](#).

### 17.4.1.14 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 13.7.6.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 17.4.1.15 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 17.1.2, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #28086) (See also [Section 17.4.1.8, “Replication of `CURRENT\_USER\(\)`”](#).)

Beginning with MySQL 5.5.1, `VERSION()` is also automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995) Beginning with MySQL 5.5.2, this is also true with regard to the `RAND()` function. (Bug #49222)

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued

by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

Beginning with MySQL 5.5.1, `SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995)

See also [Section 17.4.1.34, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES (GET_LOCK(...))`.

Beginning with MySQL 5.5.1, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #47995)

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;  
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;  
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.5.35, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the slave. (Bug #17234370, BUG# 69861)

### 17.4.1.16 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

### 17.4.1.17 Replication and LOAD DATA INFILE

In MySQL 5.5.6 and later, `LOAD DATA INFILE` is considered unsafe (see [Section 17.1.2.3](#), “Determination of Safe and Unsafe Statements in Binary Logging”).

### 17.4.1.18 Replication and the Slow Query Log

In older versions of MySQL, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. This is no longer an issue in MySQL 5.5. (Bug #23300)

### 17.4.1.19 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see [Section 17.4.1.10](#), “Replication with Differing Table Definitions on Master and Slave”).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

#### 17.4.1.20 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

#### 17.4.1.21 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 5.1.5, “Server System Variables”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 17.4.1.24, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. The default value of `sync_relay_log_info` is 0, which does not cause writes to be forced to disk; the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

#### 17.4.1.22 Replication and max\_allowed\_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

### 17.4.1.23 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in NDB Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 17.4.1.38, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See [Section 15.4, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

### 17.4.1.24 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever `binlog_format` is `STATEMENT` or `MIXED`, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see [RBL, RBR, and temporary tables](#).

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

#### 17.4.1.25 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

#### 17.4.1.26 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 17.4.1.16, “Replication and LIMIT”](#), for a detailed discussion of these.

#### 17.4.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `range` on a 5.0 master that is replicating to a 5.1 or higher slave because `RANGE` is a reserved word beginning in MySQL 5.1. Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 9.2, “Schema Object Names”](#).

#### 17.4.1.28 SET PASSWORD and Row-Based Replication

Row-based replication of `SET PASSWORD` statements from a MySQL 5.1 master to a MySQL 5.5 slave did not work correctly prior to MySQL 5.1.53 on the master and MySQL 5.5.7 on the slave (see Bug #57098, Bug #57357).

#### 17.4.1.29 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

#### 17.4.1.30 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see [Section 13.8.3, “HELP Syntax”](#)). These tables can be loaded manually as described at [Section 5.1.10, “Server-Side Help”](#).

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For

example, you would load MySQL 5.5 help content into a MySQL 5.5 master server, but not necessarily replicate that content to a MySQL 5.6 slave server for which 5.6 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from <http://dev.mysql.com/doc/index-other.html>.

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.
2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.

## Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version (enter the command on one line):

```
mysql --init-command="SET sql_log_bin=0"
mysql < fill_help_tables.sql
```

Use the `--init-command` option on each server, including the slaves, in case a slave also acts as a master to other slaves in your replication topology. The `SET` statement suppresses binary logging. After the command has been run on each server to be upgraded, you are done.

## Loading Help Table Content With Replication to Slaves

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

```
+-----+-----+-----+
| TABLE_NAME | COLUMN_NAME | COLUMN_TYPE |
+-----+-----+-----+
| help_category | url | char(128) |
```

|            |     |           |
|------------|-----|-----------|
| help_topic | url | char(128) |
|------------|-----|-----------|

For tables with the new structure, the statement produces this result:

| TABLE_NAME    | COLUMN_NAME | COLUMN_TYPE |
|---------------|-------------|-------------|
| help_category | url         | text        |
| help_topic    | url         | text        |

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.
- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

```
SET sql_log_bin=0;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
```

Then run this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

### 17.4.1.31 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 5.1.8, “Server SQL Modes”](#).

### 17.4.1.32 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDBCLUSTER TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.1.7, “Server Status Variables”](#).

### 17.4.1.33 Replication and TIMESTAMP

Older versions of MySQL (prior to 4.1) differed significantly in several ways in their handling of the `TIMESTAMP` data type from what is supported in MySQL versions 5.5 and newer; these include syntax extensions which are deprecated in MySQL 5.1, and that no longer supported in MySQL 5.5. This can cause problems (including replication failures) when replicating between MySQL Server versions, if you are using columns that are defined using the old `TIMESTAMP(N)` syntax. See [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.5”](#), for more information about the differences, how they can impact MySQL replication, and what you can do if you encounter such problems.

### 17.4.1.34 Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also [Section 17.4.1.15, “Replication and System Functions”](#).

### 17.4.1.35 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

As of MySQL 5.5.2, the server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.**

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. Prior to MySQL 5.5.6, a statement that changed both nontransactional and transactional tables was considered “mixed”. Beginning with MySQL 5.5.6, a statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a mixed statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

Beginning with MySQL 5.5.6, a mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a transactional table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

Also beginning with MySQL 5.5.6, any mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_trans_update` is `OFF`

For more information, see [Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

**Note**

A mixed statement is unrelated to mixed binary logging format.

Before MySQL 5.5.2, the rules for binary logging are similar to those just described, except that there is no `binlog_direct_non_transactional_updates` system variable to affect logging of transactional statements. Thus, the server immediately logs only the initial nontransactional statements in a transaction and caches the rest until commit time.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

Beginning with MySQL 5.5.0, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases (beginning with MySQL 5.5.0), an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** Beginning with MySQL 5.5.3, the `binlog_format` system variable is read-only as long as a transaction is in progress. (Bug #47863)

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. In MySQL 5.5, this true is even for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

### 17.4.1.36 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 5.5 marks such statements as unsafe. (Bug #45677)

### 17.4.1.37 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 13.1.33](#), “`TRUNCATE TABLE Syntax`” governing such tables. (Bug #36763)

### 17.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`

- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see [Section 17.4.1.23, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 17.1.2, “Replication Formats”](#).

In MySQL 5.5, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

**Important**

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

It is strongly recommended that you always use the same setting for the `lower_case_table_names` system variable on both master and slave. In particular, when a case-sensitive file system is used, setting this variable to 1 on the slave, but to a different value on the master, can cause two types of problems: Names of databases are not converted to lowercase; in addition, when using row-based replication names of tables are also not converted. Either of these problems can cause replication to fail. This is a known issue, which is fixed in MySQL 5.6.

### 17.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.5.31 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

## 17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.1 to a slave running MySQL 5.5, from a master running MySQL 5.5 to a slave running MySQL 5.6, and so on.

However, one may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, in MySQL 5.5, `CREATE TABLE ... SELECT` statements are permitted to change tables other than the one being created, but are no longer allowed to do so in MySQL 5.6 (see [Section 17.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#)).

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.5.1, MySQL 5.5.2, and MySQL 5.5.4 concurrently, although you could use any two of these releases together.

**Important**

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

This also has significant implications for upgrading replication servers; see [Section 17.4.3, “Upgrading a Replication Setup”](#), for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.5 or later master to a slave older than MySQL 5.1.5.

For more information about row-based replication, see [Section 17.1.2, “Replication Formats”](#).

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 17.4.1, “Replication Features and Issues”](#).

## 17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#)

When you upgrade a master to 5.5 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.5.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.5.x version, restart it, and restart replication. The 5.5 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.5 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.5.x release as the slaves, and restart it. The 5.5 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.5 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.5 format. These too are recognized by the 5.5 slaves.

In other words, when upgrading to MySQL 5.5, the slaves must be MySQL 5.5 before you can upgrade the master to 5.5. Note that downgrading from 5.5 to older versions does not work so simply: You must ensure that any 5.5 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.5”](#). It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

## 17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 17.2.1, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.

- Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is [3306](#)). For the host name, ensure that the name resolves to the correct IP address.
- Check that networking has not been disabled on the master or slave. Look for the [skip-networking](#) option in the configuration file. If present, comment it out or remove it.
- If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
- Check that you can reach the master by using [ping](#) or [traceroute/tracert](#) to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 17.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 17.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run [START SLAVE](#).
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;  
mysql> START SLAVE;
```

The value of *N* should be 1 if the next statement from the master does not use [AUTO\\_INCREMENT](#) or [LAST\\_INSERT\\_ID\( \)](#). Otherwise, the value should be 2. The reason for using a value of 2 for statements that use [AUTO\\_INCREMENT](#) or [LAST\\_INSERT\\_ID\( \)](#) is that they take two events in the binary log of the master.

See also [Section 13.4.2.4, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the master
  - All binary log files from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

---

## Chapter 18 MySQL NDB Cluster 7.2

### Table of Contents

|  |      |
|--|------|
| 18.1 NDB Cluster Overview .....  | 2135 |
| 18.1.1 NDB Cluster Core Concepts .....   | 2136 |
| 18.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions .....                                  | 2139 |
| 18.1.3 NDB Cluster Hardware, Software, and Networking Requirements .....                               | 2142 |
| 18.1.4 What is New in MySQL NDB Cluster 7.2 .....  | 2143 |
| 18.1.5 MySQL Server Using InnoDB Compared with NDB Cluster .....                                       | 2146 |
| 18.1.6 Known Limitations of NDB Cluster .....  | 2149 |
| 18.2 NDB Cluster Installation and Upgrades .....   | 2161 |
| 18.2.1 Installing NDB Cluster on Linux .....   | 2164 |
| 18.2.2 Installing NDB Cluster on Windows .....   | 2170 |
| 18.2.3 Initial Configuration of NDB Cluster .....  | 2179 |
| 18.2.4 Initial Startup of NDB Cluster .....  | 2181 |
| 18.2.5 NDB Cluster Example with Tables and Data .....  | 2182 |
| 18.2.6 Safe Shutdown and Restart of NDB Cluster .....  | 2186 |
| 18.2.7 Upgrading and Downgrading NDB Cluster 7.2 .....   | 2187 |
| 18.3 Configuration of NDB Cluster .....  | 2189 |
| 18.3.1 Quick Test Setup of NDB Cluster .....   | 2189 |
| 18.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables .....                  | 2192 |
| 18.3.3 NDB Cluster Configuration Files .....   | 2236 |
| 18.3.4 Using High-Speed Interconnects with NDB Cluster .....   | 2367 |
| 18.4 NDB Cluster Programs .....  | 2367 |
| 18.4.1 <code>ndbd</code> — The NDB Cluster Data Node Daemon .....                                      | 2368 |
| 18.4.2 <code>ndbinfo_select_all</code> — Select From <code>ndbinfo</code> Tables .....                 | 2374 |
| 18.4.3 <code>ndbmtd</code> — The NDB Cluster Data Node Daemon (Multi-Threaded) .....                   | 2376 |
| 18.4.4 <code>ndb_mgmd</code> — The NDB Cluster Management Server Daemon .....                          | 2377 |
| 18.4.5 <code>ndb_mgm</code> — The NDB Cluster Management Client .....                                  | 2385 |
| 18.4.6 <code>ndb_blob_tool</code> — Check and Repair BLOB and TEXT columns of NDB Cluster Tables ..... | 2387 |
| 18.4.7 <code>ndb_config</code> — Extract NDB Cluster Configuration Information .....                   | 2389 |
| 18.4.8 <code>ndb_cpcd</code> — Automate Testing for NDB Development .....                              | 2397 |
| 18.4.9 <code>ndb_delete_all</code> — Delete All Rows from an NDB Table .....                           | 2397 |
| 18.4.10 <code>ndb_desc</code> — Describe NDB Tables .....  | 2398 |
| 18.4.11 <code>ndb_drop_index</code> — Drop Index from an NDB Table .....                               | 2403 |
| 18.4.12 <code>ndb_drop_table</code> — Drop an NDB Table .....  | 2404 |
| 18.4.13 <code>ndb_error_reporter</code> — NDB Error-Reporting Utility .....                            | 2404 |
| 18.4.14 <code>ndb_index_stat</code> — NDB Index Statistics Utility .....                               | 2406 |
| 18.4.15 <code>ndb_move_data</code> — NDB Data Copy Utility .....                                       | 2411 |
| 18.4.16 <code>ndb_print_backup_file</code> — Print NDB Backup File Contents .....                      | 2414 |
| 18.4.17 <code>ndb_print_file</code> — Print NDB Disk Data File Contents .....                          | 2414 |
| 18.4.18 <code>ndb_print_schema_file</code> — Print NDB Schema File Contents .....                      | 2415 |
| 18.4.19 <code>ndb_print_sys_file</code> — Print NDB System File Contents .....                         | 2415 |
| 18.4.20 <code>ndb_redo_log_reader</code> — Check and Print Content of Cluster Redo Log .....           | 2416 |
| 18.4.21 <code>ndb_restore</code> — Restore an NDB Cluster Backup .....                                 | 2419 |
| 18.4.22 <code>ndb_select_all</code> — Print Rows from an NDB Table .....                               | 2434 |
| 18.4.23 <code>ndb_select_count</code> — Print Row Counts for NDB Tables .....                          | 2438 |
| 18.4.24 <code>ndb_show_tables</code> — Display List of NDB Tables .....                                | 2438 |
| 18.4.25 <code>ndb_size.pl</code> — NDBCLUSTER Size Requirement Estimator .....                         | 2440 |
| 18.4.26 <code>ndb_waiter</code> — Wait for NDB Cluster to Reach a Given Status .....                   | 2442 |

---

|   |      |
|---|------|
| 18.4.27 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs ..... | 2445 |
| 18.5 Management of NDB Cluster .....  | 2449 |
| 18.5.1 Summary of NDB Cluster Start Phases .....  | 2450 |
| 18.5.2 Commands in the NDB Cluster Management Client .....                                    | 2452 |
| 18.5.3 Online Backup of NDB Cluster .....   | 2456 |
| 18.5.4 MySQL Server Usage for NDB Cluster .....   | 2460 |
| 18.5.5 Performing a Rolling Restart of an NDB Cluster .....                                   | 2462 |
| 18.5.6 Event Reports Generated in NDB Cluster .....   | 2464 |
| 18.5.7 NDB Cluster Log Messages .....   | 2475 |
| 18.5.8 NDB Cluster Single User Mode .....   | 2490 |
| 18.5.9 Quick Reference: NDB Cluster SQL Statements .....                                      | 2491 |
| 18.5.10 ndbinfo: The NDB Cluster Information Database .....                                   | 2493 |
| 18.5.11 NDB Cluster Security Issues .....   | 2516 |
| 18.5.12 NDB Cluster Disk Data Tables .....  | 2523 |
| 18.5.13 Adding NDB Cluster Data Nodes Online .....  | 2530 |
| 18.5.14 Distributed MySQL Privileges for NDB Cluster .....                                    | 2541 |
| 18.5.15 NDB API Statistics Counters and Variables .....                                       | 2544 |

| 18.7 NDB Cluster Release Notes .....  | 2595 |

MySQL *NDB Cluster* is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Recent releases of NDB Cluster use version 7 of the [NDBCLUSTER](#) storage engine (also known as [NDB](#)) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 7.5, now available as a General Availability (GA) release beginning with version 7.5.4, incorporates version 7.5 of the [NDB](#) storage engine. NDB Cluster 7.6, currently under development and available for evaluation and testing as a Developer Preview release, uses version 7.6 of [NDB](#). Previous GA releases still available for production, NDB Cluster 7.3 and NDB Cluster 7.4, incorporate [NDB](#) versions 7.3 and 7.4, respectively.

Support for the [NDBCLUSTER](#) storage engine is not included in standard MySQL Server 5.5 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster users who build from source should use the sources provided for NDB Cluster. (Locations where the sources can be obtained are listed later in this section.)

This chapter contains information about NDB Cluster 7.2 releases through 5.5.56-ndb-7.2.30. Currently, NDB Cluster 7.5 is available as a General Availability release, and recommended for new deployments. The NDB Cluster 7.4 and NDB Cluster 7.3 release series are previous GA releases still supported in production. NDB Cluster 7.2 is a previous GA release series which is still supported, although we recommend that new deployments for production use NDB Cluster 7.5 (see [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#)). For more information about NDB Cluster 7.4 and NDB Cluster 7.3, see [MySQL NDB](#)

---

[Cluster 7.3 and NDB Cluster 7.4](#). NDB Cluster 7.6, currently under development, is now available for evaluation and testing as a Developer Preview release; for information about NDB Cluster 7.6, see [What is New in NDB Cluster 7.6](#).

Release notes for the changes in each release of NDB Cluster are located at [NDB Cluster 7.2 Release Notes](#).

**Supported Platforms.** NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <http://www.mysql.com/support/supportedplatforms/cluster.html>.

**Availability.** NDB Cluster binary and source packages are available for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

**NDB Cluster release numbers.** NDB Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.5 series of releases. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the [NDBCLUSTER](#) storage engine used in the release, and not of the MySQL server version on which the NDB Cluster release is based.

**Version strings used in NDB Cluster software.** The version string displayed by NDB Cluster programs uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

[mysql\\_server\\_version](#) represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 6.x and 7.x releases, this is “5.1”. [ndb\\_engine\\_version](#) is the version of the [NDB](#) storage engine used by this release of the NDB Cluster software. You can see this format used in the [mysql](#) client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.5.56-ndb-7.2.30 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 5.5.56-ndb-7.2.30
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the [SHOW](#) command in the [ndb\\_mgm](#) client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.5.56-ndb-7.2.30, Nodegroup: 0, *)
id=2 @10.0.10.8 (5.5.56-ndb-7.2.30, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3 @10.0.10.2 (5.5.56-ndb-7.2.30)

[mysqld(API)] 2 node(s)
id=4 @10.0.10.10 (5.5.56-ndb-7.2.30)
```

---

```
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the NDB Cluster release was branched and the version of the `NDBCLUSTER` storage engine used. For example, the full version string for NDB 7.2.4 (the first NDB Cluster production release based on MySQL Server 5.5) is `mysql-5.5.19-ndb-7.2.4`. From this we can determine the following:

- Since the portion of the version string preceding `-ndb-` is the base MySQL Server version, this means that NDB 7.2.4 derives from the MySQL 5.5.19, and contains all feature enhancements and bugfixes from MySQL 5.5 up to and including MySQL 5.5.19.
- Since the portion of the version string following `-ndb-` represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, NDB 7.2.4 uses version 7.2.4 of the `NDBCLUSTER` storage engine.

New NDB Cluster releases are numbered according to updates in the `NDB` storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, NDB 7.2.4 (as previously noted) is based on MySQL 5.5.19, while NDB 7.2.0 was based on MySQL 5.1.51 (version string: `mysql-5.1.51-ndb-7.2.0`).

**Compatibility with standard MySQL 5.5 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see [Section 18.1.6, “Known Limitations of NDB Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and NDB Cluster codebases diverge considerably, so that the standard `mysqld` cannot function as a drop-in replacement for the version of `mysqld` supplied with NDB Cluster.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from <https://github.com/mysql/mysql-server>.

The NDB Cluster development sources maintained at <https://github.com/mysql/mysql-server> are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

#### Note

As with MySQL Server 5.5, NDB Cluster 7.2 is built using `CMake`.

Currently, NDB Cluster 7.3 and NDB Cluster 7.4 releases are Generally Available (GA). We recommend that new deployments use NDB Cluster 7.4. NDB Cluster 7.1 and earlier versions are no longer in active development. For an overview of major features added in NDB Cluster 7.4, see [What is New in NDB Cluster 7.4](#). For similar information about NDB Cluster 7.3, see [What is New in NDB Cluster 7.3](#). For an overview of major features added in past NDB Cluster releases, see the *MySQL 5.1 Reference Manual*. NDB Cluster 7.5 is also available as a Developer Preview for testing of new features; for more information, see [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#).

This chapter represents a work in progress, and its contents are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL Web site at <http://www.mysql.com/products/cluster/>.

**Additional Resources.** More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see [Section A.10, “MySQL FAQ: MySQL 5.5 and NDB Cluster”](#).

- The NDB Cluster mailing list: <http://lists.mysql.com/cluster>.
- The NDB Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through [PlanetMySQL](#).

## 18.1 NDB Cluster Overview

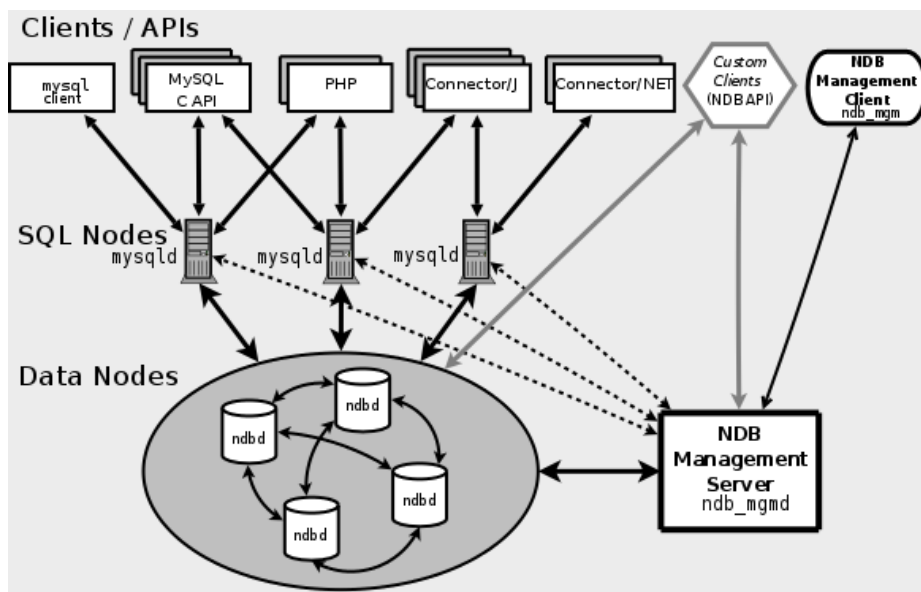

*NDB Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for “Network DataBase”). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the **NDB** storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 18.1 NDB Cluster Components**

All these programs work together to form an NDB Cluster (see [Section 18.4, “NDB Cluster Programs”](#)). When data is stored by the **NDB** storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.5 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the `NDB` storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)). Rolling restarts are also used as part of the process of adding new data nodes online (see [Section 18.5.13, “Adding NDB Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see [Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Backing up and restoring NDB Cluster databases can be done using the `NDB`-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see [Section 18.5.3, “Online Backup of NDB Cluster”](#), and [Section 18.4.21, “ndb\\_restore — Restore an NDB Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#), for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

## 18.1.1 NDB Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.

- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see [Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#)). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 18.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#)) or `ndbmt` (see [Section 18.4.3, “ndbmt — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#)).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see [Section 18.5.12, “NDB Cluster Disk Data Tables”](#), for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

#### Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in NDB Cluster, see [Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java

clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see [Using Connector/J with NDB Cluster](#).

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see [The NDB API](#).

NDB-specific Java applications can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. Support is also provided in NDB Cluster for *ClusterJPA*, an OpenJPA implementation for NDB Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See [Java and NDB Cluster](#), and [The ClusterJ API and Data Object Model](#), for more information.

The Memcache API for NDB Cluster, implemented as the loadable *ndbmemcache* storage engine for memcached version 1.6 and later, is available beginning with NDB 7.2.2. This API can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard `memcached` caching engine is included in the NDB Cluster 7.2 distribution (7.2.2 and later). Each `memcached` server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see [ndbmemcache—Memcache API for NDB Cluster](#).

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with NDB Cluster (see [Section 18.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#)). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see [The MGM API](#).

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See [MySQL™ Cluster Manager 1.3.6 User Manual](#), for more information.
