

MySQL 5.6 Reference Manual

Including MySQL NDB Cluster 7.3-7.4 Reference Guide

Abstract

This is the MySQL™ Reference Manual. It documents MySQL 5.6 through 5.6.37, as well as MySQL Cluster releases based on versions 7.3 and 7.4 of [NDB](#) through 5.6.35-ndb-7.3.17 and 5.6.35-ndb-7.4.15, respectively.

MySQL 5.6 features. This manual describes features that are not included in every edition of MySQL 5.6; such features may not be included in the edition of MySQL 5.6 licensed to you. If you have any questions about the features included in your edition of MySQL 5.6, refer to your MySQL 5.6 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the [MySQL 5.6 Release Notes](#).

For legal information, see the [Legal Notices](#).

For help with using MySQL, please visit either the [MySQL Forums](#) or [MySQL Mailing Lists](#), where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the [MySQL Documentation Library](#).

Licensing information—MySQL 5.6. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL 5.6, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL 5.6, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Licensing information—MySQL Cluster. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL NDB Cluster 7.3 or NDB 7.4, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL NDB Cluster 7.3 or NDB 7.4, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Table of Contents

| | |
|--|-----|
| Preface and Legal Notices | xxv |
| 1 General Information | 1 |
| 1.1 About This Manual | 2 |
| 1.2 Typographical and Syntax Conventions | 3 |
| 1.3 Overview of the MySQL Database Management System | 4 |
| 1.3.1 What is MySQL? | 4 |
| 1.3.2 The Main Features of MySQL | 6 |
| 1.3.3 History of MySQL | 9 |
| 1.4 What Is New in MySQL 5.6 | 9 |
| 1.5 MySQL Information Sources | 22 |
| 1.5.1 MySQL Mailing Lists | 22 |
| 1.5.2 MySQL Community Support at the MySQL Forums | 24 |
| 1.5.3 MySQL Community Support on Internet Relay Chat (IRC) | 24 |
| 1.5.4 MySQL Enterprise | 25 |
| 1.6 How to Report Bugs or Problems | 25 |
| 1.7 MySQL Standards Compliance | 29 |
| 1.7.1 MySQL Extensions to Standard SQL | 31 |
| 1.7.2 MySQL Differences from Standard SQL | 34 |
| 1.7.3 How MySQL Deals with Constraints | 35 |
| 1.8 Credits | 39 |
| 1.8.1 Contributors to MySQL | 39 |
| 1.8.2 Documenters and translators | 43 |
| 1.8.3 Packages that support MySQL | 45 |
| 1.8.4 Tools that were used to create MySQL | 46 |
| 1.8.5 Supporters of MySQL | 46 |
| 2 Installing and Upgrading MySQL | 47 |
| 2.1 General Installation Guidance | 49 |
| 2.1.1 Which MySQL Version and Distribution to Install | 49 |
| 2.1.2 How to Get MySQL | 51 |
| 2.1.3 Verifying Package Integrity Using MD5 Checksums or GnuPG | 51 |
| 2.1.4 Installation Layouts | 65 |
| 2.1.5 Compiler-Specific Build Characteristics | 65 |
| 2.2 Installing MySQL on Unix/Linux Using Generic Binaries | 65 |
| 2.3 Installing MySQL on Microsoft Windows | 68 |
| 2.3.1 MySQL Installation Layout on Microsoft Windows | 71 |
| 2.3.2 Choosing An Installation Package | 71 |
| 2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer | 72 |
| 2.3.4 MySQL Notifier | 101 |
| 2.3.5 Installing MySQL on Microsoft Windows Using a noinstall Zip Archive | 113 |
| 2.3.6 Troubleshooting a Microsoft Windows MySQL Server Installation | 122 |
| 2.3.7 Windows Postinstallation Procedures | 123 |
| 2.3.8 Upgrading MySQL on Windows | 126 |
| 2.4 Installing MySQL on OS X | 127 |
| 2.4.1 General Notes on Installing MySQL on OS X | 127 |
| 2.4.2 Installing MySQL on OS X Using Native Packages | 128 |
| 2.4.3 Installing a MySQL Launch Daemon | 135 |
| 2.4.4 Installing and Using the MySQL Preference Pane | 137 |
| 2.5 Installing MySQL on Linux | 142 |
| 2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository | 143 |
| 2.5.2 Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository | 147 |
| 2.5.3 Installing MySQL on Linux Using the MySQL APT Repository | 150 |

| | |
|---|-----|
| 2.5.4 Installing MySQL on Linux Using the MySQL SLES Repository | 150 |
| 2.5.5 Installing MySQL on Linux Using RPM Packages from Oracle | 150 |
| 2.5.6 Installing MySQL on Linux Using Debian Packages from Oracle | 156 |
| 2.5.7 Installing MySQL on Linux from the Native Software Repositories | 158 |
| 2.5.8 Installing MySQL on Linux with docker | 162 |
| 2.5.9 Installing MySQL on Linux with juju | 162 |
| 2.6 Installing MySQL Using Unbreakable Linux Network (ULN) | 162 |
| 2.7 Installing MySQL on Solaris and OpenSolaris | 162 |
| 2.7.1 Installing MySQL on Solaris Using a Solaris PKG | 163 |
| 2.7.2 Installing MySQL on OpenSolaris Using IPS | 164 |
| 2.8 Installing MySQL on FreeBSD | 166 |
| 2.9 Installing MySQL from Source | 166 |
| 2.9.1 MySQL Layout for Source Installation | 168 |
| 2.9.2 Installing MySQL Using a Standard Source Distribution | 168 |
| 2.9.3 Installing MySQL Using a Development Source Tree | 173 |
| 2.9.4 MySQL Source-Configuration Options | 175 |
| 2.9.5 Dealing with Problems Compiling MySQL | 189 |
| 2.9.6 MySQL Configuration and Third-Party Tools | 191 |
| 2.10 Postinstallation Setup and Testing | 191 |
| 2.10.1 Initializing the Data Directory | 192 |
| 2.10.2 Starting the Server | 195 |
| 2.10.3 Testing the Server | 198 |
| 2.10.4 Securing the Initial MySQL Accounts | 200 |
| 2.10.5 Starting and Stopping MySQL Automatically | 204 |
| 2.11 Upgrading or Downgrading MySQL | 205 |
| 2.11.1 Upgrading MySQL | 205 |
| 2.11.2 Downgrading MySQL | 219 |
| 2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt | 224 |
| 2.11.4 Rebuilding or Repairing Tables or Indexes | 226 |
| 2.11.5 Copying MySQL Databases to Another Machine | 227 |
| 2.12 Perl Installation Notes | 228 |
| 2.12.1 Installing Perl on Unix | 229 |
| 2.12.2 Installing ActiveState Perl on Windows | 230 |
| 2.12.3 Problems Using the Perl DBI/DBD Interface | 230 |
| 3 Tutorial | 233 |
| 3.1 Connecting to and Disconnecting from the Server | 233 |
| 3.2 Entering Queries | 234 |
| 3.3 Creating and Using a Database | 237 |
| 3.3.1 Creating and Selecting a Database | 239 |
| 3.3.2 Creating a Table | 239 |
| 3.3.3 Loading Data into a Table | 241 |
| 3.3.4 Retrieving Information from a Table | 242 |
| 3.4 Getting Information About Databases and Tables | 256 |
| 3.5 Using mysql in Batch Mode | 257 |
| 3.6 Examples of Common Queries | 258 |
| 3.6.1 The Maximum Value for a Column | 259 |
| 3.6.2 The Row Holding the Maximum of a Certain Column | 259 |
| 3.6.3 Maximum of Column per Group | 260 |
| 3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column | 260 |
| 3.6.5 Using User-Defined Variables | 261 |
| 3.6.6 Using Foreign Keys | 261 |
| 3.6.7 Searching on Two Keys | 263 |
| 3.6.8 Calculating Visits Per Day | 263 |
| 3.6.9 Using AUTO_INCREMENT | 264 |

| | |
|---|-----|
| 3.7 Using MySQL with Apache | 266 |
| 4 MySQL Programs | 267 |
| 4.1 Overview of MySQL Programs | 268 |
| 4.2 Using MySQL Programs | 273 |
| 4.2.1 Invoking MySQL Programs | 273 |
| 4.2.2 Connecting to the MySQL Server | 273 |
| 4.2.3 Specifying Program Options | 277 |
| 4.2.4 Using Options on the Command Line | 278 |
| 4.2.5 Program Option Modifiers | 280 |
| 4.2.6 Using Option Files | 280 |
| 4.2.7 Command-Line Options that Affect Option-File Handling | 286 |
| 4.2.8 Using Options to Set Program Variables | 287 |
| 4.2.9 Option Defaults, Options Expecting Values, and the = Sign | 288 |
| 4.2.10 Setting Environment Variables | 292 |
| 4.3 MySQL Server and Server-Startup Programs | 293 |
| 4.3.1 <code>mysqld</code> — The MySQL Server | 293 |
| 4.3.2 <code>mysqld_safe</code> — MySQL Server Startup Script | 293 |
| 4.3.3 <code>mysql.server</code> — MySQL Server Startup Script | 298 |
| 4.3.4 <code>mysqld_multi</code> — Manage Multiple MySQL Servers | 301 |
| 4.4 MySQL Installation-Related Programs | 305 |
| 4.4.1 <code>comp_err</code> — Compile MySQL Error Message File | 305 |
| 4.4.2 <code>mysqlbug</code> — Generate Bug Report | 306 |
| 4.4.3 <code>mysql_install_db</code> — Initialize MySQL Data Directory | 306 |
| 4.4.4 <code>mysql_plugin</code> — Configure MySQL Server Plugins | 310 |
| 4.4.5 <code>mysql_secure_installation</code> — Improve MySQL Installation Security | 312 |
| 4.4.6 <code>mysql_tzinfo_to_sql</code> — Load the Time Zone Tables | 312 |
| 4.4.7 <code>mysql_upgrade</code> — Check and Upgrade MySQL Tables | 313 |
| 4.5 MySQL Client Programs | 319 |
| 4.5.1 <code>mysql</code> — The MySQL Command-Line Tool | 319 |
| 4.5.2 <code>mysqladmin</code> — Client for Administering a MySQL Server | 344 |
| 4.5.3 <code>mysqlcheck</code> — A Table Maintenance Program | 352 |
| 4.5.4 <code>mysqldump</code> — A Database Backup Program | 360 |
| 4.5.5 <code>mysqlimport</code> — A Data Import Program | 381 |
| 4.5.6 <code>mysqlshow</code> — Display Database, Table, and Column Information | 388 |
| 4.5.7 <code>mysqlslap</code> — Load Emulation Client | 393 |
| 4.6 MySQL Administrative and Utility Programs | 401 |
| 4.6.1 <code>innochecksum</code> — Offline InnoDB File Checksum Utility | 401 |
| 4.6.2 <code>myisam_ftdump</code> — Display Full-Text Index information | 402 |
| 4.6.3 <code>myisamchk</code> — MyISAM Table-Maintenance Utility | 403 |
| 4.6.4 <code>myisamlog</code> — Display MyISAM Log File Contents | 421 |
| 4.6.5 <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables | 422 |
| 4.6.6 <code>mysql_config_editor</code> — MySQL Configuration Utility | 428 |
| 4.6.7 <code>mysqlaccess</code> — Client for Checking Access Privileges | 434 |
| 4.6.8 <code>mysqlbinlog</code> — Utility for Processing Binary Log Files | 437 |
| 4.6.9 <code>mysqldumpslow</code> — Summarize Slow Query Log Files | 458 |
| 4.6.10 <code>mysqlhotcopy</code> — A Database Backup Program | 460 |
| 4.6.11 <code>mysql_convert_table_format</code> — Convert Tables to Use a Given Storage Engine | 463 |
| 4.6.12 <code>mysql_find_rows</code> — Extract SQL Statements from Files | 464 |
| 4.6.13 <code>mysql_fix_extensions</code> — Normalize Table File Name Extensions | 465 |
| 4.6.14 <code>mysql_setpermission</code> — Interactively Set Permissions in Grant Tables | 465 |
| 4.6.15 <code>mysql_waitpid</code> — Kill Process and Wait for Its Termination | 466 |
| 4.6.16 <code>mysql_zap</code> — Kill Processes That Match a Pattern | 467 |
| 4.7 MySQL Program Development Utilities | 467 |

| | | |
|--------|---|-----|
| 4.7.1 | <code>mysql2mysql</code> — Convert mSQL Programs for Use with MySQL | 468 |
| 4.7.2 | <code>mysql_config</code> — Display Options for Compiling Clients | 468 |
| 4.7.3 | <code>my_print_defaults</code> — Display Options from Option Files | 470 |
| 4.7.4 | <code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols | 471 |
| 4.8 | Miscellaneous Programs | 471 |
| 4.8.1 | <code>perror</code> — Explain Error Codes | 471 |
| 4.8.2 | <code>replace</code> — A String-Replacement Utility | 472 |
| 4.8.3 | <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa | 473 |
| 4.9 | MySQL Program Environment Variables | 474 |
| 5 | MySQL Server Administration | 477 |
| 5.1 | The MySQL Server | 478 |
| 5.1.1 | Configuring the Server | 478 |
| 5.1.2 | Server Configuration Defaults | 480 |
| 5.1.3 | Server Option and Variable Reference | 482 |
| 5.1.4 | Server Command Options | 520 |
| 5.1.5 | Server System Variables | 557 |
| 5.1.6 | Using System Variables | 692 |
| 5.1.7 | Server Status Variables | 708 |
| 5.1.8 | Server SQL Modes | 739 |
| 5.1.9 | IPv6 Support | 748 |
| 5.1.10 | Server-Side Help | 753 |
| 5.1.11 | Server Response to Signals | 753 |
| 5.1.12 | The Server Shutdown Process | 754 |
| 5.2 | The MySQL Data Directory | 755 |
| 5.3 | The <code>mysql</code> System Database | 756 |
| 5.4 | MySQL Server Logs | 758 |
| 5.4.1 | Selecting General Query and Slow Query Log Output Destinations | 759 |
| 5.4.2 | The Error Log | 761 |
| 5.4.3 | The General Query Log | 763 |
| 5.4.4 | The Binary Log | 765 |
| 5.4.5 | The Slow Query Log | 776 |
| 5.4.6 | The DDL Log | 778 |
| 5.4.7 | Server Log Maintenance | 778 |
| 5.5 | MySQL Server Plugins | 780 |
| 5.5.1 | Server Plugins Available | 780 |
| 5.5.2 | Installing and Uninstalling Plugins | 780 |
| 5.5.3 | Obtaining Server Plugin Information | 784 |
| 5.5.4 | MySQL Enterprise Thread Pool | 785 |
| 5.6 | Running Multiple MySQL Instances on One Machine | 792 |
| 5.6.1 | Setting Up Multiple Data Directories | 793 |
| 5.6.2 | Running Multiple MySQL Instances on Windows | 794 |
| 5.6.3 | Running Multiple MySQL Instances on Unix | 797 |
| 5.6.4 | Using Client Programs in a Multiple-Server Environment | 798 |
| 5.7 | Tracing <code>mysqld</code> Using DTrace | 799 |
| 5.7.1 | <code>mysqld</code> DTrace Probe Reference | 800 |
| 6 | Security | 819 |
| 6.1 | General Security Issues | 820 |
| 6.1.1 | Security Guidelines | 820 |
| 6.1.2 | Keeping Passwords Secure | 822 |
| 6.1.3 | Making MySQL Secure Against Attackers | 830 |
| 6.1.4 | Security-Related <code>mysqld</code> Options and Variables | 832 |
| 6.1.5 | How to Run MySQL as a Normal User | 833 |
| 6.1.6 | Security Issues with <code>LOAD DATA LOCAL</code> | 834 |
| 6.1.7 | Client Programming Security Guidelines | 835 |

| | |
|---|-----|
| 6.2 The MySQL Access Privilege System | 836 |
| 6.2.1 Privileges Provided by MySQL | 837 |
| 6.2.2 Grant Tables | 842 |
| 6.2.3 Specifying Account Names | 847 |
| 6.2.4 Access Control, Stage 1: Connection Verification | 849 |
| 6.2.5 Access Control, Stage 2: Request Verification | 852 |
| 6.2.6 When Privilege Changes Take Effect | 854 |
| 6.2.7 Troubleshooting Problems Connecting to MySQL | 855 |
| 6.3 MySQL User Account Management | 859 |
| 6.3.1 User Names and Passwords | 860 |
| 6.3.2 Adding User Accounts | 861 |
| 6.3.3 Removing User Accounts | 863 |
| 6.3.4 Setting Account Resource Limits | 863 |
| 6.3.5 Assigning Account Passwords | 866 |
| 6.3.6 Password Expiration and Sandbox Mode | 867 |
| 6.3.7 Pluggable Authentication | 870 |
| 6.3.8 Proxy Users | 873 |
| 6.3.9 SQL-Based MySQL Account Activity Auditing | 878 |
| 6.4 Using Secure Connections | 879 |
| 6.4.1 OpenSSL Versus yaSSL | 880 |
| 6.4.2 Building MySQL with Support for Secure Connections | 881 |
| 6.4.3 Secure Connection Protocols and Ciphers | 882 |
| 6.4.4 Configuring MySQL to Use Secure Connections | 883 |
| 6.4.5 Command Options for Secure Connections | 885 |
| 6.4.6 Creating SSL and RSA Certificates and Keys | 889 |
| 6.4.7 Connecting to MySQL Remotely from Windows with SSH | 895 |
| 6.5 Security Plugins | 895 |
| 6.5.1 Authentication Plugins | 896 |
| 6.5.2 The Connection-Control Plugin | 919 |
| 6.5.3 The Password Validation Plugin | 925 |
| 6.5.4 MySQL Enterprise Audit | 931 |
| 6.5.5 MySQL Enterprise Firewall | 958 |
| 7 Backup and Recovery | 971 |
| 7.1 Backup and Recovery Types | 972 |
| 7.2 Database Backup Methods | 975 |
| 7.3 Example Backup and Recovery Strategy | 977 |
| 7.3.1 Establishing a Backup Policy | 978 |
| 7.3.2 Using Backups for Recovery | 980 |
| 7.3.3 Backup Strategy Summary | 980 |
| 7.4 Using mysqldump for Backups | 981 |
| 7.4.1 Dumping Data in SQL Format with mysqldump | 981 |
| 7.4.2 Reloading SQL-Format Backups | 982 |
| 7.4.3 Dumping Data in Delimited-Text Format with mysqldump | 983 |
| 7.4.4 Reloading Delimited-Text Format Backups | 984 |
| 7.4.5 mysqldump Tips | 985 |
| 7.5 Point-in-Time (Incremental) Recovery Using the Binary Log | 987 |
| 7.5.1 Point-in-Time Recovery Using Event Times | 989 |
| 7.5.2 Point-in-Time Recovery Using Event Positions | 989 |
| 7.6 MyISAM Table Maintenance and Crash Recovery | 990 |
| 7.6.1 Using myisamchk for Crash Recovery | 990 |
| 7.6.2 How to Check MyISAM Tables for Errors | 991 |
| 7.6.3 How to Repair MyISAM Tables | 992 |
| 7.6.4 MyISAM Table Optimization | 994 |
| 7.6.5 Setting Up a MyISAM Table Maintenance Schedule | 995 |

| | |
|---|------|
| 8 Optimization | 997 |
| 8.1 Optimization Overview | 998 |
| 8.2 Optimizing SQL Statements | 1000 |
| 8.2.1 Optimizing SELECT Statements | 1000 |
| 8.2.2 Optimizing Subqueries, Derived Tables, and Views | 1042 |
| 8.2.3 Optimizing INFORMATION_SCHEMA Queries | 1052 |
| 8.2.4 Optimizing Data Change Statements | 1058 |
| 8.2.5 Optimizing Database Privileges | 1059 |
| 8.2.6 Other Optimization Tips | 1059 |
| 8.3 Optimization and Indexes | 1060 |
| 8.3.1 How MySQL Uses Indexes | 1060 |
| 8.3.2 Using Primary Keys | 1061 |
| 8.3.3 Using Foreign Keys | 1061 |
| 8.3.4 Column Indexes | 1062 |
| 8.3.5 Multiple-Column Indexes | 1063 |
| 8.3.6 Verifying Index Usage | 1065 |
| 8.3.7 InnoDB and MyISAM Index Statistics Collection | 1065 |
| 8.3.8 Comparison of B-Tree and Hash Indexes | 1066 |
| 8.3.9 Use of Index Extensions | 1068 |
| 8.4 Optimizing Database Structure | 1070 |
| 8.4.1 Optimizing Data Size | 1070 |
| 8.4.2 Optimizing MySQL Data Types | 1072 |
| 8.4.3 Optimizing for Many Tables | 1074 |
| 8.4.4 Internal Temporary Table Use in MySQL | 1076 |
| 8.5 Optimizing for InnoDB Tables | 1077 |
| 8.5.1 Optimizing Storage Layout for InnoDB Tables | 1077 |
| 8.5.2 Optimizing InnoDB Transaction Management | 1078 |
| 8.5.3 Optimizing InnoDB Read-Only Transactions | 1079 |
| 8.5.4 Optimizing InnoDB Redo Logging | 1080 |
| 8.5.5 Bulk Data Loading for InnoDB Tables | 1080 |
| 8.5.6 Optimizing InnoDB Queries | 1081 |
| 8.5.7 Optimizing InnoDB DDL Operations | 1082 |
| 8.5.8 Optimizing InnoDB Disk I/O | 1082 |
| 8.5.9 Optimizing InnoDB Configuration Variables | 1083 |
| 8.5.10 Optimizing InnoDB for Systems with Many Tables | 1085 |
| 8.6 Optimizing for MyISAM Tables | 1085 |
| 8.6.1 Optimizing MyISAM Queries | 1085 |
| 8.6.2 Bulk Data Loading for MyISAM Tables | 1086 |
| 8.6.3 Optimizing REPAIR TABLE Statements | 1088 |
| 8.7 Optimizing for MEMORY Tables | 1089 |
| 8.8 Understanding the Query Execution Plan | 1090 |
| 8.8.1 Optimizing Queries with EXPLAIN | 1090 |
| 8.8.2 EXPLAIN Output Format | 1091 |
| 8.8.3 Extended EXPLAIN Output Format | 1104 |
| 8.8.4 Estimating Query Performance | 1106 |
| 8.9 Controlling the Query Optimizer | 1107 |
| 8.9.1 Controlling Query Plan Evaluation | 1107 |
| 8.9.2 Controlling Switchable Optimizations | 1107 |
| 8.9.3 Index Hints | 1110 |
| 8.10 Buffering and Caching | 1112 |
| 8.10.1 InnoDB Buffer Pool Optimization | 1113 |
| 8.10.2 The MyISAM Key Cache | 1113 |
| 8.10.3 The MySQL Query Cache | 1117 |
| 8.10.4 Caching of Prepared Statements and Stored Programs | 1124 |

| | | |
|---------|---|------|
| 8.11 | Optimizing Locking Operations | 1125 |
| 8.11.1 | Internal Locking Methods | 1125 |
| 8.11.2 | Table Locking Issues | 1128 |
| 8.11.3 | Concurrent Inserts | 1129 |
| 8.11.4 | Metadata Locking | 1130 |
| 8.11.5 | External Locking | 1131 |
| 8.12 | Optimizing the MySQL Server | 1132 |
| 8.12.1 | System Factors | 1132 |
| 8.12.2 | Optimizing Disk I/O | 1132 |
| 8.12.3 | Using Symbolic Links | 1134 |
| 8.12.4 | Optimizing Memory Use | 1137 |
| 8.12.5 | Optimizing Network Use | 1141 |
| 8.13 | Measuring Performance (Benchmarking) | 1143 |
| 8.13.1 | Measuring the Speed of Expressions and Functions | 1144 |
| 8.13.2 | The MySQL Benchmark Suite | 1144 |
| 8.13.3 | Using Your Own Benchmarks | 1145 |
| 8.13.4 | Measuring Performance with performance_schema | 1146 |
| 8.14 | Examining Thread Information | 1146 |
| 8.14.1 | Thread Command Values | 1147 |
| 8.14.2 | General Thread States | 1149 |
| 8.14.3 | Delayed-Insert Thread States | 1155 |
| 8.14.4 | Query Cache Thread States | 1156 |
| 8.14.5 | Replication Master Thread States | 1157 |
| 8.14.6 | Replication Slave I/O Thread States | 1157 |
| 8.14.7 | Replication Slave SQL Thread States | 1158 |
| 8.14.8 | Replication Slave Connection Thread States | 1159 |
| 8.14.9 | MySQL Cluster Thread States | 1160 |
| 8.14.10 | Event Scheduler Thread States | 1161 |
| 9 | Language Structure | 1163 |
| 9.1 | Literal Values | 1163 |
| 9.1.1 | String Literals | 1163 |
| 9.1.2 | Number Literals | 1166 |
| 9.1.3 | Date and Time Literals | 1166 |
| 9.1.4 | Hexadecimal Literals | 1169 |

Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 5.6, through release 5.6.37. Differences between minor versions of MySQL 5.6 are noted in the present text with reference to release numbers (5.6.x). For license information, see the [Legal Notices](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.6 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.5 Reference Manual](#) covers the 5.5 series of MySQL software releases.

If you are using MySQL 5.7, please refer to the [MySQL 5.7 Reference Manual](#).

Licensing information—MySQL 5.6. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL 5.6, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL 5.6, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Licensing information—MySQL NDB Cluster. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL NDB Cluster 7.3 or 7.4, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL NDB Cluster 7.3 or NDB 7.4, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Legal Notices

Copyright © 1997, 2017, Oracle and/or its affiliates. All rights reserved.

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous

applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

The MySQL™ software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle's express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (<http://www.fsf.org/licenses/>) or can purchase a standard commercial license from Oracle. See <http://www.mysql.com/company/legal/licensing/> for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see [Section 1.3.2, “The Main Features of MySQL”](#).
- For an overview of new MySQL features, see [Section 1.4, “What Is New in MySQL 5.6”](#). For information about the changes in each version, see the [Release Notes](#).
- For installation instructions, see [Chapter 2, *Installing and Upgrading MySQL*](#). For information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#).
- For a tutorial introduction to the MySQL Database Server, see [Chapter 3, *Tutorial*](#).

- For information about configuring and administering MySQL Server, see [Chapter 5, MySQL Server Administration](#).
- For information about security in MySQL, see [Chapter 6, Security](#).
- For information about setting up replication servers, see [Chapter 17, Replication](#).
- For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see [Chapter 25, MySQL Enterprise Edition](#).
- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see [Appendix A, MySQL 5.6 Frequently Asked Questions](#).
- For a history of new features and bug fixes, see the [Release Notes](#).

Important

To report problems or bugs, please use the instructions at [Section 1.6, “How to Report Bugs or Problems”](#). If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support.

1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 5.6, through release 5.6.37. Differences between minor versions of MySQL 5.6 are noted in the present text with reference to release numbers (5.6.x). For license information, see the [Legal Notices](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.6 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.5 Reference Manual](#) covers the 5.5 series of MySQL software releases.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at <http://dev.mysql.com/doc/>. Other formats also are available there, including HTML, PDF, and EPUB versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see <http://docbook.org/>

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See [Section 1.5.1, “MySQL Mailing Lists”](#), and [Section 1.5.2, “MySQL Community Support at the MySQL Forums”](#). If you have suggestions concerning additions or corrections to the manual itself, please send them to the <http://www.mysql.com/company/contact/>.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Chris Cole, Paul DuBois, Edward Gilmore, Stefan Hinz, David Moss, Philip Olson, Daniel Price, Daniel So, and Jon Stephens.

1.2 Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- *Text in this style* is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- *Text in this style* indicates input that you type in examples.
- *Text in this style* indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).
- *Text in this style* is used for variable input for which you should substitute a value of your own choosing.
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- *Text in this style* is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example:* “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the `%` character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *db_name*, *tbl_name*, and *col_name*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“[” and “]”) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“|”). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (“[” and “]”):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (“{” and “}”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (...) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

1.3 Overview of the MySQL Database Management System

1.3.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL Web site (<http://www.mysql.com/>) provides the latest information about MySQL software.

- **MySQL is a database management system.**

A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), <http://www.fsf.org/licenses/>, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (<http://www.mysql.com/company/legal/licensing/>).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

1.3.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 8.0: [What Is New in MySQL 8.0](#)
- MySQL 5.7: [What Is New in MySQL 5.7](#)
- MySQL 5.6: [Section 1.4, “What Is New in MySQL 5.6”](#)
- MySQL 5.5: [What Is New in MySQL 5.5](#)

Internals and Portability

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See <http://www.mysql.com/support/supportedplatforms/database.html>.
- For portability, uses [CMake](#) in MySQL 5.5 and up. Previous series use GNU Automake, Autoconf, and Libtool.
- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (<http://developer.kde.org/~sewardj/>).
- Uses multi-layered server design with independent modules.
- Designed to be fully multi-threaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables ([MyISAM](#)) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.

- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, [FLOAT](#), [DOUBLE](#), [CHAR](#), [VARCHAR](#), [BINARY](#), [VARBINARY](#), [TEXT](#), [BLOB](#), [DATE](#), [TIME](#), [DATETIME](#), [TIMESTAMP](#), [YEAR](#), [SET](#), [ENUM](#), and OpenGIS spatial types. See [Chapter 11, Data Types](#).
- Fixed-length and variable-length string types.

Statements and Functions

- Full operator and function support in the [SELECT](#) list and [WHERE](#) clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
-> FROM citizen
-> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL [GROUP BY](#) and [ORDER BY](#) clauses. Support for group functions ([COUNT\(\)](#), [AVG\(\)](#), [STD\(\)](#), [SUM\(\)](#), [MAX\(\)](#), [MIN\(\)](#), and [GROUP_CONCAT\(\)](#)).
- Support for [LEFT OUTER JOIN](#) and [RIGHT OUTER JOIN](#) with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for [DELETE](#), [INSERT](#), [REPLACE](#), and [UPDATE](#) to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
- Support for MySQL-specific [SHOW](#) statements that retrieve information about databases, storage engines, tables, and indexes. Support for the [INFORMATION_SCHEMA](#) database, implemented according to standard SQL.
- An [EXPLAIN](#) statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, [ABS](#) is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "(" that follows it. See [Section 9.3, "Keywords and Reserved Words"](#).
- You can refer to tables from different databases in the same statement.

Security

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table. Each index may consist of 1 to 16 columns or parts of columns. The maximum index width for `InnoDB` tables is either 767 bytes or 3072 bytes. See [Section 14.8.8, “Limits on InnoDB Tables”](#). The maximum index width for `MyISAM` tables is 1000 bytes. See [Section 15.2, “The MyISAM Storage Engine”](#). An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

Connectivity

- Clients can connect to MySQL Server using several protocols:
 - Clients can connect using TCP/IP sockets on any platform.
 - On Windows systems, clients can connect using named pipes if the server is started with the `--enable-named-pipe` option. Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.
 - On Unix systems, clients can connect using Unix domain socket files.
- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See [Chapter 23, Connectors and APIs](#).
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See [MySQL Connector/ODBC Developer Guide](#).
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See [MySQL Connector/J 5.1 Developer Guide](#).
- MySQL Connector/Net enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/Net is a fully managed ADO.NET driver written in 100% pure C#. See [MySQL Connector/Net Developer Guide](#).

Localization

- The server can provide error messages to clients in many languages. See [Section 10.2, “Setting the Error Message Language”](#).
- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, several Unicode character sets, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the chosen character set and collation (using `latin1` and Swedish collation by default). It is possible to change this when the MySQL server is started. To see

an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.

- The server time zone can be changed dynamically, and individual clients can specify their own time zone. See [Section 10.6, “MySQL Server Time Zone Support”](#).

Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as [MySQL Workbench](#).
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on [MyISAM](#) tables. See [Chapter 4, MySQL Programs](#).
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

1.3.3 History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as `mSQL`. This API was designed to enable third-party code that was written for use with `mSQL` to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.4 What Is New in MySQL 5.6

This section summarizes what has been added to, deprecated in, and removed from MySQL 5.6.

- [Features Added in MySQL 5.6](#)
- [Features Deprecated in MySQL 5.6](#)
- [Features Removed in MySQL 5.6](#)

Features Added in MySQL 5.6

The following features have been added to MySQL 5.6:

- **Security improvements.** These security improvements were made:
 - MySQL now provides a method for storing authentication credentials encrypted in an option file named `.mylogin.cnf`. To create the file, use the `mysql_config_editor` utility. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to a MySQL server. `mysql_config_editor` writes the `.mylogin.cnf` file using encryption so the credentials are not

stored as clear text, and its contents when decrypted by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable. For more information, see [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).

- MySQL now supports stronger encryption for user account passwords, available through an authentication plugin named `sha256_password` that implements SHA-256 password hashing. This plugin is built in, so it is always available and need not be loaded explicitly. For more information, including instructions for creating accounts that use SHA-256 passwords, see [Section 6.5.1.4, “The SHA-256 Authentication Plugin”](#).
- The `mysql.user` table now has a `password_expired` column. Its default value is 'N', but can be set to 'Y' with the new `ALTER USER` statement. After an account's password has been expired, all operations performed in subsequent connections to the server using the account result in an error until the user issues a `SET PASSWORD` statement to establish a new account password. For more information, see [Section 13.7.1.1, “ALTER USER Syntax”](#), and [Section 6.3.6, “Password Expiration and Sandbox Mode”](#).
- MySQL now has provision for checking password security:
 - In statements that assign a password supplied as a cleartext value, the value is checked against the current password policy and rejected if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` error). This affects the `CREATE USER`, `GRANT`, and `SET PASSWORD` statements. Passwords given as arguments to the `PASSWORD()` and `OLD_PASSWORD()` functions are checked as well.
 - The strength of potential passwords can be assessed using the new `VALIDATE_PASSWORD_STRENGTH()` SQL function, which takes a password argument and returns an integer from 0 (weak) to 100 (strong).

Both capabilities are implemented by the `validate_password` plugin. For more information, see [Section 6.5.3, “The Password Validation Plugin”](#).

- `mysql_upgrade` now produces a warning if it finds user accounts with passwords hashed with the older pre-4.1 hashing method. Such accounts should be updated to use more secure password hashing. See [Section 6.1.2.4, “Password Hashing in MySQL”](#)
- On Unix platforms, `mysql_install_db` supports a new option, `--random-passwords`, that provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-passwords` causes it to assign a random password to the MySQL `root` accounts, set the “password expired” flag for those accounts, and remove the anonymous-user MySQL accounts. For additional details, see [Section 4.4.3, “mysql_install_db — Initialize MySQL Data Directory”](#).
- Logging has been modified so that passwords do not appear in plain text in statements written to the general query log, slow query log, and binary log. See [Section 6.1.2.3, “Passwords and Logging”](#).

The `mysql` client no longer logs to its history file statements that refer to passwords. See [Section 4.5.1.3, “mysql Logging”](#).

- `START SLAVE` syntax has been modified to permit connection parameters to be specified for connecting to the master. This provides an alternative to storing the password in the `master.info` file. See [Section 13.4.2.5, “START SLAVE Syntax”](#).
- **MySQL Enterprise.** The format of the file generated by the audit log plugin was changed for better compatibility with Oracle Audit Vault. See [Section 6.5.4, “MySQL Enterprise Audit”](#), and [Section 6.5.4.3, “The Audit Log File”](#).

MySQL Enterprise Edition now includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see [Section 12.17, “MySQL Enterprise Encryption Functions”](#).

The audit log plugin included in MySQL Enterprise Edition now has the capability of filtering audited events based on user account and event status. Several new system variables provide DBAs with filtering control. In addition, audit log plugin reporting capability has been improved by the addition of several status variables. For more information, see [Section 6.5.4.4, “Audit Log Logging Control”](#), and [Audit Log Plugin Status Variables](#).

MySQL Enterprise Edition now includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics. For more information, see [Section 6.5.5, “MySQL Enterprise Firewall”](#).

- **Changes to server defaults.** Beginning with MySQL 5.6.6, several MySQL Server parameter defaults differ from the defaults in previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for database administrators to change settings manually. For more information, see [Section 5.1.2.1, “Changes to Server Defaults”](#).
- **InnoDB enhancements.** These [InnoDB](#) enhancements were added:
 - You can create [FULLTEXT](#) indexes on [InnoDB](#) tables, and query them using the [MATCH\(\) . . . AGAINST](#) syntax. This feature includes a new proximity search operator (@) and several new configuration options and [INFORMATION_SCHEMA](#) tables: See [Section 14.8.10, “InnoDB FULLTEXT Indexes”](#) for more information.
 - Several [ALTER TABLE](#) operations can be performed without copying the table, without blocking inserts, updates, and deletes to the table, or both. These enhancements are known collectively as [online DDL](#). See [Section 14.13, “InnoDB and Online DDL”](#) for details.
 - [InnoDB](#) now supports the [DATA DIRECTORY='directory'](#) clause of the [CREATE TABLE](#) statement, which allows you to create [InnoDB file-per-table](#) tablespaces ([.ibd](#) files) in a location outside the MySQL data directory. This enhancement provides the flexibility to create [file-per-table](#) tablespaces in locations that better suit your server environment. For example, you could place busy tables on an [SSD](#) device, or large tables on a high-capacity [HDD](#) device.

For additional information, see [Section 14.7.5, “Creating a File-Per-Table Tablespace Outside the Data Directory”](#).

- [InnoDB](#) now supports the notion of “transportable tablespaces”, allowing [file-per-table](#) tablespaces ([.ibd](#) files) to be exported from a running MySQL instance and imported into another running instance without inconsistencies or mismatches caused by buffered data, in-progress transactions, and internal bookkeeping details such as the [space ID](#) and [LSN](#).

The `FOR EXPORT` clause of the `FLUSH TABLE` command writes any unsaved changes from InnoDB memory buffers to the `.ibd` file. After copying the `.ibd` file and a separate metadata file to the other server, the `DISCARD TABLESPACE` and `IMPORT TABLESPACE` clauses of the `ALTER TABLE` statement are used to bring the table data into a different MySQL instance.

This enhancement provides the flexibility to move [file-per-table](#) tablespaces around to better suit your server environment. For example, you could move busy tables to an [SSD](#) device, or move large tables to a high-capacity [HDD](#) device. For more information, see [Section 14.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

- You can now set the [InnoDB page size](#) for uncompressed tables to 8KB or 4KB, as an alternative to the default 16KB. This setting is controlled by the `innodb_page_size` configuration option. You specify the size when creating the MySQL instance. All [InnoDB tablespaces](#) within an instance share the same page size. Smaller page sizes can help to avoid redundant or inefficient I/O for certain combinations of workload and storage devices, particularly [SSD](#) devices with small block sizes.
- Improvements to the algorithms for [adaptive flushing](#) make I/O operations more efficient and consistent under a variety of [workloads](#). The new algorithm and default configuration values are expected to improve performance and concurrency for most users. Advanced users can fine-tune their I/O responsiveness through several configuration options. See [Section 14.6.3.6, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for details.
- You can code MySQL applications that access [InnoDB](#) tables through a NoSQL-style API. This feature uses the popular [memcached](#) daemon to relay requests such as `ADD`, `SET`, and `GET` for key-value pairs. These simple operations to store and retrieve data avoid the SQL overhead such as parsing and constructing a [query execution plan](#). You can access the same data through the NoSQL API and SQL. For example, you might use the NoSQL API for fast updates and lookups, and SQL for complex queries and compatibility with existing applications. See [Section 14.20, “InnoDB memcached Plugin”](#) for details.
- Optimizer statistics for [InnoDB](#) tables are gathered at more predictable intervals and can persist across server restarts, for improved [plan stability](#). You can also control the amount of sampling done for [InnoDB](#) indexes, to make the optimizer statistics more accurate and improve the query execution plan. See [Section 14.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#) for details.
- New optimizations apply to read-only [transactions](#), improving performance and concurrency for ad-hoc queries and report-generating applications. These optimizations are applied automatically when practical, or you can specify `START TRANSACTION READ ONLY` to ensure the transaction is read-only. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for details.
- You can move the [InnoDB undo log](#) out of the [system tablespace](#) into one or more separate [tablespaces](#). The I/O patterns for the undo log make these new tablespaces good candidates to move to SSD storage, while keeping the system tablespace on hard disk storage. For details, see [Section 14.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).
- You can improve the efficiency of the [InnoDB](#) checksum feature by specifying the configuration option `innodb_checksum_algorithm=crc32`, which turns on a faster checksum algorithm. This option replaces the `innodb_checksums` option. Data written using the old checksum algorithm (option value `innodb`) is fully upward-compatible; tablespaces modified using the new checksum algorithm (option value `crc32`) cannot be downgraded to an earlier version of MySQL that does not support the `innodb_checksum_algorithm` option.
- The [InnoDB redo log](#) files now have a maximum combined size of 512GB, increased from 4GB. You can specify the larger values through the `innodb_log_file_size` option. The startup behavior now

automatically handles the situation where the size of the existing redo log files does not match the size specified by `innodb_log_file_size` and `innodb_log_files_in_group`.

- The `--innodb-read-only` option lets you run a MySQL server in read-only mode. You can access `InnoDB` tables on read-only media such as a DVD or CD, or set up a data warehouse with multiple instances all sharing the same data directory. See [Section 14.6.2, “Configuring InnoDB for Read-Only Operation”](#) for usage details.
- A new configuration option, `innodb_compression_level`, allows you to select a [compression](#) level for `InnoDB` compressed tables, from the familiar range of 0-9 used by `zlib`. You can also control whether compressed pages in the buffer pool are stored in the redo log when an update operation causes pages to be compressed again. This behavior is controlled by the `innodb_log_compressed_pages` configuration option.
- Data blocks in an `InnoDB compressed` table contain a certain amount of empty space (padding) to allow [DML](#) operations to modify the row data without re-compressing the new values. Too much padding can increase the chance of a compression failure, requiring a page split, when the data does need to be re-compressed after extensive changes. The amount of padding can now be adjusted dynamically, so that DBAs can reduce the rate of compression failures without re-creating the entire table with new parameters, or re-creating the entire instance with a different page size. The associated new configuration options are `innodb_compression_failure_threshold_pct`, `innodb_compression_pad_pct_max`.
- Several new `InnoDB`-related `INFORMATION_SCHEMA` tables provide information about the `InnoDB` buffer pool, metadata about tables, indexes, and foreign keys from the `InnoDB` data dictionary, and low-level information about performance metrics that complements the information from the Performance Schema tables.
- To ease the memory load on systems with huge numbers of tables, `InnoDB` now frees up the memory associated with an opened table using an LRU algorithm to select tables that have gone the longest without being accessed. To reserve more memory to hold metadata for open `InnoDB` tables, increase the value of the `table_definition_cache` configuration option. `InnoDB` treats this value as a “soft limit” for the number of open table instances in the `InnoDB` data dictionary cache. For additional information, refer to the `table_definition_cache` documentation.
- `InnoDB` has several internal performance enhancements, including reducing contention by splitting the kernel mutex, moving flushing operations from the main thread to a separate thread, enabling multiple purge threads, and reducing contention for the buffer pool on large-memory systems.
- `InnoDB` uses a new, faster algorithm to detect [deadlocks](#). Information about all `InnoDB` deadlocks can be written to the MySQL server error log, to help diagnose application issues.
- To avoid a lengthy [warmup](#) period after restarting the server, particularly for instances with large `InnoDB buffer pools`, you can reload pages into the buffer pool immediately after a restart. MySQL can dump a compact data file at shutdown, then consult that data file to find the [pages](#) to reload on the next restart. You can also manually dump or reload the buffer pool at any time, for example during benchmarking or after complex report-generation queries. See [Section 14.6.3.7, “Saving and Restoring the Buffer Pool State”](#) for details.
- As of MySQL 5.6.16, `innochecksum` provides support for files greater than 2GB in size. Previously, `innochecksum` only supported files up to 2GB in size.
- As of MySQL 5.6.16, new global configuration parameters, `innodb_status_output` and `innodb_status_output_locks`, allow you to dynamically enable and disable the standard `InnoDB` Monitor and `InnoDB` Lock Monitor for periodic output. Enabling and disabling monitors for periodic

output by creating and dropping specially named tables is deprecated and may be removed in a future release. For additional information, see [Section 14.17, “InnoDB Monitors”](#).

- As of MySQL 5.6.17, [Online DDL](#) support is extended to the following operations for regular and partitioned [InnoDB](#) tables:

- `OPTIMIZE TABLE`
- `ALTER TABLE ... FORCE`
- `ALTER TABLE ... ENGINE=INNODB` (when run on an [InnoDB](#) table)

[Online DDL](#) support reduces table rebuild time and permits concurrent DML. See [Section 14.13.1, “Overview of Online DDL”](#).

- **Partitioning.** These table-partitioning enhancements were added:
 - The maximum number of partitions is increased to 8192. This number includes all partitions and all subpartitions of the table.
 - It is now possible to exchange a partition of a partitioned table or a subpartition of a subpartitioned table with a nonpartitioned table that otherwise has the same structure using the `ALTER TABLE ... EXCHANGE PARTITION` statement. This can be used, for example, to import and export partitions. For more information and examples, see [Section 19.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).
 - Explicit selection of one or more partitions or subpartitions is now supported for queries, as well as for many data modification statements, that act on partitioned tables. For example, assume a table `t` with some integer column `c` has 4 partitions named `p0`, `p1`, `p2`, and `p3`. Then the query `SELECT * FROM t PARTITION (p0, p1) WHERE c < 5` returns only those rows from partitions `p0` and `p1` for which `c` is less than 5.

The following statements support explicit partition selection:

- `SELECT`
- `DELETE`
- `INSERT`
- `REPLACE`
- `UPDATE`
- `LOAD DATA.`
- `LOAD XML.`

For syntax, see the descriptions of the individual statements. For additional information and examples, see [Section 19.5, “Partition Selection”](#).

- Partition lock pruning greatly improves performance of many DML and DDL statements acting on tables with many partitions by helping to eliminate locks on partitions that are not affected by these statements. Such statements include many `SELECT`, `SELECT ... PARTITION`, `UPDATE`, `REPLACE`, `INSERT`, as well as many other statements. For more information, including a complete listing of the statements whose performance has thus been improved, see [Section 19.6.4, “Partitioning and Locking”](#).

- **Performance Schema.** The Performance Schema includes several new features:
 - Instrumentation for table input and output. Instrumented operations include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete.
 - Event filtering by table, based on schema and/or table names.
 - Event filtering by thread. More information is collected for threads.
 - Summary tables for table and index I/O, and for table locks.
 - Instrumentation for statements and stages within statements.
 - Configuration of instruments and consumers at server startup, which previously was possible only at runtime.
- **MySQL NDB Cluster.** MySQL NDB Cluster is released as a separate product; the most recent GA releases are based on MySQL 5.6 and use version 7.3 of the [NDB](#) storage engine. Clustering support is not available in mainline MySQL Server 5.6 releases. For more information about MySQL NDB Cluster 7.3, see [Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#). The latest current development version is MySQL NDB Cluster 7.4, based on version 7.4 of the [NDB](#) storage engine and MySQL Server 5.6. MySQL NDB Cluster 7.4 is currently available for testing and evaluation. The most recent MySQL NDB Cluster 7.4 release can be obtained from <http://dev.mysql.com/downloads/cluster/>.

For more information and an overview of improvements made in MySQL NDB Cluster 7.4, see [Section 18.1.4.2, “What is New in NDB Cluster 7.4”](#).

MySQL NDB Cluster 7.2, the previous GA release, is based on MySQL Server 5.5, and is still available for use in production, although we recommend that new deployments use MySQL NDB Cluster 7.3. For more information about MySQL Cluster NDB 7.2, see [MySQL NDB Cluster 7.2](#).

MySQL NDB Cluster 7.1 is also still available and supported (although we recommend that new deployments use the latest GA release series, currently MySQL NDB Cluster 7.3). These versions of MySQL Cluster are based on MySQL Server 5.1 and documented in the *MySQL 5.1 Manual*; see <https://dev.mysql.com/doc/refman/5.1/en/mysql-cluster.html>, for more information.

- **Replication and logging.** These replication enhancements were added:
 - MySQL now supports transaction-based replication using *global transaction identifiers* (also known as “GTIDs”). This makes it possible to identify and track each transaction when it is committed on the originating server and as it is applied by any slaves.

Enabling of GTIDs in a replication setup is done primarily using the new `--gtid-mode` and `--enforce-gtid-consistency` server options. For information about additional options and variables introduced in support of GTIDs, see [Section 17.1.4.5, “Global Transaction ID Options and Variables”](#).

When using GTIDs it is not necessary to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. For more information about provisioning servers for GTID replication with or without referring to binary log files, see [Section 17.1.3.3, “Using GTIDs for Failover and Scaleout”](#).

GTID-based replication is completely transaction-based, which makes it simple to check the consistency of masters and slaves. If all transactions committed on a given master are also committed on a given slave, consistency between the two servers is guaranteed.

For more complete information about the implementation and use of GTIDs in MySQL Replication, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

- MySQL row-based replication now supports row image control. By logging only those columns required for uniquely identifying and executing changes on each row (as opposed to all columns) for each row change, it is possible to save disk space, network resources, and memory usage. You can determine whether full or minimal rows are logged by setting the `binlog_row_image` server system variable to one of the values `minimal` (log required columns only), `full` (log all columns), or `noblob` (log all columns except for unneeded `BLOB` or `TEXT` columns). See [System Variables Used with Binary Logging](#), for more information.
- Binary logs written and read by the MySQL Server are now crash-safe, because only complete events (or transactions) are logged or read back. By default, the server logs the length of the event as well as the event itself and uses this information to verify that the event was written correctly. You can also cause the server to write checksums for the events using CRC32 checksums by setting the `binlog_checksum` system variable. To cause the server to read checksums from the binary log, use the `master_verify_checksum` system variable. The `--slave-sql-verify-checksum` system variable causes the slave SQL thread to read checksums from the relay log.
- MySQL now supports logging of master connection information and of slave relay log information to tables as well as files. Use of these tables can be controlled independently, by the `--master-info-repository` and `--relay-log-info-repository` server options. Setting `--master-info-repository` to `TABLE` causes connection information to be logged in the `slave_master_info` table; setting `--relay-log-info-repository` to `TABLE` causes relay log information to be logged to the `slave_relay_log_info` table. Both of these tables are created automatically, in the `mysql` system database.

In order for replication to be resilient to unexpected halts, the `slave_master_info` and `slave_relay_log_info` tables must each use a transactional storage engine, and beginning with MySQL 5.6.6, these tables are created using `InnoDB` for this reason. (Bug #13538891) If you are using a previous MySQL 5.6 release in which both of these tables use `MyISAM`, this means that, prior to starting replication, you must convert both of them to a transactional storage engine (such as `InnoDB`) if you wish for replication to be resilient to unexpected halts. You can do this in such cases by means of the appropriate `ALTER TABLE ... ENGINE=...` statements. You should *not* attempt to change the storage engine used by either of these tables while replication is actually running.

See [Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”](#), for more information.

- `mysqlbinlog` now has the capability to back up a binary log in its original binary format. When invoked with the `--read-from-remote-server` and `--raw` options, `mysqlbinlog` connects to a server, requests the log files, and writes output files in the same format as the originals. See [Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).
- MySQL now supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time. The default delay is 0 seconds. Use the new `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay.

Delayed replication can be used for purposes such as protecting against user mistakes on the master (a DBA can roll back a delayed slave to the time just before the disaster) or testing how the system behaves when there is a lag. See [Section 17.3.10, “Delayed Replication”](#).

- A replication slave having multiple network interfaces can now be caused to use only one of these (to the exclusion of the others) by using the `MASTER_BIND` option when issuing a `CHANGE MASTER TO` statement.

- The `log_bin_basename` system variable has been added. This variable contains the complete filename and path to the binary log file. Whereas the `log_bin` system variable shows only whether or not binary logging is enabled, `log_bin_basename` reflects the name set with the `--log-bin` server option.

Similarly, the `relay_log_basename` system variable shows the filename and complete path to the relay log file.

- MySQL Replication now supports parallel execution of transactions with multi-threading on the slave. When parallel execution is enabled, the slave SQL thread acts as the coordinator for a number of slave worker threads as determined by the value of the `slave_parallel_workers` server system variable. The current implementation of multi-threading on the slave assumes that data and updates are partitioned on a per-database basis, and that updates within a given database occur in the same relative order as they do on the master. However, it is not necessary to coordinate transactions between different databases. Transactions can then also be distributed per database, which means that a worker thread on the slave can process successive transactions on a given database without waiting for updates to other databases to complete.

Since transactions on different databases can occur in a different order on the slave than on the master, simply checking for the most recently executed transaction is not a guarantee that all previous transactions on the master have been executed on the slave. This has implications for logging and recovery when using a multi-threaded slave. For information about how to interpret binary logging information when using multi-threading on the slave, see [Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”](#).

- **Optimizer enhancements.** These query optimizer improvements were implemented:
 - The optimizer now more efficiently handles queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,]N;
```

That type of query is common in web applications that display only a few rows from a larger result set. For example:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;  
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

The sort buffer has a size of `sort_buffer_size`. If the sort elements for *N* rows are small enough to fit in the sort buffer (*M+N* rows if *M* was specified), the server can avoid using a merge file and perform the sort entirely in memory. For details, see [Section 8.2.1.16, “LIMIT Query Optimization”](#).

- The optimizer implements Disk-Sweep Multi-Range Read. Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data. For more information, see [Section 8.2.1.10, “Multi-Range Read Optimization”](#).
- The optimizer implements Index Condition Pushdown (ICP), an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the

[WHERE](#) condition for the rows. With ICP enabled, and if parts of the [WHERE](#) condition can be evaluated by using only fields from the index, the MySQL server pushes this part of the [WHERE](#) condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is base row be read. ICP can reduce the number of accesses the storage engine has to do against the base table and the number of accesses the MySQL server has to do against the storage engine. For more information, see [Section 8.2.1.5, “Index Condition Pushdown Optimization”](#).

- The [EXPLAIN](#) statement now provides execution plan information for [DELETE](#), [INSERT](#), [REPLACE](#), and [UPDATE](#) statements. Previously, [EXPLAIN](#) provided information only for [SELECT](#) statements. In addition, the [EXPLAIN](#) statement now can produce output in JSON format. See [Section 13.8.2, “EXPLAIN Syntax”](#).
- The optimizer more efficiently handles subqueries in the [FROM](#) clause (that is, derived tables). Materialization of subqueries in the [FROM](#) clause is postponed until their contents are needed during query execution, which improves performance. In addition, during query execution, the optimizer may add an index to a derived table to speed up row retrieval from it. For more information, see [Section 8.2.2.3, “Optimizing Derived Tables”](#).
- The optimizer uses semi-join and materialization strategies to optimize subquery execution. See [Section 8.2.2.1, “Optimizing Subqueries with Semi-Join Transformations”](#), and [Section 8.2.2.2, “Optimizing Subqueries with Materialization”](#).
- A Batched Key Access (BKA) join algorithm is now available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semi-join operations, including nested outer joins and nested semi-joins. Benefits of BKA include improved join performance due to more efficient table scanning. For more information, see [Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”](#).
- The optimizer now has a tracing capability, primarily for use by developers. The interface is provided by a set of `optimizer_trace_XXX` system variables and the `INFORMATION_SCHEMA.OPTIMIZER_TRACE` table. For details, see [MySQL Internals: Tracing the Optimizer](#).
- **Condition handling.** MySQL now supports the [GET DIAGNOSTICS](#) statement. [GET DIAGNOSTICS](#) provides applications a standardized way to obtain information from the diagnostics area, such as whether the previous SQL statement produced an exception and what it was. For more information, see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#).

In addition, several deficiencies in condition handler processing rules were corrected so that MySQL behavior is more like standard SQL:

- Block scope is used in determining which handler to select. Previously, a stored program was treated as having a single scope for handler selection.
- Condition precedence is more accurately resolved.
- Diagnostics area clearing has changed. Bug #55843 caused handled conditions to be cleared from the diagnostics area before activating the handler. This made condition information unavailable within the handler. Now condition information is available to the handler, which can inspect it with the [GET DIAGNOSTICS](#) statement. The condition information is cleared when the handler exits, if it has not already been cleared during handler execution.
- Previously, handlers were activated as soon as a condition occurred. Now they are not activated until the statement in which the condition occurred finishes execution, at which point the most appropriate handler is chosen. This can make a difference for statements that raise multiple conditions, if a

condition raised later during statement execution has higher precedence than an earlier condition and there are handlers in the same scope for both conditions. Previously, the handler for the first condition raised would be chosen, even if it had a lower precedence than other handlers. Now the handler for the condition with highest precedence is chosen, even if it is not the first condition raised by the statement.

For more information, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

- **Data types.** These data type changes have been implemented:
 - MySQL now permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 11.3.6, “Fractional Seconds in Time Values”](#).
 - Previously, at most one `TIMESTAMP` column per table could be automatically initialized or updated to the current date and time. This restriction has been lifted. Any `TIMESTAMP` column definition can have any combination of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses. In addition, these clauses now can be used with `DATETIME` column definitions. For more information, see [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).
 - In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types in terms of default value and assignment of automatic initialization and update attributes. These behaviors remain the default but now are deprecated, and can be turned off by enabling the `explicit_defaults_for_timestamp` system variable at server startup. See [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#), and [Section 5.1.5, “Server System Variables”](#).
- **Host cache.** MySQL now provides more information about the causes of errors that occur when clients connect to the server, as well as improved access to the host cache, which contains client IP address and host name information and is used to avoid DNS lookups. These changes have been implemented:
 - New `Connection_errors_xxx` status variables provide information about connection errors that do not apply to specific client IP addresses.
 - Counters have been added to the host cache to track errors that do apply to specific IP addresses, and a new `host_cache` Performance Schema table exposes the contents of the host cache so that it can be examined using `SELECT` statements. Access to host cache contents makes it possible to answer questions such as how many hosts are cached, what kinds of connection errors are occurring for which hosts, or how close host error counts are to reaching the `max_connect_errors` system variable limit.
 - The host cache size now is configurable using the `host_cache_size` system variable.

For more information, see [Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”](#), and [Section 22.10.10.1, “The host_cache Table”](#).

- **OpenGIS.** The OpenGIS specification defines functions that test the relationship between two geometry values. MySQL originally implemented these functions such that they used object bounding rectangles and returned the same result as the corresponding MBR-based functions. Corresponding versions are now available that use precise object shapes. These versions are named with an `ST_` prefix. For example, `Contains()` uses object bounding rectangles, whereas `ST_Contains()` uses object shapes. For more information, see [Section 12.15.9, “Functions That Test Spatial Relations Between Geometry Objects”](#).

Features Deprecated in MySQL 5.6

The following features are deprecated in MySQL 5.6 and may be or will be removed in a future series. Where alternatives are shown, applications should be updated to use them.

- The `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` SQL modes are deprecated and setting the `sql_mode` value to include any of them generates a warning. In MySQL 5.7, these modes do nothing. Instead, their effects are included in the effects of strict SQL mode (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES`). The motivation for the change in MySQL 5.7 is to reduce the number of SQL modes with an effect dependent on strict mode and make them part of strict mode itself.

To make advance preparation for an upgrade to MySQL 5.7, see [SQL Mode Changes in MySQL 5.7](#). That discussion provides guidelines to assess whether your applications will be affected by the SQL mode changes in MySQL 5.7.

- Relying on implicit `GROUP BY` sorting in MySQL 5.6 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.
- Pre-4.1 passwords and the `mysql_old_password` authentication plugin. Passwords stored in the older hash format used before MySQL 4.1 are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords and the `mysql_old_password` authentication plugin are now deprecated. To prevent connections using accounts that have pre-4.1 password hashes, the `secure_auth` system variable is now enabled by default. (To permit connections for accounts that have such password hashes, start the server with `--secure_auth=0`. However, because pre-4.1 passwords are deprecated, disabling `secure_auth` is also deprecated.)

DBAs are advised to convert accounts that use the `mysql_old_password` authentication plugin to use `mysql_native_password` instead. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

The `OLD_PASSWORD()` function generates pre-4.1 password hashes, as does `PASSWORD()` if the `old_passwords` system variable is set to 1. `OLD_PASSWORD()` and `old_passwords=1` are deprecated.

- The `--skip-innodb` option and its synonyms (`--innodb=OFF`, `--disable-innodb`, and so forth).
- The `date_format`, `datetime_format`, and `time_format` system variables, which are unused.
- The `have_profiling`, `profiling`, and `profiling_history_size` system variables.
- The `innodb_use_sys_malloc` and `innodb_additional_mem_pool_size` system variables.
- The `timed_mutexes` system variable. It does nothing and has no effect.
- The `--language` option. Use the `--lc-messages-dir` and `--lc-messages` options instead.
- The `IGNORE` clause for `ALTER TABLE`. `ALTER IGNORE TABLE` causes problems for replication, prevents online `ALTER TABLE` for unique index creation, and causes problems with foreign keys (rows removed in the parent table).
- The `msql2mysql`, `mysql_convert_table_format`, `mysql_find_rows`, `mysql_fix_extensions`, `mysql_setpermission`, `mysql_waitpid`, `mysql_zap`, `mysqlaccess`, and `mysqlbug` utilities.

- The `mysqlhotcopy` utility. Alternatives include `mysqldump` and MySQL Enterprise Backup.

Features Removed in MySQL 5.6

The following items are obsolete and have been removed in MySQL 5.6. Where alternatives are shown, applications should be updated to use them.

- The `--log` server option and the `log` system variable. Instead, use the `--general_log` option to enable the general query log and the `--general_log_file=file_name` option to set the general query log file name.
- The `--log-slow-queries` server option and the `log_slow_queries` system variable. Instead, use the `--slow_query_log` option to enable the slow query log and the `--slow_query_log_file=file_name` option to set the slow query log file name.
- The `--one-thread` server option. Use `--thread_handling=no-threads` instead.
- The `--safe-mode` server option.
- The `--skip-thread-priority` server option.
- The `--table-cache` server option. Use the `table_open_cache` system variable instead.
- The `--init-rpl-role` and `--rpl-recovery-rank` options, the `rpl_recovery_rank` system variable, and the `Rpl_status` status variable.
- The `engine_condition_pushdown` system variable. Use the `engine_condition_pushdown` flag of the `optimizer_switch` variable instead.
- The `have_csv`, `have_innodb`, `have_ndbcluster`, and `have_partitioning` system variables. Use `SHOW PLUGINS` or query the `PLUGINS` table in the `INFORMATION_SCHEMA` database instead.
- The `sql_big_tables` system variable. Use `big_tables` instead.
- The `sql_low_priority_updates` system variable. Use `low_priority_updates` instead.
- The `sql_max_join_size` system variable. Use `max_join_size` instead.
- The `max_long_data_size` system variable. Use `max_allowed_packet` instead.
- The `FLUSH MASTER` and `FLUSH SLAVE` statements. Use the `RESET MASTER` and `RESET SLAVE` statements instead.
- The `SLAVE START` and `SLAVE STOP` statements. Use The `START SLAVE` and `STOP SLAVE` statements.
- The `SHOW AUTHORS` and `SHOW CONTRIBUTORS` statements.
- The `OPTION` and `ONE_SHOT` modifiers for the `SET` statement.
- It is explicitly disallowed to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). It remains permissible to assign `DEFAULT` to system variables, as before.
- Most `SHOW ENGINE INNODB MUTEX` output is removed in 5.6.14. `SHOW ENGINE INNODB MUTEX` output is removed entirely in MySQL 5.7.2. Comparable information can be generated by creating views on [Performance Schema](#) tables.

1.5 MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

1.5.1 MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit <http://lists.mysql.com/>. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from lists.mysql.com to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

To have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- [announce](#)

The list for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- [mysql](#)

The main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- [bugs](#)

The list for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See [Section 1.6, “How to Report Bugs or Problems”](#).

- [internals](#)

The list for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- [mysqldoc](#)

The list for people who work on the MySQL documentation.

- [benchmarks](#)

The list for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- [packagers](#)

The list for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- [java](#)

The list for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- [win32](#)

The list for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- [myodbc](#)

The list for all topics concerning connecting to the MySQL server with ODBC.

- [gui-tools](#)

The list for all topics concerning MySQL graphical user interface tools such as MySQL Workbench.

- [cluster](#)

The list for discussion of MySQL Cluster.

- [dotnet](#)

The list for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- [plusplus](#)

The list for all topics concerning programming with the C++ API for MySQL.

- [perl](#)

The list for all topics concerning Perl support for MySQL with `DBD::mysql`.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Oracle. This puts you in direct contact with MySQL developers.

The following MySQL mailing lists are in languages other than English. These lists are not operated by Oracle.

- [<mysql-france-subscribe@yahoogroups.com>](mailto:mysql-france-subscribe@yahoogroups.com)

A French mailing list.

- [<list@tinc.net>](mailto:list@tinc.net)

A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

- [<mysql-de-request@lists.4t2.com>](mailto:mysql-de-request@lists.4t2.com)

A German mailing list. To subscribe, email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at <http://www.4t2.com/mysql/>.

- [<mysql-br-request@listas.linkway.com.br>](mailto:mysql-br-request@listas.linkway.com.br)

A Portuguese mailing list. To subscribe, email subscribe_mysql-br_your@email.address to this list.

- [<mysql-alta@elistas.net>](mailto:mysql-alta@elistas.net)

A Spanish mailing list. To subscribe, email subscribe_mysql_your@email.address to this list.

1.5.1.1 Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

1.5.2 MySQL Community Support at the MySQL Forums

The forums at <http://forums.mysql.com> are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

1.5.3 MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

freenode (see <http://www.freenode.net/> for servers)

- [#mysql](#) is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.
- [#workbench](#) is primarily for MySQL Workbench related questions and thoughts, and it is also a good place to meet the MySQL Workbench developers.

If you are looking for IRC client software to connect to an IRC network, take a look at [xChat](#) (<http://www.xchat.org/>). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at <http://www.silverex.org/download/>).

1.5.4 MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs
- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see [MySQL Enterprise](#).

1.6 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at <http://dev.mysql.com/doc/>. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.
- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see [Section B.5, “Problems and Common Errors”](#).
- Search the bugs database at <http://bugs.mysql.com/> to see whether the bug has been reported and fixed.
- Search the MySQL mailing list archives at <http://lists.mysql.com/>. See [Section 1.5.1, “MySQL Mailing Lists”](#).

- You can also use <http://www.mysql.com/search/> to search all the Web pages (including the manual) that are located at the MySQL Web site.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at <http://bugs.mysql.com/> that are corrected for a given release are noted in the release notes.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support at <http://support.oracle.com/>.

To discuss problems with other users, you can use one of the MySQL mailing lists. [Section 1.5.1, “MySQL Mailing Lists”](#).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test <script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See [Section 24.5, “Debugging and Porting MySQL”](#).

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine

whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See [How to Report Connector/ODBC Problems or Bugs](#).

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.7.10). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.
- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See [Section 24.5, “Debugging and Porting MySQL”](#).
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.
- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ... \G
      <output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ... \G
      <output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
      <A short version of the output from SELECT,
      including the time taken to run the query>
mysql> SHOW STATUS;
      <output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at <http://bugs.mysql.com/>, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.
- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's

version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.

- If your question is related to the privilege system, please include the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should execute `mysqladmin reload version` and try to connect with the program that gives you trouble.
- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.
- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.
- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:
 - The `InnoDB` crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with `InnoDB` tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.
 - For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See [Chapter 5, MySQL Server Administration](#).

If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in [Section 9.2.2, “Identifier Case Sensitivity”](#).

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See [Section 5.4.2, “The Error Log”](#). Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See [Section B.5.1, “How to Determine What Is Causing a Problem”](#).
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See [Section 2.1.1, “Which MySQL Version and Distribution to Install”](#).

1.7 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, “SQL:2003” refers to the standard released in 2003, and “SQL:2008” refers to the most recent version of the standard, released in 2008. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The [HANDLER](#) interface is an example of this strategy. See [Section 13.2.4, “HANDLER Syntax”](#).

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

We are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the [NDBCLUSTER](#) storage engine. See [Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#).

We implement XML functionality which supports most of the W3C XPath standard. See [Section 12.11, “XML Functions”](#).

Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the [sql_mode](#) system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see [Section 5.1.8, “Server SQL Modes”](#).

Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start `mysqld` with the `--ansi` option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

To achieve the same effect at runtime, execute these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@global.sql_mode;
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to `'ANSI'` because the `--ansi` option also sets the transaction isolation level.

See [Section 5.1.4, “Server Command Options”](#).

1.7.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably will not find in other SQL DBMSs. Be warned that if you use them, your code will not be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ coll FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` clause in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

- Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See [Section 9.2.2, “Identifier Case Sensitivity”](#).
- You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the `MyISAM` storage engine. For example, it is possible to rename a `MyISAM` table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

- General language syntax

- By default, strings can be enclosed by " as well as '. If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by ' and the server interprets strings enclosed by " as identifiers.
- \ is the escape character in strings.
- In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace.`
- SQL statement syntax
 - The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
 - The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See [Section 13.1.10, "CREATE DATABASE Syntax"](#), [Section 13.1.21, "DROP DATABASE Syntax"](#), and [Section 13.1.1, "ALTER DATABASE Syntax"](#).
 - The `DO` statement.
 - `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
 - The `FLUSH` and `RESET` statements.
 - The `SET` statement. See [Section 13.7.4.1, "SET Syntax for Variable Assignment"](#).
 - The `SHOW` statement. See [Section 13.7.5, "SHOW Syntax"](#). The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See [Chapter 21, INFORMATION_SCHEMA Tables](#).
 - Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA INFILE`. See [Section 13.2.6, "LOAD DATA INFILE Syntax"](#).
 - Use of `RENAME TABLE`. See [Section 13.1.32, "RENAME TABLE Syntax"](#).
 - Use of `REPLACE` instead of `DELETE` plus `INSERT`. See [Section 13.2.8, "REPLACE Syntax"](#).
 - Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See [Section 13.1.7, "ALTER TABLE Syntax"](#).
 - Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See [Section 13.1.17, "CREATE TABLE Syntax"](#).
 - Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.
 - Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.
 - The capability of dropping multiple tables with a single `DROP TABLE` statement.
 - The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.
 - `INSERT INTO tbl_name SET col_name = ...` syntax.
 - The `DELAYED` clause of the `INSERT` and `REPLACE` statements.
 - The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.

- Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See [Section 13.2.9, “SELECT Syntax”](#).
- Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.
- You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See [Section 12.18, “Aggregate \(GROUP BY\) Functions”](#).
- You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.
- The ability to set variables in a statement with the `:=` assignment operator. See [Section 9.4, “User-Defined Variables”](#).
- Data types
 - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.
 - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.
- Functions and operators
 - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
 - MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it is easy to convert use of the `||` operator to MySQL Server.
 - Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.
 - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is `latin1` (cp1252 West European) by default. If you don't like this, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
 - The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N,M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.
 - The `=`, `<>`, `<=`, `<`, `>=`, `>`, `<<`, `>>`, `<=>`, `AND`, `OR`, or `LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```
 - The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See [Section 12.14, “Information Functions”](#).
 - `LIKE` is permitted on numeric values.
 - The `REGEXP` and `NOT REGEXP` extended regular expression operators.
 - `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)

- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.
- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See [Section 12.18, “Aggregate \(GROUP BY\) Functions”](#).

1.7.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see [Section 13.7.1.6, “REVOKE Syntax”](#).
- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See [Section 12.10, “Cast Functions and Operators”](#).

1.7.2.1 SELECT INTO TABLE Differences

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See [Section 13.2.5.1, “INSERT ... SELECT Syntax”](#). For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).

1.7.2.2 UPDATE Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.7.2.3 Foreign Key Differences

The MySQL implementation of foreign keys differs from the SQL standard in the following key respects:

- If there are several rows in the parent table that have the same referenced key value, `InnoDB` acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, `InnoDB` does not permit the deletion of any of those parent rows.

[InnoDB](#) performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

- A [FOREIGN KEY](#) constraint that references a non-[UNIQUE](#) key is not standard SQL but rather an [InnoDB](#) extension.
- If [ON UPDATE CASCADE](#) or [ON UPDATE SET NULL](#) recurses to update the *same table* it has previously updated during the same cascade, it acts like [RESTRICT](#). This means that you cannot use self-referential [ON UPDATE CASCADE](#) or [ON UPDATE SET NULL](#) operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential [ON DELETE SET NULL](#), on the other hand, is possible, as is a self-referential [ON DELETE CASCADE](#). Cascading operations may not be nested more than 15 levels deep.
- In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, [InnoDB](#) sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

For information about how the [InnoDB](#) storage engine handles foreign keys, see [Section 14.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

1.7.2.4 '--' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in [Section 9.6, “Comment Syntax”](#).

Standard SQL uses “--” as a start-comment sequence. MySQL Server uses `#` as the start comment character. MySQL Server also supports a variant of the `--` comment style. That is, the `--` start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a valid expression in SQL, but `--` is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with `--` can have serious consequences.

Using our implementation requires a space following the `--` for it to be recognized as a start-comment sequence in MySQL Server. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with `--`.

1.7.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See [Section 5.1.8, “Server SQL Modes”](#).

The following sections describe how MySQL Server handles different types of constraints.

1.7.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as [INSERT](#) or [UPDATE](#)) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as [InnoDB](#), MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an [IGNORE](#) keyword for [INSERT](#), [UPDATE](#), and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using ([Section 13.2.5, “INSERT Syntax”](#), [Section 13.2.11, “UPDATE Syntax”](#), and so forth).

You can get information about the number of rows actually inserted or updated with the [mysql_info\(\)](#) C API function. You can also use the [SHOW WARNINGS](#) statement. See [Section 23.8.7.35, “mysql_info\(\)”](#), and [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

Only [InnoDB](#) tables support foreign keys. See [Section 14.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

1.7.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and [foreign key constraints](#) help keep this spread-out data consistent.

MySQL supports [ON UPDATE](#) and [ON DELETE](#) foreign key references in [CREATE TABLE](#) and [ALTER TABLE](#) statements. The available referential actions are [RESTRICT](#) (the default), [CASCADE](#), [SET NULL](#), and [NO ACTION](#).

Note

[NDB](#) does not support [ON UPDATE CASCADE](#) actions where the referenced column is the parent table's primary key.

[SET DEFAULT](#) is also supported by the MySQL Server but is currently rejected as invalid by [InnoDB](#) and [NDB](#). Since MySQL does not support deferred constraint checking, [NO ACTION](#) is treated as [RESTRICT](#).

For the exact syntax supported by MySQL for foreign keys, see [Section 13.1.17.5, “Using FOREIGN KEY Constraints”](#).

`MATCH FULL`, `MATCH PARTIAL`, and `MATCH SIMPLE` are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any `ON DELETE` or `ON UPDATE` clause used in the same statement. `MATCH` options do not have any other effect in MySQL, which in effect enforces `MATCH SIMPLE` semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created. *Exception:* MySQL Cluster requires an explicit unique key (or primary key) on the foreign key column.

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
> FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
> WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

| TABLE_SCHEMA | TABLE_NAME | COLUMN_NAME | CONSTRAINT_NAME |
|--------------|---------------|-------------|-----------------|
| fk1 | myuser | myuser_id | f |
| fk1 | product_order | customer_id | f2 |
| fk1 | product_order | product_id | f1 |

3 rows in set (0.01 sec)

Information about foreign keys on `InnoDB` tables can also be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, in the `INFORMATION_SCHEMA` database.

1.7.3.3 Constraints on Invalid Data

By default, MySQL is forgiving of invalid or improper data values and coerces them to valid values for data entry. However, you can enable strict SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See [Section 5.1.8, “Server SQL Modes”](#).

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a `NULL` into a `NOT NULL` column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that does not start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for `ENUM` and `SET` columns are handled as described in [Section 1.7.3.4, “ENUM and SET Constraints”](#).
- MySQL permits you to store certain incorrect date values into `DATE` and `DATETIME` columns (such as `'2000-02-31'` or `'2000-02-00'`). In this case, when an application has not enabled strict SQL

mode, it up to the application to validate the dates before storing them. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.

- If you try to store `NULL` into a column that doesn't take `NULL` values, an error occurs for single-row `INSERT` statements. For multiple-row `INSERT` statements or for `INSERT INTO ... SELECT` statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string (' ') for string types, and the “zero” value for date and time types. Implicit default values are discussed in [Section 11.6, “Data Type Default Values”](#).
- If an `INSERT` statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit `DEFAULT` clause. If the definition has no such `DEFAULT` clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in nonstrict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

You can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

`STRICT_TRANS_TABLES` enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.
- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

1.7.3.4 ENUM and SET Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See [Section 11.4.4, “The ENUM Type”](#), and [Section 11.4.5, “The SET Type”](#).

With strict mode enabled (see [Section 5.1.8, “Server SQL Modes”](#)), the definition of a [ENUM](#) or [SET](#) column acts as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An [ENUM](#) value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as [ENUM\('a', 'b', 'c' \)](#), values such as `' '`, `'d'`, or `'ax'` are invalid and are rejected.
- A [SET](#) value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as [SET\('a', 'b', 'c' \)](#), values such as `'d'` or `'a,b,c,d'` are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use [INSERT IGNORE](#) or [UPDATE IGNORE](#). In this case, a warning is generated rather than an error. For [ENUM](#), the value is inserted as the error member (0). For [SET](#), the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

1.8 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

1.8.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the [MySQL server](#) and the [MySQL manual](#), we wish to recognize those who have made contributions of one kind or another to the [MySQL distribution](#). Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <qwertg@mbbox.vol.it> or <qwertg@tin.it>

The initial port to Win32/NT.

- Per Eric Olsson

For constructive criticism and real testing of the dynamic record format.

- Irena Pancirov <irena@mail.yacc.it>

Win32 port with Borland compiler. [mysqlshutdown.exe](#) and [mysqlwatch.exe](#).

- David J. Hughes

For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with [mSQL](#), but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. [mysqladmin](#) and [mysql](#) client are programs that were largely influenced by their [mSQL](#) counterparts. We have put a lot of effort into making the MySQL syntax a superset of [mSQL](#). Many of the API's ideas are borrowed from [mSQL](#) to make it easy to port free [mSQL](#) programs to the MySQL API. The MySQL software doesn't contain any code from [mSQL](#). Two files in the distribution ([client/insert_test.c](#) and [client/select_test.c](#)) are based on the corresponding (noncopyrighted) files in the [mSQL](#) distribution, but are modified as examples showing the changes necessary to convert code from [mSQL](#) to MySQL Server. ([mSQL](#) is copyrighted David J. Hughes.)

- Patrick Lynch

For helping us acquire <http://www.mysql.com/>.

- Fred Lindberg

For setting up gmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <igor@frog.kiev.ua>

[mysqldump](#) (previously [msqldump](#), but ported and enhanced by Monty).

- Yuri Dario

For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

Author of [mysqlhotcopy](#).

- Zarko Mocnik <zarko.mocnik@dem.si>

Sorting for Slovenian language.

- "TAMITO" <tommy@valley.ne.jp>

The [_MB](#) character set macros and the [ujis](#) and [sjis](#) character sets.

- Joshua Chamas <joshua@chamas.com>

Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <Yves.Carlier@rug.ac.be>

[mysqlaccess](#), a program to show the access rights for a user.

- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)

For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>

Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <pixel@organic.com>

For setting up a searchable mailing list archive at his site.

- Rick Mehalick <Rick_Mehalick@i-o.com>

For [xmysql](#), a graphical X client for MySQL Server.

- Doug Sisk <sisk@wix.com>

For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <axeld@vial.ethz.ch>

For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <toni@readysoft.es>

For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <jay@pathways.sde.state.sc.us>
For providing RPM versions for MySQL 3.21.
- David Sacerdote <davids@secnet.com>
Ideas for secure checking of DNS host names.
- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>
Some support for Chinese(BIG5) characters.
- Wei He <hewei@mail.ied.ac.cn>
A lot of functionality for the Chinese(GBK) character set.
- Jan Pazdziora <adelton@fi.muni.cz>
Czech sorting order.
- Zeev Suraski <bourbon@netvision.net.il>
`FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and `bison` advisor. Active mailing list member.
- Luuk de Boer <luuk@wxs.nl>
Ported (and extended) the benchmark suite to `DBI/DBD`. Have been of great help with `crash-me` and running benchmarks. Some new date functions. The `mysql_setpermission` script.
- Alexis Mikhailov <root@medinf.chuvashia.su>
User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.
- Andreas F. Bobak <bobak@relog.ch>
The `AGGREGATE` extension to user-defined functions.
- Ross Wakelin <R.Wakelin@march.co.uk>
Help to set up InstallShield for MySQL-Win32.
- Jethro Wright III <jetman@li.net>
The `libmysql.dll` library.
- James Pereria <jpereira@iafrica.com>
Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.
- Curt Sampson <cjs@portal.ca>
Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.
- Martin Ramsch <m.ramsch@computer.org>
Examples in the MySQL Tutorial.
- Steve Harvey

For making `mysqlaccess` more secure.

- Konark IA-64 Centre of Persistent Systems Private Limited

Help with the Win64 port of the MySQL server.

- Albert Chin-A-Young.

Configure updates for Tru64, large file support and better TCP wrappers support.

- John Birrell

Emulation of `pthread_mutex()` for OS/2.

- Benjamin Pflugmann

Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.

- Jocelyn Fournier

Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

- Marc Liyanage

Maintaining the OS X packages and providing invaluable feedback on how to create OS X packages.

- Robert Rutherford

Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

- Google Inc.

We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, jehamby@lightside, psmith@BayNetworks.com, duane@connect.com.au, Ted Deppner ted@psyber.com, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch dkoch@amcity.com

Irix setup.

- Luuk de Boer luuk@wxs.nl

Benchmark questions.

- Tim Sailer <tps@users.buoy.com>

[DBD: :mysql](#) questions.

- Boyd Lynn Gerber <gerberb@zeneb.com>

SCO-related questions.

- Richard Mehalick <RM186061@shellus.com>

[xmysql](#)-related questions and basic installation questions.

- Zeev Suraski <bourbon@netvision.net.il>

Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <frankie@citel.upc.es>

General questions.

- Jonathan J Smith <jsmith@wtp.net>

Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar <sklar@student.net>

Using MySQL from PHP and Perl.

- Alistair MacDonald <A.MacDonald@uel.ac.uk>

Is flexible and can handle Linux and perhaps HP-UX.

- John Lyon <jlyon@imag.net>

Questions about installing MySQL on Linux systems, using either [.rpm](#) files or compiling from source.

- Lorvid Ltd. <lorvid@WOLFENET.com>

Simple billing/license/support/copyright issues.

- Patrick Sherrill <patrick@coconet.com>

ODBC and VisualC++ interface questions.

- Randy Harmon <rjharmon@uptimecomputers.com>

[DBD](#), Linux, some SQL syntax questions.

1.8.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois

Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.

- Kim Aldale

Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>

For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded versions were based.

- Jay Flaherty <fty@mediapulse.com>

Big parts of the Perl DBI/DBD section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

Proof-reading of the Reference Manual.

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>

French error messages.

- Petr Snajdr, <snajdr@pvt.net>

Czech error messages.

- Jaroslaw Lewandowski <jotel@itnet.com.pl>

Polish error messages.

- Miguel Angel Fernandez Roiz

Spanish error messages.

- Roy-Magne Mo <rmo@www.hivolda.no>

Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <root@timur.tatarstan.ru>

Russian error messages.

- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>

Italian error messages.

- Dirk Munzinger <dirk@trinity.saar.de>

German error messages.

- Billik Stefan <billik@sun.uniag.sk>

Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>

Romanian error messages.

- Peter Feher

Hungarian error messages.

- Roberto M. Serqueira

Portuguese error messages.

- Carsten H. Pedersen

Danish error messages.

- Arjen Lentz

Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

1.8.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at <http://solutions.mysql.com/software/>.

- Tim Bunce, Alligator Descartes

For the [DBD](#) (Perl) interface.

- Andreas Koenig <a.koenig@mind.de>

For the Perl interface for MySQL Server.

- Jochen Wiedmann <wiedmann@neckar-alb.de>

For maintaining the Perl [DBD::mysql](#) module.

- Eugene Chan <eugene@acenet.com.sg>

For porting PHP for MySQL Server.

- Georg Richter

MySQL 4.1 testing and bug hunting. New PHP 5.0 [mysqli](#) extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli <maruzz@matrice.it>

For porting iODBC (Unix ODBC).

- Xavier Leroy <Xavier.Leroy@inria.fr>

The author of LinuxThreads (used by the MySQL Server on Linux).

1.8.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

From whom we got an excellent compiler ([gcc](#)), an excellent debugger ([gdb](#)) and the [libc](#) library (from which we have borrowed [strto.c](#) to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

For a really great editor/environment.

- Julian Seward

Author of [valgrind](#), an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

For [DDD](#) (The Data Display Debugger) which is an excellent graphical front end to [gdb](#).

1.8.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the [MySQL server](#) and the [MySQL manual](#), we wish to recognize the following companies, which helped us finance the development of the [MySQL server](#), such as by paying us for developing a new feature or giving us hardware for development of the [MySQL server](#).

- VA Linux / Andover.net

Funded replication.

- NuSphere

Editing of the MySQL manual.

- Stork Design studio

The MySQL Web site in use between 1998-2000.

- Intel

Contributed to development on Windows and Linux platforms.

- Compaq

Contributed to Development on Linux/Alpha.

- SWSOft

Development on the embedded [mysqld](#) version.

- FutureQuest

The [--skip-show-database](#) option.

Chapter 2 Installing and Upgrading MySQL

Table of Contents

| | |

| 2.12.1 Installing Perl on Unix | 229 |
| 2.12.2 Installing ActiveState Perl on Windows | 230 |
| 2.12.3 Problems Using the Perl DBI/DBD Interface | 230 |

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see [Section 2.11.1, “Upgrading MySQL”](#), for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, see [Section A.8, “MySQL 5.6 FAQ: Migration”](#), which contains answers to some common questions concerning migration issues.

Installation of MySQL generally follows the steps outlined here:

1. **Determine whether MySQL runs and is supported on your platform.**

Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation. For information about those platforms that are officially supported, see <http://www.mysql.com/support/supportedplatforms/database.html> on the MySQL Web site.

2. **Choose which distribution to install.**

Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. Oracle also provides access to the MySQL source code for those who want to see recent developments and test new code. To determine which version and type of distribution you should use, see [Section 2.1.1, “Which MySQL Version and Distribution to Install”](#).

3. **Download the distribution that you want to install.**

For instructions, see [Section 2.1.2, “How to Get MySQL”](#). To verify the integrity of the distribution, use the instructions in [Section 2.1.3, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

4. **Install the distribution.**

To install MySQL from a binary distribution, use the instructions in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

To install MySQL from a source distribution or from the current development source tree, use the instructions in [Section 2.9, “Installing MySQL from Source”](#).

5. **Perform any necessary postinstallation setup.**

After installing MySQL, see [Section 2.10, “Postinstallation Setup and Testing”](#) for information about making sure the MySQL server is working properly. Also refer to the information provided in [Section 2.10.4, “Securing the Initial MySQL Accounts”](#). This section describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See [Section 2.12, “Perl Installation Notes”](#).

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `.tar.gz` package), see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

For information on building MySQL entirely from the source code distributions or the source code repositories, see [Section 2.9, “Installing MySQL from Source”](#)

For specific platform help on installation, configuration, and building from source see the corresponding platform section:

- Linux, including notes on distribution specific methods, see [Section 2.5, “Installing MySQL on Linux”](#).
- Solaris and OpenSolaris, including PKG and IPS formats, see [Section 2.7, “Installing MySQL on Solaris and OpenSolaris”](#).
- IBM AIX, see [Section 2.7, “Installing MySQL on Solaris and OpenSolaris”](#).
- FreeBSD, see [Section 2.8, “Installing MySQL on FreeBSD”](#).

- **Microsoft Windows**

For instructions on installing MySQL on Microsoft Windows, using either the MySQL Installer or Zipped binary, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

For information about managing MySQL instances, see [Section 2.3.4, “MySQL Notifier”](#).

For details and instructions on building MySQL from source code using Microsoft Visual Studio, see [Section 2.9, “Installing MySQL from Source”](#).

- **OS X**

For installation on OS X, including using both the binary package and native PKG formats, see [Section 2.4, “Installing MySQL on OS X”](#).

For information on making use of an OS X Launch Daemon to automatically start and stop MySQL, see [Section 2.4.3, “Installing a MySQL Launch Daemon”](#).

For information on the MySQL Preference Pane, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#) or the corresponding section for your platform if available. To build MySQL from source, use the instructions in [Section 2.9, “Installing MySQL from Source”](#).

2.1.1 Which MySQL Version and Distribution to Install

MySQL is available on a number of operating systems and platforms. For information about those platforms that are officially supported, see <http://www.mysql.com/support/supportedplatforms/database.html> on the MySQL Web site.

When preparing to install MySQL, decide which version and distribution format (binary or source) to use.

First, decide whether to install a development release or a General Availability (GA) release. Development releases have the newest features, but are not recommended for production use. GA releases, also called production or stable releases, are meant for production use. We recommend using the most recent GA release.

The naming scheme in MySQL 5.6 uses release names that consist of three numbers and an optional suffix; for example, **mysql-5.6.1-m1**. The numbers within the release name are interpreted as follows:

- The first number (**5**) is the major version number.
- The second number (**6**) is the minor version number. Taken together, the major and minor numbers constitute the release series number. The series number describes the stable feature set.
- The third number (**1**) is the version number within the release series. This is incremented for each new bugfix release. In most cases, the most recent version within a series is the best choice.

Release names can also include a suffix to indicate the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **mN** (for example, **m1**, **m2**, **m3**, ...) indicates a milestone number. MySQL development uses a milestone model, in which each milestone introduces a small subset of thoroughly tested features. Following the releases for one milestone, development proceeds with another small number of releases that focuses on the next set of features. From one milestone to the next, feature interfaces may change or features may even be removed, based on feedback provided by community members who try these early releases. Features within milestone releases may be considered to be of pre-production quality.
- **rc** indicates a Release Candidate (RC). Release candidates are believed to be stable, having passed all of MySQL's internal testing. New features may still be introduced in RC releases, but the focus shifts to fixing bugs to stabilize features introduced earlier within the series.
- Absence of a suffix indicates a General Availability (GA) or Production release. GA releases are stable, having successfully passed through the earlier release stages, and are believed to be reliable, free of serious bugs, and suitable for use in production systems.

Development within a series begins with milestone releases, followed by RC releases, and finally reaches GA status releases.

After choosing which MySQL version to install, decide which distribution format to install for your operating system. For most use cases, a binary distribution is the right choice. Binary distributions are available in native format for many platforms, such as RPM packages for Linux or DMG packages for OS X. Distributions are also available in more generic formats such as Zip archives or compressed `tar` files. On Windows, you can use [the MySQL Installer](#) to install a binary distribution.

Under some circumstances, it may be preferable to install MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` with features that might not be included in the standard binary distributions. Here is a list of the most common extra options used to ensure feature availability:

- `-DWITH_LIBWRAP=1` for TCP wrappers support.
- `-DWITH_ZLIB={system|bundled}` for features that depend on compression
- `-DWITH_DEBUG=1` for debugging support

For additional information, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.
- You want to read or modify the C and C++ code that makes up MySQL. For this purpose, obtain a source distribution.
- Source distributions contain more tests and examples than binary distributions.

2.1.2 How to Get MySQL

Check our downloads page at <http://dev.mysql.com/downloads/> for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see <http://dev.mysql.com/downloads/mirrors.html>. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

For RPM-based Linux platforms that use Yum as their package management system, MySQL can be installed using the [MySQL Yum Repository](#). See [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#) for details.

For a number of Debian-based Linux platforms, such as Ubuntu, MySQL can be installed using the [MySQL APT Repository](#). See [Section 2.5.3, “Installing MySQL on Linux Using the MySQL APT Repository”](#) for details.

For SUSE Linux Enterprise Server (SLES) platforms, MySQL can be installed using the [MySQL SLES Repository](#). See [Section 2.5.4, “Installing MySQL on Linux Using the MySQL SLES Repository”](#) for details.

To obtain the latest development source, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

2.1.3 Verifying Package Integrity Using MD5 Checksums or GnuPG

After downloading the MySQL package that suits your needs and before attempting to install it, make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using [GnuPG](#), the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

2.1.3.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can

verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product, and you will compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named `md5sum`, or it may be named `md5`, and some operating systems do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can also download the source code from <http://www.gnu.org/software/textutils/>. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from <http://www.fourmilab.ch/md5/>. `winMd5Sum` is a graphical MD5 checking tool that can be obtained from <http://www.nullriver.com/index/products/winmd5sum>. Our Microsoft Windows examples will assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
shell> md5sum mysql-standard-5.6.37-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-5.6.37-linux-i686.tar.gz
```

```
shell> md5.exe mysql-installer-community-5.6.37.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-5.6.37.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

Note

Make sure to verify the checksum of the *archive file* (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

2.1.3.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using [MD5 checksums](#), but requires more work.

We sign MySQL downloadable packages with [GnuPG](#) (GNU Privacy Guard). [GnuPG](#) is an Open Source alternative to the well-known Pretty Good Privacy ([PGP](#)) by Phil Zimmermann. See <http://www.gnupg.org/> for more information about [GnuPG](#) and how to obtain and install it on your system. Most Linux distributions ship with [GnuPG](#) installed by default. For more information about [GnuPG](#), see <http://www.openpgp.org/>.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from <http://pgp.mit.edu/>. The key that you want to obtain is named `mysql-build@oss.oracle.com`. Alternatively, you can copy and paste the key directly from the following text:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.4.5 (GNU/Linux)

=HFUN
-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Release Engineering
<mysql-build@oss.oracle.com>" imported
gpg: Total number processed: 1
gpg: imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, `5072E1F5`:

```
shell> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server keys.gnupg.net
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
1 new user ID
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
53 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg: new user IDs: 1
gpg: new signatures: 53
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see [Section 2.1.3.4, “Signature Checking Using RPM”](#).

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

Table 2.1 MySQL Package and Signature Files for Source files

| File Type | File Name |
|-------------------|--|
| Distribution file | <code>mysql-standard-5.6.37-linux-i686.tar.gz</code> |
| Signature file | <code>mysql-standard-5.6.37-linux-i686.tar.gz.asc</code> |

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

If the downloaded package is valid, you will see a "Good signature" similar to:

```
shell> gpg --verify mysql-standard-5.6.37-linux-i686.tar.gz.asc
gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
```

The [Good signature](#) message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```
shell> gpg --verify mysql-standard-5.6.37-linux-i686.tar.gz.asc
gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5
gpg: checking the trustdb
gpg: no ultimately trusted keys found
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: A4A9 4068 76FC BD3C 4567 70C8 8C71 8D3B 5072 E1F5
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- *gpg: no ultimately trusted keys found*: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.
- *This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.*: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

See the GPG documentation for more information on how to work with public keys.

2.1.3.3 Signature Checking Using Gpg4win for Windows

The [Section 2.1.3.2, "Signature Checking Using GnuPG"](#) section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like [Gpg4win](#). You may use a different tool but our examples are based on Gpg4win, and utilize its bundled [Kleopatra](#) GUI.

Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:

Figure 2.1 Initial screen after loading Kleopatra

Next, add the MySQL Release Engineering certificate. Do this by clicking **File, Lookup Certificates on Server**. Type "Mysql Release Engineering" into the search box and press **Search**.

Figure 2.2 Finding the MySQL Release Engineering certificate

Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose **Details...** to confirm the certificate is valid. Now, import it by clicking **Import**. An import dialog will be displayed, choose **Okay**, and this certificate will now be listed under the **Imported Certificates** tab.

Next, configure the trust level for our certificate. Select our certificate, then from the main menu select **Certificates, Change Owner Trust....** We suggest choosing **I believe checks are very accurate** for our certificate, as otherwise you might not be able to verify our signature. Select **I believe checks are very accurate** and then press **OK**.

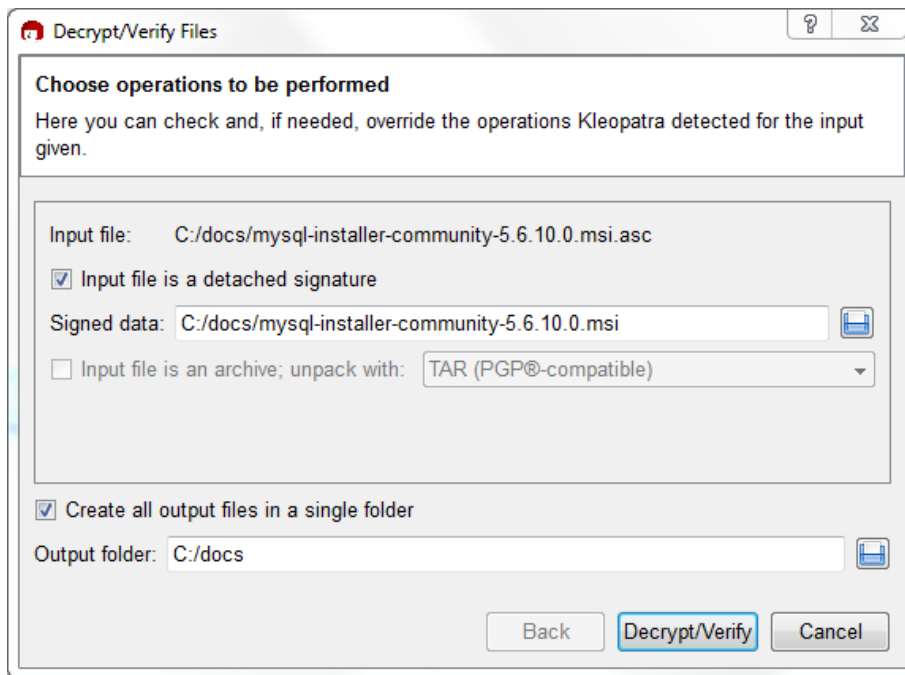

Figure 2.3 Changing the Trust level

Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

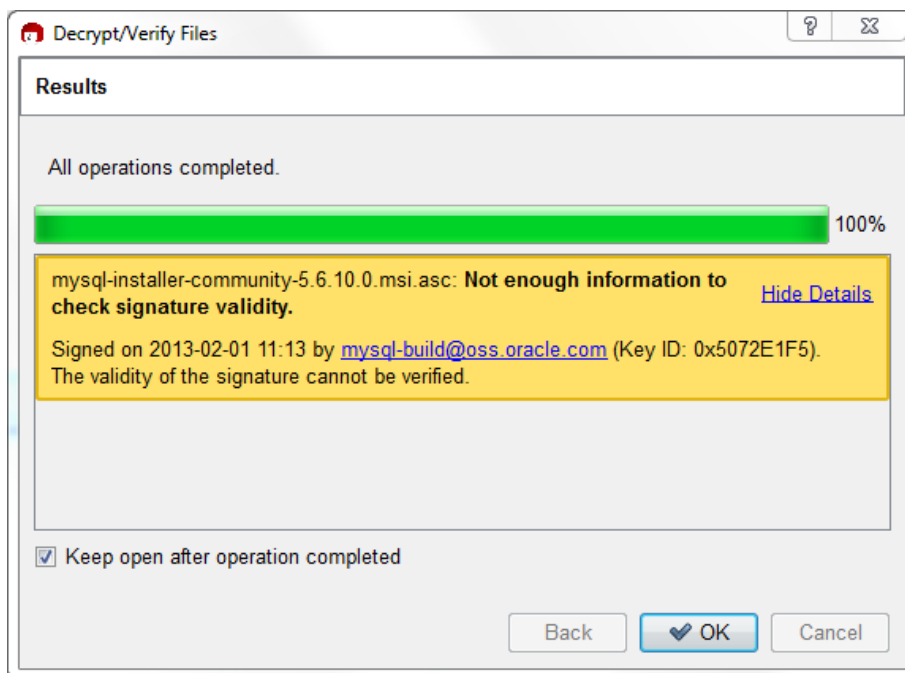

Table 2.2 MySQL Package and Signature Files for MySQL Installer for Microsoft Windows

| File Type | File Name |
|-------------------|---|
| Distribution file | <code>mysql-installer-community-5.6.37.msi</code> |
| Signature file | <code>mysql-installer-community-5.6.37.msi.asc</code> |

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (`.asc`) file into Kleopatra, or load the dialog from **File, Decrypt/Verify Files...**, and then choose either the `.msi` or `.asc` file.

Figure 2.4 The Decrypt/Verify Files dialog

Click **Decrypt/Verify** to check the file. The two most common results will look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.

Figure 2.5 The Decrypt/Verify Results: Good

Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.

Figure 2.6 The Decrypt/Verify Results: Bad

The [Section 2.1.3.2, “Signature Checking Using GnuPG”](#) section explains why you probably don't see a green `Good signature` result.

2.1.3.4 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-5.6.37-0.linux_glibc2.5.i386.rpm
MySQL-server-5.6.37-0.linux_glibc2.5.i386.rpm: md5 gpg OK
```

Note

If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#5072e1f5)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use `rpm --import` to import the key. For example:

```
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you can use this manual page:

```
shell> rpm --import http://dev.mysql.com/doc/refman/5.6/en/checking-gpg-signature.html
```

If you need to obtain the MySQL public key, see [Section 2.1.3.2, “Signature Checking Using GnuPG”](#).

2.1.4 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- [Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”](#)
- [Section 2.9.1, “MySQL Layout for Source Installation”](#)
- [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)
- [Table 2.6, “MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone”](#)
- [Table 2.5, “MySQL Installation Layout on OS X”](#)

2.1.5 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

icc (Intel C++ Compiler) Builds

A server built with `icc` has these characteristics:

- SSL support is not included.

2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include generic binary distributions in the form of compressed `tar` files (files with a `.tar.gz` extension) for a number of platforms, and binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution. For other platform-specific package formats, see the other platform-specific sections. For example, for Windows distributions, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

To obtain MySQL, see [Section 2.1.2, “How to Get MySQL”](#).

MySQL compressed `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where `VERSION` is a number (for example, `5.6.37`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

Warning

If you have previously installed MySQL using your operating system native package management system, such as `yum` or `apt-get`, you may experience problems

installing using a native binary. Make sure your previous MySQL installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check for configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory and delete them.

For information about replacing third-party packages with official MySQL packages, see the related [Apt guide](#) or [Yum guide](#).

Warning

MySQL has a dependency on the `libaio` library. Data directory initialization and subsequent server startup steps will fail if this library is not installed locally. If necessary, install it using the appropriate package manager. For example, on Yum-based systems:

```
shell> yum search libaio # search for info
shell> yum install libaio # install library
```

Or, on APT-based systems:

```
shell> apt-cache search libaio # search for info
shell> apt-get install libaio1 # install library
```

If you run into problems and need to file a bug report, please use the instructions in [Section 1.6, “How to Report Bugs or Problems”](#).

On Unix, to install a compressed `tar` file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package

| Directory | Contents of Directory |
|---------------------------|--|
| <code>bin, scripts</code> | <code>mysqld</code> server, client and utility programs |
| <code>data</code> | Log files, databases |
| <code>docs</code> | MySQL manual in Info format |
| <code>man</code> | Unix manual pages |
| <code>include</code> | Include (header) files |
| <code>lib</code> | Libraries |
| <code>share</code> | Miscellaneous support files, including error messages, sample configuration files, SQL for database installation |
| <code>sql-bench</code> | Benchmarks |

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. See [Section 2.9, “Installing MySQL from Source”](#).

To install and use a MySQL binary distribution, the command sequence looks like this:

```
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
```

```
shell> cd /usr/local
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

**Note**

This procedure assumes that you have `root` (administrator) access to your system. Alternatively, you can prefix each command using the `sudo` (Linux) or `pfexec` (OpenSolaris) command.

**Note**

The procedure does not assign passwords to MySQL accounts. To do so, use the instructions in [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

As of MySQL 5.6.8, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. For more information, see [Section 5.1.2.2, “Using a Sample Default Server Configuration File”](#).

A more detailed version of the preceding description for installing a binary distribution follows.

Create a mysql User and Group

If your system does not already have a user and group to use for running `mysqld`, you may need to create one. The following commands add the `mysql` group and the `mysql` user. You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following instructions. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

```
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
```

**Note**

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` and `-s /bin/false` options to create a user that does not have login permissions to your server host. Omit these options if your `useradd` does not support them.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```
shell> cd /usr/local
```

Obtain a distribution file using the instructions in [Section 2.1.2, “How to Get MySQL”](#). For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

The `tar` command creates a directory named `mysql-VERSION-OS`.

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
```

Next, create a symbolic link to the installation directory created by `tar`:

```
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `ln` command makes a symbolic link to the installation directory. This enables you to refer more easily to it as `/usr/local/mysql`. To avoid having to type the path name of client programs always when you are working with MySQL, you can add the `/usr/local/mysql/bin` directory to your `PATH` variable:

```
shell> export PATH=$PATH:/usr/local/mysql/bin
```

Perform Postinstallation Setup

The remainder of the installation process involves setting distribution ownership and access permissions, initializing the data directory, starting the MySQL server, and setting up the configuration file. For instructions, see [Section 2.10, “Postinstallation Setup and Testing”](#).

2.3 Installing MySQL on Microsoft Windows

MySQL is available for Microsoft Windows, for both 32-bit and 64-bit versions. For supported Windows platform information, see <http://www.mysql.com/support/supportedplatforms/database.html>.

There are different methods to install MySQL on Microsoft Windows.

MySQL Installer Method

The simplest and recommended method is to download MySQL Installer (for Windows) and let it install and configure all of the MySQL products on your system. Here is how:

1. Download MySQL Installer from <http://dev.mysql.com/downloads/installer/> and execute it.

**Note**

Unlike the standard MySQL Installer, the smaller "web-community" version does not bundle any MySQL applications but it will download the MySQL products you choose to install.

2. Choose the appropriate **Setup Type** for your system. Typically you will choose **Developer Default** to install MySQL server and other MySQL tools related to MySQL development, helpful tools like MySQL Workbench. Or, choose the **Custom** setup type to manually select your desired MySQL products.

**Note**

Multiple versions of MySQL server can exist on a single system. You can choose one or multiple versions.

3. Complete the installation process by following the MySQL Installation wizard's instructions. This will install several MySQL products and start the MySQL server.

MySQL is now installed. If you configured MySQL as a service, then Windows will automatically start MySQL server every time you restart your system.

**Note**

You probably also installed other helpful MySQL products like MySQL Workbench and MySQL Notifier on your system. Consider loading [Chapter 26, MySQL Workbench](#) to check your new MySQL server connection, and [Section 2.3.4, "MySQL Notifier"](#) to view the connection's status. By default, these two programs automatically start after installing MySQL.

This process also installs the MySQL Installer application on your system, and later you can use MySQL Installer to upgrade or reconfigure your MySQL products.

Additional Installation Information

It is possible to run MySQL as a standard application or as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see [Section 2.3.5.7, "Starting MySQL as a Windows Service"](#).

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the [Service Control Manager](#). Once installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see [Section C.10.6, "Windows Platform Limitations"](#).

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see [MySQL Connector/ODBC Developer Guide](#).

**Note**

MySQL Installer will install and configure Connector/ODBC for you.

- To use MySQL server with .NET applications, you must have the Connector/Net driver. For more information, including installation and configuration instructions, see [MySQL Connector/Net Developer Guide](#).

Note

MySQL Installer will install and configure Connector/NET for you.

MySQL distributions for Windows can be downloaded from <http://dev.mysql.com/downloads/>. See [Section 2.1.2, “How to Get MySQL”](#).

MySQL for Windows is available in several distribution formats, detailed here. Generally speaking, you should use MySQL Installer. It contains more features and MySQL products than the older MSI, is simpler to use than the Zip file, and you need no additional tools to get MySQL up and running. MySQL Installer automatically installs MySQL Server and additional MySQL products, creates an options file, starts the server, and enables you to create default user accounts. For more information on choosing a package, see [Section 2.3.2, “Choosing An Installation Package”](#).

- A MySQL Installer distribution includes MySQL Server and additional MySQL products including MySQL Workbench, MySQL Notifier, and MySQL for Excel. MySQL Installer can also be used to upgrade these products in the future.

For instructions on installing MySQL using MySQL Installer, see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).

- The standard binary distribution (packaged as a Zip file) contains all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

For instructions on installing MySQL using the Zip file, see [Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”](#).

- The source distribution format contains all the code and support files for building the executables using the Visual Studio compiler system.

For instructions on building MySQL from source on Windows, see [Section 2.9, “Installing MySQL from Source”](#).

MySQL on Windows considerations:

- **Large Table Support**

If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See [Section 13.1.17, “CREATE TABLE Syntax”](#).

- **MySQL and Virus Checking Software**

Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir`) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` parameter to your `my.ini` configuration file. For more information, see [Section 2.3.5.2, “Creating an Option File”](#).

2.3.1 MySQL Installation Layout on Microsoft Windows

For MySQL 5.6 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.6`. Some Windows users prefer to install in `C:\mysql`, the directory that formerly was used as the default. However, the layout of the subdirectories remains the same.

All of the files are located within this parent directory, using the structure shown in the following table.

Table 2.4 Default MySQL Installation Layout for Microsoft Windows

| Directory | Contents of Directory | Notes |
|--|---|--|
| <code>bin, scripts</code> | <code>mysqld</code> server, client and utility programs | |
| <code>%PROGRAMDATA%\MySQL\MySQL Server 5.6\</code> | Log files, databases | The Windows system variable <code>%PROGRAMDATA%</code> defaults to <code>C:\ProgramData</code> |
| <code>examples</code> | Example programs and scripts | |
| <code>include</code> | Include (header) files | |
| <code>lib</code> | Libraries | |
| <code>share</code> | Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation | |

If you install MySQL using the MySQL Installer, this package creates and sets up the data directory that the installed server will use, and also creates a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using this package, the template data directory can be copied to set up additional MySQL instances. See [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

2.3.2 Choosing An Installation Package

For MySQL 5.6, there are multiple installation package formats to choose from when installing MySQL on Windows.

Note

Program Database (PDB) files (with file name extension `pdb`) provide information for debugging your MySQL installation in the event of a problem. These files are included in ZIP Archive distributions (but not MSI distributions) of MySQL.

- **MySQL Installer:** This package has a file name similar to `mysql-installer-community-5.6.37.0.msi` or `mysql-installer-commercial-5.6.37.0.msi`, and utilizes MSIs to automatically install MySQL server and other products. It will download and apply updates to itself, and for each of the installed products. It also configures the additional non-server products.

The installed products are configurable, and this includes: documentation with samples and examples, connectors (such as C, C++, J, NET, and ODBC), MySQL Workbench, MySQL Notifier, MySQL for Excel, and the MySQL Server with its components.

MySQL Installer will run on all Windows platforms that are supported by MySQL (see <http://www.mysql.com/support/supportedplatforms/database.html>).

Note

Because MySQL Installer is not a native component of Microsoft Windows and depends on .NET, it will not work on minimal installation options like the "Server Core" version of Windows Server 2008.

For instructions on installing MySQL using MySQL Installer, see [Section 2.3.3, "Installing MySQL on Microsoft Windows Using MySQL Installer"](#).

- **The Noinstall Archive:** This package has a file name similar to `mysql-5.6.37-win32.zip` or `mysql-5.6.37-winx64.zip`, and contains all the files found in the Complete install package, with the exception of the GUI. It also contains PDB files. This package does not include an automated installer, and must be manually installed and configured.

MySQL Installer is recommended for most users.

Your choice of install package affects the installation process you must follow. If you choose to use MySQL Installer, see [Section 2.3.3, "Installing MySQL on Microsoft Windows Using MySQL Installer"](#). If you choose to install a Noinstall archive, see [Section 2.3.5, "Installing MySQL on Microsoft Windows Using a noinstall Zip Archive"](#).

2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer

MySQL Installer is a standalone application that manages MySQL products on Microsoft Windows. It installs, updates, removes, and configures MySQL products, and remains on the system as a separate application. MySQL Installer is only available for Microsoft Windows, and includes both GUI and command-line interfaces.

The supported MySQL products include:

- [MySQL Server](#) (one or multiple versions on the same host)
- [MySQL Workbench](#)
- [MySQL Connectors](#) (.Net / Python / ODBC / Java / C / C++)
- [MySQL Notifier](#)
- [MySQL for Excel](#)
- [MySQL for Visual Studio](#)
- [MySQL Utilities and MySQL Fabric](#)
- [MySQL Samples and Examples](#)
- [MySQL Documentation](#)

Installer Package Types

- **Full:** Bundles all of the MySQL products (including the MySQL server). The file size is over 300MB, and its name has the form `mysql-installer-community-VERSION.N.msi` where `VERSION` is the MySQL Server version number such as 5.7 and `N` is the package number, which begins at 0.
- **Web:** Only contains MySQL Installer and configuration files, and it downloads the MySQL products you choose to install. The size of this file is about 2MB; the name of the file has the form `mysql-installer-community-web-VERSION.N.msi` where `VERSION` is the MySQL Server version number such as 5.7 and `N` is the package number, which begins at 0.

As a standalone application, MySQL Installer upgrades automatically when a new version becomes available.

Installer Editions

- **Community edition:** Download this edition from <http://dev.mysql.com/downloads/installer/>. It installs the community edition of all MySQL products.
- **Commercial edition:** Download this edition from either [My Oracle Support \(MOS\)](#) or <https://edelivery.oracle.com/>. It installs the commercial version of all MySQL products, including Workbench SE/EE, MySQL Enterprise Backup, and MySQL Enterprise Firewall. It also integrates with your MOS account.

Note

Entering your MOS credentials is optional when installing bundled MySQL products, but your credentials are required when choosing non-bundled MySQL products that MySQL Installer must download.

For notes detailing the changes in each release of MySQL Installer, see [MySQL Installer Release Notes](#).

MySQL Installer is compatible with existing installations, and adds them to its list of installed components. While the standard MySQL Installer is bundled with a specific version of MySQL server, a single MySQL Installer instance can install and manage multiple MySQL server versions. For example, a single MySQL Installer instance can install (and update) versions 5.5, 5.6, and 5.7 on the same host.

Note

A single host *cannot* have both community and commercial editions of MySQL server installed. For example, if you want both MySQL Server 5.6 and 5.7 installed on a single host, both must be the same edition.

MySQL Installer handles the initial configuration and set up of the applications. For example:

- It creates the configuration file (`my.ini`) that is used to configure the MySQL server. The values written to this file are influenced by choices you make during the installation process.

Note

Some definitions are host dependent. For example, `query_cache` is enabled if the host has fewer than three cores.

- It can optionally import example databases.
- By default, a Windows service for the MySQL server is added.

- It can optionally create MySQL Server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named `Mysq1Sys` with limited privileges, which would then run the MySQL Server.

User accounts may also be added and configured in MySQL Workbench.

- Checking **Show Advanced Options** allows additional **Logging Options** to be set. This includes defining custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

MySQL Installer can optionally check for updated components and download them for you.

2.3.3.1 MySQL Installer GUI

Installing MySQL Installer adds a link to the Start menu under the **MySQL** group. Click **Start, All Programs, MySQL, MySQL Installer** to reload the MySQL Installer GUI.

Note

Full permissions are granted to the user executing MySQL Installer to all generated files, such as `my.ini`. This does not apply to files and directories for specific products, such as the MySQL server data directory in `%ProgramData%` that is owned by `SYSTEM`.

MySQL Installer requires you to accept the license agreement before it will install MySQL products.

Figure 2.7 MySQL Installer - License Agreement

Installing New Packages

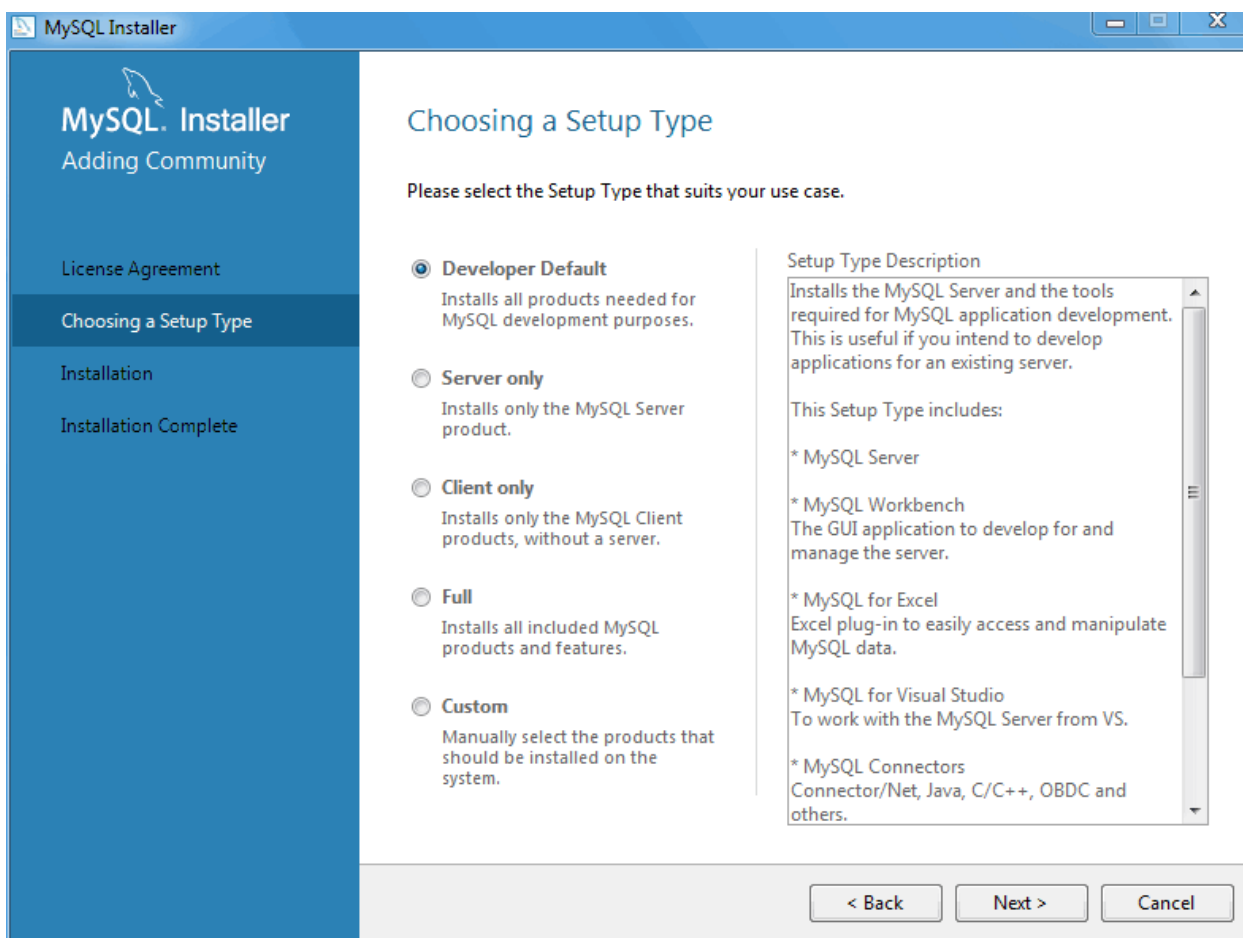

Choose the appropriate **Setup Type** for your system. This type determines which MySQL products are initially installed on your system, or select **Custom** to manually choose the products.

- **Developer:** Install all products needed to develop applications with MySQL. This is the default option.
- **Server only:** Only install the MySQL server.
- **Client only:** Only install the MySQL client products, such as MySQL Workbench. This does not include the MySQL server.
- **Full:** Install all available MySQL products.
- **Custom:** Manually select the MySQL products to install, and optionally configure custom MySQL data and installation paths.

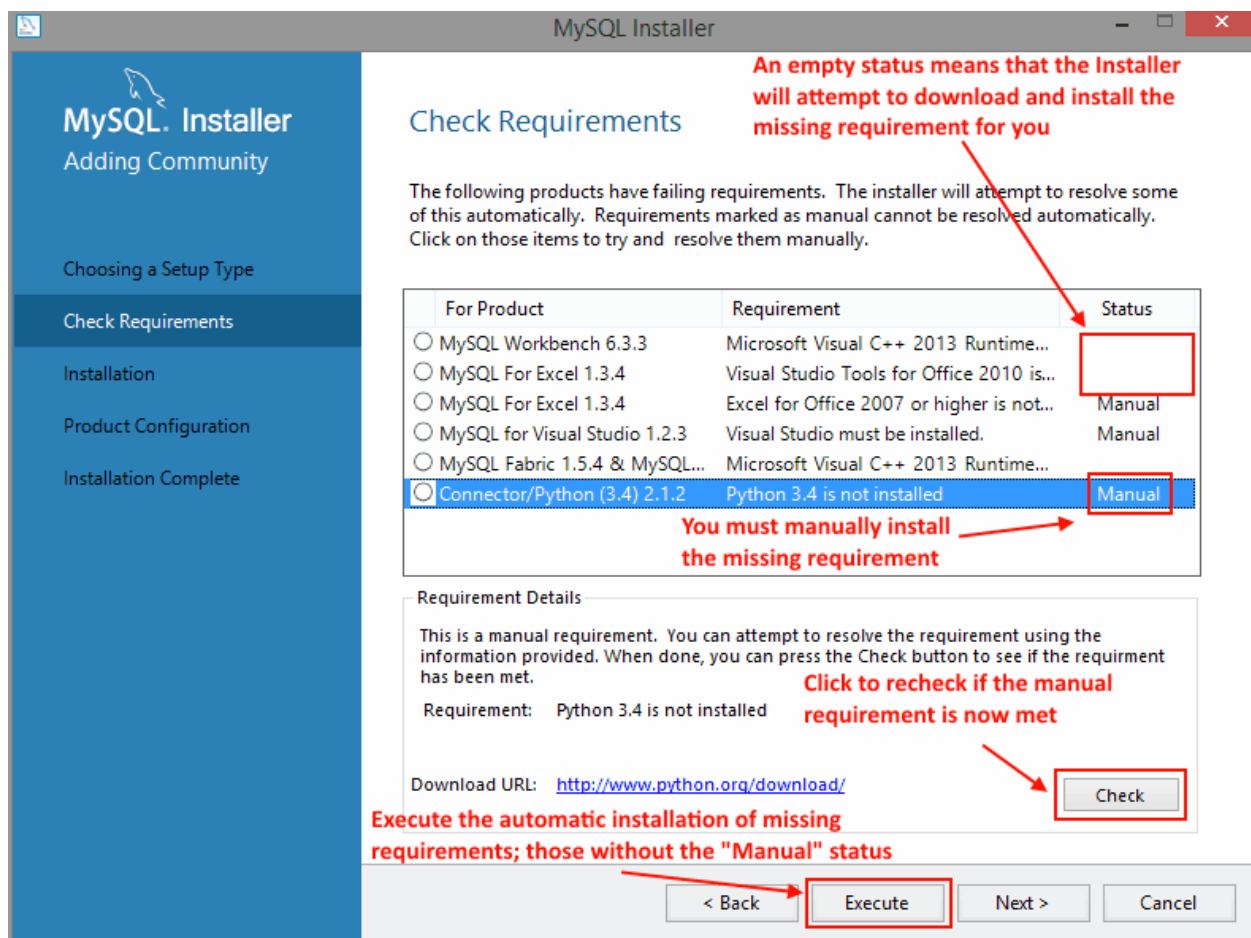

Note

After the initial installation, you may use MySQL Installer to manually select MySQL products to install or remove. In other words, MySQL Installer becomes a MySQL product management system.

Figure 2.8 MySQL Installer - Choosing a Setup Type

MySQL Installer checks your system for the external requirements (prerequisites) required to install the selected MySQL products. MySQL Installer can download and install some prerequisites, but others require manual intervention. Download and install all prerequisites that have **Status** set to "Manual". Click **Check** to recheck if a manual prerequisite was installed. After manually installing those requirements, click **Execute** to download and install the other prerequisites. Once finished, click **Next** to continue.

Figure 2.9 MySQL Installer - Check Requirements

The next window lists the MySQL products that are scheduled for installation:

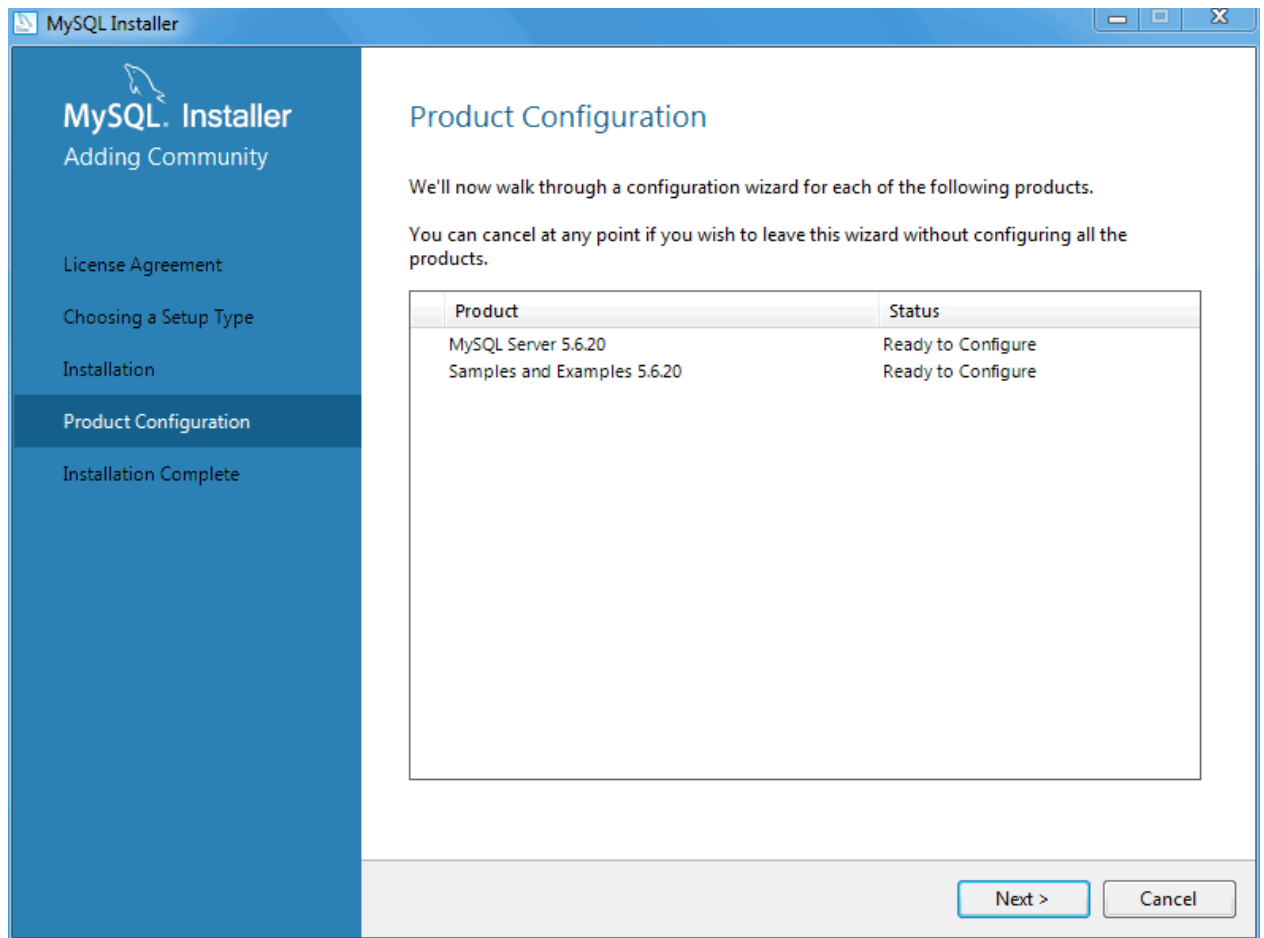

Figure 2.10 MySQL Installer - Installation Progress

As components are installed, their **Status** changes from a progress percentage to "Complete".

After all components are installed, the next step configures some of the recently installed MySQL products. The [Configuration Overview](#) window displays the progress and then loads a configuration window, if required. Our example configures MySQL Server 5.6.x.

Configuring MySQL Server

Configuring the MySQL server begins with defining several **Type and Networking** options.

Figure 2.11 MySQL Installer - Configuration Overview

Server Configuration Type

Choose the MySQL server configuration type that describes your setup. This setting defines the amount of system resources (memory) that will be assigned to your MySQL server instance.

- **Developer:** A machine that will host many other applications, and typically this is your personal workstation. This option configures MySQL to use the least amount of memory.
- **Server:** Several other applications will be running on this machine, such as a web server. This option configures MySQL to use a medium amount of memory.
- **Dedicated:** A machine that is dedicated to running the MySQL server. Because no other major applications will run on this server, such as a web server, this option configures MySQL to use the majority of available memory.

Connectivity

Connectivity options control how the connection to MySQL is made. Options include:

- **TCP/IP:** You may enable TCP/IP Networking here as otherwise only localhost connections are allowed. Also define the **Port Number** and whether to open the firewall port for network access.
- **Named Pipe:** Enable and define the pipe name, similar to using the `--enable-named-pipe` option.

- **Shared Memory:** Enable and then define the memory name, similar to using the `--shared-memory` option.

Advanced Configuration

Check **Show Advanced Options** to set additional **Logging Options**. This includes defining custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

Figure 2.12 MySQL Installer - MySQL Server Configuration: Type and Networking

MySQL Installer
MySQL Server 5.6.20

Type and Networking

Server Configuration Type
Choose the correct server configuration type for this MySQL Server installation. This setting will define how much system resources are assigned to the MySQL Server instance.
Config Type: Development Machine

Connectivity
Use the following controls to select how you would like to connect to this server.

☒ TCP/IP Port Number: 3306
☒ Open Firewall port for network access
☐ Named Pipe Pipe Name: MYSQL
☐ Shared Memory Memory Name: MYSQL

Advanced Configuration
Select the checkbox below to get additional configuration page where you can set advanced options for this server instance.
☒ Show Advanced Options

Next > Cancel

Accounts and Roles

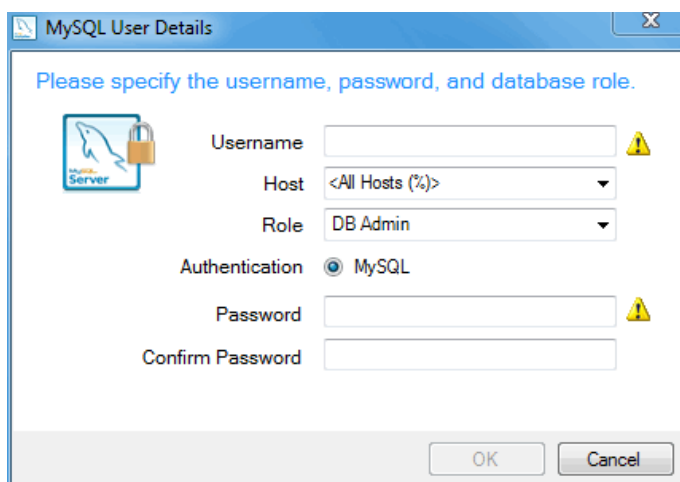

Next, define your MySQL account information. Assigning a root password is required.

Optionally, you can add additional MySQL user accounts with predefined user roles. Each predefined role, such as "DB Admin", are configured with their own set of privileges. For example, the "DB Admin" role has more privileges than the "DB Designer" role. Click the **Role** dropdown for a list of role descriptions.

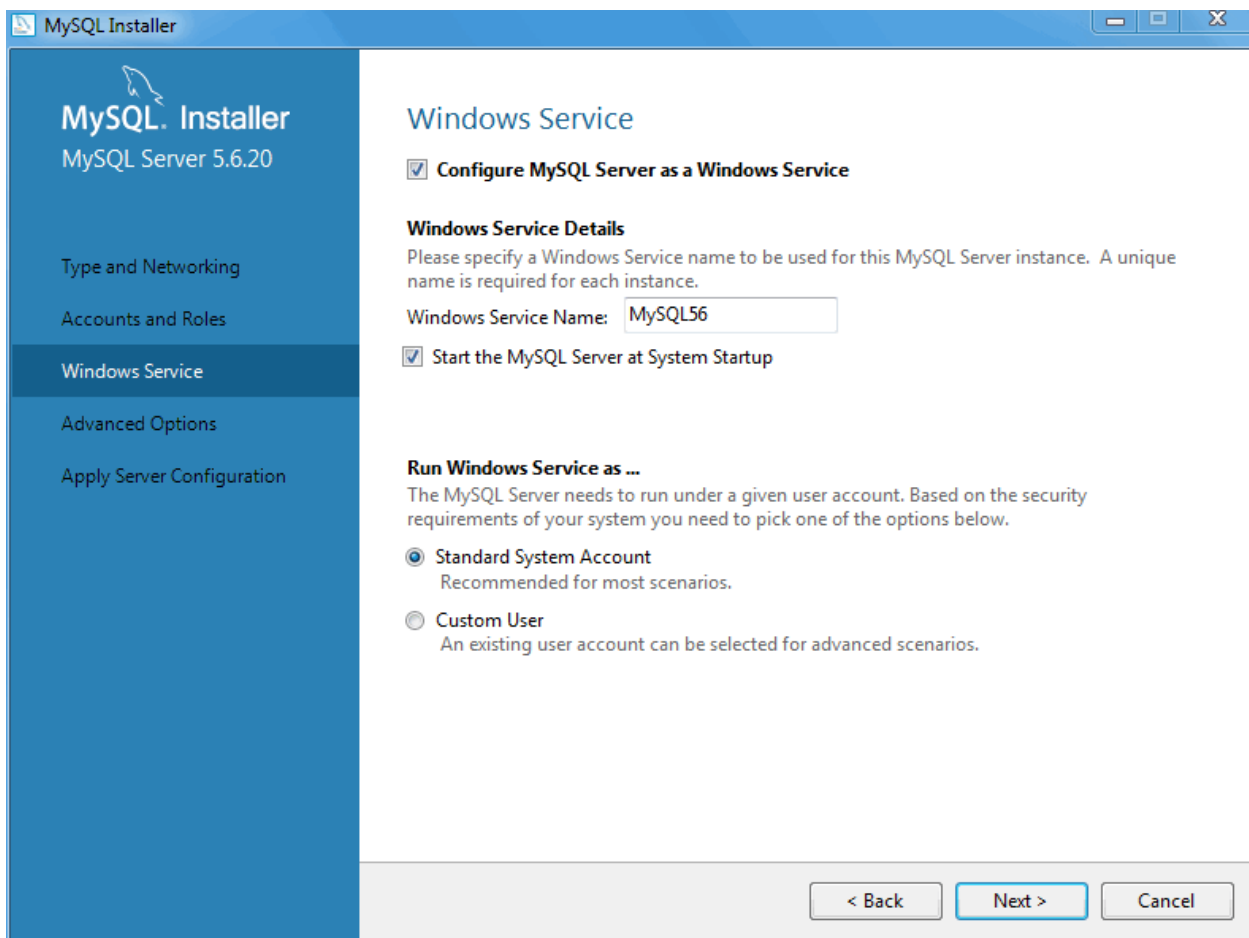

Note

If the MySQL Server is already installed, then you must also enter the **Current Root Password**.

Figure 2.13 MySQL Installer - MySQL Server Configuration: User Accounts and Roles**Figure 2.14 MySQL Installer - MySQL Server Configuration: User Accounts and Roles: Adding a User**

Windows Service

Next, configure the **Windows Service** details. This includes the service name, whether the MySQL server should be loaded at startup, and how the MySQL server Windows service is executed.

Figure 2.15 MySQL Installer - MySQL Server Configuration: Windows Service**Note**

When configuring **Run Windows Services as ...** using a **Custom User**, the custom user must have privileges to log on to Microsoft Windows as a service. The **Next** button will be disabled until this user is configured with the required privileges.

On Microsoft Windows 7, this is configured by loading the [Start Menu](#), [Control Panel](#), [Administrative Tools](#), [Local Security Policy](#), [Local Policies](#), [User Rights Assignment](#), then [Log On As A Service](#). Choose [Add User or Group](#) here to add the custom user, and then **OK, OK** to save.

Advanced Options

The next configuration step is available if the **Advanced Configuration** option was checked. This section includes options that are related to the MySQL log files:

Figure 2.16 MySQL Installer - MySQL Server Configuration: Logging Options

MySQL Installer
MySQL Server 5.6.20

Type and Networking
Accounts and Roles
Windows Service
Advanced Options
Apply Server Configuration

Advanced Options

Logging Options

Please select the logs you want to activate for this server in addition to the Error Log. On production machines it can be beneficial to separate the log files from the data.

Error Log: ...

☒ **General Log**
The general query log is a general record of what the MySQL Server is doing. It should only be used to track down issues.
File Path: ...

☒ **Slow Query Log**
The slow query log consists of SQL statements that took more than the given value of seconds to execute. It is recommended to turn this log on.
File Path: ... **Seconds:**

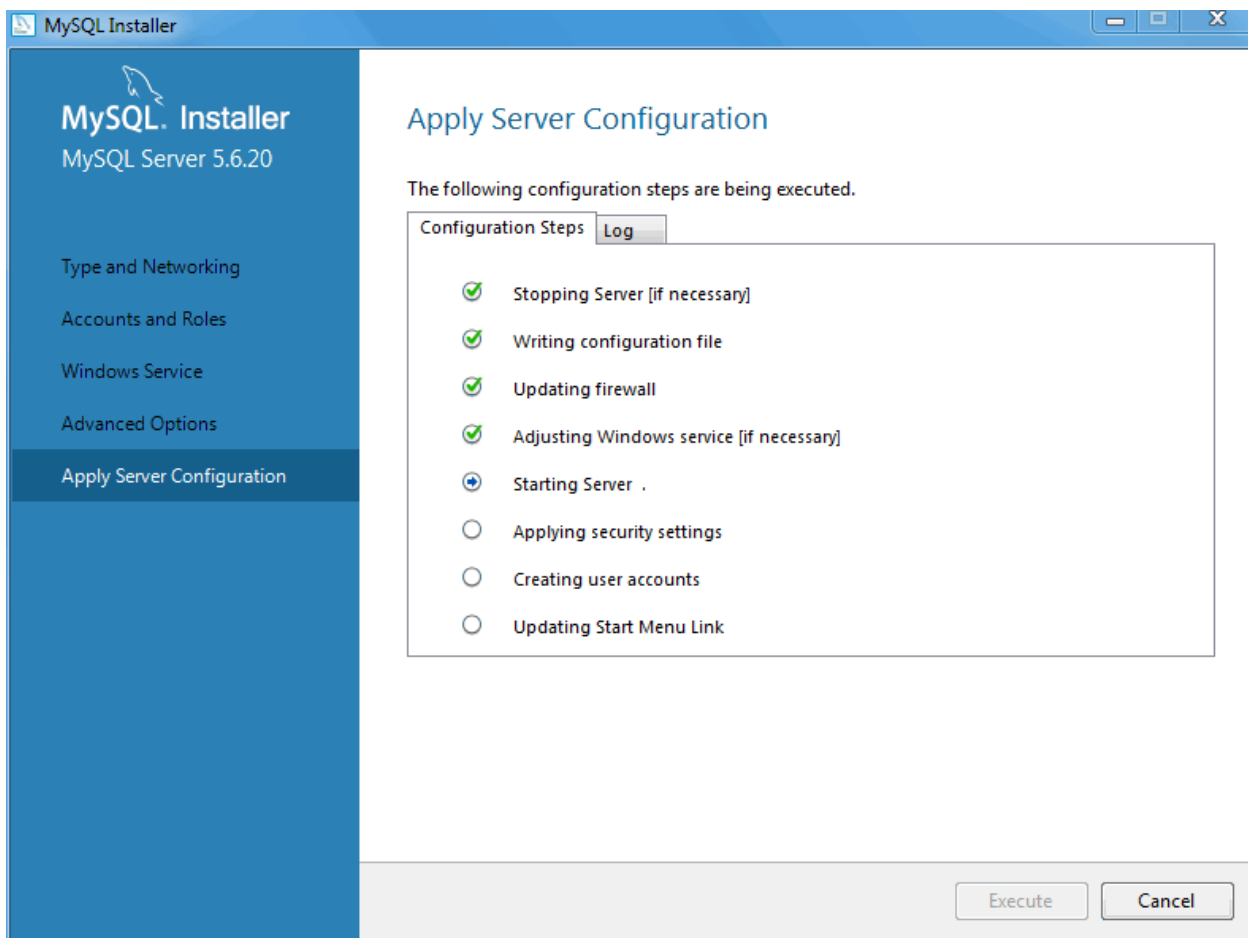

☒ **Bin Log**
The binary log contains all database events and is used for replication and data recovery operations. It has a performance impact on the server. Only a filename base should be given as the server will append an appropriate extension
File Path: ...

Server Id:

< Back Next > Cancel

Click **Next** to continue on to the final page before all of the requested changes are applied. This **Apply Server Configuration** page details the configuration steps that will be performed.

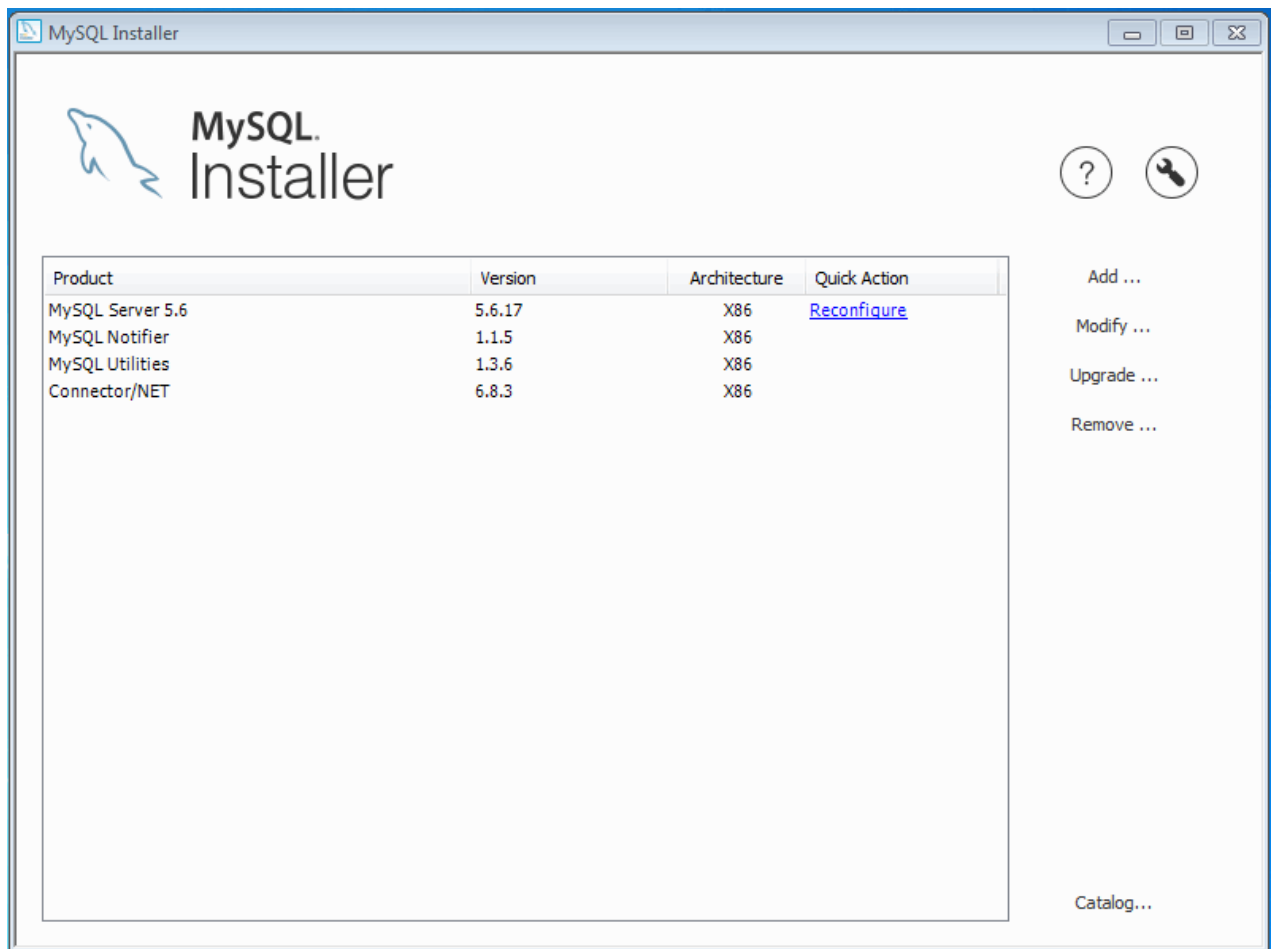

Figure 2.17 MySQL Installer - MySQL Server Configuration: Apply Server Configuration

Click **Execute** to execute the configuration steps. The icon for each step toggles from white to green on success, or the process stops on failure. Click the **Log** tab to view the log.

After the MySQL Installer configuration process is finished, MySQL Installer reloads the opening page where you can execute other installation and configuration related actions.

MySQL Installer is added to the Microsoft Windows Start menu under the [MySQL](#) group. Opening MySQL Installer loads its dashboard where installed MySQL products are listed, and other MySQL Installer actions are available:

Figure 2.18 MySQL Installer - Main Dashboard

Adding MySQL Products

Click **Add** to add new products. This loads the **Select Products and Features** page:

Figure 2.19 MySQL Installer - Select Products and Features

From here, choose the MySQL products you want to install from the left **Available Products** pane, and then click the green right arrow to queue products for installation.

Optionally, click **Edit** to open the product and features search filter:

Figure 2.20 MySQL Installer - Select Products and Features Filter

For example, you might choose to include Pre-Release products in your selections, such as a Beta product that has not yet reached General Availability (GA) status.

Select all of the MySQL products you want to install, then click **Next** to continue using the defaults, or highlight a selected product and click **Advanced Options** to optionally alter options such as the MySQL server data and installation paths. Click **Execute** to execute the installation process to install all of the selected products.

MySQL Product Catalog

MySQL Installer stores a MySQL product catalog. The catalog can be updated either manually or automatically, and the catalog change history is also available. The automatic update is enabled by default.

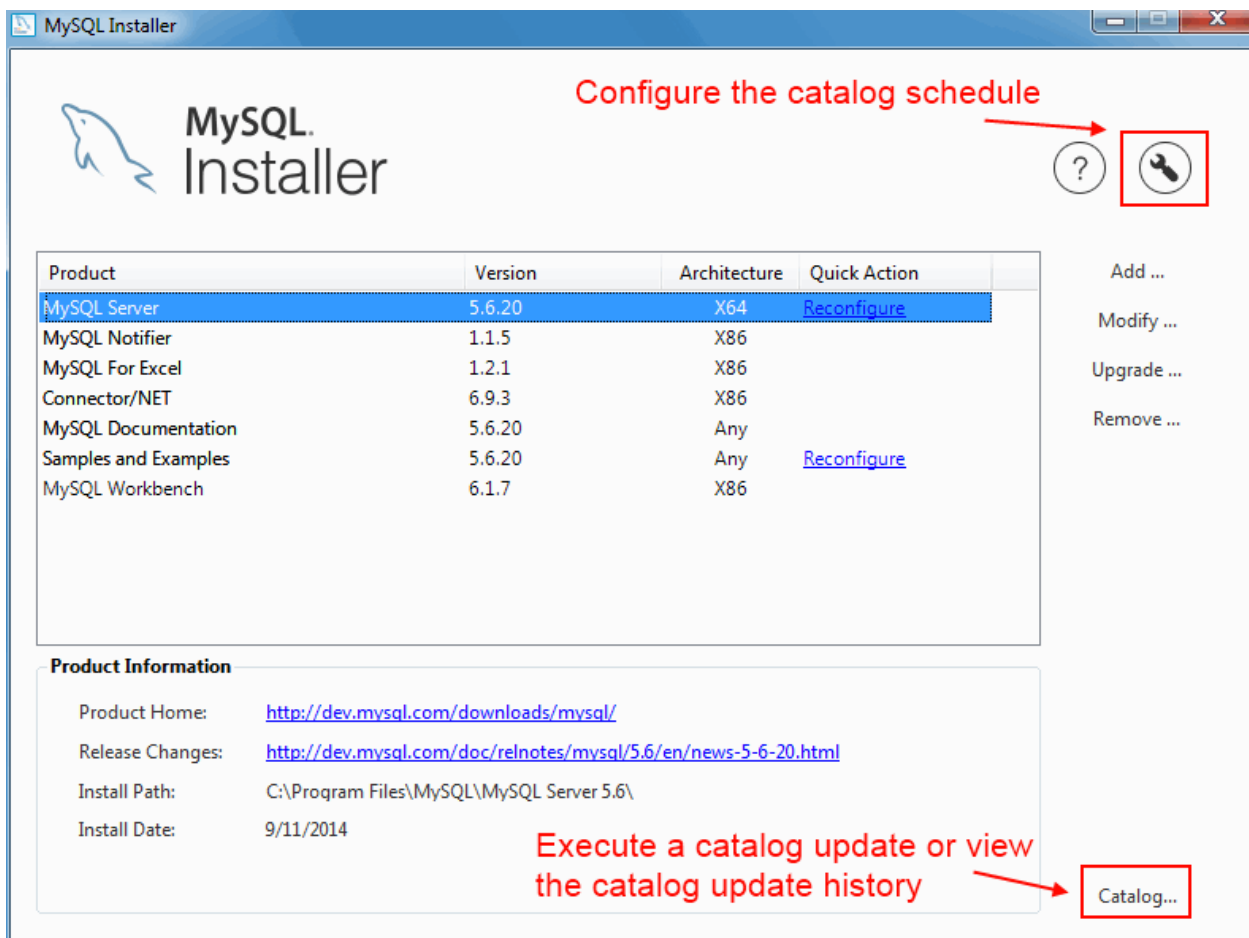

Note

The product catalog update also checks for a newer version of MySQL Installer, and prompts for an update if one is present.

Manual updates

You can update the MySQL product catalog at any time by clicking **Catalog** on the Installer dashboard.

Figure 2.21 MySQL Installer - Open the MySQL Product Catalog

From there, click **Execute** to update the product catalog.

Automatic updates

MySQL Installer can automatically update the MySQL product catalog. By default, this feature is enabled to execute each day at 12:00 AM. To configure this feature, click the wrench icon on the Installer dashboard.

The next window configures the **Automatic Catalog Update**. Enable or disable this feature, and also set the hour.

Figure 2.22 MySQL Installer - Configure the Catalog Scheduler

This option uses the Windows Task Scheduler to schedule a task named "ManifestUpdate".

Change History

MySQL Installer tracks the change history for all of the MySQL products. Click **Catalog** from the dashboard, optionally update the catalog (or, toggle the **Do not update at this time** checkbox), click **Next/Execute**, and then view the change history.

Figure 2.23 MySQL Installer - Catalog Change History

Remove MySQL Products

MySQL Installer can also remove MySQL products from your system. To remove a MySQL product, click **Remove** from the Installer dashboard. This opens a window with a list of installed MySQL products. Select the MySQL products you want to remove (uninstall), and then click **Execute** to begin the removal process.

Note

To select all MySQL products, click the ☐ checkbox to the left of the **Product** label.

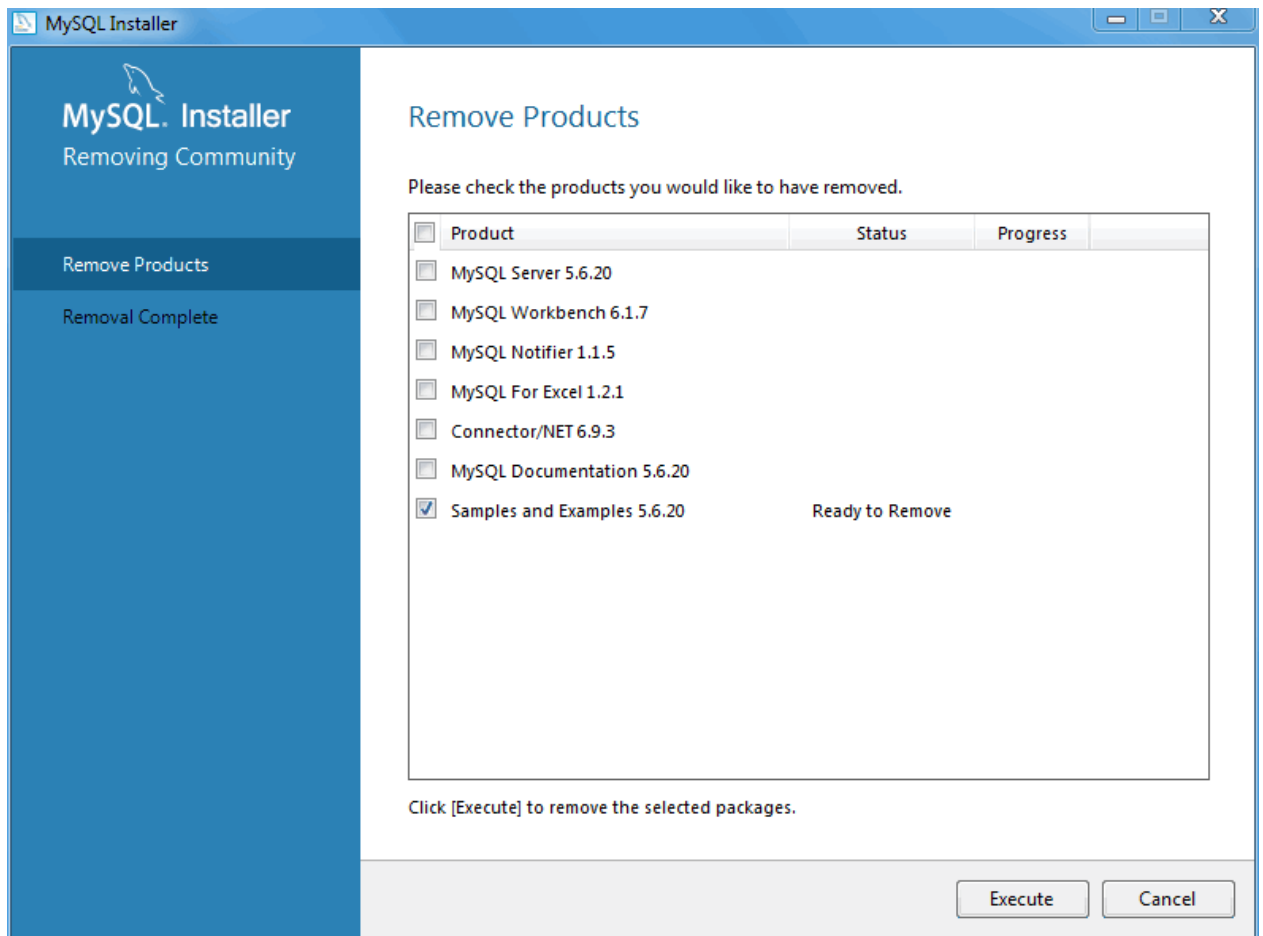

Figure 2.24 MySQL Installer - Removing Products: Select

Figure 2.25 MySQL Installer - Removing Products: Executed

Alter MySQL Products

Use MySQL Installer to modify, configure, or upgrade your MySQL product installations.

Upgrade

Upgradable MySQL products are listed on the main dashboard with an arrow icon () next to their version number.

Figure 2.26 MySQL Installer - Upgrade a MySQL Product**Note**

The "upgrade" functionality requires a current product catalog. This catalog is updated either manually or automatically (daily) by enabling the **Automatic Catalog Update** feature. For additional information, see [MySQL Product Catalog](#).

Click **Upgrade** to upgrade the available products. Our example indicates that MySQL Workbench 6.2.4 can be upgraded version 6.3.1 or 6.2.5, and MySQL server from 5.5.41 to 5.5.42.

Figure 2.27 MySQL Installer - Select Products To Upgrade

If multiple upgrade versions are available (such as our MySQL Workbench example above), select the desired version for the upgrade in the **Available Upgrades** area.

**Note**

Optionally, click the **Changes** link to view the version's release notes.

After selecting (checking) the products and versions to upgrade, click **Next** to begin the upgrade process.

Figure 2.28 MySQL Installer - Apply Updates

A MySQL server upgrade will also check and upgrade the server's database. Although optional, this step is recommended.

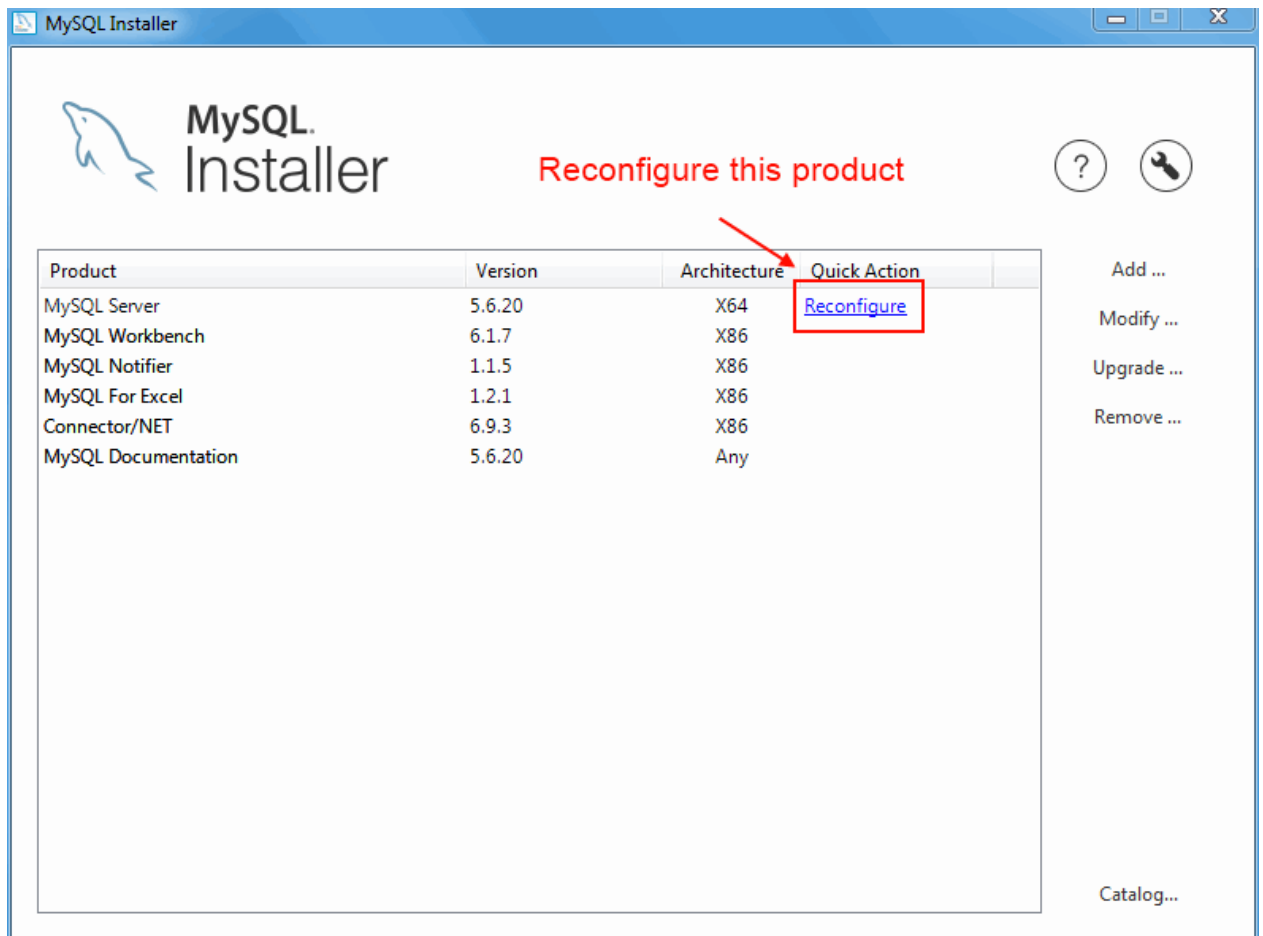

Figure 2.29 MySQL Installer - Check and Upgrade Database

Upon completion, your upgraded products will be upgraded and available to use. A MySQL server upgrade also restarts the MySQL server.

Reconfigure

Some MySQL products, such as the MySQL server, include a **Reconfigure** option. It opens the same configuration options that were set when the MySQL product was installed, and is pre-populated with the current values.

To execute, click the [Reconfigure](#) link under the **Quick Action** column on the main dashboard for the MySQL product that you want to reconfigure.

Figure 2.30 MySQL Installer - Reconfigure a MySQL Product

In the case of the MySQL server, this opens a configuration wizard that relates to the selected product. For example, for MySQL Server this includes setting the type, ports, log paths, and so on.

Modify

Many MySQL products contain feature components that can be added or removed. For example, [Debug binaries](#) and [Client Programs](#) are subcomponents of the MySQL server.

To modify the features of a product, click **Modify** on the main dashboard.

Figure 2.31 MySQL Installer - Modify Product Features

Click **Execute** to execute the modification request.

2.3.3.2 MySQL Installer Console

`MySQLInstallerConsole` provides functionality similar to the GUI version of MySQL Installer, but from the command line. It is installed when MySQL Installer is initially executed, and then available within the `MySQL Installer` directory. Typically that is in `C:\Program Files (x86)\MySQL\MySQL Installer\`, and the console must be executed with administrative privileges.

To use, invoke the Command Prompt with administrative privileges by choosing **Start, Accessories**, then right-click on **Command Prompt** and choose **Run as administrator**. And from the command line, optionally change the directory to where `MySQLInstallerConsole.exe` is located:

```
C:\> cd Program Files (x86)\MySQL\MySQL Installer for Windows
C:\Program Files (x86)\MySQL\MySQL Installer for Windows> MySQLInstallerConsole.exe help
===== Start Initialization =====
MySQL Installer is running in Community mode

Attempting to update manifest.
Initializing product requirements
Loading product catalog
Checking for product catalog snippets
Checking for product packages in the bundle
Categorizing product catalog
Finding all installed packages.
```

```
Your product catalog was last updated at 11/1/2016 4:10:38 PM
===== End Initialization =====
```

The following commands are available:

```
Configure - Configures one or more of your installed programs.
Help       - Provides list of available commands.
Install    - Install and configure one or more available MySQL programs.
List       - Provides an interactive way to list all products available.
Modify     - Modifies the features of installed products.
Remove     - Removes one or more products from your system.
Status     - Shows the status of all installed products.
Update     - Update the current product catalog.
Upgrade    - Upgrades one or more of your installed programs.
```

`MySQLInstallerConsole.exe` supports the following options, which are specified on the command line:

Note

Configuration block values that contain a colon (":") must be wrapped in double quotes. For example, `installdir="C:\MySQL\MySQL Server 5.6"`.

- `configure [product1]:[setting]=[value]; [product2]:[setting]=[value]; [...]`

Configure one or more MySQL products on your system. Multiple setting=value pairs can be configured for each product.

Switches include:

- `-showsettings` : Displays the available options for the selected product, by passing in the product name after `-showsettings`.
- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole configure -showsettings server
C:\> MySQLInstallerConsole configure server:port=3307
```

- `help [command]`

Displays a help message with usage examples, and then exits. Pass in an additional command to receive help specific to that command.

```
C:\> MySQLInstallerConsole help
C:\> MySQLInstallerConsole help install
```

- `install [product]:[features]:[config block]:[config block]:[config block]; [...]`

Install one or more MySQL products on your system.

Switches and syntax options include:

- `-type=[SetupType]` : Installs a predefined set of software. The "SetupType" can be one of the following:

Note

Non-custom setup types can only be chosen if no other MySQL products are installed.

- **Developer:** Installs a complete development environment.
- **Server:** Installs a single MySQL server
- **Client:** Installs client programs and libraries
- **Full:** Installs everything
- **Custom:** Installs user selected products. This is the default option.
- `-showsettings` : Displays the available options for the selected product, by passing in the product name after `-showsettings`.
- `-silent` : Disable confirmation prompts.
- `[config block]`: One or more configuration blocks can be specified. Each configuration block is a semicolon separated list of key value pairs. A block can include either a "config" or "user" type key, where "config" is the default type if one is not defined.

Configuration block values that contain a colon (":") must be wrapped in double quotes. For example, `installdir="C:\MySQL\MySQL Server 5.6"`.

Only one "config" type block can be defined per product. A "user" block should be defined for each user that should be created during the product's installation.

Note

Adding users is not supported when a product is being reconfigured.

- `[feature]`: The feature block is a semicolon separated list of features, or '*' to select all features.

```
C:\> MySQLInstallerConsole install server;5.6.25:*:port=3307;serverid=2:type=user;username=foo;password=bar;
C:\> MySQLInstallerConsole install server;5.6.25;x64 -silent
```

An example that passes in additional configuration blocks, broken up by ^ to fit this screen:

```
C:\> MySQLInstallerConsole install server;5.6.25;x64:*:type=config;openfirewall=true; ^
    generallog=true;binlog=true;serverid=3306;enable_tcpip=true;port=3306;rootpasswd=pass; ^
    installdir="C:\MySQL\MySQL Server 5.6":type=user;datadir="C:\MySQL\data";username=foo;password=bar
```

- `list`

Lists an interactive console where all of the available MySQL products can be searched. Execute `MySQLInstallerConsole list` to launch the console, and enter in a substring to search.

```
C:\> MySQLInstallerConsole list
```

- `modify [product1:-removelist/+addlist] [product2:-removelist/+addlist] [...]`

Modifies or displays features of a previously installed MySQL product.

- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole modify server
C:\> MySQLInstallerConsole modify server:+documentation
```

```
C:\> MySQLInstallerConsole modify server:-debug
```

- `remove [product1] [product2] [...]`

Removes one or more products from your system.

- `*` : Pass in `*` to remove all of the MySQL products.
- `-continue` : Continue the operation even if an error occurs.
- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole remove *
C:\> MySQLInstallerConsole remove server
```

- `status`

Provides a quick overview of the MySQL products that are installed on the system. Information includes product name and version, architecture, date installed, and install location.

```
C:\> MySQLInstallerConsole status
```

- `update`

Downloads the latest MySQL product catalog to your system. On success, the download catalog will be applied the next time either `MySQLInstaller.exe` or `MySQLInstallerConsole.exe` is executed.

```
C:\> MySQLInstallerConsole update
```

Note

The **Automatic Catalog Update** GUI option executes this command from the Windows Task Scheduler.

- `upgrade [product1:version] [product2:version] [...]`

Upgrades one or more products on your system. Syntax options include:

- `*` : Pass in `*` to upgrade all products to the latest version, or pass in specific products.
- `!` : Pass in `!` as a version number to upgrade the MySQL product to its latest version.
- `-silent` : Disable confirmation prompts.

```
C:\> MySQLInstallerConsole upgrade *
C:\> MySQLInstallerConsole upgrade workbench:6.3.5
C:\> MySQLInstallerConsole upgrade workbench:!
C:\> MySQLInstallerConsole upgrade workbench:6.3.5 excel:1.3.2
```

2.3.4 MySQL Notifier

MySQL Notifier is a tool that enables you to monitor and adjust the status of your local and remote MySQL server instances through an indicator that resides in the system tray. MySQL Notifier also gives quick access to MySQL Workbench through its context menu.

The MySQL Notifier is installed by MySQL Installer, and (by default) will start-up when Microsoft Windows is started.

To install, download and execute the [MySQL Installer](#), be sure the MySQL Notifier product is selected, then proceed with the installation. See the [MySQL Installer manual](#) for additional details.

For notes detailing the changes in each release of MySQL Notifier, see the [MySQL Notifier Release Notes](#).

Visit the [MySQL Notifier forum](#) for additional MySQL Notifier help and support.

Features include:

- Start, Stop, and Restart instances of the MySQL Server.
- Automatically detects (and adds) new MySQL Server services. These are listed under **Manage Monitored Items**, and may also be configured.
- The Tray icon changes, depending on the status. It's green if all monitored MySQL Server instances are running, or red if at least one service is stopped. The **Update MySQL Notifier tray icon based on service status** option, which dictates this behavior, is enabled by default for each service.
- Links to other applications like MySQL Workbench, MySQL Installer, and the MySQL Utilities. For example, choosing **Manage Instance** will load the MySQL Workbench Server Administration window for that particular instance.
- If MySQL Workbench is also installed, then the **Manage Instance** and **SQL Editor** options are available for local (but not remote) MySQL instances.
- Monitors both local and remote MySQL instances.

2.3.4.1 MySQL Notifier Usage

MySQL Notifier resides in the system tray and provides visual status information for your MySQL server instances. A green icon is displayed at the top left corner of the tray icon if the current MySQL server is running, or a red icon if the service is stopped.

MySQL Notifier automatically adds discovered MySQL services on the local machine, and each service is saved and configurable. By default, the **Automatically add new services whose name contains** option is enabled and set to `mysql`. Related **Notifications Options** include being notified when new services are either discovered or experience status changes, and are also enabled by default. And uninstalling a service will also remove the service from MySQL Notifier.

Clicking the system tray icon will reveal several options, as the follow figures show:

The Service Instance menu is the main MySQL Notifier window, and enables you to Stop, Start, and Restart the MySQL server.

Figure 2.32 MySQL Notifier Service Instance menu

The **Actions** menu includes several links to external applications (if they are installed), and a **Refresh Status** option to manually refresh the status of all monitored services (in both local and remote computers) and MySQL instances.

Note

The main menu will not show the **Actions** menu when there are no services being monitored by MySQL Notifier.

Figure 2.33 MySQL Notifier Actions menu

The **Actions**, **Options** menu configures MySQL Notifier and includes options to:

- **Use colorful status icons:** Enables a colorful style of icons for the tray of MySQL Notifier.
- **Run at Windows Startup:** Allows the application to be loaded when Microsoft Windows starts.
- **Automatically Check For Updates Every # Weeks:** Checks for a new version of MySQL Notifier, and runs this check every # weeks.
- **Automatically add new services whose name contains:** The text used to filter services and add them automatically to the monitored list of the local computer running MySQL Notifier, and on remote computers already monitoring Windows services.
- **Ping monitored MySQL Server instances every # seconds:** The interval (in seconds) to ping monitored MySQL Server instances for status changes. Longer intervals might be necessary if the list of monitored remote instances is large.
- **Notify me when a service is automatically added:** Will display a balloon notification from the taskbar when a newly discovered service is added to the monitored services list.
- **Notify me when a service changes status:** Will display a balloon notification from the taskbar when a monitored service changes its status.
- **Automatic connections migration delayed until:** When there are connections to migrate, postpone the migration by one hour, one day, one week, one month, or indefinitely.

Figure 2.34 MySQL Notifier Options menu

The **Actions**, **Manage Monitored Items** menu enables you to configure the monitored services and MySQL instances. First, with the **Services** tab open:

Figure 2.35 MySQL Notifier Manage Services menu

The **Instances** tab is similar:

Figure 2.36 MySQL Notifier Manage Instances menu

Adding a service or instance (after clicking **Add** in the **Manage Monitored Items** window) enables you to select a running Microsoft Windows service or instance connection, and configure MySQL Notifier to monitor it. Add a new service or instance by clicking service name from the list, then **OK** to accept. Multiple services and instances may be selected.

Figure 2.37 MySQL Notifier Adding new services

Add instances:

Figure 2.38 MySQL Notifier Adding new instances

Troubleshooting

For issues that are not documented here, visit the [MySQL Notifier Support Forum](#) for MySQL Notifier help and support.

- *Problem:* attempting to start/stop/restart a MySQL service might generate an error similar to "The Service **MySQLVERSION** failed the most recent status change request with the message "The service **mysqlVERSION** was not found in the Windows Services".

Explanation: this is a case-sensitivity issue, in that the service name is **MySQLVERSION** compared to having **mysqlVERSION** in the configuration file.

Solution: either update your MySQL Notifier configuration file with the correct information, or stop MySQL Notifier and delete this configuration file. The MySQL Notifier configuration file is located at `%APPDATA%\Oracle\MySQL Notifier\settings.config` where `%APPDATA%` is a variable and depends on your system. A typical location is "C:\Users\YourUsername\AppData\Running\Oracle\MySQL Notifier\settings.config" where *YourUsername* is your system's user name. In this file, and within the ServerList section, change the ServerName values from lowercase to the actual service names. For example, change **mysqlVERSION** to **MySQLVERSION**, save, and then restart MySQL Notifier. Alternatively, stop MySQL Notifier, delete this file, then restart MySQL Notifier.

- *Problem:* when connecting to a remote computer for the purpose of monitoring a remote Windows service, the **Add Service** dialog does not always show all the services shown in the Windows Services console.

Explanation: this behavior is governed by the operating system and the outcome is expected when working with nondomain user accounts. For a complete description of the behavior, see the [User Account Control and WMI](#) article from Microsoft.

Solution: when the remote computer is in a compatible domain, it is recommended that domain user accounts are used to connect through WMI to a remote computer. For detailed setup instructions using WMI, see [Section 2.3.4.2, “Setting Up Remote Monitoring in MySQL Notifier”](#).

Alternatively, when domain user accounts are not available, Microsoft provides a less secure workaround that should only be implemented with caution. For more information, see the [Description of User Account Control and remote restrictions in Windows Vista](#) KB article from Microsoft.

2.3.4.2 Setting Up Remote Monitoring in MySQL Notifier

MySQL Notifier uses Windows Management Instrumentation (WMI) to manage and monitor services on remote computers. This section explains how it works and how to set up your system to monitor remote MySQL instances.

In order to configure WMI, it is important to understand that the underlying Distributed Component Object Model (DCOM) architecture is doing the WMI work. Specifically, MySQL Notifier is using asynchronous notification queries on remote Microsoft Windows hosts as .NET events. These events send an asynchronous callback to the computer running MySQL Notifier so it knows when a service status has changed on the remote computer. Asynchronous notifications offer the best performance compared to semisynchronous notifications or synchronous notifications that use timers.

Asynchronous notification requires the remote computer to send a callback to the client computer (thus opening a reverse connection), so the Windows Firewall and DCOM settings must be properly configured for the communication to function properly.

Figure 2.39 MySQL Notifier Distributed Component Object Model (DCOM)

Most of the common errors thrown by asynchronous WMI notifications are related to Windows Firewall blocking the communication, or to DCOM / WMI settings not being set up properly. For a list of common errors with solutions, see [Common Errors](#).

The following steps are required to make WMI function. These steps are divided between two machines. A single host computer that runs MySQL Notifier (Computer A), and multiple remote machines that are being monitored (Computer B).

Computer running MySQL Notifier (Computer A)

1. Enable remote administration by either editing the **Group Policy Editor**, or using **NETSH**:

Using the **Group Policy Editor**:

- a. Click **Start**, click **Run**, type `GPEDIT.MSC`, and then click **OK**.
- b. Under the **Local Computer Policy** heading, expand **Computer Configuration**.
- c. Expand **Administrative Templates**, then **Network**, **Network Connections**, and then **Windows Firewall**.
- d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.
- e. Double-click **Windows Firewall: Allow inbound remote administration exception** to open a configuration window.
- f. Check the **Enabled** option button and then click **OK**.

Using the `NETSH` command:

**Note**

The "netsh firewall" command is deprecated as of Microsoft Server 2008 and Vista, and replaced with "netsh advfirewall firewall".

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and select **Run as Administrator**).
- b. Execute the following command:

```
NETSH advfirewall firewall set service RemoteAdmin enable
```

2. Open the DCOM port TCP 135:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and select **Run as Administrator**).
- b. Execute the following command:

```
NETSH advfirewall firewall add rule name=DCOM_TCP135 protocol=TCP localport=135 dir=in action=allow
```

3. Add the client application that contains the sink for the callback (`MySQLNotifier.exe`) to the Windows Firewall Exceptions List (use either the Windows Firewall configuration or `NETSH`):

Using the Windows Firewall configuration:

- a. In the Control Panel, double-click **Windows Firewall**.
- b. In the Windows Firewall window's left panel, click **Allow a program or feature through Windows Firewall**.
- c. In the Allowed Programs window, click **Change Settings** and do one of the following:
 - If `MySQLNotifier.exe` is in the Allowed programs and features list, make sure it is checked for the type of networks the computer connects to (Private, Public or both).
 - If `MySQLNotifier.exe` is not in the list, click **Allow another program....**

- i. In the **Add a Program** window, select the `MySQLNotifier.exe` if it exists in the Programs list, otherwise click **Browse...** and go to the directory where `MySQLNotifier.exe` was installed to select it, then click **Add**.
- ii. Make sure `MySQLNotifier.exe` is checked for the type of networks the computer connects to (Private, Public or both).

Using the `NETSH` command:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).
- b. Execute the following command, where you change "`[YOUR_INSTALL_DIRECTORY]`":

```
NETSH advfirewall firewall add rule name=MySQLNotifier program=[YOUR_INSTALL_DIRECTORY]\MySQLNotifier.exe
```

4. If Computer B is either a member of `WORKGROUP` or is in a different domain that is untrusted by Computer A, then the callback connection (Connection 2) is created as an Anonymous connection. To grant Anonymous connections DCOM Remote Access permissions:
 - a. Click **Start**, click **Run**, type `DCOMCNFG`, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Access Permissions, click **Edit Limits**.
 - e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click **OK**.

Monitored Remote Computer (Computer B)

If the user account that is logged on to the computer running the MySQL Notifier (Computer A) is a local administrator on the remote computer (Computer B), such that the same account is an administrator on Computer B, you can skip to the "Allow for remote administration" step.

Setting DCOM security to allow a non-administrator user to access a computer remotely:

1. Grant "DCOM remote launch" and activation permissions for a user or group:
 - a. Click **Start**, click **Run**, type `DCOMCNFG`, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Launch and Activation Permission, click **Edit Limits**.
 - e. In the **Launch and Activation Permission** dialog box, follow these steps if your name or your group does not appear in the Groups or user names list:
 - i. In the **Launch and Activation Permission** dialog box, click **Add**.

- ii. In the Select Users or Groups dialog box, add your name and the group in the **Enter the object names to select** box, and then click **OK**.
 - f. In the **Launch and Activation Permission** dialog box, select your user and group in the Group or user names box. In the Allow column under Permissions for User, select **Remote Launch**, select **Remote Activation**, and then click **OK**.

Grant DCOM remote access permissions:

 - a. Click **Start**, click **Run**, type `DCOMCNFG`, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Access Permissions, click **Edit Limits**.
 - e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click **OK**.

 2. Allowing non-administrator users access to a specific WMI namespace:
 - a. In the Control Panel, double-click **Administrative Tools**.
 - b. In the Administrative Tools window, double-click **Computer Management**.
 - c. In the Computer Management window, expand the **Services and Applications** tree.
 - d. Right-click the WMI Control icon and select **Properties**.
 - e. In the WMI Control Properties window, click the **Security** tab.
 - f. In the Security tab, select the namespace and click **Security**. Root/CIMV2 is a commonly used namespace.
 - g. Locate the appropriate account and check **Remote Enable** in the Permissions list.
 3. Allow for remote administration by either editing the **Group Policy Editor** or using `NETSH`:

Using the **Group Policy Editor**:

- a. Click **Start**, click **Run**, type `GPEDIT.MSC`, and then click **OK**.
- b. Under the Local Computer Policy heading, double-click **Computer Configuration**.
- c. Double-click **Administrative Templates**, then **Network**, **Network Connections**, and then **Windows Firewall**.
- d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.
- e. Click **Windows Firewall: Allow inbound remote administration exception**.
- f. On the Action menu either select **Edit**, or double-click the selection from the previous step.

- g. Check the **Enabled** radio button, and then click **OK**.

Using the [NETSH](#) command:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click Run as Administrator).
- b. Execute the following command:

```
NETSH advfirewall firewall set service RemoteAdmin enable
```

4. Confirm that the user account you are logging in with uses the [Name](#) value and not the [Full Name](#) value:
- a. In the **Control Panel**, double-click **Administrative Tools**.
- b. In the **Administrative Tools** window, double-click **Computer Management**.
- c. In the **Computer Management** window, expand the **System Tools** then **Local Users and Groups**.
- d. Click the **Users** node, and on the right side panel locate your user and make sure it uses the **Name** value to connect, and not the **Full Name** value.

Common Errors

- [0x80070005](#)
 - DCOM Security was not configured properly (see Computer B, the [Setting DCOM security...](#) step).
 - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the [Grant Anonymous connections DCOM Remote Access permissions](#) step).
- [0x8007000E](#)
 - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the [Grant Anonymous connections DCOM Remote Access permissions](#) step).
- [0x80041003](#)
 - Access to the remote WMI namespace was not configured properly (see Computer B, the [Allowing non-administrator users access to a specific WMI namespace](#) step).
- [0x800706BA](#)
 - The DCOM port is not open on the client computers (Computer A) firewall. See the [Open the DCOM port TCP 135](#) step for Computer A.
 - The remote computer (Computer B) is inaccessible because its network location is set to Public. Make sure you can access it through the Windows Explorer.

2.3.5 Installing MySQL on Microsoft Windows Using a noinstall Zip Archive

Users who are installing from the [noinstall](#) package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file
3. Choose a MySQL server type
4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

2.3.5.1 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to [Section 2.3.8, “Upgrading MySQL on Windows”](#), before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. The MySQL Installation Wizard installs MySQL under `C:\Program Files\MySQL`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See [Section 2.3.5.2, “Creating an Option File”](#).

Note

The MySQL Installer installs MySQL under `C:\Program Files\MySQL`.

4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.5.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 5.6` and `C:\Program Files\MySQL\MySQL Server 5.6\data`).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see [Section 4.2.6, “Using Option Files”](#)). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

**Note**

When using the MySQL Installer to install MySQL Server, it will create the `my.ini` at the default location. And as of MySQL Server 5.5.27, the user running MySQL Installer is granted full permissions to this new `my.ini`.

In other words, be sure that the MySQL Server user has permission to read the `my.ini` file.

You can also make use of the example option files included with your MySQL distribution; see [Section 5.1.2, “Server Configuration Defaults”](#).

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in [Section 4.2.6, “Using Option Files”](#).

The data directory is located within the `AppData` directory for the user running MySQL.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\Program Files\MySQL\MySQL Server 5.6\data`) to `E:\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

2.3.5.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 5.6.

| Binary | Description |
|---------------------------|--|
| <code>mysqld</code> | Optimized binary with named-pipe support |
| <code>mysqld-debug</code> | Like <code>mysqld</code> , but compiled with full debugging and automatic memory allocation checking |

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 5.6 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the `--enable-named-pipe` option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

2.3.5.4 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the [Noinstall](#) version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

Note

MySQL server will automatically start after using MySQL Installer, and [MySQL Notifier](#) can be used to start/stop/restart at any time.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 5.6`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see [Section 2.3.5.3, “Selecting a MySQL Server Type”](#).

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --console
```

For a server that includes [InnoDB](#) support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25 InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.6.37'  socket: ''  port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 5.6\data` by default). The error log is the file with the `.err` extension, and may be set using the `--log-error` option.

**Note**

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

2.3.5.5 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

**Note**

[MySQL Notifier](#) can also be used to start/stop/restart the MySQL server.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin" -u root shutdown
```

**Note**

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system.

**Note**

Users in the MySQL grant system are wholly independent from any login users under Microsoft Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the `C:\Program Files\MySQL\MySQL Server 5.6\data` directory. It is the file with a suffix of `.err`, or may be specified by passing in the `--`

`log-error` option. Alternatively, you can try to start the server with the `--console` option; in this case, the server may display some useful information on the screen that will help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See [Section 24.5.3, “The DEBUG Package”](#).

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

2.3.5.6 Customizing the PATH for MySQL Tools

Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\bin`)

Note

There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. The new `PATH` value should now be available to any new command shell you open, allowing you to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

2.3.5.7 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

Note

`MySQL Notifier` can also be used to monitor the status of the MySQL service.

The [Services](#) utility (the Windows [Service Control Manager](#)) can be found in the Windows Control Panel (under **Administrative Tools** on Windows Vista, and Server 2003). To avoid conflicts, it is advisable to close the [Services](#) utility while performing server installation or removal operations from the command line.

Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin"  
-u root shutdown
```

Note

If the MySQL [root](#) user account has a password, you need to invoke [mysqladmin](#) with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility [mysqladmin](#) to connect to the server and tell it to shut down. The command connects as the MySQL [root](#) user, which is the default administrative account in the MySQL grant system.

Note

Users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL [bin](#) directory to your Windows system [PATH](#) environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL [bin](#) directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\bin`), and there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the [mysql](#) client, and all MySQL command-line utilities such as [mysqladmin](#) and [mysqldump](#).

You should not add the MySQL [bin](#) directory to your Windows [PATH](#) if you are running multiple MySQL servers on the same machine.

**Warning**

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the a service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld"  
      --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

**Note**

On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. Otherwise, `mysqld.exe` will attempt to start the MySQL server.

You can also specify options as Start parameters in the Windows [Services](#) utility before you start the MySQL service.

Finally, before trying to start the MySQL service, make sure the user variables `%TEMP%` and `%TMP%` (and also `%TMPDIR%`, if it has ever been set) for the system user who is to run the service are pointing to a folder to which the user has write access. The default user for running the MySQL service is `LocalSystem`, and the default value for its `%TEMP%` and `%TMP%` is `C:\Windows\Temp`, a directory `LocalSystem` has write access to by default. However, if there are any changes to that default setup (for example, changes to the user who runs the service or to the mentioned user variables, or the `--tmpdir` option has been used to put the temporary directory somewhere else), the MySQL service might fail to run because write access to the temporary directory has not been granted to the proper user.

Starting the service

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the [Services](#) utility, or by using a `NET START MySQL` command. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the [Services](#) utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --install-manual
```

Removing the service

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` option to remove it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see [Section 2.3.5.5, “Starting MySQL from the Windows Command Line”](#).

If you encounter difficulties during installation, see [Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

For more information about stopping or removing a MySQL Windows service, see [Section 5.6.2.2, “Starting Multiple MySQL Instances as Windows Services”](#).

2.3.5.8 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqlshow"  
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqlshow" -u root mysql  
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin" version status proc  
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

If you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate `-u` and `-p` options with the commands shown previously. See [Section 4.2.2, “Connecting to the MySQL Server”](#).

For more information about `mysqlshow`, see [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

2.3.6 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. This section helps you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the [error log](#). The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the [data directory](#) specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 5.6\data`, or `C:\ProgramData\MySQL` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see [Section 5.4.2, “The Error Log”](#).

For information regarding possible errors, also consult the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

The following examples show other common error messages you might encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, it displays these messages:

```
System error 1067 has occurred.
Fatal error: Can't open and lock privilege tables:
Table 'mysql.user' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 5.6` and `C:\Program Files\MySQL\MySQL Server 5.6\data`, respectively).

This situation can occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, old and new configuration files might conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.6`, ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. Put the `my.ini` file in your Windows directory, typically `C:\WINDOWS`. To determine its exact location from the value of the `WINDIR` environment variable, issue the following command from the command prompt:

```
C:\> echo %WINDIR%
```

You can create or modify an option file with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 5.6
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in [Section 4.2.6, “Using Option Files”](#).

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See [Section 2.3.5.2, “Creating an Option File”](#).

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Installer, you might see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command line:

```
C:\> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from <http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp> and use the `delsrv mysql` syntax.

2.3.7 Windows Postinstallation Procedures

GUI tools exist that perform most of the tasks described in this section, including:

- [MySQL Installer](#): Used to install and upgrade MySQL products.

- [MySQL Workbench](#): Manages the MySQL server and edits SQL statements.
- [MySQL Notifier](#): Starts, stops, or restarts the MySQL server, and monitors its status.
- [MySQL for Excel](#): Edits MySQL data with Microsoft Excel.

On Windows, you need not create the data directory and the grant tables. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory.

Regarding passwords, if you installed MySQL using the MySQL Installer, you may have already assigned passwords to the accounts. (See [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).) Otherwise, use the password-assignment procedure given in [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

Before assigning passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see [Section 2.3.5.4, “Starting the Server for the First Time”](#)). You can also set up a MySQL service that runs automatically when Windows starts (see [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#)).

These instructions assume that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

If you installed MySQL using MySQL Installer (see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#)), the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.6`:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 5.6"
```

A common installation location for installation from a Zip package is `C:\mysql`:

```
C:\> cd C:\mysql
```

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your command interpreter to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See [Section 2.3.5.6, “Customizing the PATH for MySQL Tools”](#).

With the server running, issue the following commands to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
C:\> bin\mysqlshow
+-----+
| Databases |
+-----+
| information_schema |
| mysql |
| performance_schema |
| test |
+-----+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed MySQL using MySQL Installer, the `root` user will have been created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You must use those options if you have already secured the initial MySQL accounts.) With `-p`, the client program prompts for the `root` password. For example:

```
C:\> bin\mysqlshow -u root -p
Enter password: (enter root password here)
+-----+
|      Databases      |
+-----+
| information_schema |
| mysql              |
| performance_schema |
| test               |
+-----+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> bin\mysqlshow mysql
Database: mysql
+-----+
|      Tables      |
+-----+
| columns_priv      |
| db                 |
| event             |
| func              |
| general_log        |
| help_category      |
| help_keyword       |
| help_relation      |
| help_topic         |
| innodb_index_stats |
| innodb_table_stats |
| ndb_binlog_index   |
| plugin            |
| proc              |
| procs_priv         |
| proxies_priv       |
| servers            |
| slave_master_info  |
| slave_relay_log_info |
| slave_worker_info  |
| slow_log           |
| tables_priv        |
| time_zone          |
| time_zone_leap_second |
| time_zone_name     |
| time_zone_transition |
| time_zone_transition_type |
| user              |
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> bin\mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+-----+-----+-----+
| User | Host      | plugin                |
+-----+-----+-----+
| root | localhost | mysql_native_password |
+-----+-----+-----+
```

For more information about `mysql` and `mysqlshow`, see [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), and [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

2.3.8 Upgrading MySQL on Windows

To upgrade MySQL on Windows, follow these steps:

1. Review [Section 2.11.1, “Upgrading MySQL”](#), for additional information on upgrading MySQL that is not specific to Windows.
2. Always back up your current MySQL installation before performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).
3. Download the latest Windows distribution of MySQL from <http://dev.mysql.com/downloads/>.
4. Before upgrading MySQL, stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> NET STOP MySQL
```

If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 5.5 to 5.6, use `mysqladmin` from MySQL 5.5 as follows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin" -u root shutdown
```

Note

If the MySQL `root` user account has a password, invoke `mysqladmin` with the `-p` option and enter the password when prompted.

5. Before upgrading to MySQL 5.6 from a version previous to 4.1.5, or from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must first manually remove the previous installation and MySQL service (if the server is installed as a service).

To remove the MySQL service, use the following command:

```
C:\> C:\mysql\bin\mysqld --remove
```

If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.

6. If you are using the MySQL Installer, start it as described in [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).
7. If you are upgrading MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended. However, for upgrades (as opposed to installing for the first time), you must remove the data directory from your existing MySQL installation to avoid replacing your current data files. To do so, follow these steps:
 - a. Unzip the Zip archive in some location other than your current MySQL installation
 - b. Remove the data directory
 - c. Rezip the Zip archive

- d. Unzip the modified Zip archive on top of your existing installation

Alternatively:

- a. Unzip the Zip archive in some location other than your current MySQL installation
 - b. Remove the data directory
 - c. Move the data directory from the current MySQL installation to the location of the just-removed data directory
 - d. Remove the current MySQL installation
 - e. Move the unzipped installation to the location of the just-removed installation
8. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).)
 9. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.
 10. As Administrator, run `mysql_upgrade` to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).
 11. If you encounter errors, see [Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

2.4 Installing MySQL on OS X

For a list of OS X versions that the MySQL server supports, see <http://www.mysql.com/support/supportedplatforms/database.html>.

MySQL for OS X is available in a number of different forms:

- Native Package Installer, which uses the native OS X installer (DMG) to walk you through the installation of MySQL. For more information, see [Section 2.4.2, “Installing MySQL on OS X Using Native Packages”](#). You can use the package installer with OS X. The user you use to perform the installation must have administrator privileges.
- Compressed TAR archive, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you will need to open a `Terminal` window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

In addition to the core installation, the Package Installer also includes [Section 2.4.3, “Installing a MySQL Launch Daemon”](#) and [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#), both of which simplify the management of your installation.

For additional information on using MySQL on OS X, see [Section 2.4.1, “General Notes on Installing MySQL on OS X”](#).

2.4.1 General Notes on Installing MySQL on OS X

You should keep the following issues and notes in mind:

- As of MySQL server 5.6.26, the DMG bundles a launchd daemon instead of the deprecated startup item. Startup items do not function as of OS X 10.10 (Yosemite), so using launchd is preferred. The available MySQL preference pane under OS X **System Preferences** was also updated to use launchd.
- You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. You can do this through the [Directory Utility](#), and the `mysql` user should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.
- Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You will need to either copy the `data` directory from the old version to the new version, or alternatively specify an alternative `datadir` value to set location of the data directory. By default, the MySQL directories are installed under `/usr/local/`.
- You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see [Section 4.2.1, "Invoking MySQL Programs"](#).

- After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.
- Prior to OS X 10.7, MySQL server was bundled with OS X Server.

2.4.2 Installing MySQL on OS X Using Native Packages

Note

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on OS X Server), the preference pane, or `mysqladmin shutdown` on the command line.

To install MySQL using the package installer:

1. Download the disk image (`.dmg`) file (the community version is available [here](#)) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.

Figure 2.40 MySQL Package Installer: DMG Contents

2. Double-click the MySQL installer package. It will be named according to the MySQL version and the OS X version you have chosen. For example, if you have downloaded the package for MySQL 5.6.37 and OS X 10.8, double-click `mysql-5.6.37-osx-10.8-x86_64.pkg`.
3. You will be presented with the opening installer dialog. Click **Continue** to begin installation.

Figure 2.41 MySQL Package Installer: Introduction

4. If you have downloaded the community version of MySQL, you will be shown a copy of the relevant GNU General Public License. Click **Continue** and then **Agree** to continue.
5. From the **Installation Type** page you can either click **Install** to execute the installation wizard using all defaults, click **Customize** to alter which components to install (MySQL server, Preference Pane, Launchd Support -- all enabled by default), or click **Change Installation Location** to change the type of installation, if available.

Figure 2.42 MySQL Package Installer: Installation Type

Figure 2.43 MySQL Package Installer: Destination Select (Change Installation Location)

Figure 2.44 MySQL Package Installer: Customize

6. Click **Install** to begin the installation process.
7. Once the installation has been completed successfully, you will be shown an **Install Succeeded** message with a short summary. Now, **Close** the wizard and begin using the MySQL server.

Figure 2.45 MySQL Package Installer: Summary

MySQL server is now installed, but it is not loaded (or started) by default. Use either `launchctl` from the command line, or start MySQL by clicking "Start" using the MySQL preference pane. For additional information, see [Section 2.4.3, "Installing a MySQL Launch Daemon"](#), and [Section 2.4.4, "Installing and Using the MySQL Preference Pane"](#). Use the MySQL Preference Pane or `launchd` to configure MySQL to automatically start at bootup.

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-5.6.37-osx10.8-x86_64.dmg` installs MySQL into `/usr/local/mysql-5.6.37-osx10.8-x86_64/`. The following table shows the layout of the installation directory.

Table 2.5 MySQL Installation Layout on OS X

| Directory | Contents of Directory |
|---------------------------|--|
| <code>bin, scripts</code> | <code>mysqld</code> server, client and utility programs |
| <code>data</code> | Log files, databases |
| <code>docs</code> | Helper documents, like the Release Notes and build information |
| <code>include</code> | Include (header) files |
| <code>lib</code> | Libraries |
| <code>man</code> | Unix manual pages |

| Directory | Contents of Directory |
|------------------------------|--|
| <code>mysql-test</code> | MySQL test suite |
| <code>share</code> | Miscellaneous support files, including error messages, sample configuration files, SQL for database installation |
| <code>sql-bench</code> | Benchmarks |
| <code>support-files</code> | Scripts and sample configuration files |
| <code>/tmp/mysql.sock</code> | Location of the MySQL Unix socket |

During the package installer process, a symbolic link from `/usr/local/mysql` to the version/platform specific directory created during installation will be created automatically.

2.4.3 Installing a MySQL Launch Daemon

OS X uses launch daemons to automatically start, stop, and manage processes and applications such as MySQL.

Note

Before MySQL 5.6.26, the OS X builds installed startup items instead of launchd daemons. However, startup items do not function as of OS X 10.10 (Yosemite). The OS X builds now install launchd daemons.

By default, the installation package (DMG) on OS X installs a launchd file named `/Library/LaunchDaemons/com.oracle.oss.mysql.mysqld.plist` that contains a plist definition similar to:

```
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.
<plist version="1.0">
<dict>
  <key>Label</key>          <string>com.oracle.oss.mysql.mysqld</string>
  <key>ProcessType</key>    <string>Interactive</string>
  <key>Disabled</key>       <false/>
  <key>RunAtLoad</key>      <true/>
  <key>KeepAlive</key>      <true/>
  <key>SessionCreate</key>  <true/>
  <key>LaunchOnlyOnce</key> <false/>
  <key>UserName</key>       <string>_mysql</string>
  <key>GroupName</key>     <string>_mysql</string>
  <key>ExitTimeOut</key>    <integer>600</integer>
  <key>Program</key>       <string>/usr/local/mysql/bin/mysqld</string>
  <key>ProgramArguments</key>
    <array>
      <string>/usr/local/mysql/bin/mysqld</string>
      <string>--user=_mysql</string>
      <string>--basedir=/usr/local/mysql</string>
      <string>--datadir=/usr/local/mysql/data</string>
      <string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
      <string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
      <string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
    </array>
  <key>WorkingDirectory</key> <string>/usr/local/mysql</string>
</dict>
</plist>
```

**Note**

Some users report that adding a plist DOCTYPE declaration causes the launchd operation to fail, despite it passing the lint check. We suspect it's a copy-n-paste error. The md5 checksum of a file containing the above snippet is 60d7963a0bb2994b69b8b9c123db09df.

To enable the launchd service, you can either:

- Click **Start MySQL Server** from the MySQL preference pane.

Figure 2.46 MySQL Preference Pane: Location

Figure 2.47 MySQL Preference Pane: Usage

- Or, manually load the launchd file.

```
shell> cd /Library/LaunchDaemons
shell> sudo launchctl load -F com.oracle.oss.mysql.mysqld.plist
```

- To configure MySQL to automatically start at bootup, you can:

```
shell> sudo launchctl load -w com.oracle.oss.mysql.mysqld.plist
```

**Note**

When upgrading MySQL server, the launchd installation process will remove the old startup items that were installed with MySQL server 5.6.25 and below.

2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Installation Package includes a MySQL preference pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

This preference pane is installed by default, and is listed under your system's *System Preferences* window.

Figure 2.48 MySQL Preference Pane: Location

To install the MySQL Preference Pane:

1. Download the disk image ([.dmg](#)) file (the community version is available [here](#)) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.

Figure 2.49 MySQL Package Installer: DMG Contents

Note

Before MySQL 5.6.26, OS X packages included the deprecated startup items instead of launchd daemons, and the preference pane managed that instead of launchd.

2. Go through the process of installing the MySQL server, as described in the documentation at [Section 2.4.2, "Installing MySQL on OS X Using Native Packages"](#).
3. Click **Customize** at the **Installation Type** step. The "Preference Pane" option is listed there and enabled by default; make sure it is not deselected.

Figure 2.50 MySQL Installer on OS X: Customize

4. Complete the MySQL server installation process.

**Note**

The MySQL preference pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL preference pane has been installed, you can control your MySQL server instance using the preference pane. To use the preference pane, open the **System Preferences...** from the Apple menu. Select the MySQL preference pane by clicking the MySQL logo within the **bottom** section of the preference panes list.

Figure 2.51 MySQL Preference Pane: Location

Figure 2.52 MySQL Preference Pane: Usage

The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

- **To start the MySQL server using the preference pane:**

Click **Start MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to start the MySQL server.

- **To stop the MySQL server using the preference pane:**

Click **Stop MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to stop the MySQL server.

- **To automatically start the MySQL server when the system boots:**

Check the check box next to **Automatically Start MySQL Server on Startup**.

- **To disable automatic MySQL server startup when the system boots:**

Uncheck the check box next to **Automatically Start MySQL Server on Startup**.

You can close the [System Preferences...](#) window once you have completed your settings.

2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. We recommend that you use one of the distributions from Oracle, for which several methods for installation are available:

- Installing with Yum using the [MySQL Yum repository](#). For details, see [Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository"](#).

- Installing with APT using the [MySQL APT Repository](#). For details, see [Section 2.5.3, “Installing MySQL on Linux Using the MySQL APT Repository”](#).
- Installing with Zypper using the [MySQL SLES Repository](#). For details, see [Section 2.5.4, “Installing MySQL on Linux Using the MySQL SLES Repository”](#).
- Installing using a precompiled RPM package. For more information, see [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#).
- Installing using a precompiled Debian package. For more information, see [Section 2.5.6, “Installing MySQL on Linux Using Debian Packages from Oracle”](#).
- Installing from a generic binary package in `.tar.gz` format. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#) for more information.
- Installing using Oracle's Unbreakable Linux Network (ULN). For more information, see [Section 2.6, “Installing MySQL Using Unbreakable Linux Network \(ULN\)”](#).
- Extracting and compiling MySQL from a source distribution. For detailed instructions, see [Section 2.9, “Installing MySQL from Source”](#).

As an alternative, you can use the package manager on your system to automatically download and install MySQL with packages from the native software repositories of your Linux distribution. These native packages are often several versions behind the currently available release. You will also normally be unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. For more information on using the native package installers, see [Section 2.5.7, “Installing MySQL on Linux from the Native Software Repositories”](#).

**Note**

For many Linux installations, you will want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See [Section 4.3.3, “mysql.server — MySQL Server Startup Script”](#).

2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository

MySQL provides a Yum-style software repository for the following Linux platforms:

- EL5, EL6, and EL7-based platforms (for example, the corresponding versions of Red Hat Enterprise Linux, Oracle Linux, and CentOS)
- Fedora 24

Currently, the [MySQL Yum repository](#) for the above-mentioned platforms provides RPM packages for installing the MySQL server, client, MySQL Workbench, MySQL Utilities, Connector/ODBC, and Connector/Python (not all packages are available for all the platforms; see [Installing Additional MySQL Products and Components with Yum](#) for details).

Before You Start

As a popular, open-source software, MySQL, in its original or re-packaged form, is widely installed on many systems from various sources, including different software download sites, software repositories, and so on. The following instructions assume that MySQL is not already installed on your system

using a third-party-distributed RPM package; if that is not the case, follow the instructions given in [Section 2.11.1.2, “Upgrading MySQL with the MySQL Yum Repository”](#) or [Section 2.5.2, “Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository”](#).

Steps for a Fresh Installation of MySQL

Follow the steps below to install the latest GA release of MySQL (from the MySQL 5.7 series currently) with the MySQL Yum repository:

Adding the MySQL Yum Repository

First, add the MySQL Yum repository to your system's repository list. This is a one-time operation, which can be performed by installing an RPM provided by MySQL. Follow these steps:

- Go to the Download MySQL Yum Repository page (<http://dev.mysql.com/downloads/repo/yum/>) in the MySQL Developer Zone.
- Select and download the release package for your platform.
- Install the downloaded release package with the following command (except for EL5-based systems), replacing *platform-and-version-specific-package-name* with the name of the downloaded RPM package:

```
shell> sudo yum localinstall platform-and-version-specific-package-name.rpm
```

For an EL6-based system, the command is in the form of:

```
shell> sudo yum localinstall mysql57-community-release-el6-{version-number}.noarch.rpm
```

For an EL7-based system:

```
shell> sudo yum localinstall mysql57-community-release-el7-{version-number}.noarch.rpm
```

For Fedora 24:

```
shell> sudo dnf install mysql57-community-release-fc24-{version-number}.noarch.rpm
```

For an EL5-based system, use the following command instead:

```
shell> sudo rpm -Uvh mysql57-community-release-el5-{version-number}.noarch.rpm
```

The installation command adds the MySQL Yum repository to your system's repository list and downloads the GnuPG key to check the integrity of the software packages. See [Section 2.1.3.2, “Signature Checking Using GnuPG”](#) for details on GnuPG key checking.

You can check that the MySQL Yum repository has been successfully added by the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist enabled | grep "mysql.*-community.*"
```

Note

Once the MySQL Yum repository is enabled on your system, any system-wide update by the `yum update` command (or `dnf upgrade` for dnf-enabled

systems) will upgrade MySQL packages on your system and also replace any native third-party packages, if Yum finds replacements for them in the MySQL Yum repository; see [Section 2.11.1.2, “Upgrading MySQL with the MySQL Yum Repository”](#) and, for a discussion on some possible effects of that on your system, see [Upgrading the Shared Client Libraries](#).

Selecting a Release Series

When using the MySQL Yum repository, the latest GA series (currently MySQL 5.7) is selected for installation by default. If this is what you want, you can skip to the next step, [Installing MySQL](#).

Within the MySQL Yum repository, different release series of the MySQL Community Server are hosted in different subrepositories. The subrepository for the latest GA series (currently MySQL 5.7) is enabled by default, and the subrepositories for all other series (for example, the MySQL 5.6 series) are disabled by default. Use this command to see all the subrepositories in the MySQL Yum repository, and see which of them are enabled or disabled (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist all | grep mysql
```

To install the latest release from the latest GA series, no configuration is needed. To install the latest release from a specific series other than the latest GA series, disable the subrepository for the latest GA series and enable the subrepository for the specific series before running the installation command. If your platform supports `yum-config-manager`, you can do that by issuing these commands, which disable the subrepository for the 5.7 series and enable the one for the 5.6 series:

```
shell> sudo yum-config-manager --disable mysql57-community
shell> sudo yum-config-manager --enable mysql56-community
```

For dnf-enabled platforms:

```
shell> sudo dnf config-manager --disable mysql57-community
shell> sudo dnf config-manager --enable mysql56-community
```

Besides using `yum-config-manager` or the `dnf config-manager` command, you can also select a release series by editing manually the `/etc/yum.repos.d/mysql-community.repo` file. This is a typical entry for a release series' subrepository in the file:

```
[mysql57-community]
name=MySQL 5.7 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.7-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

Find the entry for the subrepository you want to configure, and edit the `enabled` option. Specify `enabled=0` to disable a subrepository, or `enabled=1` to enable a subrepository. For example, to install MySQL 5.6, make sure you have `enabled=0` for the above subrepository entry for MySQL 5.7, and have `enabled=1` for the entry for the 5.6 series:

```
# Enable to use MySQL 5.6
[mysql56-community]
name=MySQL 5.6 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.6-community/el/6/$basearch/
enabled=1
```

```
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

You should only enable subrepository for one release series at any time. When subrepositories for more than one release series are enabled, the latest series will be used by Yum.

Verify that the correct subrepositories have been enabled and disabled by running the following command and checking its output (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum repolist enabled | grep mysql
```

Installing MySQL

Install MySQL by the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install mysql-community-server
```

This installs the package for MySQL server (`mysql-community-server`) and also packages for the components required to run the server, including packages for the client (`mysql-community-client`), the common error messages and character sets for client and server (`mysql-community-common`), and the shared client libraries (`mysql-community-libs`).

Starting the MySQL Server

Start the MySQL server with the following command:

```
shell> sudo service mysqld start
```

This is a sample output of the above command:

```
Starting mysqld:[ OK ]
```

You can check the status of the MySQL server with the following command:

```
shell> sudo service mysqld status
```

This is a sample output of the above command:

```
mysqld (pid 3066) is running.
```

Securing the MySQL Installation

The program `mysql_secure_installation` allows you to perform important operations like setting the root password, removing anonymous users, and so on. Always run it to secure your MySQL installation:

```
shell> mysql_secure_installation
```

It is important to remember the root password you set. See [Section 4.4.5, “mysql_secure_installation — Improve MySQL Installation Security”](#) for details.

For more information on the postinstallation procedures, see [Section 2.10, “Postinstallation Setup and Testing”](#).

**Note**

Compatibility Information for EL7-based platforms: The following RPM packages from the native software repositories of the platforms are incompatible with the package from the MySQL Yum repository that installs the MySQL server. Once you have installed MySQL using the MySQL Yum repository, you will not be able to install these packages (and vice versa).

- akonadi-mysql

Installing Additional MySQL Products and Components with Yum

You can use Yum to install and manage individual components of MySQL. Some of these components are hosted in sub-repositories of the MySQL Yum repository: for example, the MySQL Connectors are to be found in the MySQL Connectors Community sub-repository, and the MySQL Workbench in MySQL Tools Community. You can use the following command to list the packages for all the MySQL components available for your platform from the MySQL Yum repository (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum --disablerepo=* --enablerepo='mysql*-community*' list available
```

Install any packages of your choice with the following command, replacing `package-name` with name of the package (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install package-name
```

For example, to install MySQL Workbench on Fedora 24:

```
shell> sudo dnf install mysql-workbench-community
```

To install the shared client libraries (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum install mysql-community-libs
```

Updating MySQL with Yum

Besides installation, you can also perform updates for MySQL products and components using the MySQL Yum repository. See [Section 2.11.1.2, “Upgrading MySQL with the MySQL Yum Repository”](#) for details.

2.5.2 Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository

For supported Yum-based platforms (see [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#), for a list), you can replace a third-party distribution of MySQL with the latest GA release (from the MySQL 5.7 series currently) from the MySQL Yum repository. According to how your third-party distribution of MySQL was installed, there are different steps to follow:

Replacing a Native Third-Party Distribution of MySQL

If you have installed a third-party distribution of MySQL from a native software repository (that is, a software repository provided by your own Linux distribution), follow these steps:

Backing Up Your Database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL Yum repository. See [Chapter 7, Backup and Recovery](#), on how to back up your database.

Adding the MySQL Yum Repository

Add the MySQL Yum repository to your system's repository list by following the instructions given in [Adding the MySQL Yum Repository](#).

Replacing the Native Third-Party Distribution by a Yum Update or a DNF Upgrade

By design, the MySQL Yum repository will replace your native, third-party MySQL with the latest GA release (from the MySQL 5.7 series currently) from the MySQL Yum repository when you perform a `yum update` command (or `dnf upgrade` for dnf-enabled systems) on the system, or a `yum update mysql-server` (or `dnf upgrade mysql-server` for dnf-enabled systems).

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work. However, *if you want to recompile applications and dynamically link them with the updated libraries*, see [Upgrading the Shared Client Libraries](#), for some special considerations.

Replacing a Nonnative Third-Party Distribution of MySQL

If you have installed a third-party distribution of MySQL from a nonnative software repository (that is, a software repository not provided by your own Linux distribution), follow these steps:

Backing Up Your Database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL Yum repository. See [Chapter 7, Backup and Recovery](#), on how to back up your database.

Stopping Yum from Receiving MySQL Packages from Third-Party, Nonnative Repositories

Before you can use the MySQL Yum repository for installing MySQL, you must stop your system from receiving MySQL packages from any third-party, nonnative Yum repositories.

For example, if you have installed MariaDB using their own software repository, get a list of the installed MariaDB packages using the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum list installed mariadb\*
```

This is a sample output for the command:

| | | |
|---------------------|----------|----------|
| MariaDB-common.i686 | 10.0.4-1 | @mariadb |
| MariaDB-compat.i686 | 10.0.4-1 | @mariadb |
| MariaDB-server.i686 | 10.0.4-1 | @mariadb |

From the command output, we can identify the installed packages (`MariaDB-common`, `MariaDB-compat`, and `MariaDB-server`) and the source of them (a nonnative software repository named `mariadb`).

As another example, if you have installed Percona using their own software repository, get a list of the installed Percona packages using the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum list installed Percona\*
```

This is a sample output for the command:

| | | |
|-------------------------------|--------------------|--------------------------------|
| Percona-Server-client-55.i686 | 5.5.39-rel36.0.el6 | @percona-release-i386 |
| Percona-Server-server-55.i686 | 5.5.39-rel36.0.el6 | @percona-release-i386 |
| Percona-Server-shared-55.i686 | 5.5.39-rel36.0.el6 | @percona-release-i386 |
| percona-release.noarch | 0.1-3 | @/percona-release-0.1-3.noarch |

From the command output, we can identify the installed packages (`Percona-Server-client`, `Percona-Server-server`, `Percona-Server-shared`, and `percona-release.noarch`) and the source of them (a nonnative software repository named `percona-release`).

If you are not sure which third-party MySQL fork you have installed, this command should reveal it and list the RPM packages installed for it, as well as the third-party repository that supplies the packages (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> yum --disablerepo=* provides mysql\*
```

The next step is to stop Yum from receiving packages from the nonnative repository. If the `yum-config-manager` utility is supported on your platform, you can, for example, use this command for stopping delivery from MariaDB (on dnf-enabled systems, use the `dnf config-manager` command instead of `yum-config-manager`):

```
shell> sudo yum-config-manager --disable mariadb
```

And use this command for stopping delivery from Percona (on dnf-enabled systems, use the `dnf config-manager` command instead of `yum-config-manager`):

```
shell> sudo yum-config-manager --disable percona-release
```

You can perform the same task by removing the entry for the software repository existing in one of the repository files under the `/etc/yum.repos.d/` directory. This is how the entry typically looks like for MariaDB:

```
[mariadb] name = MariaDB
baseurl = [base URL for repository]
gpgkey = [URL for GPG key]
gpgcheck =1
```

The entry is usually found in the file `/etc/yum.repos.d/MariaDB.repo` for MariaDB—delete the file, or remove entry from it (or from the file in which you find the entry).

Note

This step is not necessary for an installation that was configured with a Yum repository release package (like Percona) if you are going to remove the release package (`percona-release.noarch` for Percona), as shown in the uninstall command for Percona in Step 3 below.

Uninstalling the Nonnative Third-Party MySQL Distribution of MySQL

The nonnative third-party MySQL distribution must first be uninstalled before you can use the MySQL Yum repository to install MySQL. For the MariaDB packages found in Step 2 above, uninstall them with the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum remove MariaDB-common MariaDB-compat MariaDB-server
```

For the Percona packages we found in Step 2 above (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
shell> sudo yum remove Percona-Server-client-55 Percona-Server-server-55 \
Percona-Server-shared-55.i686 percona-release
```

Installing MySQL with the MySQL Yum Repository

Then, install MySQL with the MySQL Yum repository by following the instructions given in [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#): .

Important

- If you have chosen to replace your third-party MySQL distribution with a newer version of MySQL from the MySQL Yum repository, remember to run `mysql_upgrade` after the server starts, to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#) for details.
- For EL7-based platforms: See [Compatibility Information for EL7-based platforms \[147\]](#).

2.5.3 Installing MySQL on Linux Using the MySQL APT Repository

The MySQL APT repository provides `deb` packages for installing and managing the MySQL server, client, and other components on the following Linux platforms: :

- Debian 7.x (“wheezy”)
- Debian 8.x (“jessie”)
- Ubuntu 12.04 LTS (“Precise Pangolin”)
- Ubuntu 14.04 LTS (“Trusty Tahr”)
- Ubuntu 15.10 (“Wily Werewolf”)

Instructions for using the MySQL APT Repository are available in [A Quick Guide to Using the MySQL APT Repository](#).

2.5.4 Installing MySQL on Linux Using the MySQL SLES Repository

The MySQL SLES repository provides RPM packages for installing and managing the MySQL server, client, and other components on SUSE Enterprise Linux Server.

Instructions for using the MySQL SLES repository are available in [A Quick Guide to Using the MySQL SLES Repository](#).

Note

The MySQL SLES repository is now in development release. We encourage you to try it and provide us with feedback. Please report any bugs or inconsistencies you observe to our [Bugs Database](#).

2.5.5 Installing MySQL on Linux Using RPM Packages from Oracle

Note

To install or upgrade to MySQL 5.6.11 or later, be sure to read the special instructions at the end of this section.

The recommended way to install MySQL on RPM-based Linux distributions that use `glibc` is by using the RPM packages provided by Oracle. There are two sources for obtaining the Community versions of the RPM packages:

- From the MySQL software repositories, for the following platforms:
 - For EL5, EL6, or EL7-based platforms and Fedora 24, use the MySQL Yum repository (see [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#) for details).
 - For SUSE Enterprise Linux Server, use the MySQL SLES repository (see [Section 2.5.4, “Installing MySQL on Linux Using the MySQL SLES Repository”](#) for details).
- From the [MySQL Downloads page](#) in the [MySQL Developer Zone](#), which provides RPM packages that work for different platforms.

The discussion in this section applies only to the RPM packages downloaded from the MySQL Developer Zone. Installations created with these packages result in files under the system directories shown in the following table.

Table 2.6 MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone

| Directory | Contents of Directory |
|-----------------------------------|---|
| <code>/usr/bin</code> | Client programs and scripts |
| <code>/usr/sbin</code> | The <code>mysqld</code> server |
| <code>/var/lib/mysql</code> | Log files, databases |
| <code>/var/lib/mysql-files</code> | Value of <code>secure_file_priv</code> |
| <code>/usr/share/info</code> | MySQL manual in Info format |
| <code>/usr/share/man</code> | Unix manual pages |
| <code>/usr/include/mysql</code> | Include (header) files |
| <code>/usr/lib/mysql</code> | Libraries |
| <code>/usr/share/mysql</code> | Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation |
| <code>/usr/share/sql-bench</code> | Benchmarks |

Note

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead. Because of these differences, RPM packages built by Oracle check whether such RPMs built by other vendors are installed. If so, the RPM does not install and produces a message explaining this.

Conflicts can arise when an RPM from another vendor is already installed, such as when a vendor's conventions about which files belong with the server and which belong with the client library differ from the breakdown used for Oracle packages. In such cases, attempts to install an Oracle RPM with `rpm -i` may result in messages that files in the RPM to be installed conflict with files from an installed package (denoted `mysql-libs` in the following paragraphs).

Each MySQL release provides a `MySQL-shared-compat` package that is meant to replace `mysql-libs` and provides a replacement-compatible client library for older MySQL series. `MySQL-shared-compat` is set up to make `mysql-libs` obsolete, but `rpm` explicitly refuses to replace obsoleted packages when invoked with `-i` (unlike `-U`), which is why installation with `rpm -i` produces a conflict.

`MySQL-shared-compat` can safely be installed alongside `mysql-libs` because libraries are installed to different locations. Therefore, it is possible to install `MySQL-shared-compat` first, then manually remove `mysql-libs` before continuing with the installation. After `mysql-libs` is removed, the dynamic linker stops looking for the client library in the location where `mysql-libs` puts it, and the library provided by the `MySQL-shared-compat` package takes over.

Another alternative is to install packages using `yum`. In a directory containing all RPM packages for a MySQL release, `yum install MySQL*rpm` installs them in the correct order and removes `mysql-libs` in one step without conflicts.

In most cases, you need install only the `MySQL-server` and `MySQL-client` packages to get a functional standard MySQL installation. The other packages are not required for a standard installation.

As of MySQL 5.6.8, new RPM install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option that provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-passwords` causes it to assign a random password to the MySQL `root` accounts, set the “password expired” flag for those accounts, and not create anonymous-user MySQL accounts. It will be necessary after installation to start the server, connect as `root` using the initial random password, and assign a new `root` password. Until this is done, `root` cannot do anything else. This must be done for each `root` account you intend to use. To change the password, you can use the `SET PASSWORD` statement (for example, with the `mysql` client). You can also use `mysqladmin` or `mysql_secure_installation`. For additional details, see [Section 4.4.3, “mysql_install_db — Initialize MySQL Data Directory”](#). (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

Important

RPMs for MySQL Cluster. Standard MySQL server RPMs built by MySQL do not provide support for the `NDBCLUSTER` storage engine. For more information about installing MySQL Cluster from RPMs, see [Section 18.2, “NDB Cluster Installation”](#).

When upgrading a MySQL Cluster RPM installation, you must upgrade *all* installed RPMs, including the `Server` and `Client` RPMs.

For upgrades, if your installation was originally produced by installing multiple RPM packages, it is best to upgrade all the installed packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

If the data directory exists at RPM installation time, the installation process does not modify existing data. This has the effect, for example, that accounts in the grant tables are not initialized to the default set of accounts.

If you get a dependency failure when trying to install MySQL packages (for example, `error: removing these packages would break dependencies: libmysqlclient.so.10 is needed by ...`), you should also install the `MySQL-shared-compat` package, which includes the shared libraries for older releases for backward compatibility.

The following list shows the available RPM packages. The names shown here use a suffix of `.linux_glibc2.5.i386.rpm`, but particular packages can have different suffixes, described later. If you plan to install multiple RPM packages, you may wish to download the RPM Bundle `tar` file instead, which contains multiple RPM packages so that you need not download them separately.

- `MySQL-server-VERSION.linux_glibc2.5.i386.rpm`

The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

- `MySQL-client-VERSION.linux_glibc2.5.i386.rpm`

The standard MySQL client programs. You probably always want to install this package.

- `MySQL-devel-VERSION.linux_glibc2.5.i386.rpm`

The libraries and include files needed to compile other MySQL clients, such as the Perl MySQL module. Install this RPM if you intend to compile C API applications.

- `MySQL-shared-VERSION.linux_glibc2.5.i386.rpm`

The shared libraries (`libmysqlclient.so*`) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries. Install this RPM if you intend to compile or run C API applications that depend on the shared client library.

- `MySQL-shared-compat-VERSION.linux_glibc2.5.i386.rpm`

The shared libraries for older releases, but not the libraries for the current release. It contains single-threaded and thread-safe libraries. Install this package if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library dependencies.

As of MySQL 5.6.5, the `MySQL-shared-compat` RPM package enables users of Red Hat-provided `mysql-*-5.1` RPM packages to migrate to Oracle-provided `MySQL-*-5.5` packages. `MySQL-shared-compat` replaces the Red Hat `mysql-libs` package by replacing `libmysqlclient.so` files of the latter package, thus satisfying dependencies of other packages on `mysql-libs`. This change affects only users of Red Hat (or Red Hat-compatible) RPM packages. Nothing is different for users of Oracle RPM packages.

- `MySQL-embedded-VERSION.linux_glibc2.5.i386.rpm`

The embedded MySQL server library.

- `MySQL-test-VERSION.linux_glibc2.5.i386.rpm`

The MySQL test suite.

- `MySQL-VERSION.src.rpm`

The source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, SPARC).

In RPM package names, the suffix (following the `VERSION` value) has the following syntax:

```
.PLATFORM.CPU.rpm
```

The `PLATFORM` and `CPU` values indicate the type of system for which the package is built. `PLATFORM` indicates the platform and `CPU` indicates the processor type or family.

All packages are dynamically linked against [glibc](#) 2.5. The *PLATFORM* value indicates whether the package is platform independent or intended for a specific platform, as shown in the following table.

Table 2.7 MySQL Linux RPM Package Platforms

| <i>PLATFORM</i> Value | Intended Use |
|--------------------------------|--|
| linux_glibc25 | Platform independent, should run on any Linux distribution that supports glibc 2.5 |
| rhel5 | Red Hat Enterprise Linux 5 |
| el6, el7 | Enterprise Linux 6 or 7 |
| sles11, sles12 | SUSE Linux Enterprise Server 11 or 12 |

In MySQL 5.6, only [linux_glibc2.5](#) packages are available currently.

The *CPU* value indicates the processor type or family for which the package is built, as shown in the following table.

Table 2.8 MySQL Linux RPM Package CPU Identifiers

| <i>CPU</i> Value | Intended Processor Type or Family |
|----------------------------|-------------------------------------|
| i386, i686 | Pentium processor or better, 32 bit |
| x86_64 | 64-bit x86 processor |

To see all files in an RPM package (for example, a [MySQL-server](#) RPM), run a command like this (modify the platform and CPU identifiers appropriately for your system):

```
shell> rpm -qpl MySQL-server-VERSION.linux_glibc2.5.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```
shell> rpm -i MySQL-server-VERSION.linux_glibc2.5.i386.rpm
shell> rpm -i MySQL-client-VERSION.linux_glibc2.5.i386.rpm
```

To install only the client programs, install just the client RPM:

```
shell> rpm -i MySQL-client-VERSION.linux_glibc2.5.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. To learn more about this feature, see [Section 2.1.3, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you can reinstall it after you install a newer RPM.) See [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#), for more information on how MySQL can be started automatically at system startup.

In MySQL 5.6, for a new installation using RPM packages, the server boot scripts are installed, but the MySQL server is not started at the end of the installation, since the status of the server during an unattended installation is not known.

In MySQL 5.6, for an upgrade installation using RPM packages, if the MySQL server is running when the upgrade occurs, the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. If

the MySQL server is not already running when the RPM upgrade occurs, the MySQL server is not started at the end of the installation.

**Note**

Upgrading from a community version to a commercial version of MySQL requires that you first uninstall the community version and then install the commercial version. In this case, you must restart the server manually after the upgrade.

If something goes wrong, you can find more information in the binary installation section. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

**Note**

The accounts created in the MySQL grant tables for an RPM installation initially have no passwords. After starting the server, you should assign passwords to them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

An RPM installation creates a user named `mysql` and a group named `mysql` on the system using the `useradd`, `groupadd`, and `usermod` commands. Those commands require appropriate administrative privileges, which is required for locally managed users and groups (as listed in the `/etc/passwd` and `/etc/group` files) by the RPM installation process being run by `root`.

If you log in as the `mysql` user, you may find that MySQL displays “Invalid (old?) table or database name” errors that mention `.mysqlgui`, `lost+found`, `.mysqlgui`, `.bash_history`, `.fonts.cache-1`, `.lesshtst`, `.mysql_history`, `.profile`, `.viminfo`, and similar files created by MySQL or operating system utilities. You can safely ignore these error messages or remove the files or directories that cause them if you do not need them.

For nonlocal user management (LDAP, NIS, and so forth), the administrative tools may require additional authentication (such as a password), and will fail if the installing user does not provide this authentication. Even if they fail, the RPM installation will not abort but succeed, and this is intentional. If they failed, some of the intended transfer of ownership may be missing, and it is recommended that the system administrator then manually ensures some appropriate user and group exists and manually transfers ownership following the actions in the RPM spec file.

In MySQL 5.6.11, the RPM spec file has been updated, which has the following consequences:

- For a non-upgrade installation (no existing MySQL version installed), it is possible to install MySQL using `yum`.
- For upgrades, it is necessary to clean up any earlier MySQL installations. In effect, the update is performed by removing the old installations and installing the new one.

Additional details follow.

For a non-upgrade installation of MySQL 5.6.11 or later, it is possible to install using `yum`:

```
shell> yum install MySQL-server-NEWVERSION.linux_glibc2.5.i386.rpm
```

For upgrades to MySQL 5.6.11 or later, perform the upgrade by removing the old installation and installing the new one:

1. Remove the existing 5.6.*X* installation. `OLDVERSION` is the version to remove.

```
shell> rpm -e MySQL-server-OLDVERSION.linux_glibc2.5.i386.rpm
```

Repeat this step for all installed MySQL RPMs.

2. Install the new version. *NEWVERSION* is the version to install.

```
shell> rpm -ivh MySQL-server-NEWVERSION.linux_glibc2.5.i386.rpm
```

Alternatively, the removal and installation can be done using `yum`:

```
shell> yum remove MySQL-server-OLDVERSION.linux_glibc2.5.i386.rpm
shell> yum install MySQL-server-NEWVERSION.linux_glibc2.5.i386.rpm
```

For some Linux distributions, it might be necessary to increase the limit on number of file descriptors available to `mysqld`. See [Section B.5.2.18, “File Not Found and Similar Errors”](#)

2.5.6 Installing MySQL on Linux Using Debian Packages from Oracle

Oracle provides Debian packages for installing MySQL on Debian or Debian-like Linux systems. The packages are available through two different channels:

- The [MySQL APT Repository](#), supporting the Debian 7 and 8, and Ubuntu 12, 14, and 15 platforms. For details, see [Section 2.5.3, “Installing MySQL on Linux Using the MySQL APT Repository”](#).
- The [MySQL Developer Zone's Download Area](#). For details, see [Section 2.1.2, “How to Get MySQL”](#). The following are some information on the Debian packages available there and the instructions for installing them:
- You may also need to install the `libaio` library if it is not already present on your system:

```
shell> sudo apt-get install libaio1
```

- For Debian 7 and 8, and Ubuntu 12, 14, and 15:
- Various Debian packages are provided in the MySQL Developer Zone for installing different components of MySQL. The preferred method is to use the tarball bundle, which contains the packages needed for a basic setup of MySQL. The tarball bundles have names in the format of `mysql-server_MVER-DVER_CPU.deb-bundle.tar`. *MVER* is the MySQL version and *DVER* is the Linux distribution version. The *CPU* value indicates the processor type or family for which the package is built, as shown in the following table:

Table 2.9 MySQL Debian 7 and 8, and Ubuntu 12, 14, and 15 Installation Packages CPU Identifiers

| <i>CPU</i> Value | Intended Processor Type or Family |
|------------------|-------------------------------------|
| i386 | Pentium processor or better, 32 bit |
| amd64 | 64-bit x86 processor |

- After downloading the tarball, unpack it with the following command:

```
shell> tar -xvf mysql-server_MVER-DVER_CPU.deb-bundle.tar
```

- In general, install the `deb` packages unpacked from the tarball with the command (see explanations below for the extra steps required for installing the server package):

```
shell> sudo dpkg -i package-name.deb
```

There are four packages to install:

- The database common files (install this package before the other ones):

```
shell> sudo dpkg -i mysql-common_MVER-DVER_CPU.deb
```

- The MySQL server:

Install first the package for the database common files (see the last bullet), and then pre-configure your server installation by the following command:

```
shell> sudo dpkg-preconfigure mysql-community-server_MVER-DVER_CPU.deb
```

You will be asked to provide a password for the root user for your MySQL installation. You might also be asked other questions regarding the installation.

Important

Make sure you remember the root password you set. Users who want to set a password later can leave the **password** field blank in the dialogue box and just press **OK**. However, it is very important that you set the password soon using the program [mysql_secure_installation](#), as people can gain anonymous access to your MySQL server until you have secured the database's root account with a password.

Next, install the server package with the following command:

```
shell> sudo dpkg -i mysql-community-server_MVER-DVER_CPU.deb
```

- The MySQL client:

```
shell> sudo dpkg -i mysql-community-client_MVER-DVER_CPU.deb
```

- The MySQL shared client library:

```
shell> sudo dpkg -i libmysqlclient18_MVER-DVER_CPU.deb
```

Here are where the files are installed on the system:

- All configuration files (like `my.cnf`) are under `/etc`
- All binaries, libraries, headers, etc., are under `/usr`
- The data directory is under `/var`
- *For Debian 6:*
 - Debian package files directly downloaded from the MySQL Developer Zone have names in the `mysql-MVER-DVER-CPU.deb` format. `MVER` is the MySQL version and `DVER` is the Debian version. The `CPU` value indicates the processor type or family for which the package is built, as shown in the following table:

Table 2.10 MySQL Debian 6 Installation Package CPU Identifiers

| <code>CPU</code> Value | Intended Processor Type or Family |
|------------------------|-------------------------------------|
| <code>i686</code> | Pentium processor or better, 32 bit |
| <code>x86_64</code> | 64-bit x86 processor |

- After downloading a Debian package, use the following command to install it;

```
shell> dpkg -i mysql-MVER-DVER-CPU.deb
```

The Debian package installs files under the `/opt/mysql/server-5.6` directory.

Note

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

2.5.7 Installing MySQL on Linux from the Native Software Repositories

Many Linux distributions include a version of the MySQL server, client tools, and development components in their native software repositories and can be installed with the platforms' standard package management systems. This section provides basic instructions for installing MySQL using those package management systems.

Important

Native packages are often several versions behind the currently available release. You will also normally be unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. Before proceeding, we recommend that you check out the other installation options described in [Section 2.5, "Installing MySQL on Linux"](#).

Distribution specific instructions are shown below:

- **Red Hat Linux, Fedora, CentOS**

Note

For a number of Linux distributions, you can install MySQL using the MySQL Yum repository instead of the platform's native software repository. See [Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository"](#) for details.

For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
root-shell> yum install mysql mysql-server mysql-libs mysql-server
Loaded plugins: presto, refresh-packagekit
Setting up Install Process

Complete!

```

MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. An init script, to start and stop the server, will have been installed into `/etc/init.d/mysqld`. To start the MySQL server use `service`:

```
root-shell> service mysqld start
```

To enable the server to be started and stopped automatically during boot, use `chkconfig`:

```
root-shell> chkconfig --levels 235 mysqld on
```

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables will have been automatically created for you, if they do not already exist. You should, however, run `mysql_secure_installation` to set the root passwords on your server.

- **Debian, Ubuntu, Kubuntu**

Note

For Debian 7 and 8, and Ubuntu 12, 14, and 15, MySQL can be installed using the [MySQL APT Repository](#) instead of the platform's native software repository. See [Section 2.5.3, "Installing MySQL on Linux Using the MySQL APT Repository"](#) for details.

On Debian and related distributions, there are two packages for MySQL in their software repositories, `mysql-client` and `mysql-server`, for the client and server components respectively. You should specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

Note

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
  linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-common postfix
Suggested packages:
  dbshell libipc-sharedcache-perl tinyca procmail postfix-mysql postfix-pgsql
  postfix-ldap postfix-pcre sasl2-bin resolvconf postfix-cdb
The following NEW packages will be installed
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-client-5.1 mysql-common mysql-server-5.1 postfix

```

Note

The `apt-get` command will install a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database will be created, and you will be prompted for the MySQL root password (and confirmation). A configuration file will have been created in `/etc/mysql/my.cnf`. An init script will have been created in `/etc/init.d/mysql`.

The server will already be started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service will automatically be added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

• Gentoo Linux

As a source-based distribution, installing MySQL on Gentoo involves downloading the source, patching the Gentoo specifics, and then compiling the MySQL server and installing it. This process is handled automatically by the `emerge` command.

The MySQL server and client tools are provided within a single package, `dev-db/mysql`. You can obtain a list of the versions available to install by looking at the portage directory for the package:

```

root-shell> ls /usr/portage/dev-db/mysql/mysql-5.6*
mysql-5.6.27.ebuild
mysql-5.6.27-r1.ebuild
mysql-5.6.28.ebuild

```

To install a specific MySQL version, you must specify the entire atom. For example:

```
root-shell> emerge =dev-db/mysql-5.6.27-r1
```

After installation, you should initialize the data directory and set the password for the MySQL `root` user (see [Section 2.10.1, “Initializing the Data Directory”](#)). Alternatively, use the configuration interface to perform those tasks:

```
root-shell> emerge --config =dev-db/mysql-5.6.27-r1
```

During installation, a sample configuration file is created for you in `/etc/mysql/my.cnf`, and an init script is created in `/etc/init.d/mysql`.

To enable MySQL to start automatically at the normal (default) run levels, use this command:

```
root-shell> rc-update add mysql default
```

2.5.8 Installing MySQL on Linux with docker

The docker deployment framework supports easy installation and configuration of MySQL servers. For instructions, see <https://hub.docker.com/r/mysql/mysql-server/>. This page also provides extensive documentation about using MySQL under docker.

2.5.9 Installing MySQL on Linux with juju

The juju deployment framework supports easy installation and configuration of MySQL servers. For instructions, see <https://jujucharms.com/mysql/>.

2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in [Section 2.5, “Installing MySQL on Linux”](#). One of the methods, covered in this section, is installing from Oracle's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under <http://linux.oracle.com/>.

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the [ULN FAQ](#). The page also describes how to install and update packages. The MySQL packages are in the “MySQL for Oracle Linux 6” and “MySQL for Oracle Linux 7” channels for your system architecture on ULN.

Note

At the time of this writing, ULN provides MySQL 5.6 for Oracle Linux 6 and Oracle Linux 7.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, in [this section](#), particularly under [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#).

If you're updating an existing MySQL installation to an installation using ULN, the recommended procedure is to export your data using `mysqldump`, remove the existing installation, install MySQL from ULN, and load the exported data into your freshly installed MySQL.

If the existing MySQL installation you're upgrading from is from a previous release series (prior to MySQL 5.6), make sure to read the section on upgrading MySQL, [Section 2.11.1, “Upgrading MySQL”](#).

2.7 Installing MySQL on Solaris and OpenSolaris

MySQL on Solaris and OpenSolaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see [Section 2.7.1, “Installing MySQL on Solaris Using a Solaris PKG”](#).
- On OpenSolaris, the standard package repositories include MySQL packages specially built for OpenSolaris that include entries for the Service Management Framework (SMF) to enable control of the installation using the SMF administration commands. For more information, see [Section 2.7.2, “Installing MySQL on OpenSolaris Using IPS”](#).
- To use a standard `tar` binary installation, use the notes provided in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, <http://dev.mysql.com/downloads/mysql/5.6.html>.

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

```
groupadd mysql
useradd -g mysql -s /bin/false mysql
```

- If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution. In Solaris 10 and OpenSolaris `gtar` is normally located in `/usr/sfw/bin/gtar`, but may not be included in the default path definition.

- When using Solaris 10 for x86_64, you should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the `InnoDB` storage engine on this platform.
- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.
- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they will be generated using the mode 600 and owned by the superuser.

2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris and OpenSolaris using a binary package using the native Solaris PKG format instead of the binary tarball distribution.

To use this package, download the corresponding `mysql-VERSION-solaris10-PLATFORM.pkg.gz` file, then uncompress it. For example:

```
shell> gunzip mysql-5.6.37-solaris10-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
shell> pkgadd -d mysql-5.6.37-solaris10-x86_64.pkg

The following packages are available:
  1  mysql      MySQL Community Server (GPL)
      (i86pc) 5.6.37

Select package(s) you wish to process (or 'all' to process
all packages). (default: all) [?,??,q]:
```

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

By default, the PKG package installs MySQL under the root path `/opt/mysql`. You can change only the installation root path when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary `tar` file distribution.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
shell> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
shell> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
shell> mysqladmin shutdown
shell> pkgrm mysql
shell> pkgadd -d mysql-5.6.37-solaris10-x86_64.pkg
shell> mysqld_safe &
shell> mysql_upgrade
```

You should check the notes in [Section 2.11, “Upgrading or Downgrading MySQL”](#) before performing any upgrade.

2.7.2 Installing MySQL on OpenSolaris Using IPS

OpenSolaris includes standard packages for MySQL in the core repository. The MySQL packages are based on a specific release of MySQL and updated periodically. For the latest release you must use either the native Solaris PKG, `tar`, or source installations. The native OpenSolaris packages include SMF files so that you can easily control your MySQL installation, including automatic startup and recovery, using the native service management tools.

To install MySQL on OpenSolaris, use the `pkg` command. You will need to be logged in as root, or use the `pfexec` tool, as shown in the example below:

```
shell> pfexec pkg install SUNWmysql56
```

The package set installs three individual packages, [SUNWmysql56lib](#), which contains the MySQL client libraries; [SUNWmysql56r](#) which contains the root components, including SMF and configuration files; and [SUNWmysql56u](#) which contains the scripts, binary tools and other files. You can install these packages individually if you only need the corresponding components.

The MySQL files are installed into [/usr/mysql](#) which symbolic links for the sub directories ([bin](#), [lib](#), etc.) to a version specific directory. For MySQL 5.6, the full installation is located in [/usr/mysql/5.6](#). The default data directory is [/var/mysql/5.6/data](#). The configuration file is installed in [/etc/mysql/5.6/my.cnf](#). This layout permits multiple versions of MySQL to be installed, without overwriting the data and binaries from other versions.

Once installed, you must initialize the data directory (see [Section 2.10.1, “Initializing the Data Directory”](#)), and use the [mysql_secure_installation](#) to secure your installation.

Using SMF to manage your MySQL installation

Once installed, you can start and stop your MySQL server using the installed SMF configuration. The service name is [mysql](#), or if you have multiple versions installed, you should use the full version name, for example [mysql:version_56](#). To start and enable MySQL to be started at boot time:

```
shell> svcadm enable mysql
```

To view the SMF logs, use this command:

```
shell> svcadm enable svc:/application/database/mysql
```

To check whether the MySQL service is running:

```
shell> svcs -xv svc:/application/database/mysql
```

To disable MySQL from starting during boot time, and shut the MySQL server down if it is running:

```
shell> svcadm disable mysql
```

To restart MySQL, for example after a configuration file changes, use the [restart](#) option:

```
shell> svcadm restart mysql
```

You can also use SMF to configure the data directory and enable full 64-bit mode. For example, to set the data directory used by MySQL:

```
shell> svccfg
svc:> select mysql:version_56
svc:/application/database/mysql:version_56> setprop mysql/data=/data0/mysql
```

By default, the 32-bit binaries are used. To enable the 64-bit server on 64-bit platforms, set the [enable_64bit](#) parameter. For example:

```
svc:/application/database/mysql:version_56> setprop mysql/enable_64bit=1
```

You must refresh the SMF after setting these options:

```
shell> svcadm refresh mysql
```

2.8 Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at <http://www.freebsd.org/>. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -I` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

To install using the ports system:

```
# cd /usr/ports/databases/mysql56-server
# make
...
# cd /usr/ports/databases/mysql56-client
# make
...
```

The standard port installation places the server into `/usr/local/libexec/mysqld`, with the startup script for the MySQL server placed in `/usr/local/etc/rc.d/mysql-server`.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
# cd /usr/ports/databases/mysql56-server
# make deinstall
...
# cd /usr/ports/databases/mysql56-client
# make deinstall
...
```

- If you get problems with the current date in MySQL, setting the `TZ` variable should help. See [Section 4.9, “MySQL Program Environment Variables”](#).

2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see <http://www.mysql.com/support/supportedplatforms/database.html>.

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that

our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see [Section 2.1.2, “How to Get MySQL”](#). For instructions on building from a standard distribution, see [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#).

Standard distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or `mysql-VERSION.rpm`, where `VERSION` is a number like `5.6.37`. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

- Use a MySQL development tree. For information on building from one of the development trees, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

Source Installation System Requirements

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, the following system requirements must be satisfied, regardless of installation method:

- `CMake`, which is used as the build framework on all platforms. `CMake` can be downloaded from <http://www.cmake.org>.
- A good `make` program. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make` 3.75 or higher. It may already be available on your system as `gmake`. GNU `make` is available from <http://www.gnu.org/software/make/>.
- A working ANSI C++ compiler. GCC 4.2.1 or later, Sun Studio 12 or later, Visual Studio 2010 or later, and many current vendor-supplied compilers are known to work.
- Sufficient free memory. If you encounter problems such as “internal compiler error” when compiling large source files, it may be that you have too little memory. If compiling on a virtual machine, try increasing the memory allocation.
- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a `.tar.gz` compressed `tar` file: GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if

available, use a preinstalled version of GNU tar. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

- For a `.zip` Zip archive: `WinZip` or another tool that can read `.zip` files.
- For an `.rpm` RPM package: The `rpmbuild` program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- The Git revision control system is required to obtain the development source code. The [GitHub Help](#) provides instructions for downloading and installing Git on different platforms. MySQL officially joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the announcement on the MySQL Release Engineering blog: [MySQL on GitHub](#)
- `bison` 2.1 or higher, available from <http://www.gnu.org/software/bison/>. (Version 1 is no longer supported.) Use the latest version of `bison` where possible; if you experience problems, upgrade to a later version, rather than revert to an earlier one.

`bison` is available from <http://www.gnu.org/software/bison/>. `bison` for Windows can be downloaded from <http://gnuwin32.sourceforge.net/packages/bison.htm>. Download the package labeled “Complete package, excluding sources”. On Windows, the default location for `bison` is the `C:\Program Files\GnuWin32` directory. Some utilities may fail to find `bison` because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space; for example `C:\GnuWin32`.

- On OpenSolaris and Solaris Express, `m4` must be installed in addition to `bison`. `m4` is available from <http://www.gnu.org/software/m4/>.

Note

If you have to install any programs, modify your `PATH` environment variable to include any directories in which the programs are located. See [Section 4.2.10](#), “Setting Environment Variables”.

If you run into problems and need to file a bug report, please use the instructions in [Section 1.6](#), “How to Report Bugs or Problems”.

2.9.1 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under `/usr/local/mysql`. The component locations under the installation directory are the same as for binary distributions. See [Table 2.3](#), “MySQL Installation Layout for Generic Unix/Linux Binary Package”, and [Section 2.3.1](#), “MySQL Installation Layout on Microsoft Windows”. To configure installation locations different from the defaults, use the options described at [Section 2.9.4](#), “MySQL Source-Configuration Options”.

2.9.2 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at [Section 2.9](#), “Installing MySQL from Source”.
2. Obtain a distribution file using the instructions in [Section 2.1.2](#), “How to Get MySQL”.
3. Configure, build, and install the distribution using the instructions in this section.

4. Perform postinstallation procedures using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

In MySQL 5.6, `CMake` is used as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using `CMake` to build MySQL, see [How to Build MySQL Server with CMake](#).

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#).

The sequence for installation from a compressed `tar` file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#)), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:

```
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> mkdir bld
shell> cd bld
shell> cmake ..
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cd /usr/local/mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

`mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. For more information, see [Section 5.1.2.2, “Using a Sample Default Server Configuration File”](#).

A more detailed version of the source-build specific instructions is shown following.

Note

The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.10, “Postinstallation Setup and Testing”](#), for postinstallation setup and testing.

Perform Preconfiguration Setup

On Unix, set up the `mysql` user and group that will be used to run and execute the MySQL server and own the database directory. For details, see [Creating a mysql System User and Group](#), in [Section 2.2](#),

“Installing MySQL on Unix/Linux Using Generic Binaries”. Then perform the following steps as the `mysql` user, except as noted.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in [Section 2.1.2, “How to Get MySQL”](#).

Unpack the distribution into the current directory:

- To unpack a compressed `tar` file, `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf mysql-VERSION.tar.gz
```

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it:

```
shell> gunzip < mysql-VERSION.tar.gz | tar xvf -
```

Alternatively, `CMake` can uncompress and unpack the distribution:

```
shell> cmake -E tar zxvf mysql-VERSION.tar.gz
```

- To unpack a Zip archive, use `WinZip` or another tool that can read `.zip` files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Build out of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `bld` at the same level. Create the directory and go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ../mysql-src
```

The build directory needs not be outside the source tree. For example, you can build in a directory named `bld` under the top-level source tree. To do this, starting with `mysql-src` as your current working directory, create the directory `bld` and then go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree. The following instructions assume this second strategy.

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
shell> cmake .. -G "Visual Studio 12 2013"
shell> cmake .. -G "Visual Studio 12 2013 Win64"
```

On OS X, to use the Xcode IDE:

```
shell> cmake .. -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- `-DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.
- `-DCPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.
- `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

To list the configuration options, use one of the following commands:

```
shell> cmake .. -L      # overview
shell> cmake .. -LH     # overview with help text
shell> cmake .. -LAH    # all params with help text
shell> cmake ..         # interactive display
```

If `CMake` fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands in the build directory on Unix before re-running `CMake`:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you are going to send mail to a MySQL mailing list to ask for configuration assistance, first check the files in the [CMakeFiles](#) directory for useful information about the failure. To file a bug report, please use the instructions in [Section 1.6, “How to Report Bugs or Problems”](#).

Build the Distribution

On Unix:

```
shell> make
shell> make VERBOSE=1
```

The second command sets `VERBOSE` to show the commands for each compiled source.

Use `gmake` instead on systems where you are using GNU `make` and it has been installed as `gmake`.

On Windows:

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

If you have gotten to the compilation stage, but the distribution does not build, see [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#), for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

Install the Distribution

On Unix:

```
shell> make install
```

This installs the files under the configured installation directory (by default, `/usr/local/mysql`). You might need to run the command as `root`.

To install in a specific directory, add a `DESTDIR` parameter to the command line:

```
shell> make install DESTDIR="/opt/mysql"
```

Alternatively, generate installation package files that you can install where you like:

```
shell> make package
```

This operation produces one or more `.tar.gz` files that can be installed like generic binary distribution packages. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). If you run `CMake` with `-DCPACK_MONOLITHIC_INSTALL=1`, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a `.zip` archive installation package:

```
shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database
shell> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting `.zip` archive where you like. See [Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”](#).

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see [Section 2.10, “Postinstallation Setup and Testing”](#).

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

2.9.3 Installing MySQL Using a Development Source Tree

This section describes how to install MySQL from the latest development source code, which is hosted on [GitHub](#). To obtain the MySQL Server source code from this repository hosting service, you can set up a local MySQL Git repository.

On [GitHub](#), MySQL Server and other MySQL projects are found on the [MySQL](#) page. The MySQL Server project is a single repository that contains branches for several MySQL series.

MySQL officially joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the announcement on the MySQL Release Engineering blog: [MySQL on GitHub](#)

Prerequisites for Installing from Development Source

To install MySQL from a development source tree, your system must satisfy the tool requirements outlined in [Section 2.9, “Installing MySQL from Source”](#).

Setting Up a MySQL Git Repository

To set up a MySQL Git repository on your machine, use this procedure:

1. Clone the MySQL Git repository to your machine. The following command clones the MySQL Git repository to a directory named `mysql-server`. The initial download will take some time to complete, depending on the speed of your connection.

```
~$ git clone https://github.com/mysql/mysql-server.git
Cloning into 'mysql-server'...
remote: Counting objects: 1035465, done.
remote: Total 1035465 (delta 0), reused 0 (delta 0)
Receiving objects: 100% (1035465/1035465), 437.48 MiB | 5.10 MiB/s, done.
Resolving deltas: 100% (855607/855607), done.
Checking connectivity... done.
Checking out files: 100% (21902/21902), done.
```

2. When the clone operation completes, the contents of your local MySQL Git repository appear similar to the following:

```
~$ cd mysql-server

~/mysql-server$ ls
BUILD          COPYING        libmysqld     regex         tests
BUILD-CMAKE    debug          libservices   scripts       unittest
client         Docs           man           sql           VERSION
cmake          extra          mysql-test    sql-bench     vio
CMakeLists.txt include        mysys         sql-common    win
cmd-line-utils INSTALL-SOURCE packaging      storage       zlib
```

| | | | |
|-----------------|--------------------|--------|---------------|
| config.h.cmake | INSTALL-WIN-SOURCE | plugin | strings |
| configure.cmake | libmysql | README | support-files |

3. Use the `git branch -r` command to view the remote tracking branches for the MySQL repository.

```
~/mysql-server$ git branch -r
origin/5.5
origin/5.6
origin/5.7
origin/HEAD -> origin/5.7
origin/cluster-7.2
origin/cluster-7.3
origin/cluster-7.4
```

4. To view the branches that are checked out in your local repository, issue the `git branch` command. When you cloned the MySQL Git repository, the MySQL 5.7 branch was checked out automatically. The asterisk identifies the 5.7 branch as the active branch.

```
~/mysql-server$ git branch
* 5.7
```

5. To check out a different MySQL branch, run the `git checkout` command, specifying the branch name. For example, to checkout the MySQL 5.6 branch:

```
~/mysql-server$ git checkout 5.6
Branch 5.6 set up to track remote branch 5.6 from origin.
Switched to a new branch '5.6'
```

6. Run `git branch` again to verify that the MySQL 5.6 branch is present. MySQL 5.6, which is the last branch you checked out, is marked by an asterisk indicating that it is the active branch.

```
~/mysql-server$ git branch
* 5.6
5.7
```

The `git checkout` command is also used to switch branches. For example, to make MySQL 5.7 the active branch again, you would run `git checkout 5.7`.

7. To obtain changes made after your initial setup of the MySQL Git repository, switch to the branch you want to update and issue the `git pull` command:

```
~/mysql-server$ git checkout 5.6
~/mysql-server$ git pull
```

To examine the commit history, use the `git log` option:

```
~/mysql-server$ git log
```

You can also browse commit history and source code on the GitHub [MySQL](#) site.

If you see changes or code that you have a question about, send an email to the MySQL [internals](#) mailing list. See [Section 1.5.1, “MySQL Mailing Lists”](#). For information about contributing a patch, see [Contributing to MySQL Server](#).

8. After you have cloned the MySQL Git repository and have checked out the branch you want to build, you can build MySQL Server from the source code. Instructions are provided in [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#), except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL

installed and do not want to overwrite it, run `CMake` with values for the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See [Section 24.1.2, “The MySQL Test Suite”](#).

2.9.4 MySQL Source-Configuration Options

The `CMake` program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the `CMake` command line. For information about options supported by `CMake`, run either of these commands in the top-level source directory:

```
shell> cmake . -LH
shell> cmake .
```

You can also affect `CMake` using certain environment variables. See [Section 4.9, “MySQL Program Environment Variables”](#).

The following table shows the available `CMake` options. In the `Default` column, `PREFIX` stands for the value of the `CMAKE_INSTALL_PREFIX` option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

Table 2.11 MySQL Source-Configuration Option Reference (`CMake`)

| Formats | Description | Default | Introduced | Removed |
|---------------------------------------|---|--------------------------------|------------|---------|
| <code>BUILD_CONFIG</code> | Use same build options as official releases | | | |
| <code>CMAKE_BUILD_TYPE</code> | Type of build to produce | <code>RelWithDebInfo</code> | | |
| <code>CMAKE_CXX_FLAGS</code> | Flags for C++ Compiler | | | |
| <code>CMAKE_C_FLAGS</code> | Flags for C Compiler | | | |
| <code>CMAKE_INSTALL_PREFIX</code> | Installation base directory | <code>/usr/local/mysql</code> | | |
| <code>COMPILATION_COMMENT</code> | Comment about compilation environment | | | |
| <code>CPACK_MONOLITHIC_INSTALL</code> | Whether package build produces single file | <code>OFF</code> | | |
| <code>DEFAULT_CHARSET</code> | The default server character set | <code>latin1</code> | | |
| <code>DEFAULT_COLLATION</code> | The default server collation | <code>latin1_swedish_ci</code> | | |
| <code>-DWITH_SYMVER16</code> | Whether <code>libmysqlclient.so.18</code> contains both symver 16 and 18 symbols. | <code>OFF</code> | 5.6.31 | |
| <code>ENABLED_LOCAL_INFILE</code> | Whether to enable LOCAL for LOAD DATA INFILE | <code>OFF</code> | | |
| <code>ENABLED_PROFILING</code> | Whether to enable query profiling code | <code>ON</code> | | |
| <code>ENABLE_DEBUG_SYNC</code> | Whether to enable Debug Sync support | <code>ON</code> | | 5.6.36 |

MySQL Source-Configuration Options

| Formats | Description | Default | Introduced | Removed |
|--|--|--------------------------------------|------------|---------|
| ENABLE_DOWNLOADS | Whether to download optional files | OFF | | |
| ENABLE_DTRACE | Whether to include DTrace support | | | |
| ENABLE_GCOV | Whether to include gcov support | | 5.6.3 | |
| ENABLE_GPROF | Enable gprof (optimized Linux builds only) | OFF | 5.6.6 | |
| IGNORE_AIO_CHECK | With -DBUILD_CONFIG=mysql_release, ignore libaio check | OFF | 5.6.1 | |
| INNODB_PAGE_ATOMIC_REF_COUNTING | Enable or disable atomic page reference counting | ON | 5.6.16 | |
| INSTALL_BINDIR | User executables directory | PREFIX/bin | | |
| INSTALL_DOCDIR | Documentation directory | PREFIX/docs | | |
| INSTALL_DOCREADMEDIR | README file directory | PREFIX | | |
| INSTALL_INCLUDEDIR | Header file directory | PREFIX/include | | |
| INSTALL_INFODIR | Info file directory | PREFIX/docs | | |
| INSTALL_LAYOUT | Select predefined installation layout | STANDALONE | | |
| INSTALL_LIBDIR | Library file directory | PREFIX/lib | | |
| INSTALL_MANDIR | Manual page directory | PREFIX/man | | |
| INSTALL_MYSQLSHAREDIR | Shared data directory | PREFIX/share | | |
| INSTALL_MYSQLTESTDIR | mysql-test directory | PREFIX/mysql-test | | |
| INSTALL_PLUGINDIR | Plugin directory | PREFIX/lib/plugin | | |
| INSTALL_SBINDIR | Server executable directory | PREFIX/bin | | |
| INSTALL_SCRIPTDIR | Scripts directory | PREFIX/scripts | | |
| INSTALL_SECURE_FILE_PRIV_DEFAULT | secure_file_priv default value | platform specific | 5.6.34 | |
| INSTALL_SECURE_FILE_PRIV_DEFAULT_LIBMYSQLD | secure_file_priv default value for libmysqld | | 5.6.34 | |
| INSTALL_SHAREDIR | aclocal/mysql.m4 installation directory | PREFIX/share | | |
| INSTALL_SQLBENCHDIR | sql-bench directory | PREFIX | | |
| INSTALL_SUPPORTFILES | Extra support files directory | PREFIX/support-files | | |
| MEMCACHED_HOME | Path to memcached | [none] | | |
| MYSQL_DATADIR | Data directory | | | |

| Formats | Description | Default | Introduced | Removed |
|--|---|------------------------------|------------|---------|
| <code>MYSQL_MAINTAINER_MODE</code> | Whether to enable MySQL maintainer-specific development environment | <code>OFF</code> | | |
| <code>MYSQL_PROJECT_NAME</code> | Windows/OS X project name | <code>MySQL</code> | 5.6.5 | |
| <code>MYSQL_TCP_PORT</code> | TCP/IP port number | <code>3306</code> | | |
| <code>MYSQL_UNIX_ADDR</code> | Unix socket file | <code>/tmp/mysql.sock</code> | | |
| <code>ODBC_INCLUDES</code> | ODBC includes directory | | | |
| <code>ODBC_LIB_DIR</code> | ODBC library directory | | | |
| <code>OPTIMIZER_TRACE</code> | Whether to support optimizer tracing | | 5.6.3 | |
| <code>SUNPRO_CXX_LIBRARY</code> | Client link library on Solaris 10+ | | 5.6.20 | |
| <code>SYSCONFDIR</code> | Option file directory | | | |
| <code>TMPDIR</code> | tmpdir default value | | 5.6.16 | |
| <code>WITHOUT_SERVER</code> | Do not build the server | <code>OFF</code> | | |
| <code>WITHOUT_XXX_STORAGE_ENGINE</code> | Exclude storage engine xxx from build | | | |
| <code>WITH_ASAN</code> | Enable AddressSanitizer | <code>OFF</code> | 5.6.15 | |
| <code>WITH_BUNDLED_LIBEVENT</code> | Use bundled libevent when building ndbmemcache | <code>ON</code> | | |
| <code>WITH_BUNDLED_MEMCACHED</code> | Use bundled memcached when building ndbmemcache | <code>ON</code> | | |
| <code>WITH_CLASSPATH</code> | Classpath to use when building MySQL Cluster Connector for Java. Default is an empty string. | | | |
| <code>WITH_DEBUG</code> | Whether to include debugging support | <code>OFF</code> | | |
| <code>WITH_DEFAULT_COMPILER_OPTIONS</code> | Whether to use default compiler options | <code>ON</code> | 5.6.6 | |
| <code>WITH_DEFAULT_FEATURE_SET</code> | Whether to use default feature set | <code>ON</code> | 5.6.6 | |
| <code>WITH_EDITLINE</code> | Which libedit/editline library to use | <code>bundled</code> | 5.6.12 | |
| <code>WITH_EMBEDDED_SERVER</code> | Whether to build embedded server | <code>OFF</code> | | |
| <code>WITH_EMBEDDED_SHARED_LIBRARY</code> | Whether to build a shared embedded server library | <code>OFF</code> | 5.6.17 | |
| <code>WITH_ERROR_INSERT</code> | Enable error injection in the NDB storage engine. Should not be used for building binaries intended for production. | <code>OFF</code> | | |

| Formats | Description | Default | Introduced | Removed |
|---|---|----------------------|------------|---------|
| <code>WITH_EXTRA_CHARSETS</code> | Which extra character sets to include | <code>all</code> | | |
| <code>WITH_INNODB_MEMCACHED</code> | Whether to generate memcached shared libraries. | <code>OFF</code> | | |
| <code>WITH_LIBEDIT</code> | Use bundled libedit library | <code>ON</code> | | 5.6.12 |
| <code>WITH_LIBEVENT</code> | Which libevent library to use | <code>bundled</code> | 5.6.6 | |
| <code>WITH_LIBWRAP</code> | Whether to include libwrap (TCP wrappers) support | <code>OFF</code> | | |
| <code>WITH_NDBCLUSTER</code> | Build the NDB storage engine; alias for <code>WITH_NDBCLUSTER_STORAGE_ENGINE</code> | <code>ON</code> | | |
| <code>WITH_NDBCLUSTER_STORAGE_ENGINE</code> | Build the NDB storage engine | <code>ON</code> | | |
| <code>WITH_NDBMTD</code> | Build multi-threaded data node. | <code>ON</code> | | |
| <code>WITH_NDB_BINLOG</code> | Enable binary logging by default by mysqld. | <code>ON</code> | | |
| <code>WITH_NDB_DEBUG</code> | Produce a debug build for testing or troubleshooting. | <code>OFF</code> | | |
| <code>WITH_NDB_JAVA</code> | Enable building of Java and ClusterJ support. Enabled by default. Supported in MySQL Cluster only. | <code>ON</code> | | |
| <code>WITH_NDB_PORT</code> | Default port used by a management server built with this option. If this option was not used to build it, the management server's default port is 1186. | <code>[none]</code> | | |
| <code>WITH_NDB_TEST</code> | Include NDB API test programs. | <code>OFF</code> | | |
| <code>WITH_NUMA</code> | Set NUMA memory allocation policy | | 5.6.27 | |
| <code>WITH_READLINE</code> | Use bundled readline library | <code>OFF</code> | | 5.6.5 |
| <code>WITH_SSL</code> | Type of SSL support | <code>bundled</code> | | |
| <code>WITH_UNIXODBC</code> | Enable unixODBC support | <code>OFF</code> | | |
| <code>WITH_VALGRIND</code> | Whether to compile in Valgrind header files | <code>OFF</code> | | |
| <code>WITH_ZLIB</code> | Type of zlib support | <code>bundled</code> | | |
| <code>WITH_xxx_STORAGE_ENGINE</code> | Compile storage engine xxx statically into server | | | |

The following sections provide more information about [CMake](#) options.

- [General Options](#)
- [Installation Layout Options](#)

- [Storage Engine Options](#)
- [Feature Options](#)
- [Compiler Flags](#)
- [CMake Options for Compiling MySQL Cluster](#)

For boolean options, the value may be specified as 1 or [ON](#) to enable the option, or as 0 or [OFF](#) to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the [CMAKE_INSTALL_PREFIX](#), [MYSQL_TCP_PORT](#), and [MYSQL_UNIX_ADDR](#) options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the [--basedir](#), [--port](#), and [--socket](#) options for [mysqld](#). Where applicable, configuration option descriptions indicate the corresponding [mysqld](#) startup option.

General Options

- [-DBUILD_CONFIG=mysql_release](#)

This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- [-DCMAKE_BUILD_TYPE=type](#)

The type of build to produce:

- [RelWithDebInfo](#): Enable optimizations and generate debugging information. This is the default MySQL build type.
- [Debug](#): Disable optimizations and generate debugging information. This build type is also used if the [WITH_DEBUG](#) option is enabled. That is, [-DWITH_DEBUG=1](#) has the same effect as [-DCMAKE_BUILD_TYPE=Debug](#).

- [-DCPACK_MONOLITHIC_INSTALL=bool](#)

This option affects whether the [make package](#) operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

Installation Layout Options

The [CMAKE_INSTALL_PREFIX](#) option indicates the base installation directory. Other options with names of the form [INSTALL_xxx](#) that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

- [-DCMAKE_INSTALL_PREFIX=dir_name](#)

The installation base directory.

This value can be set at server startup with the [--basedir](#) option.

- [-DINSTALL_BINDIR=dir_name](#)

Where to install user programs.

- [-DINSTALL_DOCDIR=dir_name](#)

Where to install documentation.

- `-DINSTALL_DOCREADMEDIR=dir_name`

Where to install `README` files.

- `-DINSTALL_INCLUDEDIR=dir_name`

Where to install header files.

- `-DINSTALL_INFODIR=dir_name`

Where to install Info files.

- `-DINSTALL_LAYOUT=name`

Select a predefined installation layout:

- `STANDALONE`: Same layout as used for `.tar.gz` and `.zip` packages. This is the default.
- `RPM`: Layout similar to RPM packages.
- `SVR4`: Solaris package layout.
- `DEB`: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
shell> cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

- `-DINSTALL_LIBDIR=dir_name`

Where to install library files.

- `-DINSTALL_MANDIR=dir_name`

Where to install manual pages.

- `-DINSTALL_MYSQLSHAREDIR=dir_name`

Where to install shared data files.

- `-DINSTALL_MYSQLTESTDIR=dir_name`

Where to install the `mysql-test` directory. As of MySQL 5.6.12, to suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_MYSQLTESTDIR=`).

- `-DINSTALL_PLUGINDIR=dir_name`

The location of the plugin directory.

This value can be set at server startup with the `--plugin_dir` option.

- `-DINSTALL_SBINDIR=dir_name`

Where to install the `mysqld` server.

- `-DINSTALL_SCRIPTDIR=dir_name`

Where to install `mysql_install_db`.

- `-DINSTALL_SECURE_FILE_PRIVDIR=dir_name`

The default value for the `secure_file_priv` system variable. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option; see the description of the `secure_file_priv` system variable in [Section 5.1.5, “Server System Variables”](#).

This option was added in MySQL 5.6.34. To set the value for the `libmysqld` embedded server, use `INSTALL_SECURE_FILE_PRIV_EMBEDDEDIR`.

- `-DINSTALL_SECURE_FILE_PRIV_EMBEDDEDIR=dir_name`

The default value for the `secure_file_priv` system variable, for the `libmysqld` embedded server. This option was added in MySQL 5.6.34.

- `-DINSTALL_SHAREDIR=dir_name`

Where to install `aclocal/mysql.m4`.

- `-DINSTALL_SQLBENCHDIR=dir_name`

Where to install the `sql-bench` directory. To suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_SQLBENCHDIR=`).

- `-DINSTALL_SUPPORTFILESDIR=dir_name`

Where to install extra support files.

- `-DMYSQL_DATADIR=dir_name`

The location of the MySQL data directory.

This value can be set at server startup with the `--datadir` option.

- `-DODBC_INCLUDES=dir_name`

The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- `-DODBC_LIB_DIR=dir_name`

The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

- `-DSYSCONFDIR=dir_name`

The default `my.cnf` option file directory.

This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=file_name` option, where `file_name` is the full path name to the file.

- `-DTMPDIR=dir_name`

The default location to use for the `tmpdir` system variable. If unspecified, the value defaults to `P_tmpdir` in `<stdio.h>`. This option was added in MySQL 5.6.16.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the [INSTALL](#)

`PLUGIN` statement or the `--plugin-load` option before it can be used). Some plugins might not support static or dynamic building.

The `InnoDB`, `MyISAM`, `MERGE`, `MEMORY`, and `CSV` engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use `-DWITH_engine_STORAGE_ENGINE=1`. Some permissible `engine` values are `ARCHIVE`, `BLACKHOLE`, `EXAMPLE`, `FEDERATED`, `NDB` or `NDBCLUSTER` (`NDB`), `PARTITION` (partitioning support), and `PERFSCHEMA` (Performance Schema). Examples:

```
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
-DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Note

`WITH_NDBCLUSTER_STORAGE_ENGINE` is supported only when building MySQL Cluster using the MySQL Cluster sources. It cannot be used to enable clustering support in other MySQL source trees or distributions. In MySQL Cluster source distributions, it is enabled by default. See [Section 18.2.2.4, “Building NDB Cluster from Source on Linux”](#), and [Section 18.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”](#), for more information.

To exclude a storage engine from the build, use `-DWITHOUT_engine_STORAGE_ENGINE=1`. Examples:

```
-DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
-DWITHOUT_FEDERATED_STORAGE_ENGINE=1
-DWITHOUT_PARTITION_STORAGE_ENGINE=1
```

If neither `-DWITH_engine_STORAGE_ENGINE` nor `-DWITHOUT_engine_STORAGE_ENGINE` are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

Feature Options

- `-DCOMPILATION_COMMENT=string`

A descriptive comment about the compilation environment.

- `-DDEFAULT_CHARSET=charset_name`

The server character set. By default, MySQL uses the `latin1` (cp1252 West European) character set.

`charset_name` may be one of `binary`, `armscii8`, `ascii`, `big5`, `cp1250`, `cp1251`, `cp1256`, `cp1257`, `cp850`, `cp852`, `cp866`, `cp932`, `dec8`, `eucjpms`, `euckr`, `gb2312`, `gbk`, `geostd8`, `greek`, `hebrew`, `hp8`, `keybcs2`, `koi8r`, `koi8u`, `latin1`, `latin2`, `latin5`, `latin7`, `macce`, `macroman`, `sjis`, `swe7`, `tis620`, `ucs2`, `ujis`, `utf8`, `utf8mb4`, `utf16`, `utf16le`, `utf32`. The permissible character sets are listed in the `cmake/character_sets.cmake` file as the value of `CHARSETS_AVAILABLE`.

This value can be set at server startup with the `--character_set_server` option.

- `-DDEFAULT_COLLATION=collation_name`

The server collation. By default, MySQL uses `latin1_swedish_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set.

This value can be set at server startup with the `--collation_server` option.

- `-DENABLE_DEBUG_SYNC=bool`

**Note**

As of MySQL 5.6.36, `ENABLE_DEBUG_SYNC` is removed and enabling `WITH_DEBUG` enables Debug Sync.

Whether to compile the Debug Sync facility into the server. This facility is used for testing and debugging. This option is enabled by default, but has no effect unless MySQL is configured with debugging enabled. If debugging is enabled and you want to disable Debug Sync, use `-DENABLE_DEBUG_SYNC=0`.

When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysqld` with the `--debug-sync-timeout=N` option, where *N* is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) *N* becomes the default timeout for individual synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `-DENABLE_DOWNLOADS=bool`

Whether to download optional files. For example, with this option enabled, `CMake` downloads the Google Test distribution that is used by the test suite to run unit tests.

- `-DENABLE_DTRACE=bool`

Whether to include support for DTrace probes. For information about DTrace, see [Section 5.7, “Tracing mysqld Using DTrace”](#)

- `-DENABLE_GCOV=bool`

Whether to include gcov support (Linux only).

- `-DENABLE_GPROF=bool`

Whether to enable `gprof` (optimized Linux builds only). This option was added in MySQL 5.6.6.

- `-DENABLED_LOCAL_INFILE=bool`

Whether to enable `LOCAL` capability in the client library for `LOAD DATA INFILE`.

This option controls client-side `LOCAL` capability, but the capability can be set on the server side at server startup with the `--local-infile` option. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

- `-DENABLED_PROFILING=bool`

Whether to enable query profiling code (for the `SHOW PROFILE` and `SHOW PROFILES` statements).

- `-DIGNORE_AIO_CHECK=bool`

If the `-DBUILD_CONFIG=mysql_release` option is given on Linux, the `libaio` library must be linked in by default. If you do not have `libaio` or do not want to install it, you can suppress the check for it by specifying `-DIGNORE_AIO_CHECK=1`. This option was added in MySQL 5.6.1.

- `-DINNODB_PAGE_ATOMIC_REF_COUNT=bool`

Whether to enable or disable atomic page reference counting. Fetching and releasing pages from the buffer pool and tracking the page state are expensive and complex operations. Using a page mutex to track these operations does not scale well. With `INNODB_PAGE_ATOMIC_REF_COUNT=ON` (default), fetch and release is tracked using atomics where available. For platforms that do not support atomics, set `INNODB_PAGE_ATOMIC_REF_COUNT=OFF` to disable atomic page reference counting.

When atomic page reference counting is enabled (default), “[Note] InnoDB: Using atomics to ref count buffer pool pages” is printed to the error log at server startup. If atomic page reference counting is disabled, “[Note] InnoDB: Using mutexes to ref count buffer pool pages” is printed instead.

`INNODB_PAGE_ATOMIC_REF_COUNT` was introduced with the fix for MySQL Bug #68079. The option is removed in MySQL 5.7.5. Support for atomics is required to build MySQL as of MySQL 5.7.5, which makes the option obsolete.

- `-DMYSQL_MAINTAINER_MODE=bool`

Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors. It may also cause some minor changes in generated code, to initialize some variables to 0.

- `-DMYSQL_PROJECT_NAME=name`

For Windows or OS X, the project name to incorporate into the project file name. This option was added in MySQL 5.6.5.

- `-DMYSQL_TCP_PORT=port_num`

The port number on which the server listens for TCP/IP connections. The default is 3306.

This value can be set at server startup with the `--port` option.

- `-DMYSQL_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.

This value can be set at server startup with the `--socket` option.

- `-DOPTIMIZER_TRACE=bool`

Whether to support optimizer tracing. See [MySQL Internals: Tracing the Optimizer](#). This option was added in MySQL 5.6.3.

- `-DWITH_ASAN=bool`

Whether to enable AddressSanitizer, for compilers that support it. The default is off. This option was added in MySQL 5.6.15.

- `-DWITH_DEBUG=bool`

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

As of MySQL 5.6.36, enabling `WITH_DEBUG` also enables Debug Sync. For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `-DWITH_DEFAULT_FEATURE_SET=bool`

Whether to use the flags from `cmake/build_configurations/feature_set.cmake`. This option was added in MySQL 5.6.6.

- `-DWITH_EDITLINE=value`

Which `libedit/editline` library to use. The permitted values are `bundled` (the default) and `system`.

`WITH_EDITLINE` was added in MySQL 5.6.12. It replaces `WITH_LIBEDIT`, which has been removed.

- `-DWITH_EMBEDDED_SERVER=bool`

Whether to build the `libmysqld` embedded server library.

- `-DWITH_EMBEDDED_SHARED_LIBRARY=bool`

Whether to build a shared `libmysqld` embedded server library. This option was added in MySQL 5.6.17.

- `-DWITH_EXTRA_CHARSETS=name`

Which extra character sets to include:

- `all`: All character sets. This is the default.
- `complex`: Complex character sets.
- `none`: No extra character sets.

- `-DWITH_INNODB_MEMCACHED=bool`

Whether to generate memcached shared libraries (`libmemcached.so` and `innodb_engine.so`).

- `-DWITH_LIBEVENT=string`

Which `libevent` library to use. Permitted values are `bundled` (default), `system`, and `yes`. If you specify `system` or `yes`, the system `libevent` library is used if present. If the system library is not found, the bundled `libevent` library is used. The `libevent` library is required by InnoDB memcached.

- `-DWITH_LIBEDIT=bool`

Whether to use the `libedit` library bundled with the distribution.

`WITH_LIBEDIT` was removed in MySQL 5.6.12. Use `WITH_EDITLINE` instead.

- `-DWITH_LIBWRAP=bool`

Whether to include `libwrap` (TCP wrappers) support.

- `-DWITH_NUMA=bool`

Explicitly set the NUMA memory allocation policy. `CMake` sets the default `WITH_NUMA` value based on whether the current platform has NUMA support. For platforms without NUMA support, `CMake` behaves as follows:

- With no NUMA option (the normal case), `CMake` continues normally, producing only this warning: NUMA library missing or required version not available
- With `-DWITH_NUMA=ON`, `CMake` aborts with this error: NUMA library missing or required version not available

This option was added in MySQL 5.6.27.

- `-DWITH_READLINE=bool`

Whether to use the `readline` library bundled with the distribution. This option was removed in MySQL 5.6.5 because `readline` is no longer bundled.

- `-DWITH_SSL={ssl_type|path_name}`
- The type of SSL support to include (if any) or the path name to the OpenSSL installation to use.
 - `ssl_type` can be one of the following values:
 - `no`: No SSL support. This is the default before MySQL 5.6.6. As of 5.6.6, this is no longer a permitted value and the default is `bundled`.
 - `yes`: Use the system SSL library if present, else the library bundled with the distribution.
 - `bundled`: Use the SSL library bundled with the distribution. This is the default as of MySQL 5.6.6.
 - `system`: Use the system SSL library.
 - `path_name`, permitted for MySQL 5.6.7 and after, is the path name to the OpenSSL installation to use. Using this can be preferable to using the `ssl_type` value of `system`, for it can prevent CMake from detecting and using an older or incorrect OpenSSL version installed on the system. (Another permitted way to do the same thing is to set the `CMAKE_PREFIX_PATH` option to `path_name`.)

For information about using SSL support, see [Section 6.4, “Using Secure Connections”](#).

- `-DWITH_SYMVER16=bool`

If enabled, this option causes the `libmysqlclient` client library to contain extra symbols to be compatible with `libmysqlclient` on RHEL/OEL 5, 6, and 7; and Fedora releases. All symbols present in `libmysqlclient.so.16` are tagged with symver 16 in `libmysqlclient.so.18`, making those symbols have both symver 16 and 18. The default is `OFF`.

This option was added in MySQL 5.6.31.

- `-DWITH_UNIXODBC=1`

Enables unixODBC support, for Connector/ODBC.

- `-DWITH_VALGRIND=bool`

Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is `OFF`.

To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with `-DWITH_DEBUG=1`. See [Building Debug Configurations](#).

- `-DWITH_ZLIB=zlib_type`

Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `WITH_ZLIB` indicates the source of `zlib` support:

- `bundled`: Use the `zlib` library bundled with the distribution. This is the default.
- `system`: Use the system `zlib` library.
- `-DWITHOUT_SERVER=bool`

Whether to build without the MySQL server. The default is `OFF`, which does build the server.

Compiler Flags

- `-DCMAKE_C_FLAGS="flags"`

Flags for the C Compiler.

- `-DCMAKE_CXX_FLAGS="flags"`

Flags for the C++ Compiler.

- `-DWITH_DEFAULT_COMPILER_OPTIONS=bool`

Whether to use the flags from `cmake/build_configurations/compiler_options.cmake`. This option was added in MySQL 5.6.6.

Note

All optimization flags were carefully chosen and tested by the MySQL build team. Overriding them can lead to unexpected results and is done at your own risk.

- `-DSUNPRO_CXX_LIBRARY="lib_name"`

Enable linking against `libCstd` instead of `stlport4` on Solaris 10 or later. This works only for client code because the server depends on C++98. Example usage:

```
cmake -DWITHOUT_SERVER=1 -DSUNPRO_CXX_LIBRARY=Cstd
```

This option was added in MySQL 5.6.20.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

```
shell> mkdir bld
shell> cd bld
shell> cmake .. -DCMAKE_C_FLAGS=-m32 \
               -DCMAKE_CXX_FLAGS=-m32 \
               -DCMAKE_BUILD_TYPE=RelWithDebInfo
```

If you set flags that affect optimization (`-Onumber`), you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where `build_type` corresponds

to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (`RelWithDebInfo`) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```
shell> cmake .. -DCMAKE_C_FLAGS_RELWITHDEBINFO="-O3 -g" \
          -DCMAKE_CXX_FLAGS_RELWITHDEBINFO="-O3 -g"
```

CMake Options for Compiling MySQL Cluster

The following options are for use when building MySQL Cluster with the MySQL Cluster sources; they are not currently supported when using sources from the MySQL 5.6 Server tree.

- `-DMEMCACHED_HOME=dir_name`

Perform the build using the memcached (version 1.6 or later) installed in the system directory indicated by `dir_name`. Files from this installation that are used in the build include the memcached binary, header files, and libraries, as well as the `memcached_utilities` library and the header file `engine_testapp.h`.

You must leave this option unset when building `ndbmemcache` using the bundled memcached sources (`WITH_BUNDLED_MEMCACHED` option); in other words, the bundled sources are used by default).

This option was added in MySQL NDB Cluster 7.2.2.

While additional CMake options—such as for SASL authorization and for providing `dtrace` support—are available for use when compiling `memcached` from external sources, these options are currently not enabled for the `memcached` sources bundled with MySQL Cluster.

- `-DWITH_BUNDLED_LIBEVENT={ON|OFF}`

Use the `libevent` included in the MySQL Cluster sources when building MySQL Cluster with `ndbmemcached` support (MySQL NDB Cluster 7.2.2 and later). Enabled by default. OFF causes the system's `libevent` to be used instead.

- `-DWITH_BUNDLED_MEMCACHED={ON|OFF}`

Build the memcached sources included in the MySQL Cluster source tree (MySQL NDB Cluster 7.2.3 and later), then use the resulting memcached server when building the `ndbmemcache` engine. In this case, `make install` places the `memcached` binary in the installation `bin` directory, and the `ndbmemcache` engine shared library file `ndb_engine.so` in the installation `lib` directory.

This option is ON by default.

- `-DWITH_CLASSPATH=path`

Sets the classpath for building MySQL Cluster Connector for Java. The default is empty. In MySQL NDB Cluster 7.2.9 and later, this option is ignored if `-DWITH_NDB_JAVA=OFF` is used.

- `-DWITH_ERROR_INSERT={ON|OFF}`

Enables error injection in the `NDB` kernel. For testing only; not intended for use in building production binaries. The default is `OFF`.

- `-DWITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}`

Build and link in support for the `NDB` (`NDBCLUSTER`) storage engine in `mysqld`. The default is `ON`.

- `-DWITH_NDBCLUSTER={ON|OFF}`

This is an alias for `WITH_NDBCLUSTER_STORAGE_ENGINE`.

- `-DWITH_NDBMTD={ON|OFF}`

Build the multi-threaded data node executable `ndbmt.d`. The default is `ON`.

- `-DWITH_NDB_BINLOG={ON|OFF}`

Enable binary logging by default in the `mysqld` built using this option. `ON` by default.

- `-DWITH_NDB_DEBUG={ON|OFF}`

Enable building the debug versions of the MySQL Cluster binaries. `OFF` by default.

- `-DWITH_NDB_JAVA={ON|OFF}`

Enable building MySQL Cluster with Java support, including `ClusterJ`.

This option was added in MySQL NDB Cluster 7.2.9, and is `ON` by default. If you do not wish to compile MySQL Cluster with Java support, you must disable it explicitly by specifying `-DWITH_NDB_JAVA=OFF` when running `CMake`. Otherwise, if Java cannot be found, configuration of the build fails.

- `-DWITH_NDB_PORT=port`

Causes the MySQL Cluster management server (`ndb_mgmd`) that is built to use this `port` by default. If this option is unset, the resulting management server tries to use port 1186 by default.

- `-DWITH_NDB_TEST={ON|OFF}`

If enabled, include a set of NDB API test programs. The default is `OFF`.

2.9.5 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running `CMake`:

On Unix:

```
shell> make clean
shell> rm CMakeCache.txt
```

On Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running `CMake`. For instructions on building outside of the source tree, see [How to Build MySQL Server with CMake](#).

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define which C and C++ compilers to use, you can define the `CC` and `CXX` environment variables. For example:

```
shell> CC=gcc
shell> CXX=g++
shell> export CC CXX
```

To specify your own C and C++ compiler flags, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options. See [Compiler Flags](#).

To see what flags you might need to specify, invoke `mysql_config` with the `--cflags` and `--cxxflags` options.

- To see what commands are executed during the compile stage, after using `CMake` to configure MySQL, run `make VERBOSE=1` rather than just `make`.
- If compilation fails, check whether the `MYSQL_MAINTAINER_MODE` option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.
- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs.

GNU `make` 3.75 is known to work.

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install a recent version of `bison` (the GNU version of `yacc`) and use that instead.

Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of [bison](#).

For information about acquiring or updating tools, see the system requirements in [Section 2.9, “Installing MySQL from Source”](#).

2.9.6 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the [VERSION](#) file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 5.7.4-m14, the file looks like this:

```
MYSQL_VERSION_MAJOR=5
MYSQL_VERSION_MINOR=7
MYSQL_VERSION_PATCH=4
MYSQL_VERSION_EXTRA=-m14
```

If the source is not for a General Availability (GA) release, the [MYSQL_VERSION_EXTRA](#) value will be nonempty. For the example, the value corresponds to Milestone 14.

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

2.10 Postinstallation Setup and Testing

This section discusses tasks that you should perform after installing MySQL:

- If necessary, initialize the data directory and create the MySQL grant tables. For some MySQL installation methods, data directory initialization may be done for you automatically:
 - Installation on Windows
 - Installation on Linux using a server RPM or Debian distribution from Oracle.
 - Installation using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux, and others.
 - Installation on OS X using a DMG distribution.

For other platforms and installation types, including installation from generic binary and source distributions, you must initialize the data directory yourself. For instructions, see [Section 2.10.1, “Initializing the Data Directory”](#).

- For instructions, see [Section 2.10.2, “Starting the Server”](#), and [Section 2.10.3, “Testing the Server”](#).
- Assign passwords to any initial accounts in the grant tables, if that was not already done during data directory initialization. Passwords prevent unauthorized access to the MySQL server. You may also wish to restrict access to test databases. For instructions, see [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).
- Optionally, arrange for the server to start and stop automatically when your system starts and stops. For instructions, see [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).

- Optionally, populate time zone tables to enable recognition of named time zones. For instructions, see [Section 10.6, “MySQL Server Time Zone Support”](#).

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.3, “MySQL User Account Management”](#).

2.10.1 Initializing the Data Directory

After installing MySQL, you must initialize the data directory, including the tables in the `mysql` system database. For some MySQL installation methods, data directory initialization may be done automatically, as described in [Section 2.10, “Postinstallation Setup and Testing”](#). For other installation methods, including installation from generic binary and source distributions, you must initialize the data directory yourself.

This section describes how to initialize the data directory on Unix and Unix-like systems. (For Windows, see [Section 2.3.7, “Windows Postinstallation Procedures”](#).) For some suggested commands that you can use to test whether the server is accessible and working properly, see [Section 2.10.3, “Testing the Server”](#).

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server. For information about creating the account, see [Creating a `mysql` System User and Group](#), in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

1. Change location into the top-level directory of your MySQL installation, represented here by `BASEDIR`:

```
shell> cd BASEDIR
```

`BASEDIR` is likely to be something like `/usr/local/mysql`, `/usr/local`, or `/usr/bin` (for [installation with MySQL Yum repository](#), or other means). The following steps assume that you have changed location to this directory.

You will find several files and subdirectories in the `BASEDIR` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories, which contain the server as well as client and utility programs.

2. If necessary, ensure that the distribution contents are accessible to `mysql`. If you installed the distribution as `mysql`, no further action is required. If you installed the distribution as `root`, its contents will be owned by `root`. Change its ownership to `mysql` by executing the following commands as `root` in the installation directory. The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

3. If necessary, initialize the data directory, including the `mysql` database containing the initial MySQL grant tables that determine how users are permitted to connect to the server.

Typically, data directory initialization need be done only the first time you install MySQL. If you are upgrading an existing installation, you should run `mysql_upgrade` instead (see [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#)). However, the command that initializes the data directory does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

```
shell> scripts/mysql_install_db --user=mysql
```

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this if you run `mysql_install_db` as `root`, include the `--user` option as shown. Otherwise, you should execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

The `mysql_install_db` command creates the server's data directory. Under the data directory, it creates directories for the `mysql` database that holds the grant tables and the `test` database that you can use to test MySQL. The program also creates privilege table entries for the initial account or accounts. `test_`. For a complete listing and description of the grant tables, see [Section 6.2, "The MySQL Access Privilege System"](#).

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not identify the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql \
      --basedir=/opt/mysql/mysql \
      --datadir=/opt/mysql/mysql/data
```

For a more secure installation, invoke `mysql_install_db` with the `--random-passwords` option. This causes it to assign a random password to the MySQL `root` accounts, set the "password expired" flag for those accounts, and remove the anonymous-user MySQL accounts. For additional details, see [Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory"](#). (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

If you do not want to have the `test` database, you can remove it after starting the server, using the instructions in [Section 2.10.4, "Securing the Initial MySQL Accounts"](#).

If you have trouble with `mysql_install_db` at this point, see [Section 2.10.1.1, "Problems Running mysql_install_db"](#).

4. After initializing the data directory, you can establish the final installation ownership settings. To leave the installation owned by `mysql`, no action is required here. Otherwise, most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory. For some distribution types, the data directory might be named `var` rather than `data`; adjust the second command accordingly.

```
shell> chown -R root .
shell> chown -R mysql data
```

If the plugin directory (the directory named by the `plugin_dir` system variable) is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making the plugin directory read only to the server or by setting the `secure_file_priv` system variable at server startup to a directory where `SELECT` writes can be performed safely.

5. To specify options that the MySQL server should use at startup, put them in a `/etc/my.cnf` or `/etc/mysql/my.cnf` file. See [Section 5.1.2, "Server Configuration Defaults"](#). If you do not do this, the server starts with its default settings.
6. If you want MySQL to start automatically when you boot your machine, see [Section 2.10.5, "Starting and Stopping MySQL Automatically"](#).

Data directory initialization creates time zone tables in the `mysql` database but does not populate them. To do so, use the instructions in [Section 10.6, “MySQL Server Time Zone Support”](#).

2.10.1.1 Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` program is to initialize the data directory, including the tables in the `mysql` system database. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

To re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old
shell> scripts/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

```
Starting mysqld daemon with databases from XXXXXX
mysqld ended
```

In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` did not start. If you do not understand what happened, include the log when you post a bug report. See [Section 1.6, “How to Report Bugs or Problems”](#).

- **There is a `mysqld` process running**

This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once, when you first install MySQL.

- **Installing a second `mysqld` server does not work when one server is running**

This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

```
Can't start server: Bind on TCP/IP port:
Address already in use
Can't start server: Bind on unix socket...
```

For instructions on setting up multiple servers, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

- **You do not have write access to the `/tmp` directory**

If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory) or the `TMPDIR` environment variable, if it has been set, an error occurs when you run `mysql_install_db` or the `mysqld` server.

You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where *some_tmp_dir* is the full path name to some directory for which you have write permission:

```
shell> TMPDIR=/some_tmp_dir/  
shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock  
shell> export TMPDIR MYSQL_UNIX_PORT
```

Then you should be able to run `mysql_install_db` and start the server with these commands:

```
shell> scripts/mysql_install_db --user=mysql  
shell> bin/mysqld_safe --user=mysql &
```

If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

See [Section B.5.3.6, “How to Protect or Change the MySQL Unix Socket File”](#), and [Section 4.9, “MySQL Program Environment Variables”](#).

There are some alternatives to running the `mysql_install_db` program provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, use account-management statements such as `CREATE USER`, `GRANT`, and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary statements. (See [Section 13.7.1, “Account Management Statements”](#).)

To install MySQL on several machines with the same privileges, put the `CREATE USER`, `GRANT`, and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

```
shell> scripts/mysql_install_db --user=mysql  
shell> bin/mysql -u root < your_script_file
```

This enables you to avoid issuing the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you are just learning how to use `CREATE USER`, `GRANT`, and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

To re-create the grant tables, stop the server if it is running and remove the `mysql` database directory. Then run `mysql_install_db` again.

2.10.2 Starting the Server

This section describes how start the server on Unix and Unix-like systems. (For Windows, see [Section 2.3.5.4, “Starting the Server for the First Time”](#).) For some suggested commands that you can use to test whether the server is accessible and working properly, see [Section 2.10.3, “Testing the Server”](#).

Start the MySQL server like this:

```
shell> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this if you run `mysqld_safe` as `root`, include the `--user` option as shown. Otherwise, execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If the server is unable to access the data directory it starts or read the grant tables in the `mysql` database, it writes a message to its error log. Such problems can occur if you neglected to create the grant tables by initializing the data directory before proceeding to this step, or if you ran the command that initializes the data directory without the `--user` option. Remove the `data` directory and run the command with the `--user` option.

If you have other problems starting the server, see [Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”](#). For more information about `mysqld_safe`, see [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).

2.10.2.1 Troubleshooting Problems Starting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server. For additional suggestions for Windows systems, see [Section 2.3.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

If you have problems starting the server, here are some things to try:

- Check the [error log](#) to see why the server does not start. Log files are located in the [data directory](#) (typically `C:\Program Files\MySQL\MySQL Server 5.6\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. Use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables ([InnoDB](#), [NDB](#)), be sure that you have them configured the way you want before starting the server. If you are using [InnoDB](#) tables, see [Section 14.6, “InnoDB Configuration”](#) for guidelines and [Section 14.14, “InnoDB Startup Options and System Variables”](#) for option syntax.

Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the [data directory](#). The `mysqld` server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` and `--help` options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` option to `mysqld` or `mysqld_safe`, on the command line or in an option file. Otherwise, the server will not work properly. As an alternative to the `--datadir` option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir`, and `mysqld` looks for the `data` directory there.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

- Make sure that the server can access the `data directory`. The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).)

If no other server is running, execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. Track down what program this is and disable it, or tell `mysqld` to listen to a different port with the `--port` option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1      localhost
```

- If you cannot get `mysqld` to start, try to make a trace file to find the problem by using the `--debug` option. See [Section 24.5.3, “The DBUG Package”](#).

2.10.3 Testing the Server

After the data directory is initialized and you have started the server, perform some simple tests to make sure that it works satisfactorily. This section assumes that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your shell (command interpreter) to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See [Section 4.2.10, “Setting Environment Variables”](#).

Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

If you cannot connect to the server, specify a `-u root` option to connect as `root`. If you have assigned a password for the `root` account already, you'll also need to specify `-p` on the command line and enter the password when prompted. For example:

```
shell> bin/mysqladmin -u root -p version
Enter password: (enter root password here)
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin Ver 14.12 Distrib 5.6.37, for pc-linux-gnu on i686
...

Server version          5.6.37
Protocol version        10
Connection              Localhost via UNIX socket
UNIX socket             /var/lib/mysql/mysql.sock
Uptime:                 14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

Verify that you can shut down the server (include a `-p` option if the `root` account has a password already):

```
shell> bin/mysqladmin -u root shutdown
```

Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql &
```

If `mysqld_safe` fails, see [Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”](#).

Run some simple tests to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
shell> bin/mysqlshow
+-----+
| Databases |
+-----+
| information_schema |
| mysql           |
| performance_schema |
| test           |
+-----+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`.

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
shell> bin/mysqlshow mysql
Database: mysql
+-----+
| Tables |
+-----+
| columns_priv |
| db           |
| event        |
| func         |
| general_log  |
| help_category |
```

```
| help_keyword
| help_relation
| help_topic
| innodb_index_stats
| innodb_table_stats
| ndb_binlog_index
| plugin
| proc
| procs_priv
| proxies_priv
| servers
| slave_master_info
| slave_relay_log_info
| slave_worker_info
| slow_log
| tables_priv
| time_zone
| time_zone_leap_second
| time_zone_name
| time_zone_transition
| time_zone_transition_type
| user
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
shell> bin/mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+-----+
| User | Host      | plugin                |
+-----+
| root | localhost | mysql_native_password |
+-----+
```

At this point, your server is running and you can access it. To tighten security if you have not yet assigned passwords to the initial account or accounts, follow the instructions in [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

For more information about `mysql`, `mysqladmin`, and `mysqlshow`, see [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

2.10.4 Securing the Initial MySQL Accounts

The MySQL installation process involves initializing the data directory, including the `mysql` database containing the grant tables that define MySQL accounts. For details, see [Section 2.10, “Postinstallation Setup and Testing”](#).

This section describes how to assign passwords to the initial accounts created during the MySQL installation procedure, if you have not already done so.

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:

- Some accounts have the user name `root`. These are superuser accounts that have all privileges and can do anything. If these `root` accounts have empty passwords, anyone can connect to the MySQL server as `root` *without a password* and be granted all privileges.
- On Windows, `root` accounts are created that permit connections from the local host only. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, or the IPv6 address `::1`. If the user selects the **Enable root access from remote machines** option during installation, the Windows installer creates another `root` account that permits connections from any host.

- On Unix, each `root` account permits connections from the local host. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, the IPv6 address `::1`, or the actual host name or IP address.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option, so the `127.0.0.1` account is useful in that case. The `::1` account is used for IPv6 connections.

- If accounts for anonymous users were created, these have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.
- On Windows, there is one anonymous account that permits connections from the local host. Connections can be made by specifying a host name of `localhost`.
- On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP address for the other.
- The `'root'@'localhost'` account also has a row in the `mysql.proxies_priv` table that enables granting the `PROXY` privilege for `' '@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See [Section 6.3.8, “Proxy Users”](#).

To display which accounts exist in the `mysql.user` table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
```

| User | Host | Password |
|------|--------------------|----------|
| root | localhost | |
| root | myhost.example.com | |
| root | 127.0.0.1 | |
| root | ::1 | |
| | localhost | |
| | myhost.example.com | |

This output indicates that there are several `root` and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

- Assign a password to each MySQL `root` account that does not have one.
- To prevent clients from connecting as anonymous users without a password, either assign a password to each anonymous account or remove the accounts.

In addition, the `mysql.db` table contains rows that permit all accounts to access the `test` database and other databases with names that start with `test_`. This is true even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these `mysql.db` table rows.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the `root` accounts, then for the anonymous accounts. The instructions also cover how to remove anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace `new_password` in the examples with the password that you

want to use. Replace `host_name` with the name of the server host. You can determine this name from the output of the preceding `SELECT` statement. For the output shown, `host_name` is `myhost.example.com`.

Note

For additional information about setting passwords, see [Section 6.3.5, “Assigning Account Passwords”](#). If you forget your `root` password after setting it, see [Section B.5.3.2, “How to Reset the Root Password”](#).

To set up additional accounts, see [Section 6.3.2, “Adding User Accounts”](#).

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

Note

On Windows, you can also perform the process described in this section during installation with MySQL Installer (see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#)). On all platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation. MySQL Workbench is available on all platforms, and also offers the ability to manage user accounts (see [Chapter 26, MySQL Workbench](#)).

Assigning root Account Passwords

A `root` account password can be set several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `UPDATE` statement
- Use the `mysqladmin` command-line client program

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue a `SET PASSWORD` statement for each `root` account listed in the `mysql.user` table.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('new_password');
```

The last statement is unnecessary if the `mysql.user` table has no `root` account with a host value of `%`.

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('new_password');
```

You can also use a single statement that assigns a password to all `root` accounts by using `UPDATE` to modify the `mysql.user` table directly. This method works on any platform:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('new_password')
-> WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
shell> mysqladmin -u root password "new_password"
shell> mysqladmin -u root -h host_name password "new_password"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not work for the `'root'@'127.0.0.1'` or `'root'@':::1'` account. Use the `SET PASSWORD` method shown earlier.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have assigned the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

Assigning Anonymous Account Passwords

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`.

To use `SET PASSWORD` on Windows, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('new_password');
```

To use `SET PASSWORD` on Unix, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('new_password');
```

To set the anonymous-user account passwords with a single `UPDATE` statement, do this (on any platform):

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('new_password')
-> WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows on Windows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER '@'localhost';
```

On Unix, remove the anonymous accounts like this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER '@'localhost';
mysql> DROP USER '@'host_name';
```

Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. (These rows have an empty `User` column value, which for access-checking purposes matches any user name.) This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you prefer that the database not exist at all, drop it:

```
mysql> DROP DATABASE test;
```

2.10.5 Starting and Stopping MySQL Automatically

This section discusses methods for starting and stopping the MySQL server.

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- On Windows, you can set up a MySQL service that runs automatically when Windows starts. See [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).
- On Unix and Unix-like systems, you can invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).
- On systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), invoke `mysql.server`. This script is used primarily at system startup and shutdown. It usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See [Section 4.3.3, “mysql.server — MySQL Server Startup Script”](#).

- On OS X, install a launchd daemon to enable automatic MySQL startup at system startup. The daemon starts the server by invoking `mysqld_safe`. For details, see [Section 2.4.3, “Installing a MySQL Launch Daemon”](#). A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences. See [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).
- On Solaris/OpenSolaris, use the service management framework (SMF) system to initiate and control MySQL startup. For more information, see [Section 2.7.2, “Installing MySQL on OpenSolaris Using IPS”](#).

The `mysqld_safe` and `mysql.server` scripts, Solaris/OpenSolaris SMF, and the OS X Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

The following table shows which option groups the server and startup scripts read from option files.

Table 2.12 MySQL Startup Scripts and Supported Server Option Groups

| Script | Option Groups |
|---------------------------|---|
| <code>mysqld</code> | <code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld-major_version]</code> |
| <code>mysqld_safe</code> | <code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld_safe]</code> |
| <code>mysql.server</code> | <code>[mysqld]</code> , <code>[mysql.server]</code> , <code>[server]</code> |

`[mysqld-major_version]` means that groups with names like `[mysqld-5.5]` and `[mysqld-5.6]` are read by servers having versions 5.5.x, 5.6.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead.

For more information on MySQL configuration files and their structure and contents, see [Section 4.2.6, “Using Option Files”](#).

2.11 Upgrading or Downgrading MySQL

This section describes the steps to upgrade or downgrade a MySQL installation.

Upgrading is a common procedure, as you pick up bug fixes within the same MySQL release series or significant features between major MySQL releases. You perform this procedure first on some test systems to make sure everything works smoothly, and then on the production systems.

Downgrading is less common. Typically, you undo an upgrade because of some compatibility or performance issue that occurs on a production system, and was not uncovered during initial upgrade verification on the test systems. As with the upgrade procedure, perform and verify the downgrade procedure on some test systems first, before using it on a production system.

2.11.1 Upgrading MySQL

This section describes how to upgrade to a new MySQL version.

- [Supported Upgrade Methods](#)
- [Supported Upgrade Paths](#)
- [Before You Begin](#)
- [Performing an In-Place Upgrade](#)

- [Performing a Logical Upgrade](#)
- [Upgrade Troubleshooting](#)

Note

In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL `root` user. Commands that require a password for `root` also include a `-p` option. Because `-p` is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.

SQL statements can be executed using the `mysql` command-line client (connect as `root` to ensure that you have the necessary privileges).

Supported Upgrade Methods

Supported downgrade methods include:

- *In-Place Upgrade*: Involves shutting down the old MySQL version, replacing the old MySQL binaries or packages with the new ones, restarting MySQL on the existing data directory, and running `mysql_upgrade`.
- *Logical Upgrade*: Involves exporting existing data from the old MySQL version using `mysqldump`, installing the new MySQL version, loading the dump file into the new MySQL version, and running `mysql_upgrade`.

Note

MySQL recommends a `mysqldump` upgrade when upgrading from a previous release. For example, use this method when upgrading from 5.5 to 5.6.

For in-place and logical upgrade procedures, see [Performing an In-Place Upgrade](#), and [Performing a Logical Upgrade](#).

If you run MySQL Server on Windows, see [Section 2.3.8, “Upgrading MySQL on Windows”](#).

If your current MySQL installation was installed on an Enterprise Linux platform or Fedora using the MySQL Yum Repository, see [Section 2.11.1.2, “Upgrading MySQL with the MySQL Yum Repository”](#).

If your current MySQL installation was installed on Ubuntu using the MySQL APT repository, see [Section 2.11.1.3, “Upgrading MySQL with the MySQL APT Repository”](#).

Supported Upgrade Paths

Unless otherwise documented, the following upgrade paths are supported:

- Upgrading from a release series version to a newer release series version is supported. For example, upgrading from 5.6.26 to 5.6.27 is supported. Skipping release series versions is also supported. For example, upgrading from 5.6.25 to 5.6.27 is supported.
- Upgrading one release level is supported. For example, upgrading from 5.5 to 5.6 is supported. Upgrading to the latest release series version is recommended before upgrading to the next release level. For example, upgrade to the latest 5.5 release before upgrading to 5.6.
- Upgrading more than one release level is supported, but only if you upgrade one release level at a time. For example, upgrade from 5.1 to 5.5, and then to 5.6. Follow the upgrade instructions for each release, in succession.

- Direct upgrades that skip a release level (for example, upgrading directly from MySQL 5.1 to 5.6) are not recommended or supported.

The following conditions apply to all upgrade paths:

- Upgrades between General Availability (GA) status releases are supported.
- Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. For example, upgrading from 5.6.9 to 5.6.10 is not supported, as 5.6.9 is not a GA status release.
- For upgrades between versions of a MySQL release series that has reached GA status, you can move the MySQL format files and data files between different versions on systems with the same architecture. This is not necessarily true for upgrades between milestone releases. Use of milestone releases is at your own risk.

Before You Begin

Before upgrading, review the following information and perform the recommended steps:

- Before upgrading, protect your data by creating a backup of your current databases and log files. The backup should include the `mysql` system database, which contains the MySQL system tables. See [Section 7.2, “Database Backup Methods”](#).
- Review the [Release Notes](#) which provide information about features that are new in the MySQL 5.6 or differ from those found in earlier MySQL releases. Some of these changes may result in incompatibilities.
- Review [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.6”](#). This section describes changes that may require action before or after upgrading.
- Check [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are upgrading. If such changes have resulted in an incompatibility between MySQL versions, you will need to upgrade the affected tables using the instructions in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).
- If you use replication, review [Section 17.4.3, “Upgrading a Replication Setup”](#).
- If you use XA transactions with `InnoDB`, run `XA RECOVER` before upgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an `XA COMMIT` or `XA ROLLBACK` statement.
- If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.
- Rebuilding and reinstalling MySQL language interfaces is recommended whenever you install or upgrade to a new release of MySQL. This applies to MySQL interfaces such as PHP `mysql` extensions, the Perl `DBD: :mysql` module, and the Python `MySQLdb` module.

Performing an In-Place Upgrade

This section describes how to perform an [in-place upgrade](#). Review [Before you Begin](#) before proceeding.

**Note**

If you upgrade an installation originally produced by installing multiple RPM packages, upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

To perform an in-place upgrade:

1. Review the changes described in [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.6”](#) for steps to be performed before upgrading.
2. If you use [InnoDB](#), configure MySQL to perform a slow shutdown by setting `innodb_fast_shutdown` to 0. For example:

```
mysql -u root -p --execute="SET GLOBAL innodb_fast_shutdown=0"
```

With a slow shutdown, [InnoDB](#) performs a full purge and change buffer merge before shutting down, which ensures that data files are fully prepared in case of file format differences between releases.

3. Shut down the old MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. Upgrade the MySQL binaries or packages in place (replace the old binaries or packages with the new ones).
5. Start the MySQL 5.6 server, using the existing data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

6. Run `mysql_upgrade`. For example:

```
mysql_upgrade -u root -p
```

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL. `mysql_upgrade` also upgrades the `mysql` system database so that you can take advantage of new privileges or capabilities.

**Note**

`mysql_upgrade` should not be used when the server is running with `--gtid-mode=ON`. See [GTID mode and mysql_upgrade](#) for more information.

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

7. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

Performing a Logical Upgrade

This section describes how to perform a [logical upgrade](#). Review [Before you Begin](#) before proceeding.

To perform a logical upgrade:

1. Review the changes described in [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.6”](#) for steps to be performed before upgrading.
2. Export your existing data from the previous MySQL version:

```
mysqldump -u root -p
--add-drop-table --routines --events
--all-databases --force > data-for-upgrade.sql
```

Note

Use the `--routines` and `--events` options with `mysqldump` (as shown above) if your databases include stored programs. The `--all-databases` option includes all databases in the dump, including the `mysql` database that holds the system tables.

3. Shut down the old MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. Install MySQL 5.6. For installation instructions, see [Chapter 2, *Installing and Upgrading MySQL*](#).
5. Initialize a new data directory, as described at [Section 2.10.1, “Initializing the Data Directory”](#). For example:

```
scripts/mysql_install_db --user=mysql --datadir=/path/to/5.6-datadir
```

6. Start the MySQL 5.6 server, using the new data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/5.6-datadir
```

7. Load the previously created dump file into the new MySQL server. For example:

```
mysql -u root -p --force < data-for-upgrade.sql
```

8. Run `mysql_upgrade`. For example:

```
mysql_upgrade -u root -p
```

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL. `mysql_upgrade` also upgrades the `mysql` system database so that you can take advantage of new privileges or capabilities.

Note

`mysql_upgrade` should not be used when the server is running with `--gtid-mode=ON`. See [GTID mode and mysql_upgrade](#) for more information.

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

9. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/5.6-datadir
```

Upgrade Troubleshooting

- If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.
- If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.15` to `libmysqlclient.so.16`).
- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

2.11.1.1 Changes Affecting Upgrades to MySQL 5.6

Before upgrading to MySQL 5.6, review the changes described in this section to identify upgrade issues that apply to your current MySQL installation and applications.

Note

In addition to the changes outlined in this section, review the [Release Notes](#) and other important information outlined in [Before You Begin](#).

Changes marked as either **Known issue** or **Incompatible change** are incompatibilities with earlier versions of MySQL, and may require your attention *before you upgrade*. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Sometimes this involves dumping and reloading tables, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

For dump and reload instructions, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#). Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option *must* be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

Note

Beginning with MySQL 5.6.6, several MySQL Server parameters have defaults that differ from previous releases. See the notes regarding these changes under

Configuration Changes, particularly regarding overriding them to preserve backward compatibility if that is a concern.

- [Configuration Changes](#)
- [Server Changes](#)
- [SQL Changes](#)

Configuration Changes

- Beginning with MySQL 5.6.6, several MySQL Server parameters have defaults that differ from previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for the database administrator to change settings manually. These changes are subject to possible revision in future releases as we gain feedback.

In some cases, a parameter has a different static default value. In other cases, the server autosizes a parameter at startup using a formula based on other related parameters or server host configuration, rather than using a static value. For example, the setting for `back_log` now is its previous default of 50, adjusted up by an amount proportional to the value of `max_connections`. The idea behind autosizing is that when the server has information available to make a decision about a parameter setting likely to be better than a fixed default, it will.

The following table summarizes changes to defaults. Any of these can be overridden by specifying an explicit value at server startup.

| Parameter | Old Default | New Default |
|---|-------------------|--|
| <code>back_log</code> | 50 | Autosized using <code>max_connections</code> |
| <code>binlog_checksum</code> | NONE | CRC32 |
| <code>--binlog-row-event-max-size</code> | 1024 | 8192 |
| <code>flush_time</code> | 1800 (on Windows) | 0 |
| <code>innodb_autoextend_increment</code> | 8 | 64 |
| <code>innodb_buffer_pool_instances</code> | 1 | 8 (platform dependent) |
| <code>innodb_checksum_algorithm</code> | INNODB | CRC32 (changed back to INNODB in MySQL 5.6.7) |
| <code>innodb_concurrency_tickets</code> | 500 | 5000 |
| <code>innodb_file_per_table</code> | 0 | 1 |
| <code>innodb_old_blocks_time</code> | 0 | 1000 |
| <code>innodb_open_files</code> | 300 | Autosized using <code>innodb_file_per_table</code> , <code>table_open_cache</code> |
| <code>innodb_stats_on_metadata</code> | ON | OFF |
| <code>join_buffer_size</code> | 128KB | 256KB |
| <code>max_allowed_packet</code> | 1MB | 4MB |
| <code>max_connect_errors</code> | 10 | 100 |
| <code>sync_master_info</code> | 0 | 10000 |
| <code>sync_relay_log</code> | 0 | 10000 |
| <code>sync_relay_log_info</code> | 0 | 10000 |

With regard to compatibility with previous releases, the most important changes are:

- `innodb_file_per_table` is enabled (previously disabled).
- `innodb_checksum_algorithm` is `CRC32` (previously `INNODB` and changed back to `INNODB` in MySQL 5.6.7).
- `binlog_checksum` is `CRC32` (previously `NONE`).

Therefore, if you are upgrading an existing MySQL installation, have not already changed the values of these parameters from their previous defaults, and backward compatibility is a concern, you may want to explicitly set these parameters to their previous defaults. For example, put these lines in the server option file:

```
[mysqld]
innodb_file_per_table=0
innodb_checksum_algorithm=INNODB
binlog_checksum=NONE
```

Those settings preserve compatibility as follows:

- With the new default of `innodb_file_per_table` enabled, `ALTER TABLE` operations following an upgrade will move InnoDB tables that are in the system tablespace to individual `.ibd` files. Using `innodb_file_per_table=0` will prevent this from happening.
- Setting `innodb_checksum_algorithm=INNODB` permits binary downgrades after upgrading to this release. With a setting of `CRC32`, InnoDB would use checksumming that older MySQL versions cannot use.
- With `binlog_checksum=NONE`, the server can be used as a replication master without causing failure of older slaves that do not understand binary log checksums.
- As of MySQL 5.6.5, pre-4.1 passwords and the `mysql_old_password` authentication plugin are deprecated. Passwords stored in the older hash format used before MySQL 4.1 are less secure than passwords that use the native password hashing method and should be avoided. To prevent connections using accounts that have pre-4.1 password hashes, the `secure_auth` system variable is now enabled by default. (To permit connections for accounts that have such password hashes, start the server with `--secure_auth=0`.)

DBAs are advised to convert accounts that use the `mysql_old_password` authentication plugin to use `mysql_native_password` instead. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the `mysql_old_password` Plugin”](#).

Known issue: In some early development versions of MySQL 5.6 (5.6.6 to 5.6.10), the server could create accounts with a mismatched password hash and authentication plugin. For example, if the default authentication plugin is `mysql_native_password`, this sequence of statements results in an account with a plugin of `mysql_native_password` but a pre-4.1 password hash (the format used by `mysql_old_password`):

```
SET old_passwords = 1;
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The mismatch produces symptoms such as being unable to connect to the MySQL server and being unable to use `SET PASSWORD` with `OLD_PASSWORD()` or with `old_passwords=1`.

As of MySQL 5.6.11, this mismatch no longer occurs. Instead, the server produces an error:

```
mysql> SET old_passwords = 1;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
ERROR 1827 (HY000): The password hash doesn't have the expected
format. Check if the correct password algorithm is being used with
the PASSWORD() function.
```

To deal with an account affected by a mismatch, the DBA can modify either the `plugin` or `Password` column in the account's `mysql.user` table row to be consistent with the other column:

- Set `old_passwords` to 0, then assign a new password to the account using `SET PASSWORD` and `PASSWORD()`. This sets the `Password` column to have a 4.1 password hash, consistent with the `mysql_native_password` plugin. This is the preferred method of fixing the account.
- Alternatively, the DBA can change the plugin to `mysql_old_password` to make the plugin match the password hash format, then flush the privileges. This is not recommended because the `mysql_old_password` plugin and pre-4.1 password hashing are deprecated and support for them will be removed in a future version of MySQL.

Server Changes

- **Incompatible change:** It is possible for a column `DEFAULT` value to be valid for the `sql_mode` value at table-creation time but invalid for the `sql_mode` value when rows are inserted or updated. Example:

```
SET sql_mode = '';
CREATE TABLE t (d DATE DEFAULT 0);
SET sql_mode = 'NO_ZERO_DATE,STRICT_ALL_TABLES';
INSERT INTO t (d) VALUES(DEFAULT);
```

In this case, 0 should be accepted for the `CREATE TABLE` but rejected for the `INSERT`. However, the server did not evaluate `DEFAULT` values used for inserts or updates against the current `sql_mode`. In the example, the `INSERT` succeeds and inserts '0000-00-00' into the `DATE` column.

As of MySQL 5.6.13, the server applies the proper `sql_mode` checks to generate a warning or error at insert or update time.

A resulting incompatibility for replication if you use statement-based logging (`binlog_format=STATEMENT`) is that if a slave is upgraded, a nonupgraded master will execute the preceding example without error, whereas the `INSERT` will fail on the slave and replication will stop.

To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves followed by the master. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (`binlog_format=ROW`) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves followed by the master and change the master back to statement-based logging.

- **Incompatible change:** MySQL 5.6.11 and later supports `CREATE TABLE ... [SUB]PARTITION BY ALGORITHM=n [LINEAR] KEY (...)`, which can be used to create a table whose `KEY` partitioning is compatible with a MySQL 5.1 server (*n*=1). (Bug #14521864, Bug #66462) This syntax is not accepted by MySQL 5.6.10 and earlier, although it is supported in MySQL 5.5 beginning with MySQL 5.5.31. `mysqldump` in MySQL 5.5.31 and later MySQL 5.5 releases includes the `ALGORITHM` option when dumping tables using this option, but surrounds it with conditional comments, like this:

```
CREATE TABLE t1 (a INT)
```

```
/*!50100 PARTITION BY KEY */ /*!50531 ALGORITHM = 1 */ /*!50100 ( )
PARTITIONS 3 */
```

When importing a dump containing such `CREATE TABLE` statements into a MySQL 5.6.10 or earlier MySQL 5.6 server, the versioned comment is not ignored, which causes a syntax error. Therefore, prior to importing such a dump file, you must either change the comments so that the MySQL 5.6 server ignores them (by removing the string `!50531` or replacing it with `!50611`, wherever it occurs), or remove them.

This is not an issue with dump files made using MySQL 5.6.11 or later, where the `ALGORITHM` option is written using `/*!50611 ... */`.

- **Incompatible change:** For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from storage required for tables created in 5.6.4 and later. This is due to a change in 5.6.4 that permits these temporal types to have a fractional part. This change can affect the output of statements that depend on the row format, such as `CHECKSUM TABLE`. After upgrading from MySQL 5.5 to MySQL 5.6.4 or later, it is recommended that you also upgrade from MySQL 5.5 to MySQL 5.6 `TIME`, `DATETIME`, and `TIMESTAMP` types. `ALTER TABLE` currently allows the creation of tables containing temporal columns in both MySQL 5.5 and MySQL 5.6.4 (or later) binary format but this makes it more difficult to recreate tables in cases where `.frm` files are not available. Additionally, as of MySQL 5.6.4, the aforementioned temporal types are more space efficient. For more information about changes to temporal types in MySQL 5.6.4, see [Storage Requirements for Date and Time Types](#).

As of MySQL 5.6.16, `ALTER TABLE` upgrades old temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. Hence, the following statement upgrades a table containing columns in the old format:

```
ALTER TABLE tbl_name FORCE;
```

This conversion cannot be done using the `INPLACE` algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

When `ALTER TABLE` does produce a temporal-format conversion, it generates a message that can be displayed with `SHOW WARNINGS: TIME/TIMESTAMP/DATETIME columns of old format have been upgraded to the new format`.

When upgrading to MySQL 5.6.4 or later, be aware that `CHECK TABLE ... FOR UPGRADE` does not report temporal columns that use the pre-MySQL 5.6.4 format (Bug #73008, Bug #18985579). In MySQL 5.6.24, two new system variables, `avoid_temporal_upgrade` and `show_old_temporals`, were added to provide control over temporal column upgrades (Bug #72997, Bug #18985760).

- Due to the temporal type changes described in the previous incompatible change item above, importing pre-MySQL 5.6.4 tables (using `ALTER TABLE ... IMPORT TABLESPACE`) that contain `DATETIME` and `TIMESTAMP` types into MySQL 5.6.4 (or later) fails. Importing a MySQL 5.5 table with these temporal types into MySQL 5.6.4 (or later) is the mostly likely scenario for this problem to occur.

The following procedures describe workarounds that use the original pre-MySQL 5.6.4 `.frm` file to recreate a table with a row structure that is compatible with 5.6.4 (or later). The procedures involve changing the original pre-MySQL 5.6.4 `.frm` file to use the `Memory` storage engine instead of `InnoDB`, copying the `.frm` file to the data directory of the destination instance, and using `ALTER TABLE` to change the table's storage engine type back to `InnoDB`. Use the first procedure if your tables do not have foreign keys. Use the second procedure, which has additional steps, if your table includes foreign keys.

If the table does not have foreign keys:

1. Copy the table's original `.frm` file to the data directory on the server where you want to import the tablespace.
2. Modify the table's `.frm` file to use the `Memory` storage engine instead of the `InnoDB` storage engine. This modification requires changing 7 bytes in the `.frm` file that define the table's storage engine type. Using a hexadecimal editing tool:

- Change the byte at offset position 0003, which is the `legacy_db_type`, from `0c` (for `InnoDB`) to `06` (for `Memory`), as shown below:

```
00000000 fe 01 09 06 03 00 00 10 01 00 00 30 00 00 10 00
```

- The remaining 6 bytes do not have a fixed offset. Search the `.frm` file for “`InnoDB`” to locate the line with the other 6 bytes. The line appears as shown below:

```
00001010 ff 00 00 00 00 00 00 06 00 49 6e 6e 6f 44 42 00 |.....InnoDB.|
```

- Modify the bytes so that the line appears as follows:

```
00001010 ff 00 00 00 00 00 00 06 00 4d 45 4d 4f 52 59 00
```

3. Run `ALTER TABLE ... ENGINE=INNODB` to add the table definition to the `InnoDB` data dictionary. This creates the `InnoDB` table with the temporal data types in the new format. For the `ALTER TABLE` operation to complete successfully, the `.frm` file must correspond to the tablespace.
4. Import the table using `ALTER TABLE ... IMPORT TABLESPACE`.

If table has foreign keys:

1. Recreate the tables with foreign keys using table definitions from `SHOW CREATE TABLE` output. The incorrect temporal column formats do not matter at this point.
 2. Dump all foreign key definitions to a text file by selecting the foreign key information from `INFORMATION_SCHEMA.TABLE_CONSTRAINTS` and `INFORMATION_SCHEMA.KEY_COLUMN_USAGE`.
 3. Drop all tables and complete the table import process described in steps 1 to 4 in the procedure described above for tables without foreign keys.
 4. After the import operation is complete, add the foreign keys from foreign key definitions that you saved to a text file.
- **Incompatible change:** As of MySQL 5.6, the full-text stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`. If any table was created with `FULLTEXT` indexes while the server character set was `ucs2`, `utf16`, `utf16le`, or `utf32`, repair it using this statement:

```
REPAIR TABLE tbl_name QUICK;
```

- **Incompatible change:** In MySQL 5.6.20, the patch for Bug #69477 limits the size of redo log `BLOB` writes to 10% of the redo log file size. As a result of this new limit, `innodb_log_file_size` should be set to a value greater than 10 times the largest `BLOB` data size found in the rows of your tables. No

action is required if your `innodb_log_file_size` setting is already 10 times the largest `BLOB` data size or your tables contain no `BLOB` data.

In MySQL 5.6.22, the redo log `BLOB` write limit is relaxed to 10% of the *total redo log size* (`innodb_log_file_size * innodb_log_files_in_group`). (Bug #19498877)

SQL Changes

- Some keywords may be reserved in MySQL 5.6 that were not reserved in MySQL 5.5. See [Section 9.3, “Keywords and Reserved Words”](#). This can cause words previously used as identifiers to become illegal. To fix affected statements, use identifier quoting. See [Section 9.2, “Schema Object Names”](#).
- The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.6.6, `YEAR(2)` is deprecated. `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables are converted to `YEAR(4)`. For more information, see [Section 11.3.4, “YEAR\(2\) Limitations and Migrating to YEAR\(4\)”](#).
- As of MySQL 5.6.6, it is explicitly disallowed to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). This was not previously supported, or documented as permitted, but is flagged as an incompatible change in case existing code inadvertently used this construct. It remains permissible to assign `DEFAULT` to system variables, as before, but assigning `DEFAULT` to parameters or local variables now results in a syntax error.

After an upgrade to MySQL 5.6.6 or later, existing stored programs that use this construct produce a syntax error when invoked. If a `mysqldump` file from 5.6.5 or earlier is loaded into 5.6.6 or later, the load operation fails and affected stored program definitions must be changed.

- In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types:
 - `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are assigned the `NOT NULL` attribute. (Columns of other data types, if not explicitly declared as `NOT NULL`, permit `NULL` values.) Setting such a column to `NULL` sets it to the current timestamp.
 - The first `TIMESTAMP` column in a table, if not declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` clause, is automatically assigned the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.
 - `TIMESTAMP` columns following the first one, if not declared with the `NULL` attribute or an explicit `DEFAULT` clause, are automatically assigned `DEFAULT '0000-00-00 00:00:00'` (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Those nonstandard behaviors remain the default for `TIMESTAMP` but as of MySQL 5.6.6 are deprecated and this warning appears at startup:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to turn off the nonstandard behaviors, enable the new `explicit_defaults_for_timestamp` system variable at server startup. With this variable enabled, the server handles `TIMESTAMP` as follows instead:

- `TIMESTAMP` columns not explicitly declared as `NOT NULL` permit `NULL` values. Setting such a column to `NULL` sets it to `NULL`, not the current timestamp.

- No `TIMESTAMP` column is assigned the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes automatically. Those attributes must be explicitly specified.
- `TIMESTAMP` columns declared as `NOT NULL` and without an explicit `DEFAULT` clause are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is assigned the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.

To upgrade servers used for replication, upgrade the slaves first, then the master. Replication between the master and its slaves should work provided that all use the same value of `explicit_defaults_for_timestamp`:

1. Bring down the slaves, upgrade them, configure them with the desired value of `explicit_defaults_for_timestamp`, and bring them back up.

The slaves will recognize from the format of the binary logs received from the master that the master is older (predates the introduction of `explicit_defaults_for_timestamp`) and that operations on `TIMESTAMP` columns coming from the master use the old `TIMESTAMP` behavior.

2. Bring down the master, upgrade it, and configure it with the same `explicit_defaults_for_timestamp` value used on the slaves, and bring it back up.

2.11.1.2 Upgrading MySQL with the MySQL Yum Repository

For supported Yum-based platforms (see [Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”](#), for a list), you can perform an in-place upgrade for MySQL (that is, replacing the old version and then running the new version off the old data files) with the MySQL Yum repository.

Notes

- Before performing any update to MySQL, follow carefully the instructions in [Section 2.11.1, “Upgrading MySQL”](#). Among other instructions discussed there, it is especially important to back up your database before the update.
- The following instructions assume you have installed MySQL with the MySQL Yum repository or with an RPM package directly downloaded from [MySQL Developer Zone's MySQL Download page](#); if that is not the case, following the instructions in [Section 2.5.2, “Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository”](#).

Selecting^{1a} Target Series

By default, the MySQL Yum repository updates MySQL to the latest version in the release series you have chosen during installation (see [Selecting a Release Series](#) for details), which means, for example, a 5.6.x installation will NOT be updated to a 5.7.x release automatically. To update to another release series, you need to first disable the subrepository for the series that has been selected (by default, or by yourself) and enable the subrepository for your target series. To do that, see the general instructions given in [Selecting a Release Series](#). For upgrading from MySQL 5.6 to 5.7, perform the *reverse* of the steps illustrated in [Selecting a Release Series](#), disabling the subrepository for the MySQL 5.6 series and enabling that for the MySQL 5.7 series.

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. For example, if you are currently running MySQL 5.5 and wish to upgrade to 5.7, upgrade to MySQL 5.6 first before upgrading to 5.7.

**Important**

For important information about upgrading from MySQL 5.6 to 5.7, see [Upgrading from MySQL 5.6 to 5.7](#).

Upgrading MySQL

Upgrade MySQL and its components by the following command, for platforms that are not dnf-enabled:

```
sudo yum update mysql-server
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade mysql-server
```

Alternatively, you can update MySQL by telling Yum to update everything on your system, which might take considerably more time; for platforms that are not dnf-enabled:

```
sudo yum update
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade
```

Restarting MySQL

The MySQL server always restarts after an update by Yum. Once the server restarts, run `mysql_upgrade` to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see [Section 4.4.7](#), “`mysql_upgrade` — Check and Upgrade MySQL Tables” for details.

You can also update only a specific component. Use the following command to list all the installed packages for the MySQL components (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
sudo yum list installed | grep "^mysql"
```

After identifying the package name of the component of your choice, for platforms that are not dnf-enabled, update the package with the following command, replacing `package-name` with the name of the package:

```
sudo yum update package-name
```

For dnf-enabled platforms:

```
sudo dnf upgrade package-name
```

Upgrading the Shared Client Libraries

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work.

If you recompile applications and dynamically link them with the updated libraries: As typical with new versions of shared libraries where there are differences or additions in symbol versioning between the newer and older libraries (for example, between the newer, standard 5.6 shared client libraries and some

older—prior or variant—versions of the shared libraries shipped natively by the Linux distributions' software repositories, or from some other sources), any applications compiled using the updated, newer shared libraries will require those updated libraries on systems where the applications are deployed. And, as expected, if those libraries are not in place, the applications requiring the shared libraries will fail. So, be sure to deploy the packages for the shared libraries from MySQL on those systems. You can do this by adding the MySQL Yum repository to the systems (see [Adding the MySQL Yum Repository](#)) and install the latest shared libraries using the instructions given in [Installing Additional MySQL Products and Components with Yum](#).

2.11.1.3 Upgrading MySQL with the MySQL APT Repository

On Debian 7 or 8 and Ubuntu 12, 14, or 15, you can perform an in-place upgrade of MySQL and its components with the MySQL APT repository. See [Upgrading MySQL with the MySQL APT Repository](#) in [A Quick Guide to Using the MySQL APT Repository](#).

2.11.2 Downgrading MySQL

This section describes how to downgrade to an older MySQL version.

- [Supported Downgrade Methods](#)
- [Supported Downgrade Paths](#)
- [Before You Begin](#)
- [Performing an In-Place Downgrade](#)
- [Performing a Logical Downgrade](#)
- [Downgrade Troubleshooting](#)

Note

In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL `root` user. Commands that require a password for `root` also include a `-p` option. Because `-p` is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.

SQL statements can be executed using the `mysql` command-line client (connect as `root` to ensure that you have the necessary privileges).

Supported Downgrade Methods

Supported downgrade methods include:

- *In-Place Downgrade*: Involves shutting down the new MySQL version, replacing the new MySQL binaries or packages with the old ones, and restarting the old MySQL version on the new data files. In-place downgrades are supported for downgrades between GA versions within the same release series. For example, in-place downgrades are supported for downgrades from 5.6.27 to 5.6.26.
- *Logical Downgrade*: Involves using `mysqldump` to dump all tables from the new MySQL version, and then loading the dump file into the old MySQL version. Logical downgrades are supported for downgrades between GA versions within the same release series and for downgrades between release levels. For example, logical downgrades are supported for downgrades from 5.6.27 to 5.6.26 and for downgrades from 5.6 to 5.5.

Supported Downgrade Paths

Unless otherwise documented, the following downgrade paths are supported:

- Downgrading from a release series version to an older release series version is supported using all [downgrade methods](#). For example, downgrading from 5.6.27 to 5.6.26 is supported. Skipping release series versions is also supported. For example, downgrading from 5.6.27 to 5.6.25 is supported.
- Downgrading one release level is supported using the *logical downgrade* method. For example, downgrading from 5.6 to 5.5 is supported.
- Downgrading more than one release level is supported using the *logical downgrade* method, but only if you downgrade one release level at a time. For example, you can downgrade from 5.6 to 5.5, and then to 5.1.

The following conditions apply to all downgrade paths:

- Downgrades between General Availability (GA) status releases are supported.
- Downgrades between milestone releases (or from a GA release to a milestone release) are not supported. For example, downgrading from MySQL 5.6.10 to MySQL 5.6.9 is not supported, as 5.6.9 is not a GA status release.

Before You Begin

Before downgrading, the following steps are recommended:

- Review the [Release Notes](#) for the MySQL version you are downgrading from to ensure that there are no features or fixes that you really need.
- Review [Section 2.11.2.1, “Changes Affecting Downgrades from MySQL 5.6”](#). This section describes changes that may require action before or after downgrading.

Note

The downgrade procedures described in the following sections assume you are downgrading with data files created or modified by the newer MySQL version. However, if you did not modify your data after upgrading, downgrading using backups taken *before* upgrading to the new MySQL version is recommended. Many of the changes described in [Section 2.11.2.1, “Changes Affecting Downgrades from MySQL 5.6”](#) that require action before or after downgrading are not applicable when downgrading using backups taken *before* upgrading to the new MySQL version.

- Always back up your current databases and log files before downgrading. The backup should include the `mysql` database, which contains the MySQL system tables. See [Section 7.2, “Database Backup Methods”](#).
- Use of new features, new configuration options, or new configuration option values that are not supported by a previous release may cause downgrade errors or failures. Before downgrading, it is recommended that you reverse changes resulting from the use of new features and remove configuration settings that are not supported by the release you are downgrading to.
- Check [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are downgrading. If such changes have resulted in an incompatibility between MySQL versions, downgrade the affected tables using the instructions in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

- If you use XA transactions with [InnoDB](#), run [XA RECOVER](#) before downgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an [XA COMMIT](#) or [XA ROLLBACK](#) statement.

Performing an In-Place Downgrade

In-place downgrades are supported for downgrades between GA status releases within the same release series. Before proceeding, review [Before You Begin](#).

To perform an in-place downgrade:

1. Review the changes described in [Section 2.11.2.1, “Changes Affecting Downgrades from MySQL 5.6”](#) for steps to be performed before downgrading.
2. If you use [InnoDB](#), configure MySQL to perform a slow shutdown by setting [innodb_fast_shutdown](#) to 0. For example:

```
mysql -u root -p --execute="SET GLOBAL innodb_fast_shutdown=0"
```

With a slow shutdown, [InnoDB](#) performs a full purge and change buffer merge before shutting down, which ensures that data files are fully prepared in case of file format differences between releases.

3. Shut down the newer MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. After the slow shutdown, remove the [InnoDB](#) redo log files (the [ib_logfile*](#) files) from the [data](#) directory to avoid downgrade issues related to redo log file format changes that may have occurred between releases.

```
rm ib_logfile*
```

5. Downgrade the MySQL binaries or packages in-place by replacing the newer binaries or packages with the older ones.
6. Start the older (downgraded) MySQL server, using the existing data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

7. Run [mysql_upgrade](#). For example:

```
mysql_upgrade -u root -p
```

8. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown  
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

Performing a Logical Downgrade

Logical downgrades are supported for downgrades between releases within the same release series and for downgrades to the previous release level. Only downgrades between General Availability (GA) status releases are supported. Before proceeding, review [Before You Begin](#).

To perform a logical downgrade:

1. Review the changes described in [Section 2.11.2.1, “Changes Affecting Downgrades from MySQL 5.6”](#) for steps to be performed before downgrading.

2. Dump all databases. For example:

```
mysqldump -u root -p
--add-drop-table --routines --events
--all-databases --force > data-for-downgrade.sql
```

3. Shut down the newer MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. Initialize an older MySQL instance, with a new data directory. For example:

```
scripts/mysql_install_db --user=mysql
```

5. Start the older MySQL server, using the new data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/new-datadir
```

6. Load the dump file into the older MySQL server. For example:

```
mysql -u root -p --force < data-for-upgrade.sql
```

7. Run `mysql_upgrade`. For example:

```
mysql_upgrade -u root -p
```

8. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/new-datadir
```

Downgrade Troubleshooting

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, see [Section 2.11.5, “Copying MySQL Databases to Another Machine”](#).

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.

5. Reload the dump file into the older server. Your tables should be accessible.

2.11.2.1 Changes Affecting Downgrades from MySQL 5.6

Before downgrading from MySQL 5.6, review the changes described in this section. Some changes may require action before or after downgrading.

System Tables

- The `mysql.user` table in MySQL 5.6 has a `password_expired` column. The `mysql.user` table in MySQL 5.5 does not. This means that an account with an expired password in MySQL 5.6 will work normally in MySQL 5.5.
- The `mysql.host` table was removed in MySQL 5.6.7. When downgrading to a previous release, startup on the downgraded server fails with an error if the `mysql.host` table is not present. You can recreate the table manually or restore it from a backup taken prior to upgrading to MySQL 5.6.7 or higher.

Data Types

- For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from storage required for tables created in 5.6.4 and later. This is due to a change in 5.6.4 that permits these temporal types to have a fractional part. To downgrade to a version older than 5.6.4, dump affected tables with `mysqldump` before downgrading, and reload the tables after downgrading.

The following query identifies tables and columns that may be affected by this problem. Some of them are system tables in the `mysql` database (such as `columns_priv` and `proxies_priv`). This means that `mysql` is one of the databases you must dump and reload, or server startup may fail after downgrading.

```
SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, DATA_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE DATA_TYPE IN ('TIME', 'DATETIME', 'TIMESTAMP')
ORDER BY TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME;
```

InnoDB

- `InnoDB` search indexes (with a type of `FULLTEXT`), introduced in MySQL 5.6.4, are not compatible with earlier versions of MySQL, including earlier releases in the 5.6 series. Drop such indexes before performing a downgrade.

`InnoDB` tables with `FULLTEXT` indexes can be identified using an `INFORMATION_SCHEMA` query. For example:

```
SELECT a.NAME AS Table_name, b.NAME AS Index_name
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES a,
      INFORMATION_SCHEMA.INNODB_SYS_INDEXES b
WHERE a.TABLE_ID = b.TABLE_ID
      AND b.TYPE = 32;
```

- `InnoDB` small page sizes specified by the `innodb_page_size` configuration option, introduced in MySQL 5.6.4, are not compatible with earlier versions of MySQL, including earlier releases in the 5.6 series. Dump all `InnoDB` tables in instances that use a smaller `InnoDB` page size, drop the tables, and re-create and reload them after the downgrade.
- Tables created using persistent statistics table options (`STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES`) introduced in MySQL 5.6.6, are not compatible with earlier releases (Bug #70778). Remove the options from table definitions prior to downgrading. For information about these options, see [Section 14.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- The `innodb_log_file_size` default and maximum values were increased in MySQL 5.6. Before downgrading, ensure that the configured log file size is compatible with the previous release.

Replication

- As of MySQL 5.6, the `relay-log.info` file contains a line count and a replication delay value, so the file format differs from that in older versions. See [Section 17.2.2.2, “Slave Status Logs”](#). If you downgrade a slave server to a version older than MySQL 5.6, the older server will not read the file correctly. To address this, modify the file in a text editor to delete the initial line containing the number of lines.
- Beginning with MySQL 5.6.6, the MySQL Server employs Version 2 binary log events when writing the binary log. Binary logs written using Version 2 log events cannot be read by earlier versions of MySQL Server. To generate a binary log that is written using Version 1 log events readable by older servers, start the MySQL 5.6.6 or later server using `--log-bin-use-v1-row-events=1`, which forces the server to employ Version 1 events when writing the binary log.

2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt

A binary upgrade or downgrade is one that installs one version of MySQL “in place” over an existing version, without dumping and reloading tables:

1. Stop the server for the existing version if it is running.
2. Install a different version of MySQL. This is an upgrade if the new version is higher than the original version, a downgrade if the version is lower.
3. Start the server for the new version.

In many cases, the tables from the previous version of MySQL can be used without problem by the new version. However, sometimes changes occur that require tables or table indexes to be rebuilt, as described in this section. If you have tables that are affected by any of the issues described here, rebuild the tables or indexes as necessary using the instructions given in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

Table Incompatibilities

If you have `ARCHIVE` tables created in MySQL 5.0, the recommended upgrade procedure is to dump the 5.0 `ARCHIVE` tables before upgrading and reload them after upgrading.

As of MySQL 5.6.4, MySQL permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` column values. As a result, encoding and storage requirements for these temporal column types differ in tables created in MySQL 5.6.4 and later. This incompatibility is described in [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.6”](#). When upgrading to MySQL 5.6.4 or later, be aware that `CHECK TABLE ... FOR UPGRADE` does not report temporal columns that use the pre-MySQL 5.6.4 format (Bug #73008, Bug #18985579). In MySQL 5.6.24, two new system variables, `avoid_temporal_upgrade` and `show_old_temporals`, were added to provide control over temporal column upgrades (Bug #72997, Bug #18985760).

Index Incompatibilities

In MySQL 5.6.3, the length limit for index prefix keys is increased from 767 bytes to 3072 bytes, for InnoDB tables using `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`. See [Section 14.8.8, “Limits on InnoDB Tables”](#) for details. This change is also backported to MySQL 5.5.14. If you downgrade from one of these releases or higher, to an earlier release with a lower length limit, the index prefix keys could

be truncated at 767 bytes or the downgrade could fail. This issue could only occur if the configuration option `innodb_large_prefix` was enabled on the server being downgraded.

If you perform a binary upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1 or higher. This occurs due to an incompatible change in the `MyISAM` table index format in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all `MyISAM` tables. Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

Modifications to the handling of character sets or collations might change the character sort order, which causes the ordering of entries in any index that uses an affected character set or collation to be incorrect. Such changes result in several possible problems:

- Comparison results that differ from previous results
- Inability to find some index values due to misordered index entries
- Misordered `ORDER BY` results
- Tables that `CHECK TABLE` reports as being in need of repair

The solution to these problems is to rebuild any indexes that use an affected character set or collation, either by dropping and re-creating the indexes, or by dumping and reloading the entire table. In some cases, it is possible to alter affected columns to use a different collation. For information about rebuilding indexes, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

To check whether a table has indexes that must be rebuilt, consult the following list. It indicates which versions of MySQL introduced character set or collation changes that require indexes to be rebuilt. Each entry indicates the version in which the change occurred and the character sets or collations that the change affects. If the change is associated with a particular bug report, the bug number is given.

The list applies both for binary upgrades and downgrades. For example, Bug #27877 was fixed in MySQL 5.1.24, so it applies to upgrades from versions older than 5.1.24 to 5.1.24 or higher, and to downgrades from 5.1.24 or newer to versions older than 5.1.24.

In many cases, you can use `CHECK TABLE ... FOR UPGRADE` to identify tables for which index rebuilding is required. It will report this message:

```
Table upgrade required.
Please do "REPAIR TABLE `tbl_name`" or dump/reload to fix it!
```

In these cases, you can also use `mysqlcheck --check-upgrade` or `mysql_upgrade`, which execute `CHECK TABLE`. However, the use of `CHECK TABLE` applies only after upgrades, not downgrades. Also, `CHECK TABLE` is not applicable to all storage engines. For details about which storage engines `CHECK TABLE` supports, see [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

These changes cause index rebuilding to be necessary:

- MySQL 5.1.24 (Bug #27877)

Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain 'ß' LATIN SMALL LETTER SHARP S (German). The bug fix corrected an error in the original collations but introduced an incompatibility such that 'ß' compares equal to characters with which it previously compared different.

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.30 (see Bug #40053).

A workaround for this issue is implemented as of MySQL 5.1.62, 5.5.21, and 5.6.5. The workaround involves altering affected columns to use the `utf8_general_mysql500_ci` and `ucs2_general_mysql500_ci` collations, which preserve the original pre-5.1.24 ordering of `utf8_general_ci` and `ucs2_general_ci`.

2.11.4 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild a table, following changes to MySQL such as how data types or character sets are handled. For example, an error in a collation might have been corrected, requiring a table rebuild to update the indexes for character columns that use the collation. (For examples, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).) You might also need to repair or upgrade a table, as indicated by a table check operation such as that performed by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include dumping and reloading it, or using `ALTER TABLE` or `REPAIR TABLE`. `REPAIR TABLE` only applies to `MyISAM`, `ARCHIVE`, and `CSV` tables.

Note

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
mysqldump db_name t1 > dump.sql
mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
mysqldump db_name > dump.sql
mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` option:

```
mysqldump --all-databases > dump.sql
mysql < dump.sql
```

To rebuild a table with `ALTER TABLE`, use a “null” alteration; that is, an `ALTER TABLE` statement that “changes” the table to use the storage engine that it already has. For example, if `t1` is an `InnoDB` table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

If you need to rebuild an `InnoDB` table because a `CHECK TABLE` operation indicates that a table upgrade is required, use `mysqldump` to create a dump file and `mysql` to reload the file, as described earlier.

If the `CHECK TABLE` operation indicates that there is a corruption or causes `InnoDB` to fail, refer to [Section 14.21.2, “Forcing InnoDB Recovery”](#) for information about using the `innodb_force_recovery` option to restart `InnoDB`. To understand the type of problem that `CHECK TABLE` may be encountering, refer to the `InnoDB` notes in [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

For `MyISAM`, `ARCHIVE`, or `CSV` tables, you can use `REPAIR TABLE` if the table checking operation indicates that there is a corruption or that an upgrade is required. For example, to repair a `MyISAM` table, use this statement:

```
REPAIR TABLE t1;
```

`mysqlcheck --repair` provides command-line access to the `REPAIR TABLE` statement. This can be a more convenient means of repairing tables because you can use the `--databases` or `--all-databases` option to repair all tables in specific databases or all databases, respectively:

```
mysqlcheck --repair --databases db_name ...
mysqlcheck --repair --all-databases
```

For incompatibilities introduced in MySQL 5.1.24 by the fix for Bug #27877 that corrected the `utf8_general_ci` and `ucs2_general_ci` collations, a workaround is implemented as of MySQL 5.1.62, 5.5.21, and 5.6.5. Upgrade to one of those versions, then convert each affected table using one of the following methods. In each case, the workaround altering affected columns to use the `utf8_general_mysql500_ci` and `ucs2_general_mysql500_ci` collations, which preserve the original pre-5.1.24 ordering of `utf8_general_ci` and `ucs2_general_ci`.

- To convert an affected table after a binary upgrade that leaves the table files in place, alter the table to use the new collation. Suppose that the table `t1` contains one or more problematic `utf8` columns. To convert the table at the table level, use a statement like this:

```
ALTER TABLE t1
  CONVERT TO CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
```

To apply the change on a column-specific basis, use a statement like this (be sure to repeat the column definition as originally specified except for the `COLLATE` clause):

```
ALTER TABLE t1
  MODIFY c1 CHAR(N) CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
```

- To upgrade the table using a dump and reload procedure, dump the table using `mysqldump`, modify the `CREATE TABLE` statement in the dump file to use the new collation, and reload the table.

After making the appropriate changes, `CHECK TABLE` should report no error.

2.11.5 Copying MySQL Databases to Another Machine

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Note

You can copy the `.frm`, `.MYI`, and `.MYD` files for `MyISAM` tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See [Section 15.2, “The MyISAM Storage Engine”](#).

Use `mysqldump --help` to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
mysqladmin -h 'other_hostname' create db_name
mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
mysqladmin create db_name
mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
mysqladmin create db_name
gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
mkdir DUMPDIR
mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
mysqladmin create db_name          # create database
cat DUMPDIR/*.sql | mysql db_name  # create tables in database
mysqlimport db_name DUMPDIR/*.txt  # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

2.12 Perl Installation Notes

The Perl `DBI` module provides a generic interface for database access. You can write a `DBI` script that works with many different database engines without change. To use `DBI`, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl, and the `DBD::MySQL` module for `DBI` must be installed if you want to run the MySQL benchmark scripts; see [Section 8.13.2, “The MySQL Benchmark Suite”](#).

Note

Perl support is not included with MySQL distributions. You can obtain the necessary modules from <http://search.cpan.org> for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

The `DBI/DBD` interface requires Perl 5.6.0, and 5.6.1 or later is preferred. `DBI` *does not work* if you have an older version of Perl. You should use `DBD::mysql` 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 5.6.

2.12.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at <http://search.cpan.org>.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a `DBI` distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
```

```
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: <http://learn.perl.org/faq/perlfaq8.html#How-do-I-keep-my-own-module-library-directory->

2.12.2 Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from <http://www.activestate.com/Products/ActivePerl/> and install it.
2. Open a console window.
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
C:\> set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install `DBI`:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or higher.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
    die "Got error $DBI::errstr when connecting to $dsn\n";
```

2.12.3 Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).

- Modify the `-L` options used to compile `DBD:mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

You may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD:mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as [Chapter 5, MySQL Server Administration](#).)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1 Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will

also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: *****
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `*****` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: *****
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.6.37-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter SQL statements.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of [Chapter 2, Installing and Upgrading MySQL](#) that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see [Section B.5.2, "Common Errors When Using MySQL Programs"](#).

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

3.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering queries, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple query that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----+-----+
| VERSION() | CURRENT_DATE |
+-----+-----+
| 5.6.1-m4-log | 2010-08-06 |
+-----+-----+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A query normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a query, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another query.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the "rows in set" line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-----+-----+
| SIN(PI()/4) | (4+1)*5 |
+-----+-----+
| 0.70710678118655 | 25 |
+-----+-----+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
```

```
+-----+
| VERSION() |
+-----+
| 5.6.1-m4-log |
+-----+
1 row in set (0.00 sec)

+-----+
| NOW() |
+-----+
| 2010-08-06 12:17:13 |
+-----+
1 row in set (0.00 sec)
```

A query need not be given all on a single line, so lengthy queries that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
-> USER()
-> ,
-> CURRENT_DATE;

+-----+-----+
| USER() | CURRENT_DATE |
+-----+-----+
| jon@localhost | 2010-08-06 |
+-----+-----+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a query that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
-> USER()
-> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new query.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

| Prompt | Meaning |
|------------------------|---|
| <code>mysql></code> | Ready for new query |
| <code>-></code> | Waiting for next line of multiple-line query |
| <code>'></code> | Waiting for next line, waiting for completion of a string that began with a single quote (') |
| <code>"></code> | Waiting for next line, waiting for completion of a string that began with a double quote (") |
| <code>`></code> | Waiting for next line, waiting for completion of an identifier that began with a backtick (`) |
| <code>/*></code> | Waiting for next line, waiting for completion of a comment that began with / * |

Multiple-line statements commonly occur by accident when you intend to issue a query on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()  
->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()  
-> ;  
+-----+  
| USER() |  
+-----+  
| jon@localhost |  
+-----+
```

The `'>` and `>` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `'` or `"` characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `>` prompt, it means that you have entered a line containing a string that begins with a `'` or `"` quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;  
'>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the query. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;  
'> '\c  
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new query.

The ``>` prompt is similar to the `'>` and `>` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `>`, and ``>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current query.

3.3 Creating and Using a Database

Once you know how to enter SQL statements, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed `tar` file and Zip formats at <http://dev.mysql.com/doc/>.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| mysql    |
| test     |
| tmp      |
+-----+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See [Section 13.7.5.15, “SHOW DATABASES Syntax”](#).

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a statement like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

Note

If you get an error such as `ERROR 1044 (42000): Access denied for user 'micah'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see [Section 6.2, “The MySQL Access Privilege System”](#).

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this statement:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: *****
```

Important

`menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

Note

You can see at any time which database is currently selected using `SELECT DATABASE()`.

3.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
-> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be `20`. You can normally pick any length from `1` to `65535`, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+-----+
| Tables in menagerie |
+-----+
| pet                |
+-----+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name  | varchar(20) | YES | | NULL | |
```

| | | | | | | |
|---------|-------------|-----|--|------|--|--|
| owner | varchar(20) | YES | | NULL | | |
| species | varchar(20) | YES | | NULL | | |
| sex | char(1) | YES | | NULL | | |
| birth | date | YES | | NULL | | |
| death | date | YES | | NULL | | |

You can use [DESCRIBE](#) any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see [Chapter 11, Data Types](#).

3.3.3 Loading Data into a Table

After creating your table, you need to populate it. The [LOAD DATA](#) and [INSERT](#) statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in 'YYYY-MM-DD' format; this may be different from what you are used to.)

| name | owner | species | sex | birth | death |
|----------|--------|---------|-----|------------|------------|
| Fluffy | Harold | cat | f | 1993-02-04 | |
| Claws | Gwen | cat | m | 1994-03-17 | |
| Buffy | Harold | dog | f | 1989-05-13 | |
| Fang | Benny | dog | m | 1990-08-27 | |
| Bowser | Diane | dog | m | 1979-08-31 | 1995-07-29 |
| Chirpy | Gwen | bird | f | 1998-09-11 | |
| Whistler | Gwen | bird | | 1997-12-09 | |
| Slim | Benny | snake | m | 1996-04-29 | |

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the [CREATE TABLE](#) statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use [NULL](#) values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler      Gwen      bird      \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
-> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#), for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
-> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

3.3.4 Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

what_to_select indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *which_table* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *conditions_to_satisfy* specifies one or more conditions that rows must satisfy to qualify for retrieval.

3.3.4.1 Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
```

| name | owner | species | sex | birth | death |
|----------|--------|---------|------|------------|------------|
| Fluffy | Harold | cat | f | 1993-02-04 | NULL |
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
| Fang | Benny | dog | m | 1990-08-27 | NULL |
| Bowser | Diane | dog | m | 1979-08-31 | 1995-07-29 |
| Chirpy | Gwen | bird | f | 1998-09-11 | NULL |
| Whistler | Gwen | bird | NULL | 1997-12-09 | NULL |
| Slim | Benny | snake | m | 1996-04-29 | NULL |
| Puffball | Diane | hamster | f | 1999-03-30 | NULL |

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+-----+-----+-----+-----+-----+-----+
| name  | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Bowser | Diane | dog      | m    | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+-----+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+-----+-----+-----+-----+-----+-----+
| name    | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Chirpy  | Gwen  | bird     | f    | 1998-09-11 | NULL       |
| Puffball | Diane | hamster  | f    | 1999-03-30 | NULL       |
+-----+-----+-----+-----+-----+-----+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-----+-----+-----+-----+-----+-----+
| name  | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
```

| | | | | | |
|-------|--------|-----|---|------------|------|
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
|-------|--------|-----|---|------------|------|

The preceding query uses the [AND](#) logical operator. There is also an [OR](#) operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
```

| name | owner | species | sex | birth | death |
|----------|-------|---------|------|------------|-------|
| Chirpy | Gwen | bird | f | 1998-09-11 | NULL |
| Whistler | Gwen | bird | NULL | 1997-12-09 | NULL |
| Slim | Benny | snake | m | 1996-04-29 | NULL |

[AND](#) and [OR](#) may be intermixed, although [AND](#) has higher precedence than [OR](#). If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
-> OR (species = 'dog' AND sex = 'f');
```

| name | owner | species | sex | birth | death |
|-------|--------|---------|-----|------------|-------|
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |

3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the [name](#) and [birth](#) columns:

```
mysql> SELECT name, birth FROM pet;
```

| name | birth |
|----------|------------|
| Fluffy | 1993-02-04 |
| Claws | 1994-03-17 |
| Buffy | 1989-05-13 |
| Fang | 1990-08-27 |
| Bowser | 1989-08-31 |
| Chirpy | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim | 1996-04-29 |
| Puffball | 1999-03-30 |

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
```

| owner |
|--------|
| Harold |
| Gwen |
| Harold |
| Benny |
| Diane |
| Gwen |
| Gwen |
| Benny |

```
| Diane |
+-----+
```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
+-----+
| owner |
+-----+
| Benny |
| Diane |
| Gwen  |
| Harold |
+-----+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
-> WHERE species = 'dog' OR species = 'cat';
+-----+-----+-----+
| name  | species | birth      |
+-----+-----+-----+
| Fluffy | cat     | 1993-02-04 |
| Claws  | cat     | 1994-03-17 |
| Buffy  | dog     | 1989-05-13 |
| Fang   | dog     | 1990-08-27 |
| Bowser | dog     | 1989-08-31 |
+-----+-----+-----+
```

3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+-----+-----+
| name  | birth      |
+-----+-----+
| Buffy  | 1989-05-13 |
| Bowser | 1989-08-31 |
| Fang   | 1990-08-27 |
| Fluffy  | 1993-02-04 |
| Claws  | 1994-03-17 |
| Slim   | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy | 1998-09-11 |
| Puffball | 1999-03-30 |
+-----+-----+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
```

| name | birth |
|----------|------------|
| Puffball | 1999-03-30 |
| Chirpy | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim | 1996-04-29 |
| Claws | 1994-03-17 |
| Fluffy | 1993-02-04 |
| Fang | 1990-08-27 |
| Bowser | 1989-08-31 |
| Buffy | 1989-05-13 |

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
-> ORDER BY species, birth DESC;
```

| name | species | birth |
|----------|---------|------------|
| Chirpy | bird | 1998-09-11 |
| Whistler | bird | 1997-12-09 |
| Claws | cat | 1994-03-17 |
| Fluffy | cat | 1993-02-04 |
| Fang | dog | 1990-08-27 |
| Bowser | dog | 1989-08-31 |
| Buffy | dog | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim | snake | 1996-04-29 |

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` function. Its arguments are the unit in which you want the result expressed, and the two date for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An *alias* (`age`) is used to make the final output column label more meaningful.

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet;
```

| name | birth | CURDATE() | age |
|--------|------------|------------|-----|
| Fluffy | 1993-02-04 | 2003-08-19 | 10 |
| Claws | 1994-03-17 | 2003-08-19 | 9 |
| Buffy | 1989-05-13 | 2003-08-19 | 14 |
| Fang | 1990-08-27 | 2003-08-19 | 12 |

| | | | |
|----------|------------|------------|----|
| Bowser | 1989-08-31 | 2003-08-19 | 13 |
| Chirpy | 1998-09-11 | 2003-08-19 | 4 |
| Whistler | 1997-12-09 | 2003-08-19 | 5 |
| Slim | 1996-04-29 | 2003-08-19 | 7 |
| Puffball | 1999-03-30 | 2003-08-19 | 4 |

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet ORDER BY name;
```

| name | birth | CURDATE() | age |
|----------|------------|------------|-----|
| Bowser | 1989-08-31 | 2003-08-19 | 13 |
| Buffy | 1989-05-13 | 2003-08-19 | 14 |
| Chirpy | 1998-09-11 | 2003-08-19 | 4 |
| Claws | 1994-03-17 | 2003-08-19 | 9 |
| Fang | 1990-08-27 | 2003-08-19 | 12 |
| Fluffy | 1993-02-04 | 2003-08-19 | 10 |
| Puffball | 1999-03-30 | 2003-08-19 | 4 |
| Slim | 1996-04-29 | 2003-08-19 | 7 |
| Whistler | 1997-12-09 | 2003-08-19 | 5 |

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet ORDER BY age;
```

| name | birth | CURDATE() | age |
|----------|------------|------------|-----|
| Chirpy | 1998-09-11 | 2003-08-19 | 4 |
| Puffball | 1999-03-30 | 2003-08-19 | 4 |
| Whistler | 1997-12-09 | 2003-08-19 | 5 |
| Slim | 1996-04-29 | 2003-08-19 | 7 |
| Claws | 1994-03-17 | 2003-08-19 | 9 |
| Fluffy | 1993-02-04 | 2003-08-19 | 10 |
| Fang | 1990-08-27 | 2003-08-19 | 12 |
| Bowser | 1989-08-31 | 2003-08-19 | 13 |
| Buffy | 1989-05-13 | 2003-08-19 | 14 |

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
-> TIMESTAMPDIFF(YEAR,birth,death) AS age
-> FROM pet WHERE death IS NOT NULL ORDER BY age;
```

| name | birth | death | age |
|--------|------------|------------|-----|
| Bowser | 1989-08-31 | 1995-07-29 | 5 |

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See [Section 3.3.4.6, “Working with NULL Values”](#).

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

| name | birth | MONTH(birth) |
|----------|------------|--------------|
| Fluffy | 1993-02-04 | 2 |
| Claws | 1994-03-17 | 3 |
| Buffy | 1989-05-13 | 5 |
| Fang | 1990-08-27 | 8 |
| Bowser | 1989-08-31 | 8 |
| Chirpy | 1998-09-11 | 9 |
| Whistler | 1997-12-09 | 12 |
| Slim | 1996-04-29 | 4 |
| Puffball | 1999-03-30 | 3 |

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

| name | birth |
|-------|------------|
| Buffy | 1989-05-13 |

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` returns a number between 1 and 12. And `MOD(something,12)` returns a number between 0 and 11. So the addition has to be after the `MOD()`, otherwise we would go from November (11) to January (1).

3.3.4.6 Working with NULL Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values.

To test for `NULL`, use the `IS NULL` and `IS NOT NULL` operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----+-----+
| 1 IS NULL | 1 IS NOT NULL |
+-----+-----+
|          0 |              1 |
+-----+-----+
```

You cannot use arithmetic comparison operators such as `=`, `<`, or `<>` to test for `NULL`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+-----+-----+-----+-----+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+-----+-----+-----+-----+
|        NULL |        NULL |        NULL |        NULL |
+-----+-----+-----+-----+
```

Because the result of any arithmetic comparison with `NULL` is also `NULL`, you cannot obtain any meaningful results from such comparisons.

In MySQL, `0` or `NULL` means false and anything else means true. The default truth value from a boolean operation is `1`.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means “not having a value.” You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----+-----+-----+-----+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----+-----+-----+-----+
|          0 |              1 |          0 |              1 |
+-----+-----+-----+-----+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See [Section B.5.4.3, “Problems with NULL Values”](#).

3.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching enables you to use `_` to match any single character and `%` to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. You do not use `=` or `<>` when you use SQL patterns; use the `LIKE` or `NOT LIKE` comparison operators instead.

To find names beginning with `b`:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
```

| name | owner | species | sex | birth | death |
|--------|--------|---------|-----|------------|------------|
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |

To find names ending with `fy`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
```

| name | owner | species | sex | birth | death |
|--------|--------|---------|-----|------------|-------|
| Fluffy | Harold | cat | f | 1993-02-04 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |

To find names containing a `w`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```

| name | owner | species | sex | birth | death |
|----------|-------|---------|------|------------|------------|
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen | bird | NULL | 1997-12-09 | NULL |

To find names containing exactly five characters, use five instances of the `_` pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
```

| name | owner | species | sex | birth | death |
|-------|--------|---------|-----|------------|-------|
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP` and `NOT REGEXP` operators (or `RLIKE` and `NOT RLIKE`, which are synonyms).

The following list describes some characteristics of extended regular expressions:

- `.` matches any single character.
- A character class `[...]` matches any character within the brackets. For example, `[abc]` matches `a`, `b`, or `c`. To name a range of characters, use a dash. `[a-z]` matches any letter, whereas `[0-9]` matches any digit.
- `*` matches zero or more instances of the thing preceding it. For example, `x*` matches any number of `x` characters, `[0-9]*` matches any number of digits, and `.*` matches any number of anything.
- A `REGEXP` pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a `LIKE` pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use `^` at the beginning or `$` at the end of the pattern.

To demonstrate how extended regular expressions work, the `LIKE` queries shown previously are rewritten here to use `REGEXP`.

To find names beginning with `b`, use `^` to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
```

| name | owner | species | sex | birth | death |
|--------|--------|---------|-----|------------|------------|
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |

If you really want to force a `REGEXP` comparison to be case sensitive, use the `BINARY` keyword to make one of the strings a binary string. This query matches only lowercase `b` at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with `fy`, use `$` to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
```

| name | owner | species | sex | birth | death |
|--------|--------|---------|-----|------------|-------|
| Fluffy | Harold | cat | f | 1993-02-04 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |

To find names containing a `w`, use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
```

| name | owner | species | sex | birth | death |
|----------|-------|---------|------|------------|------------|
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen | bird | NULL | 1997-12-09 | NULL |

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use `^` and `$` to match the beginning and end of the name, and five instances of `.` in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
```

| name | owner | species | sex | birth | death |
|-------|--------|---------|-----|------------|-------|
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |

You could also write the previous query using the `{n}` ("repeat-*n*-times") operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
```

| name | owner | species | sex | birth | death |
|-------|--------|---------|-----|------------|-------|
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |

Section 12.5.2, “Regular Expressions”, provides more information about the syntax for regular expressions.

3.3.4.8 Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+-----+
| COUNT(*) |
+-----+
|          9 |
+-----+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Benny |         2 |
| Diane |         2 |
| Gwen  |         3 |
| Harold |         2 |
+-----+-----+
```

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+-----+-----+
| species | COUNT(*) |
+-----+-----+
| bird   |         2 |
| cat    |         2 |
| dog    |         3 |
| hamster |         1 |
| snake  |         1 |
+-----+-----+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
```

| sex | COUNT(*) |
|------|----------|
| NULL | 1 |
| f | 4 |
| m | 4 |

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

| species | sex | COUNT(*) |
|---------|------|----------|
| bird | NULL | 1 |
| bird | f | 1 |
| cat | f | 1 |
| cat | m | 1 |
| dog | f | 1 |
| dog | m | 2 |
| hamster | f | 1 |
| snake | m | 1 |

You need not retrieve an entire table when you use `COUNT()`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE species = 'dog' OR species = 'cat'
-> GROUP BY species, sex;
```

| species | sex | COUNT(*) |
|---------|-----|----------|
| cat | f | 1 |
| cat | m | 1 |
| dog | f | 1 |
| dog | m | 2 |

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE sex IS NOT NULL
-> GROUP BY species, sex;
```

| species | sex | COUNT(*) |
|---------|-----|----------|
| bird | f | 1 |
| cat | f | 1 |
| cat | m | 1 |
| dog | f | 1 |
| dog | m | 2 |
| hamster | f | 1 |
| snake | m | 1 |

If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT()...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is indeterminate. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Harold |      8 |
+-----+-----+
1 row in set (0.00 sec)
```

See also [Section 12.18.3, “MySQL Handling of GROUP BY”](#). See [Section 12.18.1, “Aggregate \(GROUP BY\) Function Descriptions”](#) for information about `COUNT(expr)` behavior and related optimizations.

3.3.4.9 Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
-> type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

| name | date | type | remark |
|--------|------------|--------|-----------------------------|
| Fluffy | 1995-05-15 | litter | 4 kittens, 3 female, 1 male |
| Buffy | 1993-06-23 | litter | 5 puppies, 2 female, 3 male |
| Buffy | 1994-06-19 | litter | 3 puppies, 3 female |
| Chirpy | 1999-03-21 | vet | needed beak straightened |
| Slim | 1997-08-03 | vet | broken rib |
| Bowser | 1991-10-12 | kennel | |

| name | date | type | remark |
|----------|------------|----------|----------------------------|
| Fang | 1991-10-12 | kennel | |
| Fang | 1998-08-28 | birthday | Gave him a new chew toy |
| Claws | 1998-03-17 | birthday | Gave him a new flea collar |
| Whistler | 1998-12-09 | birthday | First birthday |

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
-> TIMESTAMPDIF(YEAR,birth,date) AS age,
-> remark
-> FROM pet INNER JOIN event
-> ON pet.name = event.name
-> WHERE event.type = 'litter';
```

| name | age | remark |
|--------|-----|-----------------------------|
| Fluffy | 2 | 4 kittens, 3 female, 1 male |
| Buffy | 4 | 5 puppies, 2 female, 3 male |
| Buffy | 5 | 3 puppies, 3 female |

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
-> FROM pet AS p1 INNER JOIN pet AS p2
-> ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
```

| name | sex | name | sex | species |
|--------|-----|--------|-----|---------|
| Fluffy | f | Claws | m | cat |
| Buffy | f | Fang | m | dog |
| Buffy | f | Bowser | m | dog |

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
```

| DATABASE() |
|------------|
| menagerie |

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this statement:

```
mysql> SHOW TABLES;
```

| Tables_in_menagerie |
|---------------------|
| event |
| pet |

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See [Section 13.7.5.38, “SHOW TABLES Syntax”](#), for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
```

| Field | Type | Null | Key | Default | Extra |
|---------|-------------|------|-----|---------|-------|
| name | varchar(20) | YES | | NULL | |
| owner | varchar(20) | YES | | NULL | |
| species | varchar(20) | YES | | NULL | |
| sex | char(1) | YES | | NULL | |
| birth | date | YES | | NULL | |

| | | | | | | |
|-------|------|-----|--|------|--|--|
| death | date | YES | | NULL | | |
|-------|------|-----|--|------|--|--|

Field indicates the column name, **Type** is the data type for the column, **NULL** indicates whether the column can contain **NULL** values, **Key** indicates whether the column is indexed, and **Default** specifies the column's default value. **Extra** displays special information about columns: If a column was created with the **AUTO_INCREMENT** option, the value will be **auto_increment** rather than empty.

DESC is a short form of **DESCRIBE**. See [Section 13.8.1, “DESCRIBE Syntax”](#), for more information.

You can obtain the **CREATE TABLE** statement necessary to create an existing table using the **SHOW CREATE TABLE** statement. See [Section 13.7.5.12, “SHOW CREATE TABLE Syntax”](#).

If you have indexes on a table, **SHOW INDEX FROM tbl_name** produces information about them. See [Section 13.7.5.23, “SHOW INDEX Syntax”](#), for more about this statement.

3.5 Using mysql in Batch Mode

In the previous sections, you used **mysql** interactively to enter statements and view the results. You can also run **mysql** in batch mode. To do this, put the statements you want to run in a file, then tell **mysql** to read its input from the file:

```
shell> mysql < batch-file
```

If you are running **mysql** under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: *****
```

When you use **mysql** this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the **--force** command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line statements or multiple-statement sequences. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell **mysql** to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the statements.
- Some situations do not allow for interactive use, for example, when you run a query from a [cron](#) job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+-----+
| species |
+-----+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+-----+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the statements that are executed, use `mysql -v`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See [Section 4.5.1.5, “Executing SQL Statements from a Text File”](#), for more information.

3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
CREATE TABLE shop (
  article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
  dealer CHAR(20) DEFAULT '' NOT NULL,
  price DOUBLE(16,2) DEFAULT '0.00' NOT NULL,
  PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
  (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
  (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop;

+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0001 | A | 3.45 |
| 0001 | B | 3.99 |
| 0002 | A | 10.99 |
| 0003 | B | 1.45 |
| 0003 | C | 1.69 |
| 0003 | D | 1.25 |
| 0004 | D | 19.95 |
+-----+-----+-----+
```

3.6.1 The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;

+-----+
| article |
+-----+
| 4 |
+-----+
```

3.6.2 The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);

+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0004 | D | 19.95 |
+-----+-----+-----+
```

Other solutions are to use a [LEFT JOIN](#) or to sort all rows descending by price and get only the first row using the MySQL-specific [LIMIT](#) clause:

```
SELECT s1.article, s1.dealer, s1.price
```

```

FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;

SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;

```

**Note**

If there were several most expensive articles, each with a price of 19.95, the [LIMIT](#) solution would show only one of them.

3.6.3 Maximum of Column per Group

Task: Find the highest price per article.

```

SELECT article, MAX(price) AS price
FROM   shop
GROUP BY article;

```

| article | price |
|---------|-------|
| 0001 | 3.99 |
| 0002 | 10.99 |
| 0003 | 1.69 |
| 0004 | 19.95 |

3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

Task: For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```

SELECT article, dealer, price
FROM   shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);

```

| article | dealer | price |
|---------|--------|-------|
| 0001 | B | 3.99 |
| 0002 | A | 10.99 |
| 0003 | C | 1.69 |
| 0004 | D | 19.95 |

The preceding example uses a correlated subquery, which can be inefficient (see [Section 13.2.10.7, “Correlated Subqueries”](#)). Other possibilities for solving the problem are to use an uncorrelated subquery in the [FROM](#) clause or a [LEFT JOIN](#).

Uncorrelated subquery:

```

SELECT s1.article, dealer, s1.price
FROM shop s1

```

```
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
ON s1.article = s2.article AND s1.price = s2.price;
```

LEFT JOIN:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and the `s2` rows values will be `NULL`. See [Section 13.2.9.2, “JOIN Syntax”](#).

3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See [Section 9.4, “User-Defined Variables”](#).)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
```

| article | dealer | price |
|---------|--------|-------|
| 0003 | D | 1.25 |
| 0004 | D | 19.95 |

Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See [Section 13.5, “Prepared SQL Statement Syntax”](#), for more information.

3.6.6 Using Foreign Keys

In MySQL, `InnoDB` tables support checking of foreign key constraints. See [Chapter 14, *The InnoDB Storage Engine*](#), and [Section 1.7.2.3, “Foreign Key Differences”](#).

A foreign key constraint is not required merely to join two tables. For storage engines other than `InnoDB`, it is possible when defining a column to use a `REFERENCES tbl_name(col_name)` clause, which has no actual effect, and serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of `CHECK` to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).
- MySQL does not perform any sort of action on `tbl_name` such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)

- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    name CHAR(60) NOT NULL,
    PRIMARY KEY (id)
);

CREATE TABLE shirt (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
    color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
    owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
    PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+-----+
| id | name                |
+-----+
| 1  | Antonio Paz         |
| 2  | Lilliana Angelovska |
+-----+

SELECT * FROM shirt;
+-----+-----+-----+-----+
| id | style  | color  | owner |
+-----+-----+-----+-----+
| 1  | polo   | blue   | 1      |
| 2  | dress  | white  | 1      |
| 3  | t-shirt| blue   | 1      |
| 4  | dress  | orange | 2      |
| 5  | polo   | red    | 2      |
| 6  | dress  | blue   | 2      |
| 7  | t-shirt| white  | 2      |
+-----+-----+-----+-----+

SELECT s.* FROM person p INNER JOIN shirt s
    ON s.owner = p.id
    WHERE p.name LIKE 'Lilliana%'
    AND s.color <> 'white';

+-----+-----+-----+-----+
| id | style | color | owner |
```

| | | | |
|---|-------|--------|---|
| 4 | dress | orange | 2 |
| 5 | polo | red | 2 |
| 6 | dress | blue | 2 |

When used in this fashion, the [REFERENCES](#) clause is not displayed in the output of [SHOW CREATE TABLE](#) or [DESCRIBE](#):

```
SHOW CREATE TABLE shirt\G
***** 1. row *****
Table: shirt
Create Table: CREATE TABLE `shirt` (
  `id` smallint(5) unsigned NOT NULL auto_increment,
  `style` enum('t-shirt','polo','dress') NOT NULL,
  `color` enum('red','blue','orange','white','black') NOT NULL,
  `owner` smallint(5) unsigned NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The use of [REFERENCES](#) in this way as a comment or “reminder” in a column definition works with [MyISAM](#) tables.

3.6.7 Searching on Two Keys

An [OR](#) using a single key is well optimized, as is the handling of [AND](#).

The one tricky case is that of searching on two different keys combined with [OR](#):

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized. See [Section 8.2.1.3, “Index Merge Optimization”](#).

You can also solve the problem efficiently by using a [UNION](#) that combines the output of two separate [SELECT](#) statements. See [Section 13.2.9.3, “UNION Syntax”](#).

Each [SELECT](#) searches only one key and can be optimized:

```
SELECT field1_index, field2_index
  FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
  FROM test_table WHERE field2_index = '1';
```

3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
  day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
  (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
GROUP BY year,month;
```

Which returns:

```
+-----+-----+-----+
| year | month | days |
+-----+-----+-----+
| 2000 | 01    | 3    |
| 2000 | 02    | 2    |
+-----+-----+-----+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

3.6.9 Using AUTO_INCREMENT

The [AUTO_INCREMENT](#) attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
    ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+-----+-----+
| id | name   |
+-----+-----+
| 1  | dog    |
| 2  | cat    |
| 3  | penguin|
| 4  | lax    |
| 5  | whale  |
| 6  | ostrich|
+-----+-----+
```

No value was specified for the [AUTO_INCREMENT](#) column, so MySQL assigned sequence numbers automatically. You can also explicitly assign 0 to the column to generate sequence numbers, unless the [NO_AUTO_VALUE_ON_ZERO](#) SQL mode is enabled. If the column is declared [NOT NULL](#), it is also possible to assign [NULL](#) to the column to generate sequence numbers. When you insert any other value into an [AUTO_INCREMENT](#) column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the largest column value.

You can retrieve the most recent automatically generated [AUTO_INCREMENT](#) value with the [LAST_INSERT_ID\(\)](#) SQL function or the [mysql_insert_id\(\)](#) C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the [AUTO_INCREMENT](#) column that is large enough to hold the maximum sequence value you will need. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. Use the [UNSIGNED](#) attribute if possible to allow a

greater range. For example, if you use `TINYINT`, the maximum permissible sequence number is 127. For `TINYINT UNSIGNED`, the maximum is 255. See [Section 11.2.1, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#) for the ranges of all the integer types.

Note

For a multiple-row insert, `LAST_INSERT_ID()` and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an `AUTO_INCREMENT` value other than 1, set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

InnoDB Notes

For information about `AUTO_INCREMENT` usage specific to `InnoDB`, see [Section 14.8.6, “AUTO_INCREMENT Handling in InnoDB”](#).

MyISAM Notes

- For `MyISAM` tables, you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
  grp ENUM('fish','mammal','bird') NOT NULL,
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
  ('mammal','dog'),('mammal','cat'),
  ('bird','penguin'),('fish','lax'),('mammal','whale'),
  ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

| grp | id | name |
|--------|----|---------|
| fish | 1 | lax |
| mammal | 1 | dog |
| mammal | 2 | cat |
| mammal | 3 | whale |
| bird | 1 | penguin |
| bird | 2 | ostrich |

In this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

- If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL generates sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

Further Reading

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: [Section 13.1.17, “CREATE TABLE Syntax”](#), and [Section 13.1.7, “ALTER TABLE Syntax”](#).
- How `AUTO_INCREMENT` behaves depending on the `NO_AUTO_VALUE_ON_ZERO` SQL mode: [Section 5.1.8, “Server SQL Modes”](#).
- How to use the `LAST_INSERT_ID()` function to find the row that contains the most recent `AUTO_INCREMENT` value: [Section 12.14, “Information Functions”](#).

- [Section 14.8.6, “AUTO_INCREMENT Handling in InnoDB”](#)
- `AUTO_INCREMENT` and replication: [Section 17.4.1.1, “Replication and AUTO_INCREMENT”](#).
- Server-system variables related to `AUTO_INCREMENT` (`auto_increment_increment` and `auto_increment_offset`) that can be used for replication: [Section 5.1.5, “Server System Variables”](#).

3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
    "%h\" ,%{Y%m%d%H%M%S}t,%>s,\"%b\", \"%{Content-Type}o\", \
    \"%U\", \"%{Referer}i\", \"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

Chapter 4 MySQL Programs

Table of Contents

| | |
|---|-----|
| 4.1 Overview of MySQL Programs | 268 |
| 4.2 Using MySQL Programs | 273 |
| 4.2.1 Invoking MySQL Programs | 273 |
| 4.2.2 Connecting to the MySQL Server | 273 |
| 4.2.3 Specifying Program Options | 277 |
| 4.2.4 Using Options on the Command Line | 278 |
| 4.2.5 Program Option Modifiers | 280 |
| 4.2.6 Using Option Files | 280 |
| 4.2.7 Command-Line Options that Affect Option-File Handling | 286 |
| 4.2.8 Using Options to Set Program Variables | 287 |
| 4.2.9 Option Defaults, Options Expecting Values, and the = Sign | 288 |
| 4.2.10 Setting Environment Variables | 292 |
| 4.3 MySQL Server and Server-Startup Programs | 293 |
| 4.3.1 <code>mysqld</code> — The MySQL Server | 293 |
| 4.3.2 <code>mysqld_safe</code> — MySQL Server Startup Script | 293 |
| 4.3.3 <code>mysql.server</code> — MySQL Server Startup Script | 298 |
| 4.3.4 <code>mysqld_multi</code> — Manage Multiple MySQL Servers | 301 |
| 4.4 MySQL Installation-Related Programs | 305 |
| 4.4.1 <code>comp_err</code> — Compile MySQL Error Message File | 305 |
| 4.4.2 <code>mysqlbug</code> — Generate Bug Report | 306 |
| 4.4.3 <code>mysql_install_db</code> — Initialize MySQL Data Directory | 306 |
| 4.4.4 <code>mysql_plugin</code> — Configure MySQL Server Plugins | 310 |
| 4.4.5 <code>mysql_secure_installation</code> — Improve MySQL Installation Security | 312 |
| 4.4.6 <code>mysql_tzinfo_to_sql</code> — Load the Time Zone Tables | 312 |
| 4.4.7 <code>mysql_upgrade</code> — Check and Upgrade MySQL Tables | 313 |
| 4.5 MySQL Client Programs | 319 |
| 4.5.1 <code>mysql</code> — The MySQL Command-Line Tool | 319 |
| 4.5.2 <code>mysqladmin</code> — Client for Administering a MySQL Server | 344 |
| 4.5.3 <code>mysqlcheck</code> — A Table Maintenance Program | 352 |
| 4.5.4 <code>mysqldump</code> — A Database Backup Program | 360 |
| 4.5.5 <code>mysqlimport</code> — A Data Import Program | 381 |
| 4.5.6 <code>mysqlshow</code> — Display Database, Table, and Column Information | 388 |
| 4.5.7 <code>mysqlslap</code> — Load Emulation Client | 393 |
| 4.6 MySQL Administrative and Utility Programs | 401 |
| 4.6.1 <code>innochecksum</code> — Offline InnoDB File Checksum Utility | 401 |
| 4.6.2 <code>myisam_ftdump</code> — Display Full-Text Index information | 402 |
| 4.6.3 <code>myisamchk</code> — MyISAM Table-Maintenance Utility | 403 |
| 4.6.4 <code>myisamlog</code> — Display MyISAM Log File Contents | 421 |
| 4.6.5 <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables | 422 |
| 4.6.6 <code>mysql_config_editor</code> — MySQL Configuration Utility | 428 |
| 4.6.7 <code>mysqlaccess</code> — Client for Checking Access Privileges | 434 |
| 4.6.8 <code>mysqlbinlog</code> — Utility for Processing Binary Log Files | 437 |
| 4.6.9 <code>mysqldumpslow</code> — Summarize Slow Query Log Files | 458 |
| 4.6.10 <code>mysqlhotcopy</code> — A Database Backup Program | 460 |
| 4.6.11 <code>mysql_convert_table_format</code> — Convert Tables to Use a Given Storage Engine | 463 |
| 4.6.12 <code>mysql_find_rows</code> — Extract SQL Statements from Files | 464 |
| 4.6.13 <code>mysql_fix_extensions</code> — Normalize Table File Name Extensions | 465 |
| 4.6.14 <code>mysql_setpermission</code> — Interactively Set Permissions in Grant Tables | 465 |

| | | |
|--------|---|-----|
| 4.6.15 | <code>mysql_waitpid</code> — Kill Process and Wait for Its Termination | 466 |
| 4.6.16 | <code>mysql_zap</code> — Kill Processes That Match a Pattern | 467 |
| 4.7 | MySQL Program Development Utilities | 467 |
| 4.7.1 | <code>mysql2mysql</code> — Convert mSQL Programs for Use with MySQL | 468 |
| 4.7.2 | <code>mysql_config</code> — Display Options for Compiling Clients | 468 |
| 4.7.3 | <code>my_print_defaults</code> — Display Options from Option Files | 470 |
| 4.7.4 | <code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols | 471 |
| 4.8 | Miscellaneous Programs | 471 |
| 4.8.1 | <code>pererror</code> — Explain Error Codes | 471 |
| 4.8.2 | <code>replace</code> — A String-Replacement Utility | 472 |
| 4.8.3 | <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa | 473 |
| 4.9 | MySQL Program Environment Variables | 474 |

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of MySQL Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. [Section 18.4, “NDB Cluster Programs”](#), describes programs specific to MySQL Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see [Chapter 2, *Installing and Upgrading MySQL*](#), for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See [Section 4.2, “Using MySQL Programs”](#), for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See [Section 4.3.1, “`mysqld` — The MySQL Server](#)”.

- `mysqld_safe`

A server startup script. `mysqld_safe` attempts to start `mysqld`. See [Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script](#)”.

- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See [Section 4.3.3, “`mysql.server` — MySQL Server Startup Script](#)”.

- `mysqld_multi`

A server startup script that can start or stop multiple servers installed on the system. See [Section 4.3.4, “`mysqld_multi` — Manage Multiple MySQL Servers](#)”.

Several programs perform setup operations during MySQL installation or upgrading:

- `comp_err`

This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See [Section 4.4.1, “`comp_err` — Compile MySQL Error Message File](#)”.

- `mysql_install_db`

This program initializes the MySQL data directory, creates the `mysql` database and initializes its grant tables with default privileges, and sets up the `InnoDB` system tablespace. It is usually executed only once, when first installing MySQL on a system. See [Section 4.4.3, “`mysql_install_db` — Initialize MySQL Data Directory](#)”, and [Section 2.10, “Postinstallation Setup and Testing](#)”.

- `mysql_plugin`

This program configures MySQL server plugins. See [Section 4.4.4, “`mysql_plugin` — Configure MySQL Server Plugins](#)”.

- `mysql_secure_installation`

This program enables you to improve the security of your MySQL installation. See [Section 4.4.5, “`mysql_secure_installation` — Improve MySQL Installation Security](#)”.

- `mysql_tzinfo_to_sql`

This program loads the time zone tables in the `mysql` database using the contents of the host system `zoneinfo` database (the set of files describing time zones). See [Section 4.4.6, “`mysql_tzinfo_to_sql` — Load the Time Zone Tables](#)”.

- `mysql_upgrade`

This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See [Section 4.4.7, “`mysql_upgrade` — Check and Upgrade MySQL Tables](#)”.

MySQL client programs that connect to the MySQL server:

- `mysql`

The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See [Section 4.5.1, “`mysql` — The MySQL Command-Line Tool](#)”.

- `mysqladmin`

A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See [Section 4.5.2, “`mysqladmin` — Client for Administering a MySQL Server](#)”.

- `mysqlcheck`

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#).

- `mysqldump`

A client that dumps a MySQL database into a file as SQL, text, or XML. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

- `mysqlimport`

A client that imports text files into their respective tables using `LOAD DATA INFILE`. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

- `mysqlshow`

A client that displays information about databases, tables, columns, and indexes. See [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

- `mysqlslap`

A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See [Section 4.5.7, “mysqlslap — Load Emulation Client”](#).

MySQL administrative and utility programs:

- `innochecksum`

An offline InnoDB offline file checksum utility. See [Section 4.6.1, “innochecksum — Offline InnoDB File Checksum Utility”](#).

- `myisam_ftdump`

A utility that displays information about full-text indexes in MyISAM tables. See [Section 4.6.2, “myisam_ftdump — Display Full-Text Index information”](#).

- `myisamchk`

A utility to describe, check, optimize, and repair MyISAM tables. See [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

- `myisamlog`

A utility that processes the contents of a MyISAM log file. See [Section 4.6.4, “myisamlog — Display MyISAM Log File Contents”](#).

- `myisampack`

A utility that compresses MyISAM tables to produce smaller read-only tables. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

- `mysql_config_editor`

A utility that enables you to store authentication credentials in a secure, encrypted login path file named `.mylogin.cnf`. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).

- `mysqlaccess`

A script that checks the access privileges for a host name, user name, and database combination. See [Section 4.6.7, “mysqlaccess — Client for Checking Access Privileges”](#).

- `mysqlbinlog`

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

- `mysqldumpslow`

A utility to read and summarize the contents of a slow query log. See [Section 4.6.9, “mysqldumpslow — Summarize Slow Query Log Files”](#).

- `mysqlhotcopy`

A utility that quickly makes backups of `MyISAM` tables while the server is running. See [Section 4.6.10, “mysqlhotcopy — A Database Backup Program”](#).

- `mysql_convert_table_format`

A utility that converts tables in a database to use a given storage engine. See [Section 4.6.11, “mysql_convert_table_format — Convert Tables to Use a Given Storage Engine”](#).

- `mysql_find_rows`

A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See [Section 4.6.12, “mysql_find_rows — Extract SQL Statements from Files”](#).

- `mysql_fix_extensions`

A utility that converts the extensions for `MyISAM` table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See [Section 4.6.13, “mysql_fix_extensions — Normalize Table File Name Extensions”](#).

- `mysql_setpermission`

A utility for interactively setting permissions in the MySQL grant tables. See [Section 4.6.14, “mysql_setpermission — Interactively Set Permissions in Grant Tables”](#).

- `mysql_waitpid`

A utility that kills the process with a given process ID. See [Section 4.6.15, “mysql_waitpid — Kill Process and Wait for Its Termination”](#).

- `mysql_zap`

A utility that kills processes that match a pattern. See [Section 4.6.16, “mysql_zap — Kill Processes That Match a Pattern”](#).

MySQL program-development utilities:

- `msql2mysql`

A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See [Section 4.7.1, “msql2mysql — Convert mSQL Programs for Use with MySQL”](#).

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs. See [Section 4.7.2, “mysql_config — Display Options for Compiling Clients”](#).

- `my_print_defaults`

A utility that shows which options are present in option groups of option files. See [Section 4.7.3, “my_print_defaults — Display Options from Option Files”](#).

- `resolve_stack_dump`

A utility program that resolves a numeric stack trace dump to symbols. See [Section 4.7.4, “resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols”](#).

Miscellaneous utilities:

- `perror`

A utility that displays the meaning of system or MySQL error codes. See [Section 4.8.1, “pererror — Explain Error Codes”](#).

- `replace`

A utility program that performs string replacement in the input text. See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

- `resolveip`

A utility program that resolves a host name to an IP address or vice versa. See [Section 4.8.3, “resolveip — Resolve Host name to IP Address or Vice Versa”](#).

Oracle Corporation also provides the [MySQL Workbench](#) GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL. Additional GUI tools include [MySQL Notifier](#) and [MySQL for Excel](#).

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

| Environment Variable | Meaning |
|------------------------------|--|
| <code>MYSQL_UNIX_PORT</code> | The default Unix socket file; used for connections to <code>localhost</code> |
| <code>MYSQL_TCP_PORT</code> | The default port number; used for TCP/IP connections |
| <code>MYSQL_PWD</code> | The default password |
| <code>MYSQL_DEBUG</code> | Debug trace options when debugging |
| <code>TMPDIR</code> | The directory where temporary tables and files are created |

For a full list of environment variables used by MySQL programs, see [Section 4.9, “MySQL Program Environment Variables”](#).

Use of `MYSQL_PWD` is insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

4.2 Using MySQL Programs

4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. `shell>` represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh`, `ksh`, or `bash`, `%` for `csch` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (`-`, `--`) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in [Section 4.2.3, “Specifying Program Options”](#).

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in [Section 4.2.10, “Setting Environment Variables”](#).) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.2.2 Connecting to the MySQL Server

This section describes how to establish a connection to the MySQL server. For additional information if you are unable to connect, see [Section 6.2.7, “Troubleshooting Problems Connecting to MySQL”](#).

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any connection parameters explicitly:

```
shell> mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent if neither `-p` nor `--password` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. If there is no such option, `mysql` does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

```
shell> mysql --host=localhost --user=myname --password=mypass mydb
shell> mysql -h localhost -u myname -pmypass mydb
```

For password options, the password value is optional:

- If you use a `-p` or `--password` option and specify the password value, there must be *no space* between `-p` or `--password=` and the password following it.
- If you use a `-p` or `--password` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as `ps auxw`. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --host=localhost --user=myname --password mydb
shell> mysql -h localhost -u myname -p mydb
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a `--port` or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. For example:

```
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
```

The `--protocol` option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

If the server is configured to accept IPv6 connections, clients can connect over IPv6 using `--host>:::1`. See [Section 5.1.9, “IPv6 Support”](#).

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. If named-pipe connections are not enabled, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix will use a socket file by default. You will need to force a TCP/IP connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the server:

- `--host=host_name`, `-h host_name`

The host where the server is running. The default value is `localhost`.

- `--password[=pass_val]`, `-p[pass_val]`

The password of the MySQL account. As described earlier, the password value is optional, but if given, there must be *no space* between `-p` or `--password=` and the password following it. The default is to send no password.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--port=port_num, -P port_num`

The port number to use for the connection, for connections made using TCP/IP. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

```
shell> mysql --host=localhost
```

To force a TCP/IP connection to be used instead, specify a `--protocol` option:

```
shell> mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` option values and indicates the platforms on which each value may be used. The values are not case sensitive.

| <code>--protocol</code> Value | Connection Protocol | Permissible Operating Systems |
|----------------------------------|---|-------------------------------|
| TCP | TCP/IP connection to local or remote server | All |
| SOCKET | Unix socket file connection to local server | Unix only |
| PIPE | Named-pipe connection to local or remote server | Windows only |
| MEMORY | Shared-memory connection to local server | Windows only |

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--socket=file_name, -S file_name`

On Unix, the name of the Unix socket file to use, for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case sensitive.

The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--ssl*`

Options that begin with `--ssl` are used for establishing a secure connection to the server using SSL, if the server is configured with SSL support. For details, see [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--user=user_name, -u user_name`

The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=your_pass
```

[Section 4.2.6, “Using Option Files”](#), discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows only). The password can be specified using `MYSQL_PWD`, although this is insecure; see [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). For a list of variables, see [Section 4.9, “MySQL Program Environment Variables”](#).

4.2.3 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see [Section 4.2.10, “Setting Environment Variables”](#)). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but [Section 5.6.3, “Running Multiple MySQL Instances on Unix”](#), discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by processing option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
shell> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Note

As of MySQL 5.6.13, unambiguous prefixes are deprecated. If an unambiguous prefix is given, a warning occurs to provide feedback. Option prefixes are no longer supported as of MySQL 5.7; only full options are accepted.

4.2.4 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an `=` sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (-) and underscore (_) may be used interchangeably. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent. (However, the leading dashes cannot be given as underscores.)
- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024² or 1024³. For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
shell> mysqladmin --count=1K --sleep=10 ping
```

- When specifying file names as option values, avoid the use of the `~` shell metacharacter because it might not be interpreted as you expect.

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` (or `-e`) option can be used with `mysql` to pass SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```
shell> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: *****
+-----+-----+
| User | Host |
+-----+-----+
|      |      |
| root |      |
|      |      |
| jon  |      |
| root |      |
+-----+-----+
shell>
```

Note

The long form (`--execute`) is followed by an equals sign (=).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

```
shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: *****
+-----+
| VERSION() |
+-----+
| 5.6.28-debug-log |
+-----+
```

```

+-----+
+-----+
| NOW( ) |
+-----+
| 2015-11-05 20:01:28 |
+-----+

```

4.2.5 Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```

--disable-column-names
--skip-column-names
--column-names=0

```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```

--column-names
--enable-column-names
--column-names=1

```

The values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```

shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--loose-no-such-option'

```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

The `--maximum` prefix is available for `mysqld` only and permits a limit to be placed on how large client programs can set session system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-max_heap_table_size=32M` prevents any client from making the heap table size limit larger than 32M.

The `--maximum` prefix is intended for use with system variables that have a session value. If applied to a system variable that has only a global value, an error occurs. For example, with `--maximum-query_cache_size=4M`, the server produces this error:

```

Maximum value of 'query_cache_size' cannot be set

```

4.2.6 Using Option Files

Most MySQL programs can read startup options from option files (sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program.

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

Note

A MySQL program started with the `--no-defaults` option reads no option files other than `.mylogin.cnf`.

Many option files are plain text files, created using any text editor. The exception is the `.mylogin.cnf` file that contains login path options. This is an encrypted file created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). A “login path” is an option group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Client programs specify which login path to read from `.mylogin.cnf` using the `--login-path` option.

To specify an alternative login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is used by the `mysql-test-run.pl` testing utility, but also is recognized by `mysql_config_editor` and by MySQL clients such as `mysql`, `mysqladmin`, and so forth.

MySQL looks for option files in the order described in the following discussion and reads any that exist. If an option file you want to use does not exist, create it using the appropriate method, as just discussed.

Note

Option files used with MySQL Cluster programs are covered in [Section 18.3, “Configuration of NDB Cluster”](#).

On Windows, MySQL programs read startup options from the files shown in the following table, in the specified order (top files are read first, files read later take precedence).

Table 4.1 Option Files Read on Windows Systems

| File Name | Purpose |
|--|---|
| %PROGRAMDATA%\MySQL \MySQL Server 5.6\my.ini, %PROGRAMDATA %\MySQL\MySQL Server 5.6\my.cnf | Global options |
| %WINDIR%\my.ini, %WINDIR %\my.cnf | Global options |
| C:\my.ini, C:\my.cnf | Global options |
| BASEDIR\my.ini, BASEDIR\my.cnf | Global options |
| defaults-extra-file | The file specified with <code>--defaults-extra-file</code> , if any |
| %APPDATA%\MySQL \.mylogin.cnf | Login path options (clients only) |

In the preceding table, `%PROGRAMDATA%` represents the file system directory that contains application data for all users on the host. This path defaults to `C:\ProgramData` on Microsoft Windows Vista and greater,

and `C:\Documents and Settings\All Users\Application Data` on older versions of Microsoft Windows.

`%WINDIR%` represents the location of your Windows directory. This is commonly `C:\WINDOWS`. Use the following command to determine its exact location from the value of the `WINDIR` environment variable:

```
C:\> echo %WINDIR%
```

`%APPDATA%` represents the value of the Windows application data directory. Use the following command to determine its exact location from the value of the `APPDATA` environment variable:

```
C:\> echo %APPDATA%
```

`BASEDIR` represents the MySQL base installation directory. When MySQL 5.6 has been installed using MySQL Installer, this is typically `C:\PROGRAMDIR\MySQL\MySQL 5.6 Server` where `PROGRAMDIR` represents the programs directory (usually `Program Files` on English-language versions of Windows). See [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).

On Unix and Unix-like systems, MySQL programs read startup options from the files shown in the following table, in the specified order (top files are read first, files read later take precedence).

Note

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Table 4.2 Option Files Read on Unix and Unix-Like Systems

| File Name | Purpose |
|----------------------------------|---|
| <code>/etc/my.cnf</code> | Global options |
| <code>/etc/mysql/my.cnf</code> | Global options |
| <code>\$SYSCONFDIR/my.cnf</code> | Global options |
| <code>\$MYSQL_HOME/my.cnf</code> | Server-specific options (server only) |
| <code>defaults-extra-file</code> | The file specified with <code>--defaults-extra-file</code> , if any |
| <code>~/.my.cnf</code> | User-specific options |
| <code>~/.mylogin.cnf</code> | User-specific login path options (clients only) |

In the preceding table, `~` represents the current user's home directory (the value of `$HOME`).

`$SYSCONFDIR` represents the directory specified with the `$SYSCONFDIR` option to `CMake` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let `BASEDIR` and `DATADIR` represent the path names of the MySQL base directory and data directory, respectively.
- If there is a `my.cnf` file in `DATADIR` but not in `BASEDIR`, `mysqld_safe` sets `MYSQL_HOME` to `DATADIR`.

- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in `DATADIR`, `mysqld_safe` sets `MYSQL_HOME` to `BASEDIR`.

In MySQL 5.6, use of `DATADIR` as the location for `my.cnf` is deprecated.

`DATADIR` is commonly `/usr/local/mysql/data`, although this can vary per platform or installation method. The value is the data directory location built in when MySQL was compiled, not the location specified with the `--datadir` option when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files that it reads before processing any options.

If multiple instances of a given option are found, the last instance takes precedence, with one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

The following description of option file syntax applies to files that you edit manually. This excludes `.mylogin.cnf`, which is created using `mysql_config_editor` and is encrypted.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.)

The syntax for specifying options in an option file is similar to command-line syntax (see [Section 4.2.4, “Using Options on the Command Line”](#)). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- `#comment`, `;comment`

Comment lines start with `#` or `;`. A `#` comment can start in the middle of a line as well.

- `[group]`

`group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case sensitive.

- `opt_name`

This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the `=` character, something that is not true on the command line. The value optionally can be enclosed within single quotation marks or double quotation marks, which is useful if the value contains a `#` comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences `\b`, `\t`, `\n`, `\r`, `\\`, and `\s` in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. In option files, these escaping rules apply:

- A backslash followed by a valid escape sequence character is converted to the character represented by the sequence. For example, `\s` is converted to a space.
- A backslash not followed by a valid escape sequence character remains unchanged. For example, `\s` is retained as is.

The preceding rules mean that a literal backslash can be given as `\\`, or as `\` if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “`x`” is not a valid escape sequence character, `\x` becomes “`x`” rather than `\x`. See [Section 9.1.1, “String Literals”](#).

The escaping rules for option file values are especially pertinent for Windows path names, which use `\` as a path name separator. A separator in a Windows path name must be written as `\\` if it is followed by an escape sequence character. It can be written as `\\` or `\` if it is not. Alternatively, `/` may be used in Windows path names and will be treated as `\`. Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 5.6` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 5.6"
basedir="C:\\Program Files\\MySQL\\MySQL Server 5.6"
basedir="C:/Program Files/MySQL/MySQL Server 5.6"
basedir=C:\\Program\\sFiles\\MySQL\\MySQL\\sServer\\s5.6
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs provided in MySQL distributions (but *not* by `mysqld`). To understand how third-party client programs that use the C API can use option files, see the C API documentation at [Section 23.8.7.49, “mysql_options\(\)”](#).

The `[client]` group enables you to specify options that apply to all clients. For example, `[client]` is the appropriate group to use to specify the password for connecting to the server. (But make sure that the option file is accessible only by yourself, so that other people cannot discover your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

Here is a typical user option file:

```
[client]
```

```
# The following password will be sent to all standard MySQL clients
password="my password"

[mysql]
no-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive_timeout
```

To create option groups to be read only by `mysqld` servers from specific MySQL release series, use groups with names of `[mysqld-5.5]`, `[mysqld-5.6]`, and so forth. The following group indicates that the `sql_mode` setting should be used only by MySQL servers with 5.6.x version numbers:

```
[mysqld-5.6]
sql_mode=TRADITIONAL
```

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

MySQL makes no guarantee about the order in which option files in the directory will be read.

Note

Any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

If an option file contains `!include` or `!includedir` directives, files named by those directives are processed whenever the option file is processed, no matter where they appear in the file.

4.2.7 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. Because these options affect option-file handling, they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` may be used immediately after `--defaults-file`, `--defaults-extra-file`, or `--login-path`.
- On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. See [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

When specifying file names as option values, avoid the use of the `~` shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file and (on all platforms) before the login path file. (For information about the order in which option files are used, see [Section 4.2.6, “Using Option Files”](#).) If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).

A client program reads the option group corresponding to the named login path, in addition to option groups that the program reads by default. Consider this command:

```
shell> mysql --login-path=mypath
```

By default, the `mysql` client reads the `[client]` and `[mysql]` option groups. So for the command shown, `mysql` reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

Client programs read the login path file even when the `--no-defaults` option is used.

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that client programs read the `.mylogin.cnf` login path file, if it exists, even when `--no-defaults` is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--print-defaults`

Print the program name and all options that it gets from option files.

4.2.8 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#), and [Section 5.1.6, “Using System Variables”](#).

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024 , 1024^2 or 1024^3 . (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M

[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET`, you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

4.2.9 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equals sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.6.37 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| jon@%          |
+-----+
```

```
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument
```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```
shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host=--user`, and the client attempts to connect to a MySQL server running on a host named “--user”.

Options having default values always require an equals sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value `host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of `mysqld_safe`:

```
shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

After shutting down the server, restart it as follows:

```
shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                  ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
shell> tail /usr/local/mysql/var/tonfisk.err
080111 22:53:32 InnoDB: Started; log sequence number 0 46409
/usr/local/mysql/libexec/mysqld: Too many arguments (first extra is 'my-errors').
Use --verbose --help to get a list of available options
080111 22:53:32 [ERROR] Aborting

080111 22:53:32 InnoDB: Starting shutdown...
080111 22:53:34 InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 [Note] /usr/local/mysql/libexec/mysqld: Shutdown complete

080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` option supplies a default value, you must use an equals sign to assign a different value to it, as shown here:

```
shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var

shell>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]

host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```
shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equals sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]

user jon
```

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equals sign:

```
[mysql]

user=jon
```

Now the login attempt succeeds:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 5.6.37 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equals sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 5.6.37 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@tonfisk |
+-----+
1 row in set (0.00 sec)
```

Specifying an option requiring a value without a value in an option file causes the server to abort with an error. Suppose that `my.cnf` contains the following:

```
[mysqld]
log_error
relay_log
relay_log_index
```

This causes the server to fail on startup, as shown here:

```
shell> mysqld_safe &

090514 09:48:39 mysqld_safe Logging to '/home/jon/bin/mysql/var/tonfisk.err'.
090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
090514 09:48:39 mysqld_safe mysqld from pid file /home/jon/bin/mysql/var/tonfisk.pid ended
```

The `--log-error` option does not require an argument; however, the `--relay-log` option requires one, as shown in the error log (which in the absence of a specified value, defaults to `datadir/hostname.err`):

```
shell> tail -n 3 ../var/tonfisk.err

090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
090514 9:48:39 [ERROR] /home/jon/bin/mysql/libexec/mysqld: option '--relay-log' requires an argument
090514 9:48:39 [ERROR] Aborting
```

This is a change from previous behavior, where the server would have interpreted the last two lines in the example `my.cnf` file as `--relay-log=relay_log_index` and created a relay log file using “`relay_log_index`” as the base name. (Bug #25192)

4.2.10 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. [Section 4.9, “MySQL Program Environment Variables”](#), lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.3 MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

4.3.1 `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see [Section 5.1, “The MySQL Server”](#). For information about installing MySQL and setting up the initial configuration, see [Chapter 2, *Installing and Upgrading MySQL*](#).

4.3.2 `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. A description of error logging is given later in this section.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See [Section 5.1.4, “Server Command Options”](#).

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See [Section 4.2.6, “Using Option Files”](#).

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` will find and use the `--log-error` option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, but to be current you should rename such sections to `[mysqld_safe]`.

`mysqld_safe` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

Table 4.3 `mysqld_safe` Options

| Format | Description |
|------------------------------------|---|
| <code>--basedir</code> | Path to MySQL installation directory |
| <code>--core-file-size</code> | Size of core file that mysqld should be able to create |
| <code>--datadir</code> | Path to data directory |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files |
| <code>--defaults-file</code> | Read only named option file |
| <code>--help</code> | Display help message and exit |
| <code>--ledir</code> | Path to directory where server is located |
| <code>--log-error</code> | Write error log to named file |
| <code>--malloc-lib</code> | Alternative malloc library to use for mysqld |
| <code>--mysqld</code> | Name of server program to start (in ledir directory) |
| <code>--mysqld-version</code> | Suffix for server program name |
| <code>--nice</code> | Use nice program to set server scheduling priority |
| <code>--no-defaults</code> | Read no option files |
| <code>--open-files-limit</code> | Number of files that mysqld should be able to open |
| <code>--pid-file</code> | Path name of server process ID file |
| <code>--plugin-dir</code> | Directory where plugins are installed |
| <code>--port</code> | Port number on which to listen for TCP/IP connections |
| <code>--skip-kill-mysqld</code> | Do not try to kill stray mysqld processes |
| <code>--skip-syslog</code> | Do not write error messages to syslog; use error log file |
| <code>--socket</code> | Socket file on which to listen for Unix socket connections |
| <code>--syslog</code> | Write error messages to syslog |
| <code>--syslog-tag</code> | Tag suffix for messages written to syslog |
| <code>--timezone</code> | Set TZ time zone environment variable to named value |
| <code>--user</code> | Run mysqld as user having name <code>user_name</code> or numeric user ID <code>user_id</code> |

- `--help`

Display a help message and exit.

- `--basedir=dir_name`

The path to the MySQL installation directory.

- `--core-file-size=size`

The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

- `--datadir=dir_name`

The path to the data directory.

- `--defaults-extra-file=file_name`

Read this option file in addition to the usual option files. If the file does not exist or is otherwise inaccessible, the server will exit with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, the server will exit with an error. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--ledir=dir_name`

If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

As of MySQL 5.6.35, this option is accepted only on the command line, not in option files.

- `--log-error=file_name`

Write the error log to the given file. See [Section 5.4.2, “The Error Log”](#).

- `--malloc-lib=[lib_name]`

The name of the library to use for memory allocation instead of the system `malloc()` library. As of MySQL 5.6.33, the option value must be one of the directories `/usr/lib`, `/usr/lib64`, `/usr/lib/i386-linux-gnu`, or `/usr/lib/x86_64-linux-gnu`. Prior to MySQL 5.6.33, any library can be used by specifying its path name, but there is a shortcut form to enable use of the `tcmalloc` library that is shipped with binary MySQL distributions for Linux in MySQL 5.6. It is possible that the shortcut form will not work under certain configurations, in which case you should specify a path name instead.

**Note**

As of MySQL 5.6.31, MySQL distributions no longer include a `tcmalloc` library.

The `--malloc-lib` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:

- If the option is not given, or is given without a value (`--malloc-lib=`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.

- If the option is given as `--malloc-lib=tcmalloc`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib` and then in the MySQL `pkglibdir` location (for example, `/usr/local/mysql/lib` or whatever is appropriate). If `tcmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.
- If the option is given as `--malloc-lib=/path/to/some/library`, that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.
- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Linux users can use the `libtcmalloc_minimal.so` included in binary packages by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

Those lines also suffice for users on any platform who have installed a `tcmalloc` package in `/usr/lib`. To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- `--mysqld=prog_name`

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

As of MySQL 5.6.33, this option is accepted only on the command line, not in option files.

- `--mysqld-version=suffix`

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The base name is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

As of MySQL 5.6.33, this option is accepted only on the command line, not in option files.

- `--nice=priority`

Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--open-files-limit=count`

The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`.

**Note**

You must start `mysqld_safe` as `root` for this to function properly.

- `--pid-file=file_name`

The path name that `mysqld` should use for its process ID file.

- `--plugin-dir=dir_name`

The path name of the plugin directory.

- `--port=port_num`

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--skip-kill-mysqld`

Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path`

The Unix socket file that the server should use when listening for local connections.

- `--syslog, --skip-syslog`

`--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

When `syslog` is used, the `daemon.err` syslog facility/severity is used for all log messages.

- `--syslog-tag=tag`

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with identifiers of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the identifiers, use `--syslog-tag=tag`, which modifies the identifiers to be `mysqld_safe-tag` and `mysqld-tag`.

- `--timezone=timezone`

Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}`

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See [Section 2.1.4, “Installation Layouts”](#).) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).
- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

In MySQL 5.6.5 and later, `mysqld_safe` tries to use the `sleep` and `date` system utilities to determine how many times it has attempted to start this second, and—if these are present and this is greater than 5 times—is forced to wait 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- `--log-error=file_name`: Write error messages to the named error file.
- `--syslog`: Write error messages to `syslog` on systems that support the `logger` program.
- `--skip-syslog`: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.

If none of these options is given, the default is `--skip-syslog`.

If `--log-error` and `--syslog` are both given, a warning is issued and `--log-error` takes precedence.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

4.3.3 mysql.server — MySQL Server Startup Script

MySQL distributions on Unix include a script named `mysql.server`, which starts the server using `mysqld_safe`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the OS X Startup Item for MySQL.

To start or stop the server manually using the `mysql.server` script, invoke it with `start` or `stop` arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

Before `mysql.server` starts the server, it changes location to the MySQL installation directory, and then invokes `mysqld_safe`. To run the server as some specific user, add an appropriate `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file, as shown later in this section. (It is possible that you must edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you must add start and stop commands to the appropriate places in your `/etc/rc*` files.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), or a native Linux package installation, the `mysql.server` script may be installed in the `/etc/init.d` directory with the name `mysql`. See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. The script can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. Copy it to the `/etc/init.d` directory with the name `mysql`, and then make it executable:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

Note

Older Red Hat systems use the `/etc/rc.d/init.d` directory rather than `/etc/init.d`. Adjust the preceding commands accordingly. Alternatively, first create `/etc/init.d` as a symbolic link that points to `/etc/rc.d/init.d`:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. The `rc(8)` manual page states that scripts in this directory are executed only if their base name matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, but to be current you should rename such sections to `[mysql.server]`.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `/etc/my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the following options. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

Table 4.4 `mysql.server` Options

| Format | Description |
|--|--|
| <code>--basedir</code> | Path to MySQL installation directory |
| <code>--datadir</code> | Path to MySQL data directory |
| <code>--pid-file</code> | File in which server should write its process ID |
| <code>--service-startup-timeout</code> | How long to wait for server startup |

- `--basedir=dir_name`

The path to the MySQL installation directory.

- `--datadir=dir_name`

The path to the MySQL data directory.

- `--pid-file=file_name`

The path name of the file in which the server should write its process ID.

If this option is not given, `mysql.server` uses a default value of `host_name.pid`. The PID file value passed to `mysqld_safe` overrides any value specified in the `[mysqld_safe]` option file group. Because `mysql.server` reads the `[mysqld]` option file group but not the `[mysqld_safe]` group, you can ensure that `mysqld_safe` gets the same value when invoke using `mysql.server` as when invoked manually by putting the same `pid-file` setting in both the `[mysqld_safe]` and `[mysqld]` groups.

- `--service-startup-timeout=seconds`

How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

4.3.4 `mysqld_multi` — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--defaults-file` option). *N* can be any positive integer. This number is referred to in the following discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

To invoke `mysqld_multi`, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```

`start`, `stop`, `reload` (stop and restart), and `report` indicate which operation to perform. (`reload` is available as of MySQL 5.6.3.) You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named `[mysqld17]` is 17. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysql_multi --example
```

`mysql_multi` searches for option files as follows:

- With `--no-defaults`, no option files are read.
- With `--defaults-file=file_name`, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` option, if one is given. (If the option is given multiple times, the last value is used.)

Option files read are searched for `[mysql_multi]` and `[mysqlN]` option groups. The `[mysql_multi]` group can be used for options to `mysql_multi` itself. `[mysqlN]` groups can be used for options passed to specific `mysql` instances.

The `[mysqld]` or `[mysqld_safe]` groups can be used for common options read by all instances of `mysqld` or `mysqld_safe`. You can specify a `--defaults-file=file_name` option to use a different configuration file for that instance, in which case the `[mysqld]` or `[mysqld_safe]` groups from that file will be used for that instance.

`mysql_multi` supports the following options.

- `--help`

Display a help message and exit.

- `--example`

Display a sample option file.

- `--log=file_name`

Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

The `mysqld` binary to be used. You can specify `mysqld_safe` as the value for this option. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqlN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the descriptions for these options in [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).) Example:

```
[mysqld38]
mysqld = mysqld-debug
ledir  = /opt/local/mysql/libexec
```

- `--no-log`

Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password`

The password of the MySQL account to use when invoking `mysqladmin`. The password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

Silent mode; disable warnings.

- `--tcp-ip`

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

Be more verbose.

- `--version`

Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important:** Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> CREATE USER 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost';
```

See [Section 6.2, “The MySQL Access Privilege System”](#). You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. The host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)

- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`). Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. The `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:

```
-----
MY_PWD=`pwd`
# Check if we are starting this relative (for the binary release)
if test -d $MY_PWD/data/mysql -a \
    -f ./share/mysql/english/errmsg.sys -a \
    -x ./bin/mysqld
-----
```

The test performed by these lines should be successful, or you might encounter problems. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This is an example of a my.cnf file for mysqld_multi.
# Usually this file is located in home dir ~/.my.cnf or /etc/my.cnf

[mysqld_multi]
mysqld      = /usr/local/mysql/bin/mysqld_safe
mysqldadmin = /usr/local/mysql/bin/mysqldadmin
user        = multi_admin
password    = my_password

[mysqld2]
socket      = /tmp/mysql.sock2
port        = 3307
pid-file    = /usr/local/mysql/data2/hostname.pid2
datadir     = /usr/local/mysql/data2
language    = /usr/local/mysql/share/mysql/english
user        = unix_user1

[mysqld3]
mysqld      = /path/to/mysqld_safe
ledir       = /path/to/mysqld-binary/
mysqldadmin = /path/to/mysqldadmin
socket      = /tmp/mysql.sock3
port        = 3308
pid-file    = /usr/local/mysql/data3/hostname.pid3
datadir     = /usr/local/mysql/data3
language    = /usr/local/mysql/share/mysql/swedish
user        = unix_user2

[mysqld4]
socket      = /tmp/mysql.sock4
port        = 3309
```

```
pid-file    = /usr/local/mysql/data4/hostname.pid4
datadir     = /usr/local/mysql/data4
language    = /usr/local/mysql/share/mysql/estonia
user        = unix_user3

[mysqld6]
socket      = /tmp/mysql.sock6
port        = 3311
pid-file    = /usr/local/mysql/data6/hostname.pid6
datadir     = /usr/local/mysql/data6
language    = /usr/local/mysql/share/mysql/japanese
user        = unix_user4
```

See [Section 4.2.6, “Using Option Files”](#).

4.4 MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1 `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the text file located at `sql/share/errmsg-utf8.txt` in MySQL source distributions.

`comp_err` also generates `mysqld_error.h`, `mysqld_ename.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the [MySQL Internals Manual](#).

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

`comp_err` supports the following options.

- `--help, -?`

Display a help message and exit.

- `--charset=dir_name, -C dir_name`

The character set directory. The default is `../sql/share/charsets`.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:0,file_name`. The default is `d:t:0,/tmp/comp_err.trace`.

- `--debug-info, -T`

Print some debugging information when the program exits.

- `--header_file=file_name, -H file_name`

The name of the error header file. The default is `mysqld_error.h`.

- `--in_file=file_name, -F file_name`

The name of the input file. The default is `../sql/share/errmsg-utf8.txt`.

- `--name_file=file_name, -N file_name`

The name of the error name file. The default is `mysqld_ername.h`.

- `--out_dir=dir_name, -D dir_name`

The name of the output base directory. The default is `../sql/share/`.

- `--out_file=file_name, -O file_name`

The name of the output file. The default is `errmsg.sys`.

- `--statefile=file_name, -S file_name`

The name for the SQLSTATE header file. The default is `sql_state.h`.

- `--version, -V`

Display version information and exit.

4.4.2 mysqlbug — Generate Bug Report

This program is obsolete. It is deprecated as of MySQL 5.6.19 and is removed in MySQL 5.7.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

4.4.3 mysql_install_db — Initialize MySQL Data Directory

`mysql_install_db` initializes the MySQL data directory and creates the system tables that it contains, if they do not exist. It also initializes the [system tablespace](#) and related data structures needed to manage InnoDB tables. As of MySQL 5.6.8, `mysql_install_db` is a Perl script and can be used on any system with Perl installed. Before 5.6.8, it is a shell script and is available only on Unix platforms.

As of MySQL 5.6.8, on Unix platforms, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. You can find the template in or under the base installation directory. When started using `mysqld_safe`, the server uses `my.cnf` file by default. If `my.cnf` already exists, `mysql_install_db` assumes it to be in use and writes a new file named `my-new.cnf` instead.

With one exception, the settings in the default option file are commented and have no effect. The exception is that the file sets the `sql_mode` system variable to `NO_ENGINE_SUBSTITUTION, STRICT_TRANS_TABLES`. This setting produces a server configuration that results in errors rather than warnings for bad data in operations that modify transactional tables. See [Section 5.1.8, “Server SQL Modes”](#).

To invoke `mysql_install_db`, use the following syntax:

```
shell> mysql_install_db [options]
```

Because the MySQL server, `mysqld`, must access the data directory when it runs later, you should either run `mysql_install_db` from the same system account that will be used for running `mysqld`, or run it as `root` and specify the `--user` option to indicate the user name that `mysqld` will run as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql \
      --basedir=/opt/mysql/mysql \
      --datadir=/opt/mysql/mysql/data
```

Note

After `mysql_install_db` sets up the [InnoDB system tablespace](#), changes to some tablespace characteristics require setting up a whole new [instance](#). This includes the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the [innodb_data_file_path](#) and [innodb_log_file_size](#) configuration parameters are in place in the MySQL [configuration file](#) before running `mysql_install_db`. Also make sure to specify as necessary other parameters that affect the creation and location of [InnoDB](#) files, such as [innodb_data_home_dir](#) and [innodb_log_group_home_dir](#).

If those options are in your configuration file but that file is not in a location that MySQL reads by default, specify the file location using the `--defaults-extra-file` option when you run `mysql_install_db`.

Note

If you have set a custom [TMPDIR](#) environment variable when performing the installation, and the specified directory is not accessible, `mysql_install_db` may fail. If so, unset [TMPDIR](#) or set [TMPDIR](#) to point to the system temporary directory (usually `/tmp`).

`mysql_install_db` supports the following options, which can be specified on the command line or in the `[mysql_install_db]` group of an option file. (Options that are common to `mysqld` can also be specified in the `[mysqld]` group.) Other options are passed to `mysqld`. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.5 `mysql_install_db` Options

| Format | Description | Introduced | Deprecated |
|------------------------------------|--|------------|------------|
| <code>--basedir</code> | Path to base directory | | |
| <code>--builddir</code> | Path to build directory (for out-of-source builds) | | |
| <code>--cross-bootstrap</code> | For internal use | | |
| <code>--datadir</code> | Path to data directory | | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | | |
| <code>--defaults-file</code> | Read only named option file | | |
| <code>--force</code> | Run even if DNS does not work | | |
| <code>--help</code> | Display help message and exit | | |
| <code>--keep-my-cnf</code> | Keep existing my.cnf file, do not create new one | 5.6.20 | 5.6.20 |
| <code>--ldata</code> | Synonym for <code>--datadir</code> | | |
| <code>--no-defaults</code> | Read no option files | | |
| <code>--random-passwords</code> | Generate administrative account random password | 5.6.8 | |
| <code>--rpm</code> | For internal use | | |

| Format | Description | Introduced | Deprecated |
|----------------------------------|---|------------|------------|
| <code>--skip-name-resolve</code> | Use IP addresses rather than host names in grant tables | | |
| <code>--srcdir</code> | For internal use | | |
| <code>--user</code> | System login user under which to execute mysqld | | |
| <code>--verbose</code> | Verbose mode | | |
| <code>--windows</code> | For internal use | | |

- `--help`

Display a help message and exit.

- `--basedir=dir_name`

The path to the MySQL installation directory.

- `--builddir=dir_name`

For use with `--srcdir` and out-of-source builds. Set this to the location of the directory where the built files reside.

- `--cross-bootstrap`

For internal use. This option is used for building system tables on one host intended for another.

- `--datadir=dir_name`

The path to the MySQL data directory. Beginning with MySQL 5.6.8, `mysql_install_db` is more strict about the option value. Only the last component of the path name is created if it does not exist; the parent directory must already exist or an error occurs.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--force`

Cause `mysql_install_db` to run even if DNS does not work. Grant table entries normally created using host names will use IP addresses instead.

- `--keep-my-cnf`

Tell `mysql_install_db` to preserve any existing `my.cnf` file and not create a new default `my.cnf` file. This option was added in MySQL 5.6.20.

- `--ldata=dir_name`

A synonym for `--datadir`.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--random-passwords`

On Unix platforms, this option provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-passwords` causes it to perform the following actions in addition to its normal operation:

- The installation process creates a random password, assigns it to the initial MySQL `root` accounts, and sets the “password expired” flag for those accounts.
- The initial random `root` password is written to the `.mysql_secret` file in the directory named by the `HOME` environment variable. Depending on operating system, using a command such as `sudo` may cause the value of `HOME` to refer to the home directory of the `root` system user.

If `.mysql_secret` already exists, the new password information is appended to it. Each password entry includes a timestamp so that in the event of multiple install operations it is possible to determine the password associated with each one.

`.mysql_secret` is created with mode 600 to be accessible only to the system user for whom it is created.

- No anonymous-user MySQL accounts are created.

As a result of these actions, it is necessary after installation to start the server, connect as `root` using the password written to the `.mysql_secret` file, and specify a new `root` password. Until this is done, `root` cannot do anything else. This must be done for each `root` account you intend to use. To change the password, you can use the `SET PASSWORD` statement (for example, with the `mysql` client). You can also use `mysqladmin` or `mysql_secure_installation`.

New RPM install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option. (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

As of MySQL 5.6.9, new Solaris PKG install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option.

For install operations using a binary `.tar.gz` distribution or a source distribution, you can invoke `mysql_install_db` with the `--random-passwords` option manually to make your MySQL installation more secure. This is recommended, particularly for sites with sensitive data.

This option was added in MySQL 5.6.8.

- `--rpm`

For internal use. This option is used during the MySQL installation process for install operations performed using RPM packages.

- `--skip-name-resolve`

Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

- `--srcdir=dir_name`

For internal use. This option specifies the directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables.

- `--user=user_name`

The system (login) user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be the system `root` user to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--windows`

For internal use. This option is used for creating Windows distributions.

4.4.4 `mysql_plugin` — Configure MySQL Server Plugins

The `mysql_plugin` utility enables MySQL administrators to manage which plugins a MySQL server loads. It provides an alternative to manually specifying the `--plugin-load` option at server startup or using the `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements at runtime. `mysql_plugin` is available as of MySQL 5.6.3.

Depending on whether `mysql_plugin` is invoked to enable or disable plugins, it inserts or deletes rows in the `mysql.plugin` table that serves as a plugin registry. (To perform this operation, `mysql_plugin` invokes the MySQL server in bootstrap mode. This means that the server must not already be running.) For normal server startups, the server loads and enables plugins listed in `mysql.plugin` automatically. For additional control over plugin activation, use `--plugin_name` options named for specific plugins, as described in [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

Each invocation of `mysql_plugin` reads a configuration file to determine how to configure the plugins contained in a single plugin library file. To invoke `mysql_plugin`, use this syntax:

```
mysql_plugin [options] plugin {ENABLE|DISABLE}
```

`plugin` is the name of the plugin to configure. `ENABLE` or `DISABLE` (not case sensitive) specify whether to enable or disable components of the plugin library named in the configuration file. The order of the `plugin` and `ENABLE` or `DISABLE` arguments does not matter.

For example, to configure components of a plugin library file named `myplugins.so` on Linux or `myplugins.dll` on Windows, specify a `plugin` value of `myplugins`. Suppose that this plugin library contains three plugins, `plugin1`, `plugin2`, and `plugin3`, all of which should be configured under `mysql_plugin` control. By convention, configuration files have a suffix of `.ini` and the same base name as the plugin library, so the default configuration file name for this plugin library is `myplugins.ini`. The configuration file contents look like this:

```
myplugins
plugin1
plugin2
plugin3
```

The first line in the `myplugins.ini` file is the name of the library file, without any extension such as `.so` or `.dll`. The remaining lines are the names of the components to be enabled or disabled. Each value in

the file should be on a separate line. Lines on which the first character is '#' are taken as comments and ignored.

To enable the plugins listed in the configuration file, invoke `mysql_plugin` this way:

```
shell> mysql_plugin myplugins ENABLE
```

To disable the plugins, use `DISABLE` rather than `ENABLE`.

An error occurs if `mysql_plugin` cannot find the configuration file or plugin library file, or if `mysql_plugin` cannot start the MySQL server.

`mysql_plugin` supports the following options, which can be specified on the command line or in the `[mysqld]` group of any option file. For options specified in a `[mysqld]` group, `mysql_plugin` recognizes the `--basedir`, `--datadir`, and `--plugin-dir` options and ignores others. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.6 `mysql_plugin` Options

| Format | Description |
|----------------------------------|--|
| <code>--basedir</code> | The server base directory |
| <code>--datadir</code> | The server data directory |
| <code>--help</code> | Display help message and exit |
| <code>--my-print-defaults</code> | Path to <code>my_print_defaults</code> |
| <code>--mysqld</code> | Path to server |
| <code>--no-defaults</code> | Do not read configuration file |
| <code>--plugin-dir</code> | Directory where plugins are installed |
| <code>--plugin-ini</code> | The plugin configuration file |
| <code>--print-defaults</code> | Show configuration file defaults |
| <code>--verbose</code> | Verbose mode |
| <code>--version</code> | Display version information and exit |

- `--help, -?`
Display a help message and exit.
- `--basedir=dir_name, -b dir_name`
The server base directory.
- `--datadir=dir_name, -d dir_name`
The server data directory.
- `--my-print-defaults=file_name, -b file_name`
The path to the `my_print_defaults` program.
- `--mysqld=file_name, -b file_name`
The path to the `mysqld` server.
- `--no-defaults, -p`

Do not read values from the configuration file. This option enables an administrator to skip reading defaults from the configuration file.

With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--no-defaults`.

- `--plugin-dir=dir_name, -p dir_name`

The server plugin directory.

- `--plugin-ini=file_name, -i file_name`

The `mysql_plugin` configuration file. Relative path names are interpreted relative to the current directory. If this option is not given, the default is `plugin.ini` in the plugin directory, where `plugin` is the `plugin` argument on the command line.

- `--print-defaults, -P`

Display the default values from the configuration file. This option causes `mysql_plugin` to print the defaults for `--basedir`, `--datadir`, and `--plugin-dir` if they are found in the configuration file. If no value for a variable is found, nothing is shown.

With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--print-defaults`.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.4.5 `mysql_secure_installation` — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

Invoke `mysql_secure_installation` without arguments:

```
shell> mysql_secure_installation
```

When executed, the script prompts you to determine which actions to perform.

4.4.6 `mysql_tzinfo_to_sql` — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and OS X. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in [Section 10.6, “MySQL Server Time Zone Support”](#).

`mysql_tzinfo_to_sql` can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

4.4.7 mysql_upgrade — Check and Upgrade MySQL Tables

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL Server. `mysql_upgrade` also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies.

You should execute `mysql_upgrade` each time you upgrade MySQL.

If you install MySQL from RPM packages on Linux, you must install the server and client RPMs. `mysql_upgrade` is included in the server RPM but requires the client RPM because the latter includes `mysqlcheck`. (See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#).)

Note

On Windows Server 2008, Vista, and newer, you must run `mysql_upgrade` with administrator privileges. You can do this by running a Command Prompt as

Administrator and running the command. Failure to do so may result in the upgrade failing to execute correctly.

Caution

You should always back up your current MySQL installation *before* performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).

Some upgrade incompatibilities may require special handling before you upgrade your MySQL installation and run `mysql_upgrade`. See [Section 2.11.1, “Upgrading MySQL”](#), for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

To use `mysql_upgrade`, make sure that the server is running. Then invoke it like this:

```
shell> mysql_upgrade [options]
```

After running `mysql_upgrade`, stop the server and restart it so that any changes made to the system tables take effect.

If you have multiple MySQL server instances running, invoke `mysql_upgrade` with connection parameters appropriate for connecting to the desired server. For example, with servers running on the local host on ports 3306 through 3308, upgrade each of them by connecting to the appropriate port:

```
shell> mysql_upgrade --protocol=tcp -P 3306 [other_options]
shell> mysql_upgrade --protocol=tcp -P 3307 [other_options]
shell> mysql_upgrade --protocol=tcp -P 3308 [other_options]
```

For local host connections on Unix, the `--protocol=tcp` option forces a connection using TCP/IP rather than the Unix socket file.

`mysql_upgrade` executes the following commands to check and repair tables and to upgrade the system tables:

```
mysqlcheck --no-defaults --databases
--fix-db-names --fix-table-names mysql
mysqlcheck --no-defaults --check-upgrade --databases
--auto-repair mysql
mysql < fix_priv_tables
mysqlcheck --no-defaults --all-databases
--skip-database=mysql --fix-db-names --fix-table-names
mysqlcheck --no-defaults --check-upgrade --all-databases
--skip-database=mysql --auto-repair
```

Notes about the preceding commands:

- `mysql_upgrade` also adds `--write-binlog` or `--skip-write-binlog` to the `mysqlcheck` commands, depending on whether the `--write-binlog` option was specified on the `mysql_upgrade` command.
- Because `mysql_upgrade` invokes `mysqlcheck` with the `--all-databases` option, it processes all tables in all databases, which might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables.
- For details about what checks the `--check-upgrade` option entails, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement (see [Section 13.7.2.2, “CHECK TABLE Syntax”](#)).

- `fix_priv_tables` represents a script generated internally by `mysql_upgrade` that contains SQL statements to upgrade the tables in the `mysql` database.

All checked and repaired tables are marked with the current MySQL version number. This ensures that next time you run `mysql_upgrade` with the same version of the server, it can tell whether there is any need to check or repair the table again.

`mysql_upgrade` also saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` option.

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

By default, `mysql_upgrade` runs as the MySQL `root` user. If the `root` password is expired when you run `mysql_upgrade`, you will see a message that your password is expired and that `mysql_upgrade` failed as a result. To correct this, reset the `root` password to unexpire it and run `mysql_upgrade` again:

```
shell> mysql -u root -p
Enter password: **** <- enter root password here
mysql> SET PASSWORD = PASSWORD('root-password');
mysql> quit

shell> mysql_upgrade [options]
```

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` groups of an option file. Unrecognized options are passed to `mysqlcheck`. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.7 `mysql_upgrade` Options

| Format | Description | Introduced |
|--------------------------------------|---|------------|
| <code>--basedir</code> | Not used | |
| <code>--character-sets-dir</code> | Directory where character sets are installed | |
| <code>--compress</code> | Compress all information sent between client and server | |
| <code>--datadir</code> | Not used | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | 5.6.2 |
| <code>--default-character-set</code> | Specify default character set | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--force</code> | Force execution even if <code>mysql_upgrade</code> has already been executed for current version of MySQL | |
| <code>--help</code> | Display help message and exit | |
| <code>--host</code> | Connect to MySQL server on given host | |
| <code>--login-path</code> | Read login path options from <code>.mylogin.cnf</code> | 5.6.6 |

| Format | Description | Introduced |
|--|--|------------|
| <code>--no-defaults</code> | Read no option files | |
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | 5.6.2 |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--print-defaults</code> | Print default options | |
| <code>--protocol</code> | Connection protocol to use | |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use | |
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--tmpdir</code> | Directory for temporary files | |
| <code>--upgrade-system-tables</code> | Update only system tables, not data | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version-check</code> | Check for proper server version | 5.6.12 |
| <code>--write-binlog</code> | Write all statements to binary log | |

- `--help`

Display a short help message and exit.

- `--basedir=dir_name`

The path to the MySQL installation directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--compress`

Compress all information sent between the client and the server if both support compression.

- `--datadir=dir_name`

The path to the data directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql_upgrade.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql_upgrade` normally reads the `[client]` and `[mysql_upgrade]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql_upgrade` also reads the `[client_other]` and `[mysql_upgrade_other]` groups.

- `--force`

Ignore the `mysql_upgrade_info` file and force execution even if `mysql_upgrade` has already been executed for the current version of MySQL.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysql_upgrade` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql_upgrade` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--tmpdir=dir_name, -t dir_name`

The path name of the directory to use for creating temporary files.

- `--upgrade-system-tables, -s`

Upgrade only the system tables, do not upgrade data.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server. The default user name is `root`.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--version-check, -k`

Check the version of the server to which `mysql_upgrade` is connecting to verify that it is the same as the version for which `mysql_upgrade` was built. If not, `mysql_upgrade` exits. This option is enabled by default; to disable the check, use `--skip-version-check`. This option was added in MySQL 5.6.12.

- `--write-binlog`

Cause binary logging to be enabled while `mysql_upgrade` runs. In MySQL 5.6.6 and earlier, this was the default behavior. (To disable binary logging during the upgrade, it was necessary to use the inverse of this option, by starting the program with `--skip-write-binlog`.) Beginning with MySQL 5.6.7, binary logging by `mysql_upgrade` is disabled by default (Bug #14221043). Invoke the program explicitly with `--write-binlog` if you want its actions to be written to the binary log. (Also beginning with MySQL 5.6.7, the `--skip-write-binlog` option effectively does nothing.)

Running `mysql_upgrade` is not recommended with a MySQL Server that is running with global transaction identifiers enabled (Bug #13833710). This is because enabling GTIDs means that any updates which `mysql_upgrade` might need to perform on system tables using a nontransactional storage engine such as `MyISAM` to fail. See [Section 17.1.3.4, “Restrictions on Replication with GTIDs”](#), for more information.

4.5 MySQL Client Programs

This section describes client programs that connect to the MySQL server.

4.5.1 `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with `;`, `\g`, or `\G` and press Enter.

Typing **Control+C** causes `mysql` to attempt to kill the current statement. If this cannot be done, or **Control+C** is typed again before the statement is killed, `mysql` exits.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client logs statements executed interactively to a history file. See [Section 4.5.1.3, “mysql Logging”](#).

4.5.1.1 mysql Options

`mysql` supports the following options, which can be specified on the command line or in the `[mysql]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.8 `mysql` Options

| Format | Description | Introduced |
|-------------------------------------|---|------------|
| <code>--auto-rehash</code> | Enable automatic rehashing | |
| <code>--auto-vertical-output</code> | Enable automatic vertical result set display | |
| <code>--batch</code> | Do not use history file | |
| <code>--binary-mode</code> | Disable <code>\r\n</code> - to - <code>\n</code> translation and treatment of <code>\0</code> as end-of-query | 5.6.3 |
| <code>--bind-address</code> | Use specified network interface to connect to MySQL Server | 5.6.1 |
| <code>--character-sets-dir</code> | Directory where character sets are installed | |
| <code>--column-names</code> | Write column names in results | |
| <code>--column-type-info</code> | Display result set metadata | |
| <code>--comments</code> | Whether to retain or strip comments in statements sent to the server | |
| <code>--compress</code> | Compress all information sent between client and server | |

| Format | Description | Introduced |
|---|---|------------|
| <code>--connect-expired-password</code> | Indicate to server that client can handle expired-password sandbox mode. | 5.6.12 |
| <code>--connect_timeout</code> | Number of seconds before connection timeout | |
| <code>--database</code> | The database to use | |
| <code>--debug</code> | Write debugging log; supported only if MySQL was built with debugging support | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | |
| <code>--default-character-set</code> | Specify default character set | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--delimiter</code> | Set the statement delimiter | |
| <code>--enable-cleartext-plugin</code> | Enable cleartext authentication plugin | 5.6.7 |
| <code>--execute</code> | Execute the statement and quit | |
| <code>--force</code> | Continue even if an SQL error occurs | |
| <code>--help</code> | Display help message and exit | |
| <code>--histignore</code> | Patterns specifying which statements to ignore for logging | 5.6.8 |
| <code>--host</code> | Connect to MySQL server on given host | |
| <code>--html</code> | Produce HTML output | |
| <code>--ignore-spaces</code> | Ignore spaces after function names | |
| <code>--init-command</code> | SQL statement to execute after connecting | |
| <code>--line-numbers</code> | Write line numbers for errors | |
| <code>--local-infile</code> | Enable or disable for LOCAL capability for LOAD DATA INFILE | |
| <code>--login-path</code> | Read login path options from .mylogin.cnf | 5.6.6 |
| <code>--max_allowed_packet</code> | Maximum packet length to send to or receive from server | |
| <code>--max_join_size</code> | The automatic limit for rows in a join when using --safe-updates | |
| <code>--named-commands</code> | Enable named mysql commands | |
| <code>--net_buffer_length</code> | Buffer size for TCP/IP and socket communication | |
| <code>--no-auto-rehash</code> | Disable automatic rehashing | |
| <code>--no-beep</code> | Do not beep when errors occur | |
| <code>--no-defaults</code> | Read no option files | |
| <code>--one-database</code> | Ignore statements except those for the default database named on the command line | |
| <code>--pager</code> | Use the given command for paging query output | |

| Format | Description | Introduced |
|---|---|------------|
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--print-defaults</code> | Print default options | |
| <code>--prompt</code> | Set the prompt to the specified format | |
| <code>--protocol</code> | Connection protocol to use | |
| <code>--quick</code> | Do not cache each query result | |
| <code>--raw</code> | Write column values without escape conversion | |
| <code>--reconnect</code> | If the connection to the server is lost, automatically try to reconnect | |
| <code>--i-am-a-dummy, --safe-updates</code> | Allow only UPDATE and DELETE statements that specify key values | |
| <code>--secure-auth</code> | Do not send passwords to server in old (pre-4.1) format | |
| <code>--select_limit</code> | The automatic limit for SELECT statements when using --safe-updates | |
| <code>--server-public-key-path</code> | Path name to file containing RSA public key | 5.6.6 |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--show-warnings</code> | Show warnings after each statement if there are any | |
| <code>--sigint-ignore</code> | Ignore SIGINT signals (typically the result of typing Control +C) | |
| <code>--silent</code> | Silent mode | |
| <code>--skip-auto-rehash</code> | Disable automatic rehashing | |
| <code>--skip-column-names</code> | Do not write column names in results | |
| <code>--skip-line-numbers</code> | Skip line numbers for errors | |
| <code>--skip-named-commands</code> | Disable named mysql commands | |
| <code>--skip-pager</code> | Disable paging | |
| <code>--skip-reconnect</code> | Disable reconnecting | |
| <code>--socket</code> | For connections to localhost, the Unix socket file or Windows named pipe to use | |
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |

| Format | Description | Introduced |
|---------------------------------------|--|------------|
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--table</code> | Display output in tabular format | |
| <code>--tee</code> | Append a copy of output to named file | |
| <code>--unbuffered</code> | Flush the buffer after each query | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version</code> | Display version information and exit | |
| <code>--vertical</code> | Print query output rows vertically (one line per column value) | |
| <code>--wait</code> | If the connection cannot be established, wait and retry instead of aborting | |
| <code>--xml</code> | Produce XML output | |

- `--help, -?`

Display a help message and exit.

- `--auto-rehash`

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command or its `\#` shortcut if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

Note

This feature requires a MySQL client that is compiled with the **readline** library. Typically, the **readline** library is not available on Windows.

- `--auto-vertical-output`

Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.)

- `--batch, -B`

Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--binary-mode`

This option helps when processing `mysqlbinlog` output that may contain `BLOB` values. By default, `mysql` translates `\r\n` in statement strings to `\n` and interprets `\0` as the statement terminator. --

`binary-mode` disables both features. It also disables all `mysql` commands except `charset` and `delimiter` in non-interactive mode (for input piped to `mysql` or loaded using the `source` command).

This option was added in MySQL 5.6.3.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--column-names`

Write column names in results.

- `--column-type-info`

Display result set metadata.

- `--comments, -c`

Whether to preserve comments in statements sent to the server. The default is `--skip-comments` (discard comments), enable with `--comments` (preserve comments).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--connect-expired-password`

Indicate to the server that the client can handle sandbox mode if the account used to connect has an expired password. This can be useful for noninteractive invocations of `mysql` because normally the server disconnects noninteractive clients that attempt to connect using an account with an expired password. (See [Section 6.3.6, “Password Expiration and Sandbox Mode”](#).) This option was added in MySQL 5.6.12.

- `--database=db_name, -D db_name`

The database to use. This is useful primarily in an option file.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql.trace`.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Use `charset_name` as the default character set for the client and connection.

This option can be useful if the operating system uses one character set and the `mysql` client by default uses another. In this case, output may be formatted incorrectly. You can usually fix such issues by using this option to force the client to use the system character set instead.

For more information, see [Section 10.1.4, “Connection Character Sets and Collations”](#), and [Section 10.5, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--delimiter=str`

Set the statement delimiter. The default is the semicolon character (`;`).

- `--disable-named-commands`

Disable named commands. Use the `*` form only, or use named commands only at the beginning of a line ending with a semicolon (`;`). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See [Section 4.5.1.2, “mysql Commands”](#).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.7, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.6.7.

- `--execute=statement, -e statement`

Execute the statement and quit. The default output format is like that produced with `--batch`. See [Section 4.2.4, “Using Options on the Command Line”](#), for some examples. With this option, `mysql` does not use the history file.

- `--force, -f`

Continue even if an SQL error occurs.

- `--histignore`

A colon-separated list of one or more patterns specifying statements to ignore for logging purposes. These patterns are added to the default pattern list ("`*IDENTIFIED*:*PASSWORD*`"). The value specified for this option affects logging of statements written to the history file. For more information, see [Section 4.5.1.3, “mysql Logging”](#). This option was added in MySQL 5.6.8.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--html, -H`

Produce HTML output.

- `--ignore-spaces, -i`

Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see [Section 5.1.8, “Server SQL Modes”](#)).

- `--init-command=str`

SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.

- `--line-numbers`

Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--local-infile[={0|1}]`

Enable or disable `LOCAL` capability for `LOAD DATA INFILE`. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling `LOCAL` has no effect if the server does not also support it.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--named-commands, -G`

Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See [Section 4.5.1.2, “mysql Commands”](#).

- `--no-auto-rehash, -A`

This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash`.

- `--no-beep, -b`

Do not beep when errors occur.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--one-database, -o`

Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on [USE](#) statements.

Initially, `mysql` executes statements in the input because specifying a database `db_name` on the command line is equivalent to inserting `USE db_name` at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that `mysql` is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.
- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.
- `--pager[=command]`

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. [Section 4.5.1.2, “mysql Commands”](#), discusses output paging further.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysql` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--prompt=format_str`

Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in [Section 4.5.1.2, “mysql Commands”](#).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick, -q`

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw, -r`

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+-----+
| CHAR(92) |
+-----+
| \       |
+-----+
```

```
% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- `--reconnect`

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

- `--safe-updates`, `--i-am-a-dummy`, `-U`

Permit only those `UPDATE` and `DELETE` statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-updates` on the command line. See [Section 4.5.1.6, “mysql Tips”](#), for more information about this option.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. As of MySQL 5.6.7, this option is enabled by default; use `--skip-secure-auth` to disable it.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1 passwordss are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

Note

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--server-public-key-path=file_name`

The path name to a file containing the server RSA public key. The file must be in PEM format. The public key is used for RSA encryption of the client password for connections to the server made using accounts that authenticate with the `sha256_password` plugin. This option is ignored for client accounts that do not authenticate with that plugin. It is also ignored if password encryption is not needed, as is the case when the client connects to the server using an SSL connection.

The server sends the public key to the client as needed, so it is not necessary to use this option for RSA password encryption to occur. It is more efficient to do so because then the server need not send the key.

For additional discussion regarding use of the `sha256_password` plugin, including how to get the RSA public key, see [Section 6.5.1.4, “The SHA-256 Authentication Plugin”](#).

This option is available only if MySQL was built using OpenSSL. It was added in MySQL 5.6.6 under the name `--server-public-key` and renamed in 5.6.7 to `--server-public-key-path`.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--show-warnings`

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore`

Ignore `SIGINT` signals (typically the result of typing **Control+C**).

- `--silent, -s`

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--skip-column-names, -N`

Do not write column names in results.

- `--skip-line-numbers, -L`

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--table, -t`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=file_name`

Append a copy of output to the given file. This option works only in interactive mode. [Section 4.5.1.2, “mysql Commands”](#), discusses tee files further.

- `--unbuffered, -n`

Flush the buffer after each query.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait, -w`

If the connection cannot be established, wait and retry instead of aborting.

- `--xml, -X`

Produce XML output.

```
<field name="column_name">NULL</field>
```

The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#) for details.

The XML output also uses an XML namespace, as shown here:

```
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"
<?xml version="1.0"?>

<resultset statement="SHOW VARIABLES LIKE 'version%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  <row>
    <field name="Variable_name">version</field>
    <field name="Value">5.0.40-debug</field>
  </row>

  <row>
    <field name="Variable_name">version_comment</field>
    <field name="Value">Source distribution</field>
  </row>

  <row>
    <field name="Variable_name">version_compile_machine</field>
    <field name="Value">i686</field>
  </row>

  <row>
    <field name="Variable_name">version_compile_os</field>
    <field name="Value">suse-linux-gnu</field>
  </row>
</resultset>
```

(See Bug #25946.)

You can also set the following variables by using `--var_name=value`.

- `connect_timeout`

The number of seconds before connection timeout. (Default value is 0.)

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- `max_join_size`

The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `net_buffer_length`

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `select_limit`

The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

4.5.1.2 mysql Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?          (\?) Synonym for 'help'.
clear      (\c) Clear command.
connect    (\r) Reconnect to the server. Optional arguments are db and host.
delimiter  (\d) Set statement delimiter.
edit       (\e) Edit command with $EDITOR.
ego        (\G) Send command to mysql server, display result vertically.
exit       (\q) Exit mysql. Same as quit.
go         (\g) Send command to mysql server.
help       (\h) Display this help.
nopager    (\n) Disable pager, print to stdout.
notee      (\t) Don't write into outfile.
pager      (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print      (\p) Print current command.
prompt     (\R) Change your mysql prompt.
quit       (\q) Quit mysql.
rehash     (\#) Rebuild completion hash.
source     (\.) Execute an SQL script file. Takes a file name as an argument.
status     (\s) Get status information from the server.
system     (\!) Execute a system shell command.
tee        (\T) Set outfile [to_outfile]. Append everything into given
           outfile.
use        (\u) Use another database. Takes database name as argument.
charset    (\C) Switch to another charset. Might be needed for processing
           binlog with multi-byte charsets.
warnings   (\W) Show warnings after every statement.
nowarning  (\w) Don't show warnings after every statement.

For server side help, type 'help contents'
```

If `mysql` is invoked with the `--binary-mode` option, all `mysql` commands are disabled except `charset` and `delimiter` in non-interactive mode (for input piped to `mysql` or loaded using the `source` command).

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multiple-line `/* ... */` comments is not supported.

- `help [arg], \h [arg], \? [arg], ? [arg]`

Display a help message listing the available `mysql` commands.

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see [Section 4.5.1.4, “mysql Server-Side Help”](#).

- `charset charset_name, \C charset_name`

Change the default character set and issue a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- `clear, \c`

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name host_name], \r [db_name host_name]`

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter str, \d str`

Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (`;`).

The delimiter string can be specified as an unquoted or quoted argument on the `delimiter` command line. Quoting can be done with either single quote (`'`), double quote (`"`), or backtick (```) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (`\`) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

`mysql` interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as `x`, you will be unable to use the word `INDEX` in statements. `mysql` interprets this as `INDE` followed by the delimiter `x`.

When the delimiter recognized by `mysql` is set to something other than the default of `;`, instances of that character are sent to the server without interpretation. However, the server itself still interprets `;` as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see [Section 23.8.17, “C API Support for Multiple Statement Execution”](#)), and for parsing the body of stored procedures and functions, triggers, and events (see [Section 20.1, “Defining Stored Programs”](#)).

- `edit, \e`

Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

The `edit` command works only in Unix.

- `ego, \G`

Send the current statement to the server to be executed and display the result using vertical format.

- `exit, \q`

Exit `mysql`.

- `go, \g`

Send the current statement to the server to be executed.

- `nopager, \n`

Disable output paging. See the description for `pager`.

The `nopager` command works only in Unix.

- `notee, \t`

Disable output copying to the tee file. See the description for `tee`.

- `nowarning, \w`

Disable display of warnings after each statement.

- `pager [command], \P [command]`

Enable output paging. By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print, \p`

Print the current input statement without executing it.

- `prompt [str], \R [str]`

Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `quit, \q`

Exit `mysql`.

- `rehash, \#`

Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- `source file_name, \. file_name`

Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\\`.

- `status, \s`

Provide status information about the connection and the server you are using. If you are running in `--safe-updates` mode, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command, \! command`

Execute the given command using your default command interpreter.

The `system` command works only in Unix.

- `tee [file_name], \T [file_name]`

By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- `use db_name, \u db_name`

Use `db_name` as the default database.

- `warnings, \W`

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
shell> man less
```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \  
      | tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

| Option | Description |
|-----------------|--|
| <code>\c</code> | A counter that increments for each statement you issue |
| <code>\D</code> | The full current date |
| <code>\d</code> | The default database |
| <code>\h</code> | The server host |
| <code>\l</code> | The current delimiter |
| <code>\m</code> | Minutes of the current time |
| <code>\n</code> | A newline character |
| <code>\O</code> | The current month in three-letter format (Jan, Feb, ...) |
| <code>\o</code> | The current month in numeric format |
| <code>\P</code> | am/pm |
| <code>\p</code> | The current TCP/IP port or socket file |
| <code>\R</code> | The current time, in 24-hour military time (0–23) |
| <code>\r</code> | The current time, standard 12-hour time (1–12) |
| <code>\S</code> | Semicolon |
| <code>\s</code> | Seconds of the current time |
| <code>\t</code> | A tab character |
| <code>\U</code> | Your full <code>user_name@host_name</code> account name |
| <code>\u</code> | Your user name |

| Option | Description |
|-----------------|--|
| <code>\v</code> | The server version |
| <code>\w</code> | The current day of the week in three-letter format (Mon, Tue, ...) |
| <code>\Y</code> | The current year, four digits |
| <code>\y</code> | The current year, two digits |
| <code>_</code> | A space |
| <code>\</code> | A space (a space follows the backslash) |
| <code>\'</code> | Single quote |
| <code>\"</code> | Double quote |
| <code>\\</code> | A literal <code>\</code> backslash character |
| <code>\x</code> | <code>x</code> , for any “ <code>x</code> ” not listed above |

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\\u@\\h) [\\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
shell> mysql --prompt="(\\u@\\h) [\\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\\u@\\h) [\\d]>\\_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in [Section 4.2.6, “Using Option Files”](#).) The overlap may cause you problems if you use single backslashes. For example, `\\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS>` format:

```
[mysql]
prompt="\\r:\\m:\\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\\R`) command. For example:

```
mysql> prompt (\\u@\\h) [\\d]>\\_
PROMPT set to '(\\u@\\h) [\\d]>\\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

4.5.1.3 mysql Logging

On Unix, the `mysql` client logs statements executed interactively to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

How Logging Occurs

Statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the `--batch` or `--execute` option.
- Statements are ignored and not logged if they match any pattern in the “ignore” list. This list is described later.
- `mysql` logs each nonignored, nonempty statement line individually.
- If a nonignored statement spans multiple lines (not including the terminating delimiter), `mysql` concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
-> 'Today is'
-> ,
-> CURDATE()
-> ;
```

In this case, `mysql` logs the “SELECT”, “‘Today is’”, “,”, “CURDATE()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()\n` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

As of MySQL 5.6.8, `mysql` ignores for logging purposes statements that match any pattern in the “ignore” list. By default, the pattern list is `"*IDENTIFIED*: *PASSWORD*"`, to ignore statements that refer to passwords. Pattern matching is not case sensitive. Within patterns, two characters are special:

- `?` matches any single character.
- `*` matches any sequence of zero or more characters.

To specify additional patterns, use the `--histignore` option or set the `MYSQL_HISTIGNORE` environment variable. (If both are specified, the option value takes precedence.) The value should be a colon-separated list of one or more patterns, which are appended to the default pattern list.

Patterns specified on the command line might need to be quoted or escaped to prevent your command interpreter from treating them specially. For example, to suppress logging for `UPDATE` and `DELETE` statements in addition to statements that refer to passwords, invoke `mysql` like this:

```
shell> mysql --histignore="*UPDATE*:*DELETE"
```

Controlling the History File

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

4.5.1.4 mysql Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.10, “Server-Side Help”](#)).

If there is no match for the search string, the search fails:

```
mysql> help me

Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
  Account Management
  Administration
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Language Structure
  Plugins
  Storage Engines
  Stored Routines
  Table Maintenance
  Transactions
  Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
    SHOW
    SHOW BINARY LOGS
    SHOW ENGINE
    SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015     | 724935    |
| binlog.000016     | 733481    |
+-----+-----+
```

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP rep%` returns a list of topics that begin with `rep`:

```
mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
    REPAIR TABLE
    REPEAT FUNCTION
    REPEAT LOOP
    REPLACE
    REPLACE FUNCTION
```

4.5.1.5 Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` option, which causes each statement to be displayed before the result that it produces.

`mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8`.

For more information about batch mode, see [Section 3.5, “Using mysql in Batch Mode”](#).

4.5.1.6 mysql Tips

This section describes some techniques that can help you use `mysql` more effectively.

Input-Line Editing

`mysql` supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the **left-arrow** and **right-arrow** keys move horizontally within the current input line, and the **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines. **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press **Enter**.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build `mysql` (for example, the `libedit` or `readline` library).

Documentation for the `libedit` and `readline` libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: `.editrc` for `libedit` and `.inputrc` for `readline`.

For example, in `libedit`, **Control+W** deletes everything before the current cursor position and **Control+U** deletes the entire line. In `readline`, **Control+W** deletes the word before the cursor and **Control+U** deletes everything before the current cursor position. If `mysql` was built using `libedit`, a user who prefers the `readline` behavior for these two keys can put the following lines in the `.editrc` file (creating the file if necessary):

```
bind "^W" ed-delete-prev-word
bind "^U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only `bind` at the end of `.editrc`. `mysql` will show the bindings when it starts.

Unicode Support on Windows

Windows provides APIs based on UTF-16LE for reading from and writing to the console. As of MySQL 5.6.2, the `mysql` client for Windows is able to use these APIs. As of 5.6.3, the Windows installer creates an item in the MySQL menu named `MySQL command line client - Unicode`. This item invokes the `mysql` client with properties set to communicate through the console to the MySQL server using Unicode.

To take advantage of this support manually, run `mysql` within a console that uses a compatible Unicode font and set the default character set to a Unicode character set that is supported for communication with the server:

1. Open a console window.
2. Go to the console window properties, select the font tab, and choose Lucida Console or some other compatible Unicode font. This is necessary because console windows start by default using a DOS raster font that is inadequate for Unicode.
3. Execute `mysql.exe` with the `--default-character-set=utf8` (or `utf8mb4`) option. This option is necessary because `utf16le` is not supported as a connection character set.

With those changes, `mysql` will use the Windows APIs to communicate with the console using UTF-16LE, and communicate with the server using UTF-8. (The menu item mentioned previously sets the font and character set as just described.)

To avoid those steps each time you run `mysql`, you can create a shortcut that invokes `mysql.exe`. The shortcut should set the console font to Lucida Console or some other compatible Unicode font, and pass the `--default-character-set=utf8` (or `utf8mb4`) option to `mysql.exe`.

Alternatively, create a shortcut that only sets the console font, and set the character set in the `[mysql]` group of your `my.ini` file:

```
[mysql]
default-character-set=utf8
```

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
***** 1. row *****
  msg_nro: 3068
    date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
   reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
    sbj: UTF-8
   txt: >>>> "Thimble" == Thimble Smith writes:

Thimble> Hi. I think this is a good idea. Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my
Thimble> TODO list and see what happens.

Yes, please do that.
```

```
Regards,
Monty
      file: inbox-jani-1
      hash: 190402944
1 row in set (0.09 sec)
```

Using the `--safe-updates` Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET sql_safe_updates=1, sql_select_limit=1000, max_join_size=1000000;
```

See [Section 5.1.5, “Server System Variables”](#).

The `SET` statement has the following effects:

- You are not permitted to execute an `UPDATE` or `DELETE` statement unless you specify a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;

UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large `SELECT` results to 1,000 rows unless the statement includes a `LIMIT` clause.
- The server aborts multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

Disabling mysql Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
```

```

Connection id:      1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+-----+
| a      |
+-----+
| NULL   |
+-----+
1 row in set (0.05 sec)

```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see [Section 23.8.16, “Controlling Automatic Reconnection Behavior”](#).

4.5.2 mysqladmin — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- `create db_name`

Create a new database named `db_name`.

- `debug`

Tell the server to write debug information to the error log. Format and content of this information is subject to change.

This includes information about the Event Scheduler. See [Section 20.4.5, “Event Scheduler Status”](#).

- `drop db_name`

Delete the database named `db_name` and all its tables.

- `extended-status`

Display the server status variables and their values.

- `flush-hosts`

Flush all information in the host cache.

- `flush-logs`

Flush all logs.

- `flush-privileges`

Reload the grant tables (same as `reload`).

- `flush-status`

Clear status variables.

- `flush-tables`

Flush all tables.

- `flush-threads`

Flush the thread cache.

- `kill id,id,...`

Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

- `old-password new_password`

This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See [Section 6.1.2.4, “Password Hashing in MySQL”](#).)

- `password new_password`

Set a new password. This changes the password to `new_password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

If the `new_password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

In MySQL 5.6, the new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

Caution

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- `ping`

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- `processlist`

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See [Section 13.7.5.30, “SHOW PROCESSLIST Syntax”](#).)

- `reload`

Reload the grant tables.

- `refresh`

Flush all tables and close and open log files.

- `shutdown`

Stop the server.

- `start-slave`

Start replication on a slave server.

- `status`

Display a short server status message.

- `stop-slave`

Stop replication on a slave server.

- `variables`

Display the server system variables and their values.

- `version`

Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+-----+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host      | db | Command | Time | State | Info          |
+-----+-----+-----+-----+-----+-----+-----+
| 51 | monty | localhost |    | Query   | 0    |      | show processlist |
+-----+-----+-----+-----+-----+-----+
Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime`

The number of seconds the MySQL server has been running.

- `Threads`

The number of active threads (clients).

- `Questions`

The number of questions (queries) from clients since the server was started.

- `Slow queries`

The number of queries that have taken more than `long_query_time` seconds. See [Section 5.4.5, “The Slow Query Log”](#).

- `Opens`

The number of tables the server has opened.

- `Flush tables`

The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- `Open tables`

The number of tables that currently are open.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.9 `mysqladmin` Options

| Format | Description | Introduced |
|--|--|------------|
| <code>--bind-address</code> | Use specified network interface to connect to MySQL Server | 5.6.1 |
| <code>--compress</code> | Compress all information sent between client and server | |
| <code>--connect_timeout</code> | Number of seconds before connection timeout | |
| <code>--count</code> | Number of iterations to make for repeated command execution | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | |
| <code>--default-character-set</code> | Specify default character set | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--enable-cleartext-plugin</code> | Enable cleartext authentication plugin | 5.6.7 |
| <code>--force</code> | Continue even if an SQL error occurs | |
| <code>--help</code> | Display help message and exit | |
| <code>--host</code> | Connect to MySQL server on given host | |

| Format | Description | Introduced |
|--|--|------------|
| <code>--login-path</code> | Read login path options from <code>.mylogin.cnf</code> | 5.6.6 |
| <code>--no-beep</code> | Do not beep when errors occur | |
| <code>--no-defaults</code> | Read no option files | |
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--print-defaults</code> | Print default options | |
| <code>--protocol</code> | Connection protocol to use | |
| <code>--relative</code> | Show the difference between the current and previous values when used with the <code>--sleep</code> option | |
| <code>--secure-auth</code> | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--shutdown_timeout</code> | The maximum number of seconds to wait for server shutdown | |
| <code>--silent</code> | Silent mode | |
| <code>--sleep</code> | Execute commands repeatedly, sleeping for delay seconds in between | |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use | |
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version</code> | Display version information and exit | |
| <code>--vertical</code> | Print query output rows vertically (one line per column value) | |
| <code>--wait</code> | If the connection cannot be established, wait and retry instead of aborting | |

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count=N, -c N`

The number of iterations to make for repeated command execution if the `--sleep` option is given.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqladmin.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysqladmin` normally reads the `[client]` and `[mysqladmin]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqladmin` also reads the `[client_other]` and `[mysqladmin_other]` groups.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.7](#), “The Cleartext Client-Side Authentication Plugin”.) This option was added in MySQL 5.6.7.

- `--force, -f`

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6](#), “`mysql_config_editor` — MySQL Configuration Utility”. This option was added in MySQL 5.6.6.

- `--no-beep, -b`

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6](#), “`mysql_config_editor` — MySQL Configuration Utility”.)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqladmin` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1](#), “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqladmin` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--relative, -r`

Show the difference between the current and previous values when used with the `--sleep` option. This option works only with the `extended-status` command.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1 passwordss are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

**Note**

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--silent, -s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Execute commands repeatedly, sleeping for `delay` seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count], -w[count]`

If the connection cannot be established, wait and retry instead of aborting. If a `count` value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value`.

- `connect_timeout`

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

4.5.3 mysqlcheck — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#), for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for `mysql_upgrade` because that program invokes `mysqlcheck` to check all tables and repair them if necessary.)

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in [Section 13.7.2, “Table Maintenance Statements”](#).

The `MyISAM` storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on `MyISAM` tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note      : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies. This will be the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
shell> mysqlcheck [options] db_name [tbl_name ...]
shell> mysqlcheck [options] --databases db_name ...
shell> mysqlcheck [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

| Command | Meaning |
|----------------------------|---|
| <code>mysqlrepair</code> | The default option is <code>--repair</code> |
| <code>mysqlanalyze</code> | The default option is <code>--analyze</code> |
| <code>mysqloptimize</code> | The default option is <code>--optimize</code> |

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.10 `mysqlcheck` Options

| Format | Description | Introduced |
|------------------------------|---|------------|
| <code>--all-databases</code> | Check all tables in all databases | |
| <code>--all-in-1</code> | Execute a single statement for each database that names all the tables from that database | |

| Format | Description | Introduced |
|--|--|------------|
| <code>--analyze</code> | Analyze the tables | |
| <code>--auto-repair</code> | If a checked table is corrupted, automatically fix it | |
| <code>--bind-address</code> | Use specified network interface to connect to MySQL Server | 5.6.1 |
| <code>--character-sets-dir</code> | Directory where character sets are installed | |
| <code>--check</code> | Check the tables for errors | |
| <code>--check-only-changed</code> | Check only tables that have changed since the last check | |
| <code>--check-upgrade</code> | Invoke CHECK TABLE with the FOR UPGRADE option | |
| <code>--compress</code> | Compress all information sent between client and server | |
| <code>--databases</code> | Interpret all arguments as database names | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | 5.6.2 |
| <code>--default-character-set</code> | Specify default character set | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--enable-cleartext-plugin</code> | Enable cleartext authentication plugin | 5.6.28 |
| <code>--extended</code> | Check and repair tables | |
| <code>--fast</code> | Check only tables that have not been closed properly | |
| <code>--fix-db-names</code> | Convert database names to 5.1 format | |
| <code>--fix-table-names</code> | Convert table names to 5.1 format | |
| <code>--force</code> | Continue even if an SQL error occurs | |
| <code>--help</code> | Display help message and exit | |
| <code>--host</code> | Connect to MySQL server on given host | |
| <code>--login-path</code> | Read login path options from .mylogin.cnf | 5.6.6 |
| <code>--medium-check</code> | Do a check that is faster than an --extended operation | |
| <code>--no-defaults</code> | Read no option files | |
| <code>--optimize</code> | Optimize the tables | |
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | 5.6.2 |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--print-defaults</code> | Print default options | |
| <code>--protocol</code> | Connection protocol to use | |
| <code>--quick</code> | The fastest method of checking | |

| Format | Description | Introduced |
|--|--|------------|
| <code>--repair</code> | Perform a repair that can fix almost anything except unique keys that are not unique | |
| <code>--secure-auth</code> | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--silent</code> | Silent mode | |
| <code>--skip-database</code> | Omit this database from performed operations | 5.6.11 |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use | |
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--tables</code> | Overrides the <code>--databases</code> or <code>-B</code> option | |
| <code>--use-frm</code> | For repair operations on MyISAM tables | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version</code> | Display version information and exit | |
| <code>--write-binlog</code> | Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. <code>--skip-write-binlog</code> adds <code>NO_WRITE_TO_BINLOG</code> to these statements. | |

- `--help, -?`

Display a help message and exit.

- `--all-databases, -A`

Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line, except that the `INFORMATION_SCHEMA` and `performance_schema` databases are not checked. They can be checked by explicitly naming them with the `--databases` option.

- `--all-in-1, -1`

Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze, -a`

Analyze the tables.

- `--auto-repair`

If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--check, -c`

Check the tables for errors. This is the default operation.

- `--check-only-changed, -C`

Check only tables that have changed since the last check or that have not been closed properly.

- `--check-upgrade, -g`

Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option automatically enables the `--fix-db-names` and `--fix-table-names` options.

- `--compress`

Compress all information sent between the client and the server if both support compression.

- `--databases, -B`

Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlcheck` normally reads the `[client]` and `[mysqlcheck]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlcheck` also reads the `[client_other]` and `[mysqlcheck_other]` groups.

- `--extended, -e`

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.7, “The Cleartext Client-Side Authentication Plugin”](#).)

This option was added in MySQL 5.6.28.

- `--fast, -F`

Check only tables that have not been closed properly.

- `--fix-db-names`

Convert database names to 5.1 format. Only database names that contain special characters are affected.

- `--fix-table-names`

Convert table names to 5.1 format. Only table names that contain special characters are affected. This option also applies to views.

- `--force, -f`

Continue even if an SQL error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--medium-check, -m`

Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--optimize, -o`

Optimize the tables.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlcheck` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlcheck` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick, -q`

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair, -r`

Perform a repair that can fix almost anything except unique keys that are not unique.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1 passwordss are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

**Note**

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--silent, -s`

Silent mode. Print only error messages.

- `--skip-database=db_name`

Do not include the named database (case sensitive) in the operations performed by `mysqlcheck`. This option was added in MySQL 5.6.11.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--tables`

Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--use-frm`

For repair operations on `MyISAM` tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print information about the various stages of program operation.

- `--version, -V`

Display version information and exit.

- `--write-binlog`

This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup.

4.5.4 `mysqldump` — A Database Backup Program

The `mysqldump` client utility performs [logical backups](#), producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server. The `mysqldump` command can also generate output in CSV, other delimited text, or XML format.

- [Performance and Scalability Considerations](#)
- [Invocation Syntax](#)
- [Option Syntax - Alphabetical Summary](#)
- [Connection Options](#)
- [Option-File Options](#)
- [DDL Options](#)
- [Debug Options](#)

- [Help Options](#)
- [Internationalization Options](#)
- [Replication Options](#)
- [Format Options](#)
- [Filtering Options](#)
- [Performance Options](#)
- [Transactional Options](#)
- [Option Groups](#)
- [Examples](#)
- [Restrictions](#)

`mysqldump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, and `LOCK TABLES` if the `--single-transaction` option is not used. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate `CREATE` privileges for objects created by those statements.

`mysqldump` output can include `ALTER DATABASE` statements that change the database collation. These may be used when dumping stored programs to preserve their character encodings. To reload a dump file containing such statements, the `ALTER` privilege for the affected database is required.

Note

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```
shell> mysqldump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see [Section 10.1.4, “Connection Character Sets and Collations”](#)), so the dump file will not load correctly. To work around this issue, use the `--result-file` option, which creates the output in ASCII format:

```
shell> mysqldump [options] --result-file=dump.sql
```

Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a [physical](#) backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily [InnoDB](#) tables, or if you have a mix of [InnoDB](#) and [MyISAM](#) tables, consider using the [mysqlbackup](#) command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for [InnoDB](#) backups with minimal disruption; it can also back up tables from [MyISAM](#) and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See [Section 25.2, “MySQL Enterprise Backup Overview”](#).
- If your tables are primarily [MyISAM](#) tables, consider using the [mysqlhotcopy](#) instead, for better performance than [mysqldump](#) of backup and restore operations. See [Section 4.6.10, “mysqlhotcopy — A Database Backup Program”](#).

[mysqldump](#) can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the [--quick](#) option (or [--opt](#), which enables [--quick](#)). The [--opt](#) option (and hence [--quick](#)) is enabled by default, so to enable memory buffering, use [--skip-quick](#).

If you are using a recent version of [mysqldump](#) to generate a dump to be reloaded into a very old MySQL server, use the [--skip-opt](#) option instead of the [--opt](#) or [--extended-insert](#) option.

For additional information about [mysqldump](#), see [Section 7.4, “Using mysqldump for Backups”](#).

Invocation Syntax

There are in general three ways to use [mysqldump](#)—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
shell> mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following [db_name](#), or use the [--databases](#) or [--all-databases](#) option.

To see a list of the options your version of [mysqldump](#) supports, issue the command [mysqldump --help](#).

Option Syntax - Alphabetical Summary

[mysqldump](#) supports the following options, which can be specified on the command line or in the [\[mysqldump\]](#) and [\[client\]](#) groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.11 [mysqldump](#) Options

| Format | Description | Introduced |
|-------------------------------------|--|------------|
| --add-drop-database | Add DROP DATABASE statement before each CREATE DATABASE statement | |
| --add-drop-table | Add DROP TABLE statement before each CREATE TABLE statement | |
| --add-drop-trigger | Add DROP TRIGGER statement before each CREATE TRIGGER statement | |
| --add-locks | Surround each table dump with LOCK TABLES and UNLOCK TABLES statements | |
| --all-databases | Dump all tables in all databases | |

| Format | Description | Introduced |
|--|---|------------|
| <code>--allow-keywords</code> | Allow creation of column names that are keywords | |
| <code>--apply-slave-statements</code> | Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output | |
| <code>--bind-address</code> | Use specified network interface to connect to MySQL Server | 5.6.1 |
| <code>--character-sets-dir</code> | Directory where character sets are installed | |
| <code>--comments</code> | Add comments to dump file | |
| <code>--compact</code> | Produce more compact output | |
| <code>--compatible</code> | Produce output that is more compatible with other database systems or with older MySQL servers | |
| <code>--complete-insert</code> | Use complete INSERT statements that include column names | |
| <code>--compress</code> | Compress all information sent between client and server | |
| <code>--create-options</code> | Include all MySQL-specific table options in CREATE TABLE statements | |
| <code>--databases</code> | Interpret all name arguments as database names | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | |
| <code>--default-character-set</code> | Specify default character set | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--delayed-insert</code> | Write INSERT DELAYED statements rather than INSERT statements | |
| <code>--delete-master-logs</code> | On a master replication server, delete the binary logs after performing the dump operation | |
| <code>--disable-keys</code> | For each table, surround INSERT statements with statements to disable and enable keys | |
| <code>--dump-date</code> | Include dump date as "Dump completed on" comment if --comments is given | |
| <code>--dump-slave</code> | Include CHANGE MASTER statement that lists binary log coordinates of slave's master | |
| <code>--enable-cleartext-plugin</code> | Enable cleartext authentication plugin | 5.6.28 |
| <code>--events</code> | Dump events from dumped databases | |
| <code>--extended-insert</code> | Use multiple-row INSERT syntax | |
| <code>--fields-enclosed-by</code> | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE | |

| Format | Description | Introduced |
|---|---|------------|
| --fields-escaped-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE | |
| --fields-optionally-enclosed-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE | |
| --fields-terminated-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE | |
| --flush-logs | Flush MySQL server log files before starting dump | |
| --flush-privileges | Emit a FLUSH PRIVILEGES statement after dumping mysql database | |
| --force | Continue even if an SQL error occurs during a table dump | |
| --help | Display help message and exit | |
| --hex-blob | Dump binary columns using hexadecimal notation | |
| --host | Host to connect to (IP address or hostname) | |
| --ignore-table | Do not dump given table | |
| --include-master-host-port | Include MASTER_HOST/MASTER_PORT options in CHANGE MASTER statement produced with --dump-slave | |
| --insert-ignore | Write INSERT IGNORE rather than INSERT statements | |
| --lines-terminated-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE | |
| --lock-all-tables | Lock all tables across all databases | |
| --lock-tables | Lock all tables before dumping them | |
| --log-error | Append warnings and errors to named file | |
| --login-path | Read login path options from .mylogin.cnf | 5.6.6 |
| --master-data | Write the binary log file name and position to the output | |
| --max_allowed_packet | Maximum packet length to send to or receive from server | |
| --net_buffer_length | Buffer size for TCP/IP and socket communication | |
| --no-autocommit | Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements | |
| --no-create-db | Do not write CREATE DATABASE statements | |
| --no-create-info | Do not write CREATE TABLE statements that re-create each dumped table | |
| --no-data | Do not dump table contents | |
| --no-defaults | Read no option files | |
| --no-set-names | Same as --skip-set-charset | |
| --no-tablespaces | Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in output | |

| Format | Description | Introduced |
|--|---|------------|
| <code>--opt</code> | Shorthand for <code>--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset</code> . | |
| <code>--order-by-primary</code> | Dump each table's rows sorted by its primary key, or by its first unique index | |
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--print-defaults</code> | Print default options | |
| <code>--protocol</code> | Connection protocol to use | |
| <code>--quick</code> | Retrieve rows for a table from the server a row at a time | |
| <code>--quote-names</code> | Quote identifiers within backtick characters | |
| <code>--replace</code> | Write REPLACE statements rather than INSERT statements | |
| <code>--result-file</code> | Direct output to a given file | |
| <code>--routines</code> | Dump stored routines (procedures and functions) from dumped databases | |
| <code>--secure-auth</code> | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| <code>--set-charset</code> | Add SET NAMES default_character_set to output | |
| <code>--set-gtid-purged</code> | Whether to add SET @@GLOBAL.GTID_PURGED to output | 5.6.9 |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--single-transaction</code> | Issue a BEGIN SQL statement before dumping data from server | |
| <code>--skip-add-drop-table</code> | Do not add a DROP TABLE statement before each CREATE TABLE statement | |
| <code>--skip-add-locks</code> | Do not add locks | |
| <code>--skip-comments</code> | Do not add comments to dump file | |
| <code>--skip-compact</code> | Do not produce more compact output | |
| <code>--skip-disable-keys</code> | Do not disable keys | |
| <code>--skip-extended-insert</code> | Turn off extended-insert | |
| <code>--skip-opt</code> | Turn off options set by <code>--opt</code> | |
| <code>--skip-quick</code> | Do not retrieve rows for a table from the server a row at a time | |
| <code>--skip-quote-names</code> | Do not quote identifiers | |
| <code>--skip-set-charset</code> | Do not write SET NAMES statement | |
| <code>--skip-triggers</code> | Do not dump triggers | |
| <code>--skip-tz-utc</code> | Turn off tz-utc | |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use | |

| Format | Description | Introduced |
|---------------------------------------|--|------------|
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--tab</code> | Produce tab-separated data files | |
| <code>--tables</code> | Override <code>--databases</code> or <code>-B</code> option | |
| <code>--triggers</code> | Dump triggers for each dumped table | |
| <code>--tz-utc</code> | Add <code>SET TIME_ZONE='+00:00'</code> to dump file | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version</code> | Display version information and exit | |
| <code>--where</code> | Dump only rows selected by given WHERE condition | |
| <code>--xml</code> | Produce XML output | |

Connection Options

The `mysqldump` command logs into a MySQL server to extract information. The following options specify how to connect to the MySQL server, either on the same machine or a remote system.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.7, “The Cleartext Client-Side Authentication Plugin”](#).)

This option was added in MySQL 5.6.28.

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqldump` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqldump` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1 passwordss are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

**Note**

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

You can also set the following variables by using `--var_name=value` syntax:

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

- `net_buffer_length`

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `net_buffer_length` bytes long. If you increase this variable, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.

Option-File Options

These options are used to control which option files to read.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqldump` normally reads the `[client]` and `[mysqldump]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqldump` also reads the `[client_other]` and `[mysqldump_other]` groups.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--print-defaults`

Print the program name and all options that it gets from option files.

DDL Options

Usage scenarios for `mysqldump` include setting up an entire new MySQL instance (including database tables), and replacing data inside an existing instance with existing databases and tables. The following options let you specify which things to tear down and set up when restoring a dump, by encoding various DDL statements within the dump file.

- `--add-drop-database`

Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- `--add-drop-table`

Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-trigger`

Write a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

- `--all-tablespaces, -Y`

Adds to a table dump all SQL statements needed to create any tablespaces used by an `NDB` table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to MySQL Cluster tables.

- `--no-create-db, -n`

Suppress the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- `--no-create-info, -t`

Do not write `CREATE TABLE` statements that create each dumped table.

Note

This option does *not* exclude statements creating log file groups or tablespaces from `mysqldump` output; however, you can use the `--no-tablespaces` option for this purpose.

- `--no-tablespaces, -y`

This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

- `--replace`

Write `REPLACE` statements rather than `INSERT` statements.

Debug Options

The following options print debugging information, encode debugging information in the dump file, or let the dump operation proceed regardless of potential problems.

- `--allow-keywords`

Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--comments, -i`

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default value is `d:t:o,/tmp/mysqldump.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--dump-date`

If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

```
-- Dump completed on DATE
```

However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.

- `--force, -f`

Continue even if an SQL error occurs during a table dump.

One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

- `--log-error=file_name`
Log warnings and errors by appending them to the named file. The default is to do no logging.
- `--skip-comments`
See the description for the `--comments` option.
- `--verbose, -v`
Verbose mode. Print more information about what the program does.

Help Options

The following options display information about the `mysqldump` command itself.

- `--help, -?`
Display a help message and exit.
- `--version, -V`
Display version information and exit.

Internationalization Options

The following options change how the `mysqldump` command represents character data with national language settings.

- `--character-sets-dir=dir_name`
The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).
- `--default-character-set=charset_name`
Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#). If no character set is specified, `mysqldump` uses `utf8`.
- `--no-set-names, -N`
Turns off the `--set-charset` setting, the same as specifying `--skip-set-charset`.
- `--set-charset`
Write `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

Replication Options

The `mysqldump` command is frequently used to create an empty instance, or an instance including data, on a slave server in a replication configuration. The following options apply to dumping and restoring data on replication master and slave servers.

- `--apply-slave-statements`
For a slave dump produced with the `--dump-slave` option, add a `STOP SLAVE` statement before the `CHANGE MASTER TO` statement and a `START SLAVE` statement at the end of the output.
- `--delete-master-logs`

On a master replication server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. This option automatically enables `--master-data`.

- `--dump-slave[=value]`

This option is similar to `--master-data` except that it is used to dump a replication slave server to produce a dump file that can be used to set up another server as a slave that has the same master as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped slave's master. These are the master server coordinates from which the slave should start replicating.

`--dump-slave` causes the coordinates from the master to be used rather than those of the dumped server, as is done by the `--master-data` option. In addition, specifying this option causes the `--master-data` option to be overridden, if used, and effectively ignored.

The option value is handled the same way as for `--master-data` (setting no value or 1 causes a `CHANGE MASTER TO` statement to be written to the dump, setting 2 causes the statement to be written but encased in SQL comments) and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

This option causes `mysqldump` to stop the slave SQL thread before the dump and restart it again after.

In conjunction with `--dump-slave`, the `--apply-slave-statements` and `--include-master-host-port` options can also be used.

- `--include-master-host-port`

For the `CHANGE MASTER TO` statement in a slave dump produced with the `--dump-slave` option, add `MASTER_HOST` and `MASTER_PORT` options for the host name and TCP/IP port number of the slave's master.

- `--master-data[=value]`

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

This option requires the `RELOAD` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master, using the `--dump-slave` option, which overrides `--master-data` and causes it to be ignored if both options are used.

Prior to MySQL 5.6.4, this option was required for dumping the replication log tables (see [Section 17.2.2, “Replication Relay and Status Logs”](#)).

- `--set-gtid-purged=value`

This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a `SET @@global.gtid_purged` statement to the output. This option may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

The following table shows the permitted option values. The default value is `AUTO`.

| Value | Meaning |
|-------------------|---|
| <code>OFF</code> | Add no <code>SET</code> statement to the output. |
| <code>ON</code> | Add a <code>SET</code> statement to the output. An error occurs if GTIDs are not enabled on the server. |
| <code>AUTO</code> | Add a <code>SET</code> statement to the output if GTIDs are enabled on the server. |

The `--set-gtid-purged` option has the following effect on binary logging when the dump file is reloaded:

- `--set-gtid-purged=OFF`: `SET @@SESSION.SQL_LOG_BIN=0;` is not added to the output.
- `--set-gtid-purged=ON`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output.
- `--set-gtid-purged=AUTO`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output if GTIDs are enabled on the server you are backing up (that is, if `AUTO` evaluates to `ON`).

This option was added in MySQL 5.6.9.

Format Options

The following options specify how to represent the entire dump file or certain kinds of data in the dump file. They also control whether certain optional information is written to the dump file.

- `--compact`

Produce more compact output. This option enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

- `--compatible=name`

Produce output that is more compatible with other database systems or with older MySQL servers. The value of `name` can be `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, or `no_field_options`. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See [Section 5.1.8, “Server SQL Modes”](#).

This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

This option requires a server version of 4.1.0 or higher. With older servers, it does nothing.

- `--complete-insert, -c`

Use complete `INSERT` statements that include column names.

- `--create-options`

Include all MySQL-specific table options in the `CREATE TABLE` statements.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options are used with the `--tab` option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

- `--lines-terminated-by=...`

This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--quote-names, -Q`

Quote identifiers (such as database, table, and column names) within ``` characters. If the `ANSI_QUOTES` SQL mode is enabled, identifiers are quoted within `"` characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- `--result-file=file_name, -r file_name`

Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

This option should be used on Windows to prevent newline `\n` characters from being converted to `\r\n` carriage return/newline sequences.

- `--tab=dir_name, -T dir_name`

Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

Note

This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. Because the server creates files `*.txt` file in the directory that you specify, the directory must be writable by the server and the MySQL account that you use must have the `FILE` privilege. Because `mysqldump` creates `*.sql` in the same directory, it must be writable by your system login account.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

Column values are converted to the character set specified by the `--default-character-set` option.

- `--tz-utc`

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--xml, -X`

Write dump output as well-formed XML.

NULL, 'NULL', and Empty Values: For a column named `column_name`, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

| Value: | XML Representation: |
|---|---|
| <code>NULL</code> (<i>unknown value</i>) | <code><field name="column_name" xsi:nil="true" /></code> |
| <code>' '</code> (<i>empty string</i>) | <code><field name="column_name"></field></code> |
| <code>'NULL'</code> (<i>string value</i>) | <code><field name="column_name">NULL</field></code> |

The output from the `mysql` client when run using the `--xml` option also follows the preceding rules. (See [Section 4.5.1.1, “mysql Options”](#).)

XML output from `mysqldump` includes the XML namespace, as shown here:

```
shell> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">

<field name="District">Kabul</field>
<field name="Population">1780000</field>
</row>
...
<row>
<field name="ID">4079</field>
```

```
<field name="Name">Rafah</field>
<field name="CountryCode">PSE</field>
<field name="District">Rafah</field>
<field name="Population">92020</field>
</row>
</table_data>
</database>
</mysqldump>
```

Prior to MySQL 5.6.5, this option prevented the `--routines` option from working correctly—that is, no stored routines, triggers, or events could be dumped in XML format. (Bug #11760384, Bug #52792)

Filtering Options

The following options control which kinds of schema objects are written to the dump file: by category, such as triggers or events; by name, for example, choosing which databases and tables to dump; or even filtering rows from the table data using a [WHERE](#) clause.

- `--all-databases, -A`

Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

Prior to MySQL 5.6.4, the `slave_master_info` and `slave_relay_log_info` tables (see [Section 17.2.2, “Replication Relay and Status Logs”](#)) were not included by this option.

- `--databases, -B`

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

This option may be used to dump the `INFORMATION_SCHEMA` and `performance_schema` databases, which normally are not dumped even with the `--all-databases` option. (Also use the `--skip-lock-tables` option.)

- `--events, -E`

Include Event Scheduler events for the dumped databases in the output. This option requires the `EVENT` privileges for those databases.

The output generated by using `--events` contains `CREATE EVENT` statements to create the events. However, these statements do not include attributes such as the event creation and modification timestamps, so when the events are reloaded, they are created with timestamps equal to the reload time.

If you require events to be created with their original timestamp attributes, do not use `--events`. Instead, dump and reload the contents of the `mysql.event` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

- `--ignore-table=db_name.tbl_name`

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--no-data, -d`

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- `--routines, -R`

Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the `SELECT` privilege for the `mysql.proc` table.

The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps, so when the routines are reloaded, they are created with timestamps equal to the reload time.

If you require routines to be created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the `mysql.proc` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

Prior to MySQL 5.6.5, this option had no effect when used together with the `--xml` option. (Bug #11760384, Bug #52792)

- `--tables`

Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

To be able to dump a table's triggers, you must have the `TRIGGER` privilege for the table.

- `--where='where_condition', -w 'where_condition'`

Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

Examples:

```
--where="user='jimf' "  
-w"userid>1"  
-w"userid<1"
```

Performance Options

The following options are the most relevant for the performance particularly of the restore operations. For large data sets, restore operation (processing the `INSERT` statements in the dump file) is the most time-consuming part. When it is urgent to restore data quickly, plan and test the performance of this stage in advance. For restore times measured in hours, you might prefer an alternative backup and restore solution, such as [MySQL Enterprise Backup](#) for `InnoDB`-only and mixed-use databases, or `mysqlhotcopy` for `MyISAM`-only databases.

Performance is also affected by the [transactional options](#), primarily for the dump operation.

- `--delayed-insert`

For those nontransactional tables that support the `INSERT DELAYED` syntax, use that statement rather than regular `INSERT` statements.

As of MySQL 5.6.6, `DELAYED` inserts are deprecated, so this option will be removed in a future release.

- `--disable-keys, -K`

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of `MyISAM` tables.

- `--extended-insert, -e`

Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--insert-ignore`

Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--opt`

This option, enabled by default, is shorthand for the combination of `--add-drop-table` `--add-locks` `--create-options` `--disable-keys` `--extended-insert` `--lock-tables` `--quick` `--set-charset`. It gives a fast dump operation and produces a dump file that can be reloaded into a MySQL server quickly.

Because the `--opt` option is enabled by default, you only specify its converse, the `--skip-opt` to turn off several default settings. See the discussion of [mysqldump option groups](#) for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- `--quick, -q`

This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--skip-opt`

See the description for the `--opt` option.

Transactional Options

The following options trade off the performance of the dump operation, against the reliability and consistency of the exported data.

- `--add-locks`

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

- `--flush-logs, -F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables`, `--master-data`, or `--`

`single-transaction`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked by `FLUSH TABLES WITH READ LOCK`. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables`, `--master-data`, or `--single-transaction`.

- `--flush-privileges`

Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

- `--lock-all-tables, -x`

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- `--lock-tables, -l`

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

- `--no-autocommit`

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- `--order-by-primary`

Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but makes the dump operation take considerably longer.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--single-transaction`

This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqldump` to retrieve the table contents to obtain incorrect contents or fail.

The `--single-transaction` option and the `--lock-tables` option are mutually exclusive because `LOCK TABLES` causes any pending transactions to be committed implicitly.

To dump large tables, combine the `--single-transaction` option with the `--quick` option.

Option Groups

- The `--opt` option turns on several settings that work together to perform a fast dump operation. All of these settings are on by default, because `--opt` is on by default. Thus you rarely if ever specify `--opt`. Instead, you can turn these settings off as a group by specifying `--skip-opt`, the optionally re-enable certain settings by specifying the associated options later on the command line.
- The `--compact` option turns off several settings that control whether optional statements and comments appear in the output. Again, you can follow this option with other options that re-enable certain settings, or turn all the settings on by using the `--skip-compact` form.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

Examples

To make a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

To load the dump file back into the server:

```
shell> mysql db_name < backup-file.sql
```

Another way to reload the dump file:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

You can dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, `mysqldump` provides a way of making an online backup:

```
shell> mysqldump --all-databases --master-data --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see [Section 5.4.4, “The Binary Log”](#)) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2  
      > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see [Section 7.2, “Database Backup Methods”](#), and [Section 7.3, “Example Backup and Recovery Strategy”](#).

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)
- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

Restrictions

`mysqldump` does not dump the `INFORMATION_SCHEMA` or `performance_schema` database by default. To dump either of these, name it explicitly on the command line. You can also name it with the `--databases` option. Also, use the `--skip-lock-tables` option.

`mysqldump` does not dump the MySQL Cluster `ndbinfo` information database.

Before MySQL 5.6.6, `mysqldump` does not dump the `general_log` or `slow_query_log` tables for dumps of the `mysql` database. As of 5.6.6, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

If you encounter problems backing up views due to insufficient privileges, see [Section C.5, “Restrictions on Views”](#) for a workaround.

4.5.5 mysqlimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.12 `mysqlimport` Options

| Format | Description | Introduced |
|--|--|------------|
| <code>--bind-address</code> | Use specified network interface to connect to MySQL Server | 5.6.1 |
| <code>--columns</code> | This option takes a comma-separated list of column names as its value | |
| <code>--compress</code> | Compress all information sent between client and server | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | 5.6.2 |
| <code>--default-character-set</code> | Specify default character set | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--delete</code> | Empty the table before importing the text file | |
| <code>--enable-cleartext-plugin</code> | Enable cleartext authentication plugin | 5.6.28 |
| <code>--fields-enclosed-by</code> | This option has the same meaning as the corresponding clause for <code>LOAD DATA INFILE</code> | |
| <code>--fields-escaped-by</code> | This option has the same meaning as the corresponding clause for <code>LOAD DATA INFILE</code> | |
| <code>--fields-optionally-enclosed-by</code> | This option has the same meaning as the corresponding clause for <code>LOAD DATA INFILE</code> | |
| <code>--fields-terminated-by</code> | This option has the same meaning as the corresponding clause for <code>LOAD DATA INFILE</code> | |
| <code>--force</code> | Continue even if an SQL error occurs | |
| <code>--help</code> | Display help message and exit | |
| <code>--host</code> | Connect to MySQL server on given host | |
| <code>--ignore</code> | See the description for the <code>--replace</code> option | |

| Format | Description | Introduced |
|--|---|------------|
| <code>--ignore-lines</code> | Ignore the first N lines of the data file | |
| <code>--lines-terminated-by</code> | This option has the same meaning as the corresponding clause for LOAD DATA INFILE | |
| <code>--local</code> | Read input files locally from the client host | |
| <code>--lock-tables</code> | Lock all tables for writing before processing any text files | |
| <code>--login-path</code> | Read login path options from .mylogin.cnf | 5.6.6 |
| <code>--low-priority</code> | Use LOW_PRIORITY when loading the table. | |
| <code>--no-defaults</code> | Read no option files | |
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | 5.6.2 |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--print-defaults</code> | Print default options | |
| <code>--protocol</code> | Connection protocol to use | |
| <code>--replace</code> | The --replace and --ignore options control handling of input rows that duplicate existing rows on unique key values | |
| <code>--secure-auth</code> | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--silent</code> | Produce output only when errors occur | |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use | |
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--use-threads</code> | Number of threads for parallel file-loading | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version</code> | Display version information and exit | |

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--columns=column_list, -c column_list`

This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical *debug_options* string is *d:t:o,file_name*. The default is *d:t:o*.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use *charset_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysqlimport` normally reads the `[client]` and `[mysqlimport]` groups. If the `--`

`defaults-group-suffix=_other` option is given, `mysqlimport` also reads the `[client_other]` and `[mysqlimport_other]` groups.

- `--delete, -D`

Empty the table before importing the text file.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.7, “The Cleartext Client-Side Authentication Plugin”](#).)

This option was added in MySQL 5.6.28.

- `--fields-terminated-by=..., --fields-enclosed-by=..., --fields-optionally-enclosed-by=..., --fields-escaped-by=...`

These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--force, -f`

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--host=host_name, -h host_name`

Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore, -i`

See the description for the `--replace` option.

- `--ignore-lines=N`

Ignore the first *N* lines of the data file.

- `--lines-terminated-by=...`

This option has the same meaning as the corresponding clause for `LOAD DATA INFILE`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--local, -L`

Read input files locally from the client host.

- `--lock-tables, -l`

Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See

[Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--low-priority`

Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlimport` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlimport` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--replace, -r`

The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same

unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1 passwordss are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

**Note**

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--silent, -s`

Silent mode. Produce output only when errors occur.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--use-threads=N`

Load files in parallel using `N` threads.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE impptest(id INT, n VARCHAR(30))' test
shell> ed
a
100      Max Sydow
101      Count Dracula
.
w impptest.txt
32
q
shell> od -c impptest.txt
0000000  1  0  0  \t  M  a  x           S  y  d  o  w  \n  1  0
0000020  1  \t  C  o  u  n  t           D  r  a  c  u  l  a  \n
0000040
shell> mysqlimport --local test impptest.txt
test.impptest: Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
shell> mysql -e 'SELECT * FROM impptest' test
+-----+-----+
| id  | n                |
+-----+-----+
| 100 | Max Sydow        |
| 101 | Count Dracula    |
+-----+-----+
```

4.5.6 mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See [Section 13.7.5, “SHOW Syntax”](#). The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (`*`, `?`, `%`, or `_`), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. `*` and `?` characters are converted into SQL `%` and `_` wildcard characters. This might cause some confusion when you try to display the columns for a table with a `_` in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra `%` last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.13 mysqlshow Options

| Format | Description | Introduced |
|--|--|------------|
| <code>--bind-address</code> | Use specified network interface to connect to MySQL Server | 5.6.1 |
| <code>--compress</code> | Compress all information sent between client and server | |
| <code>--count</code> | Show the number of rows per table | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | 5.6.2 |
| <code>--default-character-set</code> | Specify default character set | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--enable-cleartext-plugin</code> | Enable cleartext authentication plugin | 5.6.28 |
| <code>--help</code> | Display help message and exit | |
| <code>--host</code> | Connect to MySQL server on given host | |
| <code>--keys</code> | Show table indexes | |
| <code>--login-path</code> | Read login path options from .mylogin.cnf | 5.6.6 |
| <code>--no-defaults</code> | Read no option files | |
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | 5.6.2 |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--print-defaults</code> | Print default options | |
| <code>--protocol</code> | Connection protocol to use | |
| <code>--secure-auth</code> | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--show-table-type</code> | Show a column indicating the table type | |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use | |
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |

| Format | Description | Introduced |
|---------------------------------------|--|------------|
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--status</code> | Display extra information about each table | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version</code> | Display version information and exit | |

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count`

Show the number of rows per table. This can be slow for non-MyISAM tables.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical *debug_options* string is *d:t:o,file_name*. The default is *d:t:o*.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use *charset_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlshow` normally reads the `[client]` and `[mysqlshow]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlshow` also reads the `[client_other]` and `[mysqlshow_other]` groups.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.7, “The Cleartext Client-Side Authentication Plugin”](#).)

This option was added in MySQL 5.6.28.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--keys, -k`

Show table indexes.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlshow` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlshow` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

**Note**

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--show-table-type, -t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--status, -i`

Display extra information about each table.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.5.7 mysqlslap — Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke `mysqlslap` like this:

```
shell> mysqlslap [options]
```

Some options such as `--create` or `--query` enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
--create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
--query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
--number-int-cols=2 --number-char-cols=3
--auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by `;` and multiple insert statements delimited by `;`. The `--query` file will have multiple queries delimited by `;`. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
--iterations=5 --query=query.sql --create=create.sql
--delimiter=";"
```

`mysqlslap` supports the following options, which can be specified on the command line or in the `[mysqlslap]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.14 `mysqlslap` Options

| Format | Description | Introduced |
|--|--|------------|
| <code>--auto-generate-sql</code> | Generate SQL statements automatically when they are not supplied in files or using command options | |
| <code>--auto-generate-sql-add-autoincrement</code> | Add <code>AUTO_INCREMENT</code> column to automatically generated tables | |
| <code>--auto-generate-sql-execute-number</code> | Specify how many queries to generate automatically | |
| <code>--auto-generate-sql-guid-primary</code> | Add a GUID-based primary key to automatically generated tables | |
| <code>--auto-generate-sql-load-type</code> | Specify the test load type | |
| <code>--auto-generate-sql-secondary-indexes</code> | Specify how many secondary indexes to add to automatically generated tables | |
| <code>--auto-generate-sql-unique-query-number</code> | How many different queries to generate for automatic tests. | |
| <code>--auto-generate-sql-unique-write-number</code> | How many different queries to generate for <code>--auto-generate-sql-write-number</code> | |
| <code>--auto-generate-sql-write-number</code> | How many row inserts to perform on each thread | |
| <code>--commit</code> | How many statements to execute before committing. | |
| <code>--compress</code> | Compress all information sent between client and server | |
| <code>--concurrency</code> | Number of clients to simulate when issuing the <code>SELECT</code> statement | |
| <code>--create</code> | File or string containing the statement to use for creating the table | |

| Format | Description | Introduced |
|--|---|------------|
| <code>--create-schema</code> | Schema in which to run the tests | |
| <code>--csv</code> | Generate output in comma-separated values format | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | 5.6.2 |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--delimiter</code> | Delimiter to use in SQL statements | |
| <code>--detach</code> | Detach (close and reopen) each connection after each N statements | |
| <code>--enable-cleartext-plugin</code> | Enable cleartext authentication plugin | 5.6.7 |
| <code>--engine</code> | Storage engine to use for creating the table | |
| <code>--help</code> | Display help message and exit | |
| <code>--host</code> | Connect to MySQL server on given host | |
| <code>--iterations</code> | Number of times to run the tests | |
| <code>--login-path</code> | Read login path options from <code>.mylogin.cnf</code> | 5.6.6 |
| <code>--no-defaults</code> | Read no option files | |
| <code>--no-drop</code> | Do not drop any schema created during the test run | 5.6.3 |
| <code>--number-char-cols</code> | Number of VARCHAR columns to use if <code>--auto-generate-sql</code> is specified | |
| <code>--number-int-cols</code> | Number of INT columns to use if <code>--auto-generate-sql</code> is specified | |
| <code>--number-of-queries</code> | Limit each client to approximately this number of queries | |
| <code>--only-print</code> | Do not connect to databases. mysqlslap only prints what it would have done | |
| <code>--password</code> | Password to use when connecting to server | |
| <code>--pipe</code> | On Windows, connect to server using named pipe | |
| <code>--plugin-dir</code> | Directory where plugins are installed | 5.6.2 |
| <code>--port</code> | TCP/IP port number to use for connection | |
| <code>--post-query</code> | File or string containing the statement to execute after the tests have completed | |
| <code>--post-system</code> | String to execute using <code>system()</code> after the tests have completed | |
| <code>--pre-query</code> | File or string containing the statement to execute before running the tests | |
| <code>--pre-system</code> | String to execute using <code>system()</code> before running the tests | |
| <code>--print-defaults</code> | Print default options | |

| Format | Description | Introduced |
|--|--|------------|
| <code>--protocol</code> | Connection protocol to use | |
| <code>--query</code> | File or string containing the SELECT statement to use for retrieving data | |
| <code>--secure-auth</code> | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| <code>--shared-memory-base-name</code> | The name of shared memory to use for shared-memory connections | |
| <code>--silent</code> | Silent mode | |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use | |
| <code>--ssl</code> | Enable secure connection | |
| <code>--ssl-ca</code> | Path of file that contains list of trusted SSL CAs | |
| <code>--ssl-capath</code> | Path of directory that contains trusted SSL CA certificates in PEM format | |
| <code>--ssl-cert</code> | Path of file that contains X509 certificate in PEM format | |
| <code>--ssl-cipher</code> | List of permitted ciphers to use for connection encryption | |
| <code>--ssl-crl</code> | Path of file that contains certificate revocation lists | 5.6.3 |
| <code>--ssl-crlpath</code> | Path of directory that contains certificate revocation list files | 5.6.3 |
| <code>--ssl-key</code> | Path of file that contains X509 key in PEM format | |
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Verbose mode | |
| <code>--version</code> | Display version information and exit | |

- `--help, -?`

Display a help message and exit.

- `--auto-generate-sql, -a`

Generate SQL statements automatically when they are not supplied in files or using command options.

- `--auto-generate-sql-add-autoincrement`

Add an `AUTO_INCREMENT` column to automatically generated tables.

- `--auto-generate-sql-execute-number=N`

Specify how many queries to generate automatically.

- `--auto-generate-sql-guid-primary`

Add a GUID-based primary key to automatically generated tables.

- `--auto-generate-sql-load-type=type`

Specify the test load type. The permissible values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`.

- `--auto-generate-sql-secondary-indexes=N`

Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- `--auto-generate-sql-unique-query-number=N`

How many different queries to generate for automatic tests. For example, if you run a `key` test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- `--auto-generate-sql-unique-write-number=N`

How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10.

- `--auto-generate-sql-write-number=N`

How many row inserts to perform. The default is 100.

- `--commit=N`

How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--concurrency=N, -c N`

The number of parallel clients to simulate.

- `--create=value`

The file or string containing the statement to use for creating the table.

- `--create-schema=value`

The schema in which to run the tests.

Note

If the `--auto-generate-sql` option is also given, `mysqlslap` drops the schema at the end of the test run. To avoid this, use the `--no-drop` option as well.

- `--csv[=file_name]`

Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlslap.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysqlslap` normally reads the `[client]` and `[mysqlslap]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlslap` also reads the `[client_other]` and `[mysqlslap_other]` groups.

- `--delimiter=str, -F str`

The delimiter to use in SQL statements supplied in files or using command options.

- `--detach=N`

Detach (close and reopen) each connection after each *N* statements. The default is 0 (connections are not detached).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.5.1.7, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.6.7.

- `--engine=engine_name, -e engine_name`

The storage engine to use for creating tables.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--iterations=N, -i N`

The number of times to run the tests.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--no-drop`

Prevent `mysqlslap` from dropping any schema it creates during the test run. This option was added in MySQL 5.6.3.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--number-char-cols=N, -x N`

The number of `VARCHAR` columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N, -y N`

The number of `INT` columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`

Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

```
shell> mysqlslap --delimiter=";" --number-of-queries=10
        --query="use test;insert into t values(null)"
```

- `--only-print`

Do not connect to databases. `mysqlslap` only prints what it would have done.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlslap` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlslap` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--post-query=value`

The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--post-system=str`

The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value`

The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- `--pre-system=str`

The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--query=value, -q value`

The file or string containing the `SELECT` statement to use for retrieving data.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1 passwordss are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

**Note**

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. This option applies only if the server supports shared-memory connections.

- `--silent, -s`

Silent mode. No output.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.6 MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

4.6.1 `innochecksum` — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for `InnoDB` files. This tool reads an `InnoDB` tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches cause `InnoDB` to deliberately shut down a running server, it may be preferable to use this tool rather than waiting for an in-production server to encounter the damaged pages. As of MySQL 5.6.16, `innochecksum` supports files greater than 2GB in size. Previously, `innochecksum` only supported files up to 2GB in size.

`innochecksum` does not support tablespaces that contain compressed pages.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
shell> innochecksum [options] file_name
```

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `-c`
Print a count of the number of pages in the file.
- `-d`
Debug mode; prints checksums for each page.
- `-e num`
End at this page number.
- `-p num`
Check only this page number.
- `-s num`
Start at this page number.
- `-v`
Verbose mode; print a progress indicator every five seconds.

4.6.2 `myisam_ftdump` — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```
CREATE TABLE mytexttable  
(
```

```
id    INT NOT NULL,  
txt   TEXT NOT NULL,  
PRIMARY KEY (id),  
FULLTEXT (txt)  
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this:

```
shell> myisam_ftdump -c mytexttable 1 | sort -r
```

`myisam_ftdump` supports the following options:

- `--help, -h -?`
Display a help message and exit.
- `--count, -c`
Calculate per-word statistics (counts and global weights).
- `--dump, -d`
Dump the index, including data offsets and word weights.
- `--length, -l`
Report the length distribution.
- `--stats, -s`
Report global index statistics. This is the default operation if no other operation is specified.
- `--verbose, -v`
Verbose mode. Print more output about what the program does.

4.6.3 myisamchk — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), and [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

The use of `myisamchk` with partitioned tables is not supported.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the `MyISAM` tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all `MyISAM` tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all `MyISAM` tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \
  --key_buffer_size=64M --myisam_sort_buffer_size=64M \
  --read_buffer_size=1M --write_buffer_size=1M \
  /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with `myisamchk`, see [Section 4.6.3.6, “myisamchk Memory Usage”](#).

For additional information about using `myisamchk`, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Important

You must ensure that no other program is using the tables while you are running `myisamchk`. The most effective means of doing so is to shut down the MySQL server while running `myisamchk`, or to lock all tables that `myisamchk` is being used on.

Otherwise, when you run `myisamchk`, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more `MyISAM` tables.

If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`.

However, the easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

`myisamchk` supports the following options, which can be specified on the command line or in the `[myisamchk]` group of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.15 `myisamchk` Options

| Format | Description | Introduced | Deprecated |
|--------------------------------------|--|------------|------------|
| <code>--analyze</code> | Analyze the distribution of key values | | |
| <code>--backup</code> | Make a backup of the .MYD file as file_name-time.BAK | | |
| <code>--block-search</code> | Find the record that a block at the given offset belongs to | | |
| <code>--check</code> | Check the table for errors | | |
| <code>--check-only-changed</code> | Check only tables that have changed since the last check | | |
| <code>--correct-checksum</code> | Correct the checksum information for the table | | |
| <code>--data-file-length</code> | Maximum length of the data file (when re-creating data file when it is full) | | |
| <code>--debug</code> | Write debugging log | | |
| <code>--decode_bits</code> | Decode_bits | | |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | | |
| <code>--defaults-file</code> | Read only named option file | | |
| <code>--defaults-group-suffix</code> | Option group suffix value | | |
| <code>--description</code> | Print some descriptive information about the table | | |
| <code>--extend-check</code> | Do very thorough table check or repair that tries to recover every possible row from the data file | | |

| Format | Description | Introduced | Deprecated |
|--|---|------------|------------|
| <code>--fast</code> | Check only tables that haven't been closed properly | | |
| <code>--force</code> | Do a repair operation automatically if myisamchk finds any errors in the table | | |
| <code>--force</code> | Overwrite old temporary files. For use with the <code>-r</code> or <code>-o</code> option | | |
| <code>--ft_max_word_len</code> | Maximum word length for FULLTEXT indexes | | |
| <code>--ft_min_word_len</code> | Minimum word length for FULLTEXT indexes | | |
| <code>--ft_stopword_file</code> | Use stopwords from this file instead of built-in list | | |
| <code>--HELP</code> | Display help message and exit | | |
| <code>--help</code> | Display help message and exit | | |
| <code>--information</code> | Print informational statistics about the table that is checked | | |
| <code>--key_buffer_size</code> | Size of buffer used for index blocks for MyISAM tables | | |
| <code>--keys-used</code> | A bit-value that indicates which indexes to update | | |
| <code>--max-record-length</code> | Skip rows larger than the given length if myisamchk cannot allocate memory to hold them | | |
| <code>--medium-check</code> | Do a check that is faster than an <code>--extend-check</code> operation | | |
| <code>--myisam_block_size</code> | Block size to be used for MyISAM index pages | | |
| <code>--myisam_sort_buffer_size</code> | The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE | 5.6.9 | |
| <code>--no-defaults</code> | Read no option files | | |
| <code>--parallel-recover</code> | Uses the same technique as <code>-r</code> and <code>-n</code> , but creates all the keys in parallel, using different threads (beta) | | |
| <code>--print-defaults</code> | Print default options | | |
| <code>--quick</code> | Achieve a faster repair by not modifying the data file. | | |
| <code>--read_buffer_size</code> | Each thread that does a sequential scan allocates a buffer of this size for each table it scans | | |
| <code>--read-only</code> | Do not mark the table as checked | | |
| <code>--recover</code> | Do a repair that can fix almost any problem except unique keys that aren't unique | | |
| <code>--safe-recover</code> | Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found | | |
| <code>--set-auto-increment</code> | Force AUTO_INCREMENT numbering for new records to start at the given value | | |
| <code>--set-collation</code> | Specify the collation to use for sorting table indexes | | |
| <code>--silent</code> | Silent mode | | |

| Format | Description | Introduced | Deprecated |
|----------------------------------|---|------------|------------|
| <code>--sort_buffer_size</code> | The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE | | 5.6.9 |
| <code>--sort-index</code> | Sort the index tree blocks in high-low order | | |
| <code>--sort_key_blocks</code> | sort_key_blocks | | |
| <code>--sort-records</code> | Sort records according to a particular index | | |
| <code>--sort-recover</code> | Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large | | |
| <code>--stats_method</code> | Specifies how MyISAM index statistics collection code should treat NULLs | | |
| <code>--tmpdir</code> | Path of the directory to be used for storing temporary files | | |
| <code>--unpack</code> | Unpack a table that was packed with myisampack | | |
| <code>--update-state</code> | Store information in the .MYI file to indicate when the table was checked and whether the table crashed | | |
| <code>--verbose</code> | Verbose mode | | |
| <code>--version</code> | Display version information and exit | | |
| <code>--write_buffer_size</code> | Write buffer size | | |

4.6.3.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help, -?`

Display a help message and exit. Options are grouped by type of operation.

- `--HELP, -H`

Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/myisamchk.trace`.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `myisamchk` normally reads the `[myisamchk]` group. If the `--defaults-group-suffix=_other` option is given, `myisamchk` also reads the `[myisamchk_other]` group.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--silent, -s`

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

| Variable | Default Value |
|-------------------------------------|----------------------------|
| <code>decode_bits</code> | 9 |
| <code>ft_max_word_len</code> | version-dependent |
| <code>ft_min_word_len</code> | 4 |
| <code>ft_stopword_file</code> | built-in list |
| <code>key_buffer_size</code> | 523264 |
| <code>myisam_block_size</code> | 1024 |
| <code>myisam_sort_key_blocks</code> | 16 |
| <code>read_buffer_size</code> | 262136 |
| <code>sort_buffer_size</code> | 2097144 |
| <code>sort_key_blocks</code> | 16 |
| <code>stats_method</code> | <code>nulls_unequal</code> |

| Variable | Default Value |
|--------------------------------|---------------|
| <code>write_buffer_size</code> | 262136 |

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`. As of MySQL 5.6.9, `myisam_sort_buffer_size` is available as an alternative name to `sort_buffer_size`. `myisam_sort_buffer_size` is preferable to `sort_buffer_size` because its name corresponds to the `myisam_sort_buffer_size` server system variable that has a similar meaning. `sort_buffer_size` should be considered deprecated.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in [Section 5.1.5, “Server System Variables”](#), and [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes on `MyISAM` tables. `ft_stopword_file` names the stopwords file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopwords file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
```

```
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

4.6.3.2 myisamchk Check Options

`myisamchk` supports the following options for table checking operations:

- `--check, -c`

Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed, -C`

Check only tables that have changed since the last check.

- `--extend-check, -e`

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

See also the description of this option under table repair options.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--fast, -F`

Check only tables that haven't been closed properly.

- `--force, -f`

Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information, -i`

Print informational statistics about the table that is checked.

- `--medium-check, -m`

Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only, -T`

Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state, -U`

Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

4.6.3.3 myisamchk Repair Options

`myisamchk` supports the following options for table repair operations (operations performed when an option such as `--recover` or `--safe-recover` is given):

- `--backup, -B`

Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--correct-checksum`

Correct the checksum information for the table.

- `--data-file-length=len, -D len`

The maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check, -e`

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--force, -f`

Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val, -k val`

For `myisamchk`, the option value is a bit value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks, -l`

Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len`

Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover, -p`

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick, -q`

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover, -r`

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with `MyISAM` tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

- `--safe-recover, -o`

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-collation=name`

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover, -n`

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=dir_name, -t dir_name`

The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (:) on Unix and the semicolon (;) on Windows.

- `--unpack, -u`

Unpack a table that was packed with `myisampack`.

4.6.3.4 Other myisamchk Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze, -a`

Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset, -b offset`

Find the record that a block at the given offset belongs to.

- `--description, -d`

Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--set-auto-increment[=value], -A[value]`

Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If *value* is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index, -S`

Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N, -R N`

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

4.6.3.5 Obtaining Table Information with myisamchk

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d tbl_name`

Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv tbl_name`

Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- `myisamchk -eis tbl_name`

Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

This is like `-eis`, but tells you what is being done.

The *tbl_name* argument can be either the name of a MyISAM table or the name of its index file, as described in [Section 4.6.3](#), “myisamchk — MyISAM Table-Maintenance Utility”. Multiple *tbl_name* arguments can be given.

Suppose that a table named *person* has the following structure. (The *MAX_ROWS* table option is included so that in the example output from *myisamchk* shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id          INT NOT NULL AUTO_INCREMENT,
  last_name   VARCHAR(20) NOT NULL,
  first_name  VARCHAR(20) NOT NULL,
  birth       DATE,
  death       DATE,
  PRIMARY KEY (id),
  INDEX (last_name, first_name),
  INDEX (birth)
) MAX_ROWS = 1000000;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw---- 1 mysql mysql 9347072 Aug 19 11:47 person.MYD
-rw-rw---- 1 mysql mysql 6066176 Aug 19 11:47 person.MYI
```

Example of *myisamchk -dvv* output:

```
MyISAM file:      person
Record format:    Packed
Character set:    latin1_swedish_ci (8)
File-version:     1
Creation time:    2009-08-19 16:47:41
Recover time:     2009-08-19 16:47:56
Status:           checked,analyzed,optimized keys
Auto increment key: 1 Last value: 306688
Data records:      306688 Deleted blocks: 0
Datafile parts:    306688 Deleted data: 0
Datafile pointer (bytes): 4 Keyfile pointer (bytes): 3
Datafile length:   9347072 Keyfile length: 6066176
Max datafile length: 4294967294 Max keyfile length: 17179868159
Recordlength:      54

table description:
Key Start Len Index Type Rec/key Root Blocksize
1 2 4 unique long 1 99328 1024
2 6 20 multip. varchar prefix 512 3563520 1024
 27 20 varchar 512
3 48 3 multip. uint24 NULL 306688 6065152 1024

Field Start Length Nullpos Nullbit Type
1 1 1
2 2 4 no zeros
3 6 21 varchar
4 27 21 varchar
5 48 3 1 1 no zeros
6 51 3 1 2 no zeros
```

Explanations for the types of information *myisamchk* produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- `MyISAM file`
Name of the `MyISAM` (index) file.
- `Record format`
The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`. (`Packed` corresponds to what `SHOW TABLE STATUS` reports as `Dynamic`.)
- `Chararacter set`
The table default character set.
- `File-version`
Version of `MyISAM` format. Always 1.
- `Creation time`
When the data file was created.
- `Recover time`
When the index/data file was last reconstructed.
- `Status`
Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.
- `Auto increment key, Last value`
The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.
- `Data records`
The number of rows in the table.
- `Deleted blocks`
How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, "MyISAM Table Optimization"](#).
- `Datafile parts`
For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.
- `Deleted data`
How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See [Section 7.6.4, "MyISAM Table Optimization"](#).
- `Datafile pointer`
The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

How long the table data file can become, in bytes.

- `Max keyfile length`

How long the table index file can become, in bytes.

- `Recordlength`

How much space each row takes, in bytes.

The `table description` part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- `Key`

This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two `table description` lines for the second index. This indicates that it is a multiple-part index with two parts.

- `Start`

Where in the row this portion of the index starts.

- `Len`

How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- `Index`

Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip.` (multiple).

- `Type`

What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

Address of the root index block.

- `Blocksize`

The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- `Field`

The column number.

- `Start`

The byte position of the column within table rows.

- `Length`

The length of the column in bytes.

- `Nullpos, Nullbit`

For columns that can be `NULL`, `MyISAM` stores `NULL` values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The `Nullpos` and `Nullbit` values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is `NULL`.

The position and number of bytes used to store `NULL` flags is shown in the line for field 1. This is why there are six `Field` lines for the `person` table even though it has only five columns.

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant `N` bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

The `Huff tree` and `Bits` fields are displayed if the table has been compressed with `myisampack`. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#), for an example of this information.

Example of `myisamchk -eiv` output:

```
Checking MyISAM file: person
Data records: 306688 Deleted blocks: 0
- check file-size
- check record delete-chain
No recordlinks
- check key delete-chain
block_size 1024:
- check index reference
- check data record references index: 1
Key: 1: Keyblocks used: 98% Packed: 0% Max levels: 3
- check data record references index: 2
Key: 2: Keyblocks used: 99% Packed: 97% Max levels: 3
- check data record references index: 3
Key: 3: Keyblocks used: 98% Packed: -14% Max levels: 3
Total: Keyblocks used: 98% Packed: 89%

- check records and index references
*** LOTS OF ROW NUMBERS DELETED ***

Records: 306688 M.recordlength: 25 Packed: 83%
Recordspace used: 97% Empty space: 2% Blocks/Record: 1.00
Record blocks: 306688 Delete blocks: 0
Record data: 7934464 Deleted data: 0
Lost space: 256512 Linkdata: 1156096

User time 43.08, System time 1.68
Maximum resident set size 0, Integral resident set size 0
Non-physical pagefaults 0, Physical pagefaults 0, Swaps 0
Blocks in 0 out 7, Messages in 0 out 0, Signals 0
Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)
```

`myisamchk -eiv` output includes the following information:

- `Data records`

The number of rows in the table.

- `Deleted blocks`

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Key`

The key number.

- `Keyblocks used`

What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- `Packed`

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- `Max levels`

How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

How many rows are in the table.

- `M.recordlength`

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

What percentage of the data file is used.

- `Empty space`

What percentage of the data file is unused.

- `Blocks/Record`

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Recordblocks`

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`

How many blocks (links) are deleted.

- `Recorddata`

How many bytes in the data file are used.

- Deleted data

How many bytes in the data file are deleted (unused).

- Lost space

If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- Linkdata

When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

4.6.3.6 myisamchk Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --myisam_sort_buffer_size=256M \
           --key_buffer_size=512M \
           --read_buffer_size=64M \
           --write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=dir_name` option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.
- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=dir_name`). The following formula yields the amount of space required:

$$(\text{largest_key} + \text{row_pointer_length}) * \text{number_of_rows} * 2$$

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see Section 4.6.3.5, “Obtaining Table Information with `myisamchk`”). The `row_pointer_length` and `number_of_rows` values are the `Datafile pointer` and `Data records` values in the table description. To determine the `largest_key` value, check the `Key` lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

4.6.4 myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a `MyISAM` log file. To create such a file, start the server with a `--log-isam=log_file` option.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?, -I`

Display a help message and exit.

- `-c N`

Execute only `N` commands.

- `-f N`

Specify the maximum number of open files.

- `-i`

Display extra information before exiting.

- `-o offset`

Specify the starting offset.

- `-p N`

Remove `N` components from path.

- `-r`

Perform a recovery operation.

- `-R record_pos_file record_pos`

Specify record position file and record position.

- `-u`

Perform an update operation.

- `-v`

Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- `-w write_file`

Specify the write file.

- `-V`

Display version information.

4.6.5 myisampack — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses MyISAM tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).
- `myisampack` does not support partitioned tables.

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, use `myisamchk -rq` to rebuild its indexes. [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--help, -?`

Display a help message and exit.

- `--backup, -b`

Make a backup of each table's data file using the name `tbl_name.OLD`.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--force, -f`

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named `tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD` exists. With `--force`, `myisampack` packs the table anyway.

- `--join=big_tbl_name, -j big_tbl_name`

Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified.

- `--silent, -s`

Silent mode. Write output only when errors occur.

- `--test, -t`

Do not actually pack the table, just test packing it.

- `--tmpdir=dir_name, -T dir_name`

Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose, -v`

Verbose mode. Write information about the progress of the packing operation and its result.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r-- 1 monty my 994128 Apr 17 19:00 station.MYD
-rw-rw-r-- 1 monty my 53248 Apr 17 19:00 station.MYI
-rw-rw-r-- 1 monty my 5767 Apr 17 19:00 station.frm

myisampack displays the following kinds of information:

- **normal**

The number of columns for which no extra packing is used.

- **empty-space**

The number of columns containing values that are only spaces. These occupy one bit.

- **empty-zero**

The number of columns containing values that are only binary zeros. These occupy one bit.

- **empty-fill**

The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a **BIGINT** column (eight bytes) can be stored as a **TINYINT** column (one byte) if all its values are in the range from **-128** to **127**.

- **pre-space**

The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- **end-space**

The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

The number of columns for which all values are zero.

- `Original trees`

The initial number of Huffman trees.

- `After join`

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant `N` bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

After you run `myisampack`, use `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

4.6.6 `mysql_config_editor` — MySQL Configuration Utility

The `mysql_config_editor` utility (available as of MySQL 5.6.6) enables you to store authentication credentials in an encrypted login path file named `.mylogin.cnf`. The file location is the `%APPDATA%\MySQL` directory on Windows and the current user's home directory on non-Windows systems. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server.

The unencrypted format of the `.mylogin.cnf` login path file consists of option groups, similar to other option files. Each option group in `.mylogin.cnf` is called a “login path,” which is a group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Think of a login path option group as a set of options that specify which MySQL server to connect to and which account to authenticate as. Here is an unencrypted example:

```
[client]
user = mydefaultname
password = mydefaultpass
host = 127.0.0.1
[mypath]
user = myothername
password = myotherpass
host = localhost
```

When you invoke a client program to connect to the server, the client uses `.mylogin.cnf` in conjunction with other option files. Its precedence is higher than other option files, but less than options specified explicitly on the client command line. For information about the order in which option files are used, see [Section 4.2.6, “Using Option Files”](#).

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is recognized by `mysql_config_editor`, by standard MySQL clients (`mysql`, `mysqladmin`, and so forth), and by the `mysql-test-run.pl` testing utility.

Programs use groups in the login path file as follows:

- `mysql_config_editor` operates on the `client` login path by default if you specify no `--login-path=name` option to indicate explicitly which login path to use.
- Without a `--login-path` option, client programs read the same option groups from the login path file that they read from other option files. Consider this command:

```
shell> mysql
```

By default, the `mysql` client reads the `[client]` and `[mysql]` groups from other option files, so it reads them from the login path file as well.

- With a `--login-path` option, client programs additionally read the named login path from the login path file. The option groups read from other option files remain the same. Consider this command:

```
shell> mysql --login-path=mypath
```

The `mysql` client reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

- Client programs read the login path file even when the `--no-defaults` option is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present.

`mysql_config_editor` encrypts the `.mylogin.cnf` file so it cannot be read as cleartext, and its contents when decrypted by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable. `mysql_config_editor` provides a `print` command for displaying the login path file contents, but even in this case, password values are masked so as never to appear in a way that other users can see them.

The encryption used by `mysql_config_editor` prevents passwords from appearing in `.mylogin.cnf` as cleartext and provides a measure of security by preventing inadvertent password exposure. For example, if you display a regular unencrypted `my.cnf` option file on the screen, any passwords it contains are visible for anyone to see. With `.mylogin.cnf`, that is not true. But the encryption used will not deter a determined attacker and you should not consider it unbreakable. A user who can gain system administration privileges on your machine to access your files could decrypt the `.mylogin.cnf` file with some effort.

The login path file must be readable and writable to the current user, and inaccessible to other users. Otherwise, `mysql_config_editor` ignores it, and client programs do not use it, either.

Invoke `mysql_config_editor` like this:

```
shell> mysql_config_editor [program_options] command [command_options]
```

If the login path file does not exist, `mysql_config_editor` creates it.

Command arguments are given as follows:

- `program_options` consists of general `mysql_config_editor` options.
- `command` indicates what action to perform on the `.mylogin.cnf` login path file. For example, `set` writes a login path to the file, `remove` removes a login path, and `print` displays login path contents.
- `command_options` indicates any additional options specific to the command, such as the login path name and the values to use in the login path.

The position of the command name within the set of program arguments is significant. For example, these command lines have the same arguments, but produce different results:

```
shell> mysql_config_editor --help set
shell> mysql_config_editor set --help
```

The first command line displays a general `mysql_config_editor` help message, and ignores the `set` command. The second command line displays a help message specific to the `set` command.

Suppose that you want to establish a `client` login path that defines your default connection parameters, and an additional login path named `remote` for connecting to the MySQL server the host `remote.example.com`. You want to log in as follows:

- By default, to the local server with a user name and password of `localuser` and `localpass`
- To the remote server with a user name and password of `remoteuser` and `remotepass`

To set up the login paths in the `.mylogin.cnf` file, use the following `set` commands. Enter each command on a single line, and enter the appropriate passwords when prompted:

```
shell> mysql_config_editor set --login-path=client
      --host=localhost --user=localuser --password
Enter password: enter password "localpass" here
shell> mysql_config_editor set --login-path=remote
      --host=remote.example.com --user=remoteuser --password
Enter password: enter password "remotepass" here
```

`mysql_config_editor` uses the `client` login path by default, so the `--login-path=client` option can be omitted from the first command without changing its effect.

To see what `mysql_config_editor` writes to the `.mylogin.cnf` file, use the `print` command:

```
shell> mysql_config_editor print --all
[client]
user = localuser
password = *****
host = localhost
[remote]
user = remoteuser
password = *****
host = remote.example.com
```

The `print` command displays each login path as a set of lines beginning with a group header indicating the login path name in square brackets, followed by the option values for the login path. Password values are masked and do not appear as cleartext.

If you do not specify `--all` to display all login paths or `--login-path=name` to display a named login path, the `print` command displays the `client` login path by default, if there is one.

As shown by the preceding example, the login path file can contain multiple login paths. In this way, `mysql_config_editor` makes it easy to set up multiple “personalities” for connecting to different MySQL servers, or for connecting to a given server using different accounts. Any of these can be selected by name later using the `--login-path` option when you invoke a client program. For example, to connect to the remote server, use this command:

```
shell> mysql --login-path=remote
```

Here, `mysql` reads the `[client]` and `[mysql]` option groups from other option files, and the `[client]`, `[mysql]`, and `[remote]` groups from the login path file.

To connect to the local server, use this command:

```
shell> mysql --login-path=client
```

Because `mysql` reads the `client` and `mysql` login paths by default, the `--login-path` option does not add anything in this case. That command is equivalent to this one:

```
shell> mysql
```

Options read from the login path file take precedence over options read from other option files. Options read from login path groups appearing later in the login path file take precedence over options read from groups appearing earlier in the file.

`mysql_config_editor` adds login paths to the login path file in the order you create them, so you should create more general login paths first and more specific paths later. If you need to move a login path within the file, you can remove it, then recreate it to add it to the end.

When you use the `set` command with `mysql_config_editor` to create a login path, you need not specify all possible option values (host name, user name, password, port, socket). Only those values given are written to the path. Any missing values required later can be specified when you invoke a client path to connect to the MySQL server, either in other option files or on the command line. Any options specified on the command line override those specified in the login path file or other option files. For example, if the credentials in the `remote` login path also apply for the host `remote2.example.com`, connect to the server on that host like this:

```
shell> mysql --login-path=remote --host=remote2.example.com
```

mysql_config_editor General Options

`mysql_config_editor` supports the following general options, which may be used preceding any command named on the command line. For descriptions of command-specific options, see [mysql_config_editor Commands and Command-Specific Options](#).

Table 4.16 `mysql_config_editor` General Options

| Format | Description |
|------------------------|--------------------------------------|
| <code>--debug</code> | Write debugging log |
| <code>--help</code> | Display help message and exit |
| <code>--verbose</code> | Verbose mode |
| <code>--version</code> | Display version information and exit |

- `--help, -?`

Display a general help message and exit.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where *command* is a command other than `help`:

```
shell> mysql_config_editor command --help
```

- `--debug[=debug_options], -# debug_options`

Write a debugging log. A typical *debug_options* string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql_config_editor.trace`.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option may be helpful in diagnosing problems if an operation does not have the effect you expect.

- `--version, -V`

Display version information and exit.

mysql_config_editor Commands and Command-Specific Options

This section describes the permitted `mysql_config_editor` commands, and, for each one, the command-specific options permitted following the command name on the command line.

In addition, `mysql_config_editor` supports general options that can be used preceding any command. For descriptions of these options, see [mysql_config_editor General Options](#).

`mysql_config_editor` supports these commands:

- `help`

Display a general help message and exit. This command takes no following options.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where *command* is a command other than `help`:

```
shell> mysql_config_editor command --help
```

- `print [options]`

Print the contents of the login path file in unencrypted form, with the exception that passwords are displayed as `*****`.

The default login path name is `client` if no login path is named. If both `--all` and `--login-path` are given, `--all` takes precedence.

The `print` command permits these options following the command name:

- `--help, -?`

Display a help message for the `print` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--all`

Print the contents of all login paths in the login path file.

- `--login-path=name, -G name`

Print the contents of the named login path.

- `remove [options]`

Remove a login path from the login path file, or modify a login path by removing options from it.

This command removes from the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `remove` removes the entire login path. For example, this command removes only the `user` option from the `mypath` login path rather than the entire `mypath` login path:

```
shell> mysql_config_editor remove --login-path=mypath --user
```

This command removes the entire `mypath` login path:

```
shell> mysql_config_editor remove --login-path=mypath
```

The `remove` command permits these options following the command name:

- `--help, -?`

Display a help message for the `remove` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--host, -h`

Remove the host name from the login path. This option was added in MySQL 5.6.9.

- `--login-path=name, -G name`

The login path to remove or modify. The default login path name is `client` if this option is not given.

- `--password, -p`

Remove the password from the login path. This option was added in MySQL 5.6.9.

- `--port, -P`

Remove the TCP/IP port number from the login path. This option was added in MySQL 5.6.11.

- `--socket, -S`

Remove the Unix socket file name from the login path. This option was added in MySQL 5.6.11.

- `--user, -u`

Remove the user name from the login path. This option was added in MySQL 5.6.9.

- `--warn, -w`

Warn and prompt the user for confirmation if the command attempts to remove the default login path (`client`) and `--login-path=client` was not specified. This option is enabled by default; use `--skip-warn` to disable it.

- `reset [options]`

Empty the contents of the login path file.

The `reset` command permits these options following the command name:

- `--help, -?`

Display a help message for the `reset` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `set [options]`

Write a login path to the login path file.

This command writes to the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `mysql_config_editor` writes the login path as an empty group.

The `set` command permits these options following the command name:

- `--help, -?`

Display a help message for the `set` command and exit.

To see a general help message, use `mysql_config_editor --help`.

- `--host=host_name, -h host_name`

The host name to write to the login path.

- `--login-path=name, -G name`

The login path to create. The default login path name is `client` if this option is not given.

- `--password, -p`

Prompt for a password to write to the login path. After `mysql_config_editor` displays the prompt, type the password and press Enter. To prevent other users from seeing the password, `mysql_config_editor` does not echo it.

To specify an empty password, press Enter at the password prompt. The resulting login path written to the login path file will include a line like this:

```
password =
```

- `--port=port_num, -P port_num`

The TCP/IP port number to write to the login path. This option was added in MySQL 5.6.11.

- `--socket=file_name, -S file_name`

The Unix socket file name to write to the login path. This option was added in MySQL 5.6.11.

- `--user=user_name, -u user_name`

The user name to write to the login path.

- `--warn, -w`

Warn and prompt the user for confirmation if the command attempts to overwrite an existing login path. This option is enabled by default; use `--skip-warn` to disable it.

4.6.7 mysqlaccess — Client for Checking Access Privileges

Note

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. Note that `mysqlaccess` checks access using only the `user` and `db` tables. It does not check table, column, or routine privileges specified in the `tables_priv`, `columns_priv`, or `procs_priv` tables.

Invoke `mysqlaccess` like this:

```
shell> mysqlaccess [host_name [user_name [db_name]]] [options]
```

`mysqlaccess` supports the following options.

Table 4.17 `mysqlaccess` Options

| Format | Description |
|---------------------------|---|
| <code>--brief</code> | Generate reports in single-line tabular format |
| <code>--commit</code> | Copy the new access privileges from the temporary tables to the original grant tables |
| <code>--copy</code> | Reload the temporary grant tables from original ones |
| <code>--db</code> | Specify the database name |
| <code>--debug</code> | Specify the debug level |
| <code>--help</code> | Display help message and exit |
| <code>--host</code> | Connect to MySQL server on given host |
| <code>--howto</code> | Display some examples that show how to use <code>mysqlaccess</code> |
| <code>--old_server</code> | Assume that the server is an old MySQL server (prior to MySQL 3.21) |
| <code>--password</code> | Password to use when connecting to server |
| <code>--plan</code> | Display suggestions and ideas for future releases |
| <code>--preview</code> | Show the privilege differences after making changes to the temporary grant tables |
| <code>--relnotes</code> | Display release notes |
| <code>--rhost</code> | Connect to MySQL server on given host |
| <code>--rollback</code> | Undo the most recent changes to the temporary grant tables. |
| <code>--spassword</code> | Password to use when connecting to server as the superuser |
| <code>--superuser</code> | Specify the user name for connecting as the superuser |
| <code>--table</code> | Generate reports in table format |
| <code>--user</code> | MySQL user name to use when connecting to server |
| <code>--version</code> | Display version information and exit |

- `--help, -?`

Display a help message and exit.

- `--brief, -b`

Generate reports in single-line tabular format.

- `--commit`

Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)

- `--copy`

Reload the temporary grant tables from original ones.

- `--db=db_name, -d db_name`

Specify the database name.

- `--debug=N`

Specify the debug level. *N* can be an integer from 0 to 3.

- `--host=host_name, -h host_name`

The host name to use in the access privileges.

- `--howto`

Display some examples that show how to use `mysqlaccess`.

- `--old_server`

Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE` clauses.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlaccess` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

- `--plan`

Display suggestions and ideas for future releases.

- `--preview`

Show the privilege differences after making changes to the temporary grant tables.

- `--relnotes`

Display the release notes.

- `--rhost=host_name, -H host_name`

Connect to the MySQL server on the given host.

- `--rollback`

Undo the most recent changes to the temporary grant tables.

- `--spassword[=password], -P[password]`

The password to use when connecting to the server as the superuser. If you omit the `password` value following the `--spassword` or `-P` option on the command line, `mysqlaccess` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

- `--superuser=user_name, -U user_name`

Specify the user name for connecting as the superuser.

- `--table, -t`

Generate reports in table format.

- `--user=user_name, -u user_name`

The user name to use in the access privileges.

- `--version, -v`

Display version information and exit.

If your MySQL distribution is installed in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = '/usr/local/bin/mysql'; # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

4.6.8 mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in [Section 5.4.4, “The Binary Log”](#), and [Section 17.2.2, “Replication Relay and Status Logs”](#).

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See [Section 17.1.2, “Replication Formats”](#), for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309 9:28:36 server id 123 end_log_pos 245
  Query thread_id=3350 exec_time=11 error_code=0
```

In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. `server id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed

the event. `exec_time` is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master. The difference serves as an indicator of how much replication lags behind the master. `error_code` indicates the result from executing the event. Zero means that no error occurred.

Note

When using event groups, the file offsets of events may be grouped together and the comments of events may be grouped together. Do not mistake these grouped events for blank file offsets.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`; they are ignored except when you also use the `--read-from-remote-server` option.

When running `mysqlbinlog` against a large binary log, be careful that the filesystem has enough space for the resulting files. To configure the directory that `mysqlbinlog` uses for temporary files, use the `TMPDIR` environment variable.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.18 `mysqlbinlog` Options

| Format | Description | Introduced |
|--|---|------------|
| <code>--base64-output</code> | Print binary log entries using base-64 encoding | |
| <code>--bind-address</code> | Use specified network interface to connect to MySQL Server | 5.6.1 |
| <code>--binlog-row-event-max-size</code> | Binary log max event size | |
| <code>--character-sets-dir</code> | Directory where character sets are installed | |
| <code>--connection-server-id</code> | Used for testing and debugging. See text for applicable default values and other particulars. | 5.6.20 |
| <code>--database</code> | List entries for just this database | |
| <code>--debug</code> | Write debugging log | |
| <code>--debug-check</code> | Print debugging information when program exits | |
| <code>--debug-info</code> | Print debugging information, memory, and CPU statistics when program exits | |
| <code>--default-auth</code> | Authentication plugin to use | 5.6.2 |
| <code>--defaults-extra-file</code> | Read named option file in addition to usual option files | |
| <code>--defaults-file</code> | Read only named option file | |
| <code>--defaults-group-suffix</code> | Option group suffix value | |
| <code>--disable-log-bin</code> | Disable binary logging | |
| <code>--exclude-gtids</code> | Do not show any of the groups in the GTID set provided | 5.6.5 |

| Format | Description | Introduced |
|---|--|------------|
| --force-if-open | Read binary log files even if open or not closed properly | |
| --force-read | If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning | |
| --help | Display help message and exit | |
| --hexdump | Display a hex dump of the log in comments | |
| --host | Connect to MySQL server on given host | |
| --idempotent | Cause the server to use idempotent mode while processing binary log updates from this session only | |
| --include-gtids | Show only the groups in the GTID set provided | 5.6.5 |
| --local-load | Prepare local temporary files for LOAD DATA INFILE in the specified directory | |
| --login-path | Read login path options from .mylogin.cnf | 5.6.6 |
| --no-defaults | Read no option files | |
| --offset | Skip the first N entries in the log | |
| --password | Password to use when connecting to server | |
| --plugin-dir | Directory where plugins are installed | 5.6.2 |
| --port | TCP/IP port number to use for connection | |
| --print-defaults | Print default options | |
| --protocol | Connection protocol to use | |
| --raw | Write events in raw (binary) format to output files | |
| --read-from-remote-master | Read the binary log from a MySQL master rather than reading a local log file | 5.6.5 |
| --read-from-remote-server | Read binary log from MySQL server rather than local log file | |
| --result-file | Direct output to named file | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --server-id | Extract only those events created by the server having the given server ID | |
| --server-id-bits | Tell mysqlbinlog how to interpret server IDs in binary log when log was written by a mysqld having its server-id-bits set to less than the maximum; supported only by MySQL Cluster version of mysqlbinlog | |
| --set-charset | Add a SET NAMES charset_name statement to the output | |
| --shared-memory-base-name | The name of shared memory to use for shared-memory connections | |
| --short-form | Display only the statements contained in the log | |
| --skip-gtids | Do not print any GTIDs; use this when writing a dump file from binary logs containing GTIDs. | 5.6.5 |
| --socket | For connections to localhost, the Unix socket file to use | |
| --ssl-crl | Path of file that contains certificate revocation lists | 5.6.3 |
| --ssl-crlpath | Path of directory that contains certificate revocation list files | 5.6.3 |

| Format | Description | Introduced |
|---|--|------------|
| <code>--ssl-mode</code> | Security state of connection to server | 5.6.30 |
| <code>--start-datetime</code> | Read binary log from first event with timestamp equal to or later than datetime argument | |
| <code>--start-position</code> | Read binary log from first event with position equal to or greater than argument | |
| <code>--stop-datetime</code> | Stop reading binary log at first event with timestamp equal to or greater than datetime argument | |
| <code>--stop-never</code> | Stay connected to server after reading last binary log file | |
| <code>--stop-never-slave-server-id</code> | Slave server ID to report when connecting to server | |
| <code>--stop-position</code> | Stop reading binary log at first event with position equal to or greater than argument | |
| <code>--to-last-log</code> | Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log | |
| <code>--user</code> | MySQL user name to use when connecting to server | |
| <code>--verbose</code> | Reconstruct row events as SQL statements | |
| <code>--verify-binlog-checksum</code> | Verify checksums in binary log | 5.6.1 |
| <code>--version</code> | Display version information and exit | |

- `--help, -?`

Display a help message and exit.

- `--base64-output=value`

This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case sensitive):

- `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). If no `--base64-output` option is given, the effect is the same as `--base64-output=AUTO`.

Note

Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- `NEVER` causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.
- `DECODE-ROWS` specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` option. Like `NEVER`, `DECODE-ROWS` suppresses display of `BINLOG` statements, but unlike `NEVER`, it does not exit with an error if a row event is found.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 4.6.8.2, “mysqlbinlog Row Event Display”](#).

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

This option is supported beginning with MySQL 5.6.1.

- `--binlog-row-event-max-size=N`

| Command-Line Format | <code>--binlog-row-event-max-size=#</code> | |
|-------------------------------------|--|----------------------|
| Permitted Values (64-bit platforms) | Type | numeric |
| | Default | 4294967040 |
| | Min Value | 256 |
| | Max Value | 18446744073709547520 |

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 4GB.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--connection-server-id=server_id`

This option is used to test a MySQL server for support of the `BINLOG_DUMP_NON_BLOCK` connection flag, which was inadvertently removed in MySQL 5.6.5, and restored in MySQL 5.6.20 (Bug #18000079, Bug #71178). It is not required for normal operation.

The effective default and minimum values for this option depend on whether `mysqlbinlog` is run in blocking mode or non-blocking mode. When `mysqlbinlog` is run in blocking mode, the default (and minimum) value is 1; when run in non-blocking mode, the default (and minimum) value is 0.

This option was added in MySQL 5.6.20.

- `--database=db_name, -d db_name`

This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while `db_name` is been selected as the default database by `USE`.

The `--database` option for `mysqlbinlog` is similar to the `--binlog-do-db` option for `mysqld`, but can be used to specify only one database. If `--database` is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--binlog-do-db` depend on whether statement-based or row-based logging is in use.

Statement-based logging. The `--database` option works as follows:

- While `db_name` is the default database, statements are output whether they modify tables in `db_name` or a different database.

- Unless `db_name` is selected as the default database, statements are not output, even if they modify tables in `db_name`.
- There is an exception for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE`. The database being *created*, *altered*, or *dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based-logging:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j) VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i) VALUES(102);
INSERT INTO db2.t2 (j) VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
INSERT INTO db2.t2 (j) VALUES(202);
INSERT INTO t2 (j) VALUES(203);
```

`mysqlbinlog --database=test` does not output the first two `INSERT` statements because there is no default database. It outputs the three `INSERT` statements following `USE test`, but not the three `INSERT` statements following `USE db2`.

`mysqlbinlog --database=db2` does not output the first two `INSERT` statements because there is no default database. It does not output the three `INSERT` statements following `USE test`, but does output the three `INSERT` statements following `USE db2`.

Row-based logging. `mysqlbinlog` outputs only entries that change tables belonging to `db_name`. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. `mysqlbinlog --database=test` outputs only those entries that modify `t1` in the test database, regardless of whether `USE` was issued or what the default database is.

If a server is running with `binlog_format` set to `MIXED` and you want it to be possible to use `mysqlbinlog` with the `--database` option, you must ensure that tables that are modified are in the database selected by `USE`. (In particular, no cross-database updates should be used.)

Prior to MySQL 5.6.10, the `--database` option did not work correctly with a log written by a GTID-enabled MySQL server. (Bug #15912728)

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlbinlog.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

A hint about the client-side authentication plugin to use. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlbinlog` normally reads the `[client]` and `[mysqlbinlog]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlbinlog` also reads the `[client_other]` and `[mysqlbinlog_other]` groups.

- `--disable-log-bin, -D`

Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

This option requires that you have the `SUPER` privilege. It causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. The `SET` statement is ineffective unless you have the `SUPER` privilege.

- `--exclude-gtids=gtid_set`

Do not display any of the groups listed in the `gtid_set`. Added in MySQL 5.6.5.

- `--force-if-open, -F`

Read binary log files even if they are open or were not closed properly.

- `--force-read, -f`

With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--hexdump, -H`

Display a hex dump of the log in comments, as described in [Section 4.6.8.1, “mysqlbinlog Hex Dump Format”](#). The hex output can be helpful for replication debugging.

- `--host=host_name, -h host_name`

Get the binary log from the MySQL server on the given host.

- `--include-gtids=gtid_set`

Display only the groups listed in the `gtid_set`. Added in MySQL 5.6.5.

- `--local-load=dir_name, -l dir_name`

Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

**Important**

These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program.

- `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file, if it exists, is read in all cases. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. (`.mylogin.cnf` is created by the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).)

- `--offset=N, -o N`

Skip the first `N` entries in the log.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlbinlog` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlbinlog` does not find it. See [Section 6.3.7, “Pluggable Authentication”](#).

This option was added in MySQL 5.6.2.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for connecting to a remote server.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--raw`

By default, `mysqlbinlog` reads binary log files and writes events in text format. The `--raw` option tells `mysqlbinlog` to write them in their original binary format. Its use requires that `--read-from-remote-server` also be used because the files are requested from a server. `mysqlbinlog` writes one output file for each file read from the server. The `--raw` option can be used to make a backup of a server's binary log. With the `--stop-never` option, the backup is “live” because `mysqlbinlog` stays connected to the server. By default, output files are written in the current directory with the same names as the original log files. Output file names can be modified using the `--result-file` option. For more information, see [Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

This option was added in MySQL 5.6.0.

- `--read-from-remote-master=type`

Read binary logs from a MySQL server with the `COM_BINLOG_DUMP` or `COM_BINLOG_DUMP_GTID` commands by setting the option value to either `BINLOG-DUMP-NON-GTIDS` or `BINLOG-DUMP-GTIDS`, respectively. If `--read-from-remote-master=BINLOG-DUMP-GTIDS` is combined with `--exclude-gtids`, transactions can be filtered out on the master, avoiding unnecessary network traffic.

See also the description for `--read-from-remote-server`.

This option was added in MySQL 5.6.5.

- `--read-from-remote-server, -R`

Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

As of MySQL 5.6.5, this option is like `--read-from-remote-master=BINLOG-DUMP-NON-GTIDS`.

- `--result-file=name, -r name`

Without the `--raw` option, this option indicates the file to which `mysqlbinlog` writes text output. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server, writing them by default in the current directory using the same names as the original log file. In this case, the `--result-file` option value is treated as a prefix that modifies output file names.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1

passwords are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).

Note

This option is deprecated and will be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--server-id=id`

Display only those events created by the server having the given server ID.

- `--server-id-bits=N`

Use only the first *N* bits of the `server_id` to identify the server. If the binary log was written by a `mysqld` with `server-id-bits` set to less than 32 and user data stored in the most significant bit, running `mysqlbinlog` with `--server-id-bits` set to 32 enables this data to be seen.

This option is supported only by the versions of `mysqlbinlog` supplied with the MySQL Cluster distribution, or built from the MySQL Cluster sources.

- `--set-charset=charset_name`

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--short-form, -s`

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems.

- `--skip-gtids[=(true|false)]`

Do not display any GTIDs in the output. This is needed when writing to a dump file from one or more binary logs containing GTIDs, as shown in this example:

```
shell> mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
shell> mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
shell> mysql -u root -p -e "source /tmp/dump.sql"
```

The use of this option is otherwise not normally recommended in production.

This option was added in MySQL 5.6.5.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime`

Start reading the binary log at the first event having a timestamp equal to or later than the *datetime* argument. The *datetime* value is relative to the local time zone on the machine where you run *mysqlbinlog*. The value should be in a format accepted for the *DATETIME* or *TIMESTAMP* data types. For example:

```
shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--start-position=N, -j N`

Start reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the first log file named on the command line.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-datetime=datetime`

Stop reading the binary log at the first event having a timestamp equal to or later than the *datetime* argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` option for information about the *datetime* value.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-never`

This option is used with `--read-from-remote-server`. It tells *mysqlbinlog* to remain connected to the server. Otherwise *mysqlbinlog* exits when the last log file has been transferred from the server. `--stop-never` implies `--to-last-log`, so only the first log file to transfer need be named on the command line.

`--stop-never` is commonly used with `--raw` to make a live binary log backup, but also can be used without `--raw` to maintain a continuous text display of log events as the server generates them.

This option was added in MySQL 5.6.0.

- `--stop-never-slave-server-id=id`

With `--stop-never`, *mysqlbinlog* reports a server ID of 65535 when it connects to the server. `--stop-never-slave-server-id` explicitly specifies the server ID to report. It can be used to avoid a conflict with the ID of a slave server or another *mysqlbinlog* process. See [Section 4.6.8.4, “Specifying the mysqlbinlog Server ID”](#).

This option was added in MySQL 5.6.0.

- `--stop-position=N`

Stop reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--to-last-log, -t`

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to a remote server.

- `--verbose, -v`

Reconstruct row events and display them as commented SQL statements. If this option is given twice (by passing in either `"-vv"` or `"--verbose --verbose"`), the output includes comments to indicate column data types and some metadata, and row query log events if so configured.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 4.6.8.2, “mysqlbinlog Row Event Display”](#).

- `--verify-binlog-checksum, -c`

Verify checksums in binary log files. This option was added in MySQL 5.6.1.

- `--version, -V`

Display version information and exit.

Prior to MySQL 5.6.11, the `mysqlbinlog` version number shown was 3.3. In MySQL 5.6.11 and later, this is 3.4. (Bug #15894381, Bug #67643)

You can also set the following variable by using `--var_name=value` syntax:

- `open_files_limit`

Specify the number of open file descriptors to reserve.

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#)). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

If the statements produced by `mysqlbinlog` may contain BLOB values, these may cause problems when `mysql` processes them. In this case, invoke `mysql` with the `--binary-mode` option.

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* `mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

Warning

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

4.6.8.1 mysqlbinlog Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```

/*!40019 SET @@session.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position   Timestamp   Type      Master ID      Size      Master Pos    Flags
# 00000004 9d fc 5c 43 0f 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
# 00000017 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c |..5.0.15.debug.1|
# 00000027 6f 67 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |og.....|
# 00000037 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |.....|
# 00000047 00 00 00 00 9d fc 5c 43 13 38 0d 00 08 00 12 00 |.....C.8.....|
# 00000057 04 04 04 04 12 00 00 4b 00 04 1a |.....K...|
#          Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
#          at startup
ROLLBACK;

```

Hex dump output currently contains the elements in the following list. This format is subject to change. (For more information about binary log format, see [MySQL Internals: The Binary Log](#).)

- **Position:** The byte position within the log file.
- **Timestamp:** The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type:** The event type code. In the example shown, '0f' indicates a `FORMAT_DESCRIPTION_EVENT`. The following table lists the possible type codes.

| Type | Name | Meaning |
|------|--------------------|---|
| 00 | UNKNOWN_EVENT | This event should never be present in the log. |
| 01 | START_EVENT_V3 | This indicates the start of a log file written by MySQL 4 or earlier. |
| 02 | QUERY_EVENT | The most common type of events. These contain statements executed on the master. |
| 03 | STOP_EVENT | Indicates that master has stopped. |
| 04 | ROTATE_EVENT | Written when the master switches to a new log file. |
| 05 | INTVAR_EVENT | Used for <code>AUTO_INCREMENT</code> values or when the <code>LAST_INSERT_ID()</code> function is used in the statement. |
| 06 | LOAD_EVENT | Used for <code>LOAD DATA INFILE</code> in MySQL 3.23. |
| 07 | SLAVE_EVENT | Reserved for future use. |
| 08 | CREATE_FILE_EVENT | Used for <code>LOAD DATA INFILE</code> statements. This indicates the start of execution of such a statement. A temporary file is created on the slave. Used in MySQL 4 only. |
| 09 | APPEND_BLOCK_EVENT | Contains data for use in a <code>LOAD DATA INFILE</code> statement. The data is stored in the temporary file on the slave. |
| 0a | EXEC_LOAD_EVENT | Used for <code>LOAD DATA INFILE</code> statements. The contents of the temporary file is stored in the table on the slave. Used in MySQL 4 only. |
| 0b | DELETE_FILE_EVENT | Rollback of a <code>LOAD DATA INFILE</code> statement. The temporary file should be deleted on the slave. |
| 0c | NEW_LOAD_EVENT | Used for <code>LOAD DATA INFILE</code> in MySQL 4 and earlier. |
| 0d | RAND_EVENT | Used to send information about random values if the <code>RAND()</code> function is used in the statement. |
| 0e | USER_VAR_EVENT | Used to replicate user variables. |

| Type | Name | Meaning |
|------|--------------------------|---|
| 0f | FORMAT_DESCRIPTION_EVENT | This indicates the start of a log file written by MySQL 5 or later. |
| 10 | XID_EVENT | Event indicating commit of an XA transaction. |
| 11 | BEGIN_LOAD_QUERY_EVENT | Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later. |
| 12 | EXECUTE_LOAD_QUERY_EVENT | Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later. |
| 13 | TABLE_MAP_EVENT | Information about a table definition. Used in MySQL 5.1.5 and later. |
| 14 | PRE_GA_WRITE_ROWS_EVENT | Row data for a single table that should be created. Used in MySQL 5.1.5 to 5.1.17. |
| 15 | PRE_GA_UPDATE_ROWS_EVENT | Row data for a single table that needs to be updated. Used in MySQL 5.1.5 to 5.1.17. |
| 16 | PRE_GA_DELETE_ROWS_EVENT | Row data for a single table that should be deleted. Used in MySQL 5.1.5 to 5.1.17. |
| 17 | WRITE_ROWS_EVENT | Row data for a single table that should be created. Used in MySQL 5.1.18 and later. |
| 18 | UPDATE_ROWS_EVENT | Row data for a single table that needs to be updated. Used in MySQL 5.1.18 and later. |
| 19 | DELETE_ROWS_EVENT | Row data for a single table that should be deleted. Used in MySQL 5.1.18 and later. |
| 1a | INCIDENT_EVENT | Something out of the ordinary happened. Added in MySQL 5.1.18. |

- **Master ID:** The server ID of the master that created the event.
- **Size:** The size in bytes of the event.
- **Master Pos:** The position of the next event in the original master log file.
- **Flags:** 16 flags. The following flags are used. The others are reserved for future use.

| Flag | Name | Meaning |
|------|-----------------------------|---|
| 01 | LOG_EVENT_BINLOG_IN_USE_F | Log file correctly closed. (Used only in <code>FORMAT_DESCRIPTION_EVENT</code> .) If this flag is set (if the flags are, for example, '01 00') in a <code>FORMAT_DESCRIPTION_EVENT</code> , the log file has not been properly closed. Most probably this is because of a master crash (for example, due to power failure). |
| 02 | | Reserved for future use. |
| 04 | LOG_EVENT_THREAD_SPECIFIC_F | Set if the event is dependent on the connection it was executed in (for example, '04 00'), for example, if the event uses temporary tables. |
| 08 | LOG_EVENT_SUPPRESS_USE_F | Set in some circumstances when the event is not dependent on the default database. |

4.6.8.2 mysqlbinlog Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `--base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
  id    INT NOT NULL,
  name  VARCHAR(20) NOT NULL,
  date  DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, `mysqlbinlog` displays row events encoded as base-64 strings using `BINLOG` statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
shell> mysqlbinlog log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAANoAAAAABEAAAAAAAAABHRlc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAQABEAAAAAAAAEAA//8AQAAAAVhcHBsZQ==
'/*!*/;
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356    Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAC4BAAAAABEAAAAAAAAABHRlc3QAAXQAawMPCgIUAAQ=
fAS3SBgBAAAAANGAAQABAAQABEAAAAAAAAEAA///AEAAAAFYXBwbGx4AQAAARwZWYyIbIP
'/*!*/;
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442    Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAJABAAAAABEAAAAAAAAABHRlc3QAAXQAawMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAQABEAAAAAAAAEAA//4AQAAARwZWYyIbIP
'/*!*/;
```

To see the row events as comments in the form of “pseudo-SQL” statements, run `mysqlbinlog` with the `--verbose` or `-v` option. The output will contain lines beginning with `###`:

```
shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAANoAAAAABEAAAAAAAAABHRlc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAQABEAAAAAAAAEAA//8AQAAAAVhcHBsZQ==
```

```

'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F

BINLOG '

###   @3='2009:01:01'

```

Specify `--verbose` or `-v` twice to also display data types and some metadata for each column. The output will contain an additional comment following each column change:

```

shell> mysqlbinlog -vv log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F

...
# at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAAIAAAJABAAAAABEAAAAAAAAABHRlc3QAAXQAAMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAQABEAAAAAAAAEAA//4AQAAARwZWfyIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
### @1=1 /* INT meta=0 nullable=0 is_null=0 */
### @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
### @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */

```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```

shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1 end_log_pos 258 Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
### @1=1
### @2='apple'
### @3=NULL
...
# at 302
#080828 15:03:08 server id 1 end_log_pos 356 Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
### @1=1
### @2='apple'
### @3=NULL
### SET
### @1=1
### @2='pear'
### @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
### @1=1
### @2='pear'
### @3='2009:01:01'

```

Note

You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.

- Character set information is not available in the binary log, which affects string column display:
- There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.
- For multibyte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` will be used as the data type for values from either of these column types:

```
CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2
```

- Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `--base64-output=NEVER` option can be used to prevent this header from being written.

4.6.8.3 Using mysqlbinlog to Back Up Binary Log Files

By default, `mysqlbinlog` reads binary log files and displays their contents in text format. This enables you to examine events within the files more easily and to re-execute them (for example, by using the output as input to `mysql`). `mysqlbinlog` can read log files directly from the local file system, or, with the `--read-from-remote-server` option, it can connect to a server and request binary log contents from that server. `mysqlbinlog` writes text output to its standard output, or to the file named as the value of the `--result-file=file_name` option if that option is given.

As of MySQL 5.6, `mysqlbinlog` can read binary log files and write new files containing the same content—that is, in binary format rather than text format. This capability enables you to easily back up a binary log in its original format. `mysqlbinlog` can make a static backup, backing up a set of log files and stopping when the end of the last file is reached. It can also make a continuous (“live”) backup, staying connected to the server when it reaches the end of the last log file and continuing to copy new events as they are generated. In continuous-backup operation, `mysqlbinlog` runs until the connection ends (for example, when the server exits) or `mysqlbinlog` is forcibly terminated. When the connection ends, `mysqlbinlog` does not wait and retry the connection, unlike a slave replication server. To continue a live backup after the server has been restarted, you must also restart `mysqlbinlog`.

Binary log backup requires that you invoke `mysqlbinlog` with two options at minimum:

- The `--read-from-remote-server` (or `-R`) option tells `mysqlbinlog` to connect to a server and request its binary log. (This is similar to a slave replication server connecting to its master server.)
- The `--raw` option tells `mysqlbinlog` to write raw (binary) output, not text output.

Along with `--read-from-remote-server`, it is common to specify other options: `--host` indicates where the server is running, and you may also need to specify connection options such as `--user` and `--password`.

Several other options are useful in conjunction with `--raw`:

- `--stop-never`: Stay connected to the server after reaching the end of the last log file and continue to read new events.
- `--stop-never-slave-server-id=id`: The server ID that `mysqlbinlog` reports to the server when `--stop-never` is used. The default is 65535. This can be used to avoid a conflict with the ID of a slave server or another `mysqlbinlog` process. See [Section 4.6.8.4, “Specifying the mysqlbinlog Server ID”](#).
- `--result-file`: A prefix for output file names, as described later.

To back up a server's binary log files with `mysqlbinlog`, you must specify file names that actually exist on the server. If you do not know the names, connect to the server and use the `SHOW BINARY LOGS` statement to see the current names. Suppose that the statement produces this output:

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name      | File_size |
+-----+-----+
| binlog.000130 | 27459     |
| binlog.000131 | 13719     |
| binlog.000132 | 43268     |
+-----+-----+
```

With that information, you can use `mysqlbinlog` to back up the binary log to the current directory as follows (enter each command on a single line):

- To make a static backup of `binlog.000130` through `binlog.000132`, use either of these commands:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  binlog.000130 binlog.000131 binlog.000132

mysqlbinlog --read-from-remote-server --host=host_name --raw
  --to-last-log binlog.000130
```

The first command specifies every file name explicitly. The second names only the first file and uses `--to-last-log` to read through the last. A difference between these commands is that if the server happens to open `binlog.000133` before `mysqlbinlog` reaches the end of `binlog.000132`, the first command will not read it, but the second command will.

- To make a live backup in which `mysqlbinlog` starts with `binlog.000130` to copy existing log files, then stays connected to copy new events as the server generates them:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  --stop-never binlog.000130
```

With `--stop-never`, it is not necessary to specify `--to-last-log` to read to the last log file because that option is implied.

Output File Naming

Without `--raw`, `mysqlbinlog` produces text output and the `--result-file` option, if given, specifies the name of the single file to which all output is written. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server. By default, `mysqlbinlog` writes the files in the current directory with the same names as the original log files. To modify the output file names, use the `--result-file` option. In conjunction with `--raw`, the `--result-file` option value is treated as a prefix that modifies the output file names.

Suppose that a server currently has binary log files named `binlog.000999` and up. If you use `mysqlbinlog --raw` to back up the files, the `--result-file` option produces output file names as

shown in the following table. You can write the files to a specific directory by beginning the `--result-file` value with the directory path. If the `--result-file` value consists only of a directory name, the value must end with the pathname separator character. Output files are overwritten if they exist.

| <code>--result-file</code> Option | Output File Names |
|-----------------------------------|---|
| <code>--result-file=x</code> | <code>xbinlog.000999</code> and up |
| <code>--result-file=/tmp/</code> | <code>/tmp/binlog.000999</code> and up |
| <code>--result-file=/tmp/x</code> | <code>/tmp/xbinlog.000999</code> and up |

Example: mysqldump + mysqlbinlog for Backup and Restore

The following example describes a simple scenario that shows how to use `mysqldump` and `mysqlbinlog` together to back up a server's data and binary log, and how to use the backup to restore the server if data loss occurs. The example assumes that the server is running on host `host_name` and its first binary log file is named `binlog.000999`. Enter each command on a single line.

Use `mysqlbinlog` to make a continuous backup of the binary log:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
--stop-never binlog.000999
```

Use `mysqldump` to create a dump file as a snapshot of the server's data. Use `--all-databases`, `--events`, and `--routines` to back up all data, and `--master-data=2` to include the current binary log coordinates in the dump file.

```
mysqldump --host=host_name --all-databases --events --routines --master-data=2> dump_file
```

Execute the `mysqldump` command periodically to create newer snapshots as desired.

If data loss occurs (for example, if the server crashes), use the most recent dump file to restore the data:

```
mysql --host=host_name -u root -p < dump_file
```

Then use the binary log backup to re-execute events that were written after the coordinates listed in the dump file. Suppose that the coordinates in the file look like this:

```
-- CHANGE MASTER TO MASTER_LOG_FILE='binlog.001002', MASTER_LOG_POS=27284;
```

If the most recent backed-up log file is named `binlog.001004`, re-execute the log events like this:

```
mysqlbinlog --start-position=27284 binlog.001002 binlog.001003 binlog.001004
| mysql --host=host_name -u root -p
```

You might find it easier to copy the backup files (dump file and binary log files) to the server host to make it easier to perform the restore operation, or if MySQL does not allow remote `root` access.

4.6.8.4 Specifying the mysqlbinlog Server ID

When invoked with the `--read-from-remote-server` option, `mysqlbinlog` connects to a MySQL server, specifies a server ID to identify itself, and requests binary log files from the server. You can use `mysqlbinlog` to request log files from a server in several ways:

- Specify an explicitly named set of files: For each file, `mysqlbinlog` connects and issues a `Binlog dump` command. The server sends the file and disconnects. There is one connection per file.
- Specify the beginning file and `--to-last-log`: `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files and disconnects.
- Specify the beginning file and `--stop-never` (which implies `--to-last-log`): `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files, but does not disconnect after sending the last one.

With `--read-from-remote-server` only, `mysqlbinlog` connects using a server ID of 0, which tells the server to disconnect after sending the last requested log file.

With `--read-from-remote-server` and `--stop-never`, `mysqlbinlog` connects using a nonzero server ID, so the server does not disconnect after sending the last log file. The server ID is 65535 by default, but this can be changed with `--stop-never-slave-server-id`.

Thus, for the first two ways of requesting files, the server disconnects because `mysqlbinlog` specifies a server ID of 0. It does not disconnect if `--stop-never` is given because `mysqlbinlog` specifies a nonzero server ID.

4.6.9 `mysqldumpslow` — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see [Section 5.4.5, “The Slow Query Log”](#)). `mysqldumpslow` parses MySQL slow query log files and prints a summary of their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Invoke `mysqldumpslow` like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

`mysqldumpslow` supports the following options.

Table 4.19 `mysqldumpslow` Options

| Format | Description |
|----------------------|---|
| <code>-a</code> | Do not abstract all numbers to N and strings to S |
| <code>-n</code> | Abstract numbers with at least the specified digits |
| <code>--debug</code> | Write debugging information |
| <code>-g</code> | Only consider statements that match the pattern |
| <code>--help</code> | Display help message and exit |
| <code>-h</code> | Host name of the server in the log file name |
| <code>-i</code> | Name of the server instance |
| <code>-l</code> | Do not subtract lock time from total time |
| <code>-r</code> | Reverse the sort order |
| <code>-s</code> | How to sort output |
| <code>-t</code> | Display only first num queries |

| Format | Description |
|------------------------|--------------|
| <code>--verbose</code> | Verbose mode |

- `--help`
Display a help message and exit.
- `-a`
Do not abstract all numbers to `N` and strings to `'S'`.
- `--debug, -d`
Run in debug mode.
- `-g pattern`
Consider only queries that match the (`grep`-style) pattern.
- `-h host_name`
Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is `*` (match all).
- `-i name`
Name of server instance (if using `mysql.server` startup script).
- `-l`
Do not subtract lock time from total time.
- `-n N`
Abstract numbers with at least `N` digits within names.
- `-r`
Reverse the sort order.
- `-s sort_type`
How to sort the output. The value of `sort_type` should be chosen from the following list:
 - `t, at`: Sort by query time or average query time
 - `l, al`: Sort by lock time or average lock time
 - `r, ar`: Sort by rows sent or average rows sent
 - `c`: Sort by countBy default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).
- `-t N`
Display only the first `N` queries in the output.
- `--verbose, -v`

Verbose mode. Print more information about what the program does.

Example of usage:

```
shell> mysqldumpslow

Reading mysql slow query log from /usr/local/mysql/data/mysqld51-apple-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t1 select * from t1
```

4.6.10 mysqlhotcopy — A Database Backup Program

Note

This utility is deprecated in MySQL 5.6.20 and removed in MySQL 5.7

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `FLUSH TABLES`, `LOCK TABLES`, and `cp` or `scp` to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ARCHIVE` tables. It runs on Unix.

To use `mysqlhotcopy`, you must have read access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, the `RELOAD` privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` privilege (to be able to lock the tables).

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (~):

```
shell> mysqlhotcopy db_name./~regex/
```

`mysqlhotcopy` supports the following options, which can be specified on the command line or in the `[mysqlhotcopy]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see [Section 4.2.6, “Using Option Files”](#).

Table 4.20 `mysqlhotcopy` Options

| Format | Description |
|---------------------------|--|
| <code>--addtodest</code> | Do not rename target directory (if it exists); merely add files to it |
| <code>--allowold</code> | Do not abort if a target exists; rename it by adding an <code>_old</code> suffix |
| <code>--checkpoint</code> | Insert checkpoint entries |

| Format | Description |
|----------------------------|--|
| <code>--chroot</code> | Base directory of the chroot jail in which mysqld operates |
| <code>--debug</code> | Write debugging log |
| <code>--dryrun</code> | Report actions without performing them |
| <code>--flushlog</code> | Flush logs after all tables are locked |
| <code>--help</code> | Display help message and exit |
| <code>--host</code> | Connect to MySQL server on given host |
| <code>--keepold</code> | Do not delete previous (renamed) target when done |
| <code>--method</code> | The method for copying files |
| <code>--noindices</code> | Do not include full index files in the backup |
| <code>--old_server</code> | Connect to server that does not support FLUSH TABLES tbl_list WITH READ LOCK |
| <code>--password</code> | Password to use when connecting to server |
| <code>--port</code> | TCP/IP port number to use for connection |
| <code>--quiet</code> | Be silent except for errors |
| <code>--regexp</code> | Copy all databases with names that match the given regular expression |
| <code>--resetmaster</code> | Reset the binary log after locking all the tables |
| <code>--resetslave</code> | Reset the master.info file after locking all the tables |
| <code>--socket</code> | For connections to localhost, the Unix socket file to use |
| <code>--tmpdir</code> | The temporary directory |
| <code>--user</code> | MySQL user name to use when connecting to server |

- `--help, -?`
Display a help message and exit.
- `--addtodest`
Do not rename target directory (if it exists); merely add files to it.
- `--allowold`
Do not abort if a target exists; rename it by adding an `_old` suffix.
- `--checkpoint=db_name.tbl_name`
Insert checkpoint entries into the specified database `db_name` and table `tbl_name`.
- `--chroot=dir_name`
Base directory of the `chroot` jail in which `mysqld` operates. The `dir_name` value should match that of the `--chroot` option given to `mysqld`.
- `--debug`
Enable debug output.
- `--dryrun, -n`

Report actions without performing them.

- `--flushlog`

Flush logs after all tables are locked.

- `--host=host_name, -h host_name`

The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.

- `--keepold`

Do not delete previous (renamed) target when done.

- `--method=command`

The method for copying files (`cp` or `scp`). The default is `cp`.

- `--noindices`

Do not include full index files for `MyISAM` tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with `myisamchk -rq`.

- `--password=password, -ppassword`

The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num, -P port_num`

The TCP/IP port number to use when connecting to the local server.

- `--old_server`

In MySQL 5.6, `mysqlhotcopy` uses `FLUSH TABLES tbl_list WITH READ LOCK` to flush and lock tables. Use the `--old_server` option if the server is older than 5.5.3, which is when that statement was introduced.

- `--quiet, -q`

Be silent except for errors.

- `--record_log_pos=db_name.tbl_name`

Record master and slave status in the specified database `db_name` and table `tbl_name`.

- `--regexp=expr`

Copy all databases with names that match the given regular expression.

- `--resetmaster`

Reset the binary log after locking all the tables.

- `--resetslave`

Reset the master info repository file or table after locking all the tables.

- `--socket=path, -S path`

The Unix socket file to use for connections to `localhost`.

- `--suffix=str`

The suffix to use for names of copied databases.

- `--tmpdir=dir_name`

The temporary directory. The default is `/tmp`.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
shell> perldoc mysqlhotcopy
```

4.6.11 `mysql_convert_table_format` — Convert Tables to Use a Given Storage Engine

Note

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_convert_table_format` converts the tables in a database to use a particular storage engine (`MyISAM` by default). `mysql_convert_table_format` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see [Section 2.12](#), “Perl Installation Notes”).

Invoke `mysql_convert_table_format` like this:

```
shell> mysql_convert_table_format [options]db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- `--help`

Display a help message and exit.

- `--force`

Continue even if errors occur.

- `--host=host_name`

Connect to the MySQL server on the given host.

- `--password=password`

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num`

The TCP/IP port number to use for the connection.

- `--socket=path`

For connections to `localhost`, the Unix socket file to use.

- `--type=engine_name`

Specify the storage engine that the tables should be converted to use. The default is `MyISAM` if this option is not given.

- `--user=user_name`

The MySQL user name to use when connecting to the server.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--version`

Display version information and exit.

4.6.12 `mysql_find_rows` — Extract SQL Statements from Files

Note

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain `USE db_name` or `SET` statements. The utility expects statements to be terminated with semicolon (`;`) characters.

Invoke `mysql_find_rows` like this:

```
shell> mysql_find_rows [options] [file_name ...]
```

Each `file_name` argument should be the name of file containing SQL statements. If no file names are given, `mysql_find_rows` reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
mysql_find_rows --regexp=problem_table update-log.1 update-log.2
```

`mysql_find_rows` supports the following options:

- `--help, --Information`
Display a help message and exit.
- `--regexp=pattern`
Display queries that match the pattern.
- `--rows=N`
Quit after displaying *N* queries.
- `--skip-use-db`
Do not include `USE db_name` statements in the output.
- `--start_row=N`
Start output from this row.

4.6.13 `mysql_fix_extensions` — Normalize Table File Name Extensions

Note

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_fix_extensions` converts the extensions for `MyISAM` (or `ISAM`) table files to their canonical forms. It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mysql_fix_extensions` like this, where `data_dir` is the path name to the MySQL data directory.

```
shell> mysql_fix_extensions data_dir
```

4.6.14 `mysql_setpermission` — Interactively Set Permissions in Grant Tables

Note

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. `mysql_setpermission` is written in Perl and requires that the `DBI` and `DBD:mysql` Perl modules be installed (see [Section 2.12, “Perl Installation Notes”](#)).

Invoke `mysql_setpermission` like this:

```
shell> mysql_setpermission [options]
```

`options` should be either `--help` to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mysql_setpermissions` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

`mysql_setpermission` supports the following options:

- `--help`

Display a help message and exit.

- `--host=host_name`

Connect to the MySQL server on the given host.

- `--password=password`

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num`

The TCP/IP port number to use for the connection.

- `--socket=path`

For connections to `localhost`, the Unix socket file to use.

- `--user=user_name`

The MySQL user name to use when connecting to the server.

4.6.15 `mysql_waitpid` — Kill Process and Wait for Its Termination

`mysql_waitpid` signals a process to terminate and waits for the process to exit. It uses the `kill()` system call and Unix signals, so it runs on Unix and Unix-like systems.

This program is deprecated as of MySQL 5.6.19 and is removed in MySQL 5.7.

Invoke `mysql_waitpid` like this:

```
shell> mysql_waitpid [options] pid wait_time
```

`mysql_waitpid` sends signal 0 to the process identified by `pid` and waits up to `wait_time` seconds for the process to terminate. `pid` and `wait_time` must be positive integers.

If process termination occurs within the wait time or the process does not exist, `mysql_waitpid` returns 0. Otherwise, it returns 1.

If the `kill()` system call cannot handle signal 0, `mysql_waitpid()` uses signal 1 instead.

mysql_waitpid supports the following options:

- `--help, -?, -I`

Display a help message and exit.

- `--verbose, -v`

Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.

- `--version, -V`

Display version information and exit.

4.6.16 mysql_zap — Kill Processes That Match a Pattern

mysql_zap kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

This program is deprecated as of MySQL 5.6.19 and is removed in MySQL 5.7.

Invoke `mysql_zap` like this:

```
shell> mysql_zap [-signal] [-?If] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the `-signal` option is given, it specifies the name or number of the signal to send to each process. Otherwise, `mysql_zap` tries first with `TERM` (signal 15) and then with `KILL` (signal 9).

mysql_zap supports the following additional options:

- `--help, -?, -I`

Display a help message and exit.

- `-f`

Force mode. `mysql_zap` attempts to kill each process without confirmation.

- `-t`

Test mode. Display information about each process but do not kill it.

4.7 MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```
shell> my_print_defaults client mysql
--port=3306
```

```
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note

For developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

4.7.1 msql2mysql — Convert mSQL Programs for Use with MySQL

Note

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`msql2mysql` uses the `replace` utility to make the function name substitutions. See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

4.7.2 mysql_config — Display Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

`mysql_config` supports the following options.

- `--cflags`

C Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use `--include` for more portable options that contain only include paths.

- `--cxxflags`

Like `--cflags`, but for C++ compiler flags. This option was added in MySQL 5.6.4.

- `--include`

Compiler options to find MySQL include files.

- `--libmysqld-libs, --embedded-libs, --embedded`

Libraries and options required to link with `libmysqld`, the MySQL embedded server.

- `--libs`

Libraries and options required to link with the MySQL client library.

- `--libs_r`

Libraries and options required to link with the thread-safe MySQL client library. In MySQL 5.6, all client libraries are thread-safe, so this option need not be used. The `--libs` option can be used in all cases.

- `--plugindir`

The default plugin directory path name, defined when configuring MySQL.

- `--port`

The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

The default Unix socket file, defined when configuring MySQL.

- `--variable=var_name`

Display the value of the named configuration variable. Permitted `var_name` values are `pkgincludedir` (the header file directory), `pkglibdir` (the library directory), and `plugindir` (the plugin directory).

- `--version`

Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
--cflags           [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--cxxflags         [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--include          [-I/usr/local/mysql/include/mysql]
--libs             [-L/usr/local/mysql/lib/mysql -lmysqlclient
                  -lpthread -lm -lrt -lssl -lcrypto -ldl]
--libs_r          [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                  -lpthread -lm -lrt -lssl -lcrypto -ldl]
--plugindir        [/usr/local/mysql/lib/plugin]
--socket           [/tmp/mysql.sock]
--port             [3306]
--version          [5.6.11]
--libmysqld-libs   [-L/usr/local/mysql/lib/mysql -lmysqld
                  -lpthread -lm -lrt -lssl -lcrypto -ldl -lcrypt]
```

```
--variable=VAR  VAR is one of:
    pkgincludedir [/usr/local/mysql/include]
    pkglibdir     [/usr/local/mysql/lib]
    pluginindir   [/usr/local/mysql/lib/plugin]
```

You can use `mysql_config` within a command line using backticks to include the output that it produces for particular options. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```
gcc -c `mysql_config --cflags` progname.c
gcc -o progname progname.o `mysql_config --libs`
```

4.7.3 my_print_defaults — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```
shell> my_print_defaults mysqlcheck client
--user=myusername
--password=secret
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- `--help, -?`

Display a help message and exit.

- `--config-file=file_name, --defaults-file=file_name, -c file_name`

Read only the given option file.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.

- `--defaults-extra-file=file_name, --extra-file=file_name, -e file_name`

Read this option file after the global option file but (on Unix) before the user option file.

- `--defaults-group-suffix=suffix, -g suffix`

In addition to the groups named on the command line, read groups that have the given suffix.

- `--login-path=name, -l name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#). This option was added in MySQL 5.6.6.

- `--no-defaults, -n`

Return an empty string.

- `--show, -s`

As of MySQL 5.6.25, `my_print_defaults` masks passwords by default. Use this option to display passwords in cleartext.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

4.7.4 `resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols

`resolve_stack_dump` resolves a numeric stack dump to symbols.

Invoke `resolve_stack_dump` like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack track from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

`resolve_stack_dump` supports the following options.

- `--help, -h`

Display a help message and exit.

- `--numeric-dump-file=file_name, -n file_name`

Read the stack trace from the given file.

- `--symbols-file=file_name, -s file_name`

Use the given symbols file.

- `--version, -V`

Display version information and exit.

For more information, see [Section 24.5.1.5, “Using a Stack Trace”](#).

4.8 Miscellaneous Programs

4.8.1 `pererror` — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the `perror` utility.

`perror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `perror` like this:

```
shell> perror [options] errorcode ...
```

Example:

```
shell> perror 13 64
OS error code 13: Permission denied
OS error code 64: Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, invoke `perror` with the `--ndb` option:

```
shell> perror --ndb errorcode
```

The meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- `--help`, `--info`, `-I`, `-?`

Display a help message and exit.

- `--ndb`

Print the error message for a MySQL Cluster error code.

- `--silent`, `-s`

Silent mode. Print only the error message.

- `--verbose`, `-v`

Verbose mode. Print error code and message. This is the default behavior.

- `--version`, `-V`

Display version information and exit.

4.8.2 `replace` — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

from represents a string to look for and *to* represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. *replace* prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, *replace* reads the standard input and writes to the standard output.

replace uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps *a* and *b* in the given files, *file1* and *file2*:

```
shell> replace a b b a -- file1 file2 ...
```

The *replace* program is used by *msql2mysql*. See [Section 4.7.1, “msql2mysql — Convert mSQL Programs for Use with MySQL”](#).

replace supports the following options.

- `-?`, `-I`
Display a help message and exit.
- `-#debug_options`
Enable debugging.
- `-s`
Silent mode. Print less information what the program does.
- `-v`
Verbose mode. Print more information about what the program does.
- `-V`
Display version information and exit.

4.8.3 resolveip — Resolve Host name to IP Address or Vice Versa

The *resolveip* utility resolves host names to IP addresses and vice versa.

Invoke *resolveip* like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

resolveip supports the following options.

- `--help`, `--info`, `-?`, `-I`
Display a help message and exit.
- `--silent`, `-s`
Silent mode. Produce less output.

- `--version, -V`

Display version information and exit.

4.9 MySQL Program Environment Variables

This section lists environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables. In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See [Section 4.2.6, “Using Option Files”](#).

| Variable | Description |
|------------------------------------|--|
| CXX | The name of your C++ compiler (for running <code>CMake</code>). |
| CC | The name of your C compiler (for running <code>CMake</code>). |
| DBI_USER | The default user name for Perl DBI. |
| DBI_TRACE | Trace options for Perl DBI. |
| HOME | The default path for the <code>mysql</code> history file is <code>\$HOME/.mysql_history</code> . |
| LD_RUN_PATH | Used to specify the location of <code>libmysqlclient.so</code> . |
| LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN | Enable <code>mysql_clear_password</code> authentication plugin; see Section 6.5.1.7, “The Cleartext Client-Side Authentication Plugin” . |
| LIBMYSQL_PLUGIN_DIR | Directory in which to look for client plugins. |
| LIBMYSQL_PLUGINS | Client plugins to preload. |
| MYSQL_DEBUG | Debug trace options when debugging. |
| MYSQL_GROUP_SUFFIX | Option group suffix value (like specifying <code>--defaults-group-suffix</code>). |
| MYSQL_HISTFILE | The path to the <code>mysql</code> history file. If this variable is set, its value overrides the default for <code>\$HOME/.mysql_history</code> . |
| MYSQL_HISTIGNORE | Patterns specifying statements not to log to <code>\$HOME/.mysql_history</code> . |
| MYSQL_HOME | The path to the directory in which the server-specific <code>my.cnf</code> file resides. |
| MYSQL_HOST | The default host name used by the <code>mysql</code> command-line client. |
| MYSQL_OPENSSL_UDF_DH_MAXKEYLENGTH | Maximum key length for <code>CREATE_DH_PARAMETERS()</code> . See Section 12.17.2, “Enterprise Encryption Usage and Examples” . |
| MYSQL_OPENSSL_UDF_DSA_MAXKEYLENGTH | Maximum DSA key length for <code>CREATE_ASYMMETRIC_PRIV_KEY()</code> . See Section 12.17.2, “Enterprise Encryption Usage and Examples” . |
| MYSQL_OPENSSL_UDF_RSA_MAXKEYLENGTH | Maximum RSA key length for <code>CREATE_ASYMMETRIC_PRIV_KEY()</code> . See Section 12.17.2, “Enterprise Encryption Usage and Examples” . |
| MYSQL_PS1 | The command prompt to use in the <code>mysql</code> command-line client. |
| MYSQL_PWD | The default password when connecting to <code>mysqld</code> . Using this is insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security” . |
| MYSQL_TCP_PORT | The default TCP/IP port number. |
| MYSQL_TEST_LOGIN_FILE | The name of the <code>.mylogin.cnf</code> login path file. |
| MYSQL_UNIX_PORT | The default Unix socket file name; used for connections to <code>localhost</code> . |
| PATH | Used by the shell to find MySQL programs. |

| Variable | Description |
|------------------------|---|
| <code>TMPDIR</code> | The directory in which temporary files are created. |
| <code>TZ</code> | This should be set to your local time zone. See Section B.5.3.7, “Time Zone Problems” . |
| <code>UMASK</code> | The user-file creation mode when creating files. See note following table. |
| <code>UMASK_DIR</code> | The user-directory creation mode when creating directories. See note following table. |
| <code>USER</code> | The default user name on Windows when connecting to <code>mysqld</code> . |

For information about the `mysql` history file, see [Section 4.5.1.3, “mysql Logging”](#).

`MYSQL_TEST_LOGIN_FILE` is the path name of the login path file (the file created by `mysql_config_editor`). If not set, the default value is `%APPDATA%\MySQL\.mylogin.cnf` directory on Windows and `$HOME/.mylogin.cnf` on non-Windows systems. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).

The default `UMASK` and `UMASK_DIR` values are `0660` and `0700`, respectively. MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because `0600` octal is `384` decimal.

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `($UMASK | 0600)` as the mode for file creation, so that newly created files have a mode in the range from `0600` to `0666` (all values octal).
- If `UMASK_DIR` is set, `mysqld` uses `($UMASK_DIR | 0700)` as the base mode for directory creation, which then is AND-ed with `~(~$UMASK & 0666)`, so that newly created directories have a mode in the range from `0700` to `0777` (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

MySQL Server ([mysqld](#)) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

- Server configuration
- The data directory, particularly the [mysql](#) system database
- The server log files
- Management of multiple servers on a single machine

For additional information on administrative topics, see also:

- [Chapter 6, Security](#)

- [Section 14.6, “InnoDB Configuration”](#)
- [Chapter 7, *Backup and Recovery*](#)
- [Chapter 17, *Replication*](#)
- [Chapter 19, *Partitioning*](#)

5.1 The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.
- Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.
- Server status variables. These variables contain counters and statistics about runtime operation.
- How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.
- The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

Note

Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see [Section 13.7.5.17, “SHOW ENGINES Syntax”](#).

5.1.1 Configuring the Server

The MySQL server, `mysqld`, has many command options and system variables that can be set at startup to configure its operation. To determine the command option and system variable values used by the server, execute this command:

```
shell> mysqld --verbose --help
```

The command produces a list of all `mysqld` options and configurable system variables. Its output includes the default option and variable values and looks something like this:

```

abort-slave-event-count      0
allow-suspicious-udfs       FALSE
archive                      ON
auto-increment-increment    1
auto-increment-offset       1
autocommit                   TRUE
automatic-sp-privileges      TRUE
back-log                     80
basedir                      /home/jon/bin/mysql-5.6/
...
tmpdir                       /tmp
transaction-alloc-block-size 8192
transaction-isolation        REPEATABLE-READ
transaction-prealloc-size    4096
transaction-read-only        FALSE

```

```
updatable-views-with-limit    YES
verbose                      TRUE
wait-timeout                  28800
```

To see the current system variable values used by the server as it runs, connect to it and execute this statement:

```
mysql> SHOW VARIABLES;
```

To see some statistical and status indicators for a running server, execute this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also is available using the `mysqladmin` command:

```
shell> mysqladmin variables
shell> mysqladmin extended-status
```

For a full description of all command options, system variables, and status variables, see these sections:

- [Section 5.1.4, “Server Command Options”](#)
- [Section 5.1.5, “Server System Variables”](#)
- [Section 5.1.7, “Server Status Variables”](#)

More detailed monitoring information is available from the Performance Schema; see [Chapter 22, MySQL Performance Schema](#).

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally better performance results from giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` and `table_open_cache`. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations.

- If you have at least 1-2GB of memory and many tables and want maximum performance with a moderate number of clients, use something like this:

```
shell> mysqld_safe --key_buffer_size=384M --table_open_cache=4000 \
        --sort_buffer_size=4M --read_buffer_size=1M &
```

- If you have only 256MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
shell> mysqld_safe --key_buffer_size=64M --sort_buffer_size=1M
```

If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

- With little memory and lots of connections, use something like this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \
        --read_buffer_size=100K &
```

Or even this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \
        --table_open_cache=32 --read_buffer_size=8K \
        --net_buffer_length=1K &
```

If you are performing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, increase the value of `read_rnd_buffer_size` to speed up the reading of rows following sorting operations.

You can make use of the example option files included with your MySQL distribution; see [Section 5.1.2, “Server Configuration Defaults”](#).

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file. See [Section 4.2.6, “Using Option Files”](#).

5.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see [Section 5.1.4, “Server Command Options”](#), and [Section 5.1.5, “Server System Variables”](#).

5.1.2.1 Changes to Server Defaults

Beginning with MySQL 5.6.6, several MySQL Server parameter defaults differ from the defaults in previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for database administrators to change settings manually.

In some cases, a parameter has a different fixed default value. In other cases, the server autosizes a parameter at startup using a formula based on other related parameters or server host configuration, rather than using a fixed value. For example, the setting for `back_log` is its previous default of 50, adjusted up by an amount proportional to the value of `max_connections`. The idea behind autosizing is that when the server has information available to make a decision about a parameter setting likely to be better than a fixed default, it will.

The following table summarizes changes to defaults. The Version column indicates when each default changed. For variables that are autosized, the main variable description provides additional detail about the sizing algorithm. See [Section 5.1.5, “Server System Variables”](#), and [Section 14.14, “InnoDB Startup Options and System Variables”](#). Any of these default settings can be overridden by specifying an explicit value at server startup.

Table 5.1 Changes to Server Defaults in MySQL 5.6

| Parameter | Old Default | New Default | Version |
|--|-------------------|--|---------|
| <code>back_log</code> | 50 | Autosized using <code>max_connections</code> | 5.6.6 |
| <code>binlog_checksum</code> | NONE | CRC32 | 5.6.6 |
| <code>--binlog-row-event-max-size</code> | 1024 | 8192 | 5.6.6 |
| <code>flush_time</code> | 1800 (on Windows) | 0 | 5.6.6 |
| <code>host_cache_size</code> | 128 | Autosized using <code>max_connections</code> | 5.6.8 |
| <code>innodb_autoextend_increment</code> | 8 | 64 | 5.6.6 |

| Parameter | Old Default | New Default | Version |
|--|-------------------------------------|--|---------|
| <code>innodb_buffer_pool_instances</code> | 1 | 8 (platform dependent) | 5.6.6 |
| <code>innodb_concurrency_tickets</code> | 500 | 5000 | 5.6.6 |
| <code>innodb_data_file_path</code> | <code>ibdata1:10M:autoextend</code> | <code>ibdata1:12M:autoextend</code> | 5.6.7 |
| <code>innodb_file_per_table</code> | 0 | 1 | 5.6.6 |
| <code>innodb_log_file_size</code> | 5MB | 48MB | 5.6.8 |
| <code>innodb_old_blocks_time</code> | 0 | 1000 | 5.6.6 |
| <code>innodb_open_files</code> | 300 | Autosized using <code>innodb_file_per_table</code> , <code>table_open_cache</code> | 5.6.6 |
| <code>innodb_stats_on_metadata</code> | ON | OFF | 5.6.6 |
| <code>join_buffer_size</code> | 128KB | 256KB | 5.6.6 |
| <code>max_allowed_packet</code> | 1MB | 4MB | 5.6.6 |
| <code>max_connect_errors</code> | 10 | 100 | 5.6.6 |
| <code>open_files_limit</code> | 0 | Autosized using <code>max_connections</code> | 5.6.8 |
| <code>performance_schema</code> | OFF | ON | 5.6.6 |
| <code>performance_schema_events_waits_history_long_size</code> | 10000 | Autosized | 5.6.6 |
| <code>performance_schema_events_waits_history_size</code> | 10 | Autosized | 5.6.6 |
| <code>performance_schema_max_cond_instances</code> | 1000 | Autosized | 5.6.6 |
| <code>performance_schema_max_file_instances</code> | 10000 | Autosized | 5.6.6 |
| <code>performance_schema_max_mutex_instances</code> | 1000000 | Autosized | 5.6.6 |
| <code>performance_schema_max_rwlock_instances</code> | 1000000 | Autosized | 5.6.6 |
| <code>performance_schema_max_table_handles</code> | 100000 | Autosized | 5.6.6 |
| <code>performance_schema_max_table_instances</code> | 50000 | Autosized | 5.6.6 |
| <code>performance_schema_max_thread_instances</code> | 1000 | Autosized | 5.6.6 |

In MySQL 5.6.6, the default for `innodb_checksum_algorithm` was changed from `INNODB` to `CRC32`. For compatibility reasons, the default was returned in 5.6.7 to `INNODB`.

5.1.2.2 Using a Sample Default Server Configuration File

As of MySQL 5.6.8, on Unix platforms, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. You can find the template in or under the base installation directory. When started using `mysqld_safe`, the server uses `my.cnf` file by default. If `my.cnf` already exists, `mysql_install_db` assumes it to be in use and writes a new file named `my-new.cnf` instead.

With one exception, the settings in the default option file are commented and have no effect. The exception is that the file changes the `sql_mode` system variable from its default of `NO_ENGINE_SUBSTITUTION` to also include `STRICT_TRANS_TABLES`:

```
sql_mode=NO_ENGINE_SUBSTITUTION,STRICT_TRANS_TABLES
```

This setting produces a server configuration that results in errors rather than warnings for bad data in operations that modify transactional tables. See [Section 5.1.8, “Server SQL Modes”](#).

The `my-default.cnf` template replaces the older sample option files formerly supplied with MySQL distributions (`my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`). As of MySQL 5.6.8, these older files are no longer distributed.

On Windows, MySQL Installer interacts with the user and creates a file named `my.ini` in the base installation directory as the default option file. If you install on Windows from a Zip archive, you can copy the `my-default.ini` template file in the base installation directory to `my.ini` and use the latter as the default option file.

Note

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

On any platform, after completing the installation process, you can edit the default option file at any time to modify the parameters used by the server. For example, to use a parameter setting in the file that is commented with a `#` character at the beginning of the line, remove the `#`, and modify the parameter value if necessary. To disable a setting, either add a `#` to the beginning of the line or remove it.

For additional information about option file format and syntax, see [Section 4.2.6, “Using Option Files”](#).

Before MySQL 5.6.8, MySQL distributions include several sample option files that can be used as a basis for tuning the MySQL server. Look for files named `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`, which are sample files for small, medium, large, and very large systems. On Windows, the extension is `.ini` rather than `.cnf`.

For a binary distribution, look for the sample files in or under your installation directory. If you have a source distribution, look in the `support-files` directory. To use a sample file as a base configuration file, rename a copy of it and place the copy in the appropriate location. Regarding names and appropriate location, see the general information provided in [Section 4.2.6, “Using Option Files”](#).

5.1.3 Server Option and Variable Reference

The following table provides a list of all the command line options, server and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with notification of where each option/variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding server system or status variable, the variable name is noted immediately below the corresponding option. For status variables, the scope of the variable is shown

(Scope) as either global, session, or both. Please see the corresponding sections for details on setting and using the options and variables. Where appropriate, a direct link to further information on the item as available.

For a version of this table that is specific to MySQL Cluster, see [Section 18.3.2.5, “NDB Cluster mysqld Option and Variable Reference”](#).

Table 5.2 Option/Variable Summary

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|---|----------|-------------|------------|------------|-----------|---------|
| abort-slave-event-count | Yes | Yes | | | | |
| Aborted_clients | | | | Yes | Global | No |

^aThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

^bThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

5.1.4 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in [Section 4.2.3, “Specifying Program Options”](#). The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See [Section 4.2.6, “Using Option Files”](#). That section also describes option file format and syntax.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where `xxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute this command:

```
mysqld --help
```

To see the full list, use this command:

```
mysqld --verbose --help
```

Some of the items in the list are actually system variables that can be set at server startup. These can be displayed at runtime using the `SHOW VARIABLES` statement. Some items displayed by the preceding `mysqld` command do not appear in `SHOW VARIABLES` output; this is because they are options only and not system variables.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See [Section 6.1.4, “Security-Related mysqld Options and Variables”](#).
- SSL-related options: See [Section 6.4.5, “Command Options for Secure Connections”](#).
- Binary log control options: See [Section 5.4.4, “The Binary Log”](#).
- Replication-related options: See [Section 17.1.4, “Replication and Binary Logging Options and Variables”](#).
- Options for loading plugins such as pluggable storage engines: See [Section 5.5.2, “Installing and Uninstalling Plugins”](#).
- Options specific to particular storage engines: See [Section 14.14, “InnoDB Startup Options and System Variables”](#) and [Section 15.2.1, “MyISAM Startup Options”](#).

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

You can also set the values of server system variables at server startup by using variable names as options. To assign a value to a server system variable, use an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` sets the `key_buffer_size` variable to a value of 32MB.

When you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup.

You can change the values of most system variables at runtime with the `SET` statement. See [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).

[Section 5.1.5, “Server System Variables”](#), provides a full description for all variables, and additional information for setting them at server startup and runtime. For information on changing system variables, see [Section 5.1.1, “Configuring the Server”](#).

- `--help, -?`

| | |
|----------------------------|---------------------|
| Command-Line Format | <code>--help</code> |
|----------------------------|---------------------|

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

| | | |
|----------------------------|--------------------------------------|--------------------|
| Command-Line Format | <code>--allow-suspicious-udfs</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See [Section 24.4.2.6, “UDF Security Precautions”](#).

- `--ansi`

| | |
|----------------------------|---------------------|
| Command-Line Format | <code>--ansi</code> |
|----------------------------|---------------------|

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See [Section 1.7, “MySQL Standards Compliance”](#), and [Section 5.1.8, “Server SQL Modes”](#).

- `--basedir=dir_name, -b dir_name`

| | | |
|----------------------------|---------------------------------|----------------------|
| Command-Line Format | <code>--basedir=dir_name</code> | |
| System Variable | Name | <code>basedir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- `--big-tables`

| | | |
|----------------------------|---------------------------|-------------------------|
| Command-Line Format | <code>--big-tables</code> | |
| System Variable | Name | <code>big_tables</code> |

| | | |
|-------------------------|-------------------------|-----------------|
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | OFF |

Enable large result sets by saving all temporary sets in files. This option prevents most “table full” errors, but also slows down queries for which in-memory tables would suffice. The server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=addr`

| | | |
|------------------------------------|----------------------------------|---------------------------|
| Command-Line Format | <code>--bind-address=addr</code> | |
| System Variable (>= 5.6.1) | Name | <code>bind_address</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.5) | Type | string |
| | Default | <code>0.0.0.0</code> |
| Permitted Values (>= 5.6.6) | Type | string |
| | Default | <code>*</code> |

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, use the `--bind-address=addr` option at server startup, where `addr` is an IPv4 or IPv6 address or a host name. If `addr` is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is permitted (and is the default) as of MySQL 5.6.6.
- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces. This is the default before MySQL 5.6.6.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `:::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- `--binlog-format={ROW|STATEMENT|MIXED}`

| | | |
|--|-------------------------------------|----------------------------|
| Command-Line Format | <code>--binlog-format=format</code> | |
| System Variable | Name | <code>binlog_format</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>STATEMENT</code> |
| | Valid Values | <code>ROW</code> |
| | | <code>STATEMENT</code> |
| | | <code>MIXED</code> |
| Permitted Values (>= 5.6.10-ndb-7.3.1) | Type | enumeration |
| | Default | <code>MIXED</code> |
| | Valid Values | <code>ROW</code> |
| | | <code>STATEMENT</code> |
| | | <code>MIXED</code> |

Specify whether to use row-based, statement-based, or mixed replication. Statement-based is the default in MySQL 5.6. See [Section 17.1.2, “Replication Formats”](#).

Under some conditions, changing this variable at runtime is not possible, or causes replication to fail. See [Section 5.4.4.2, “Setting The Binary Log Format”](#), for more information.

Setting the binary logging format without enabling binary logging sets the `binlog_format` global system variable and logs a warning.

- `--bootstrap`

| | |
|----------------------------|--------------------------|
| Command-Line Format | <code>--bootstrap</code> |
|----------------------------|--------------------------|

This option is used by the `mysql_install_db` program to create the MySQL privilege tables without having to start a full MySQL server.

In MySQL 5.6.6 and later, replication and global transaction identifiers are automatically disabled whenever this option is used (Bug #13992602). See [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

When the server operates in bootstrap mode, some functionality is unavailable that limits the statements permitted in any file named by the `--init-file` option. For more information, see the description of that option.

- `--character-sets-dir=dir_name`

| | | |
|----------------------------|--|---------------------------------|
| Command-Line Format | <code>--character-sets-dir=dir_name</code> | |
| System Variable | Name | <code>character_sets_dir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--character-set-client-handshake`

| | | |
|----------------------------|---|-------------------|
| Command-Line Format | <code>--character-set-client-handshake</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>TRUE</code> |

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- `--character-set-filesystem=charset_name`

| | | |
|----------------------------|--|---------------------------------------|
| Command-Line Format | <code>--character-set-filesystem=name</code> | |
| System Variable | Name | <code>character_set_filesystem</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>binary</code> |

The file system character set. This option sets the `character_set_filesystem` system variable.

- `--character-set-server=charset_name, -C charset_name`

| | | |
|----------------------------|-------------------------------------|-----------------------------------|
| Command-Line Format | <code>--character-set-server</code> | |
| System Variable | Name | <code>character_set_server</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>latin1</code> |

Use `charset_name` as the default server character set. See [Section 10.5, “Character Set Configuration”](#). If you use this option to specify a nondefault character set, you should also use `--collation-server` to specify the collation.

- `--chroot=dir_name, -r dir_name`

| | | |
|----------------------------|--------------------------------|----------------|
| Command-Line Format | <code>--chroot=dir_name</code> | |
| Permitted Values | Type | directory name |

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure.

Note

Use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=collation_name`

| | | |
|----------------------------|---------------------------------|--------------------------------|
| Command-Line Format | <code>--collation-server</code> | |
| System Variable | Name | <code>collation_server</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>latin1_swedish_ci</code> |

Use `collation_name` as the default server collation. See [Section 10.5, “Character Set Configuration”](#).

- `--console`

| | |
|----------------------------|------------------------|
| Command-Line Format | <code>--console</code> |
| Platform Specific | Windows |

(Windows only.) Write error log messages to `stderr` and `stdout`. `mysqld` does not close the console window if this option is used.

If both `--log-error` and `--console` are specified, `--log-error` takes precedence. The server writes to the log file, but not to the console.

- `--core-file`

| | | |
|----------------------------|--------------------------|------------------|
| Command-Line Format | <code>--core-file</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On OS X, a core file named

`core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysqld_safe`. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#). On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

- `--datadir=dir_name, -h dir_name`

| | | |
|----------------------------|---------------------------------|----------------------|
| Command-Line Format | <code>--datadir=dir_name</code> | |
| System Variable | Name | <code>datadir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The path to the data directory.

- `--debug[=debug_options], -# [debug_options]`

| | | |
|-----------------------------------|--------------------------------------|--|
| Command-Line Format | <code>--debug[=debug_options]</code> | |
| System Variable | Name | <code>debug</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (Unix) | Type | string |
| | Default | <code>d:t:i:o,/tmp/mysqld.trace</code> |
| Permitted Values (Windows) | Type | string |
| | Default | <code>d:t:i:O,\mysqld.trace</code> |

If MySQL is configured with the `-DWITH_DEBUG=1` CMake option, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:O,\mysqld.trace` on Windows.

Using `-DWITH_DEBUG=1` to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

For more information, see [Section 24.5.3, “The DBUG Package”](#).

- `--debug-sync-timeout[=N]`

| | |
|----------------------------|---------------------------------------|
| Command-Line Format | <code>--debug-sync-timeout[=#]</code> |
|----------------------------|---------------------------------------|

| Permitted Values | Type | integer |
|------------------|------|---------|
|------------------|------|---------|

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` CMake option (see [Section 2.9.4, “MySQL Source-Configuration Options”](#)). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `--default-authentication-plugin=plugin_name`

| | | |
|----------------------------|--|------------------------------------|
| Introduced | 5.6.6 | |
| Command-Line Format | <code>--default-authentication-plugin=plugin_name</code> | |
| Permitted Values | Type | enumeration |
| | Default | <code>mysql_native_password</code> |
| | Valid Values | <code>mysql_native_password</code> |
| | | <code>sha256_password</code> |

This option sets the default authentication plugin. Permitted values are `mysql_native_password` (use MySQL native passwords) and `sha256_password` (use SHA-256 passwords). For more information about these plugins, see [Section 6.5.1.1, “The Native Authentication Plugin”](#), and [Section 6.5.1.4, “The SHA-256 Authentication Plugin”](#). This option was added in MySQL 5.6.6.

Note

Prior to MySQL 5.6.17, if you use this option to change the default authentication plugin to a value other than `mysql_native_password`, clients older than MySQL 5.5.7 cannot connect because they do not understand the resulting change to the authentication protocol.

In MySQL 5.6, there is no server system variable that corresponds to the `--default-authentication-plugin` option; to read the value set for this option, you must check the running MySQL Server process to see what options, if any, were employed when invoking `mysqld` (on Linux systems, you can do this with `ps ax | grep mysqld` or similar), and possibly the server options file as well. This is a known issue which is resolved in MySQL 5.7. (Bug #68858, Bug #16595944)

The `--default-authentication-plugin` value affects these aspects of server operation:

- It determines which authentication plugin the server assigns to new accounts created by `CREATE USER` and `GRANT` statements that do not name a plugin explicitly with an `IDENTIFIED WITH` clause.
- It sets the `old_passwords` system variable at startup to the value that is consistent with the password hashing method required by the default plugin. The `old_passwords` value affects hashing of passwords specified in the `IDENTIFIED BY` clause of `CREATE USER` and `GRANT`, and passwords specified as the argument to the `PASSWORD()` function.
- For an account created with either of the following statements, the server associates the account with the default authentication plugin and assigns the account the given password, hashed according to the value of `old_passwords`.

```
CREATE USER ... IDENTIFIED BY 'cleartext password';
GRANT ... IDENTIFIED BY 'cleartext password';
```

- For an account created with either of the following statements, the statement fails if the password hash is not encrypted using the hash format required by the default authentication plugin. Otherwise, the server associates the account with the default authentication plugin and assigns the account the given password hash.

```
CREATE USER ... IDENTIFIED BY PASSWORD 'encrypted password';
GRANT ... IDENTIFIED BY PASSWORD 'encrypted password';
```

- `--default-storage-engine=type`

| Command-Line Format | <code>--default-storage-engine=name</code> | |
|---------------------|--|-------------------------------------|
| System Variable | Name | <code>default_storage_engine</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>InnoDB</code> |

Set the default storage engine for tables. See [Chapter 15, Alternative Storage Engines](#). As of MySQL 5.6.3, this option sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `--default-time-zone=timezone`

| Command-Line Format | <code>--default-time-zone=name</code> | |
|---------------------|---------------------------------------|--------|
| Permitted Values | Type | string |

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-file=file_name`

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Note

This must be the first option on the command line if it is used, except that if the server is started with the `--defaults-file` and `--install` (or `--install-manual`) options, `--install` (or `--install-manual`) must be first.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqld` normally reads the `[mysqld]` group. If the `--defaults-group-suffix=_other` option is given, `mysqld` also reads the `[mysqld_other]` group.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--delay-key-write[={OFF|ON|ALL}]`

| Command-Line Format | <code>--delay-key-write[=name]</code> | |
|---------------------|---------------------------------------|------------------------------|
| System Variable | Name | <code>delay_key_write</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>ON</code> |
| | Valid Values | <code>ON</code> |
| | | <code>OFF</code> |
| | | <code>ALL</code> |

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for `MyISAM` tables. `OFF` disables delayed key writes. `ON` enables delayed key writes for those tables that were created with the `DELAY_KEY_WRITE` option. `ALL` delays key writes for all `MyISAM` tables. See [Section 5.1.1, “Configuring the Server”](#), and [Section 15.2.1, “MyISAM Startup Options”](#).

Note

If you set this variable to `ALL`, you should not use `MyISAM` tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

- `--des-key-file=file_name`

| Command-Line Format | <code>--des-key-file=file_name</code> |
|---------------------|---------------------------------------|
|---------------------|---------------------------------------|

Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` and `DES_DECRYPT()` functions.

- `--enable-named-pipe`

| | |
|----------------------------|----------------------------------|
| Command-Line Format | <code>--enable-named-pipe</code> |
| Platform Specific | Windows |

Enable support for named pipes. This option applies only on Windows.

- `--engine-condition-pushdown={ON|OFF}`

| | | |
|---------------------|--|---|
| Deprecated | 5.5.3, by optimizer_switch | |
| Removed | 5.6.1 | |
| Command-Line Format | <code>--engine-condition-pushdown</code> | |
| System Variable | Name | engine_condition_pushdown |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | ON |

Formerly, this option set the [engine_condition_pushdown](#) system variable; the option and the variable were both removed in MySQL 5.6.1. For more information, see [Section 8.2.1.4, “Engine Condition Pushdown Optimization”](#).

- `--event-scheduler[=value]`

| | | |
|---------------------|--|------------------------------|
| Command-Line Format | <code>--event-scheduler[=value]</code> | |
| System Variable | Name | <code>event_scheduler</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>OFF</code> |
| | Valid Values | <code>ON</code> |
| | | <code>OFF</code> |
| | | <code>DISABLED</code> |

Enable or disable, and start or stop, the event scheduler.

For detailed information, see [The --event-scheduler Option](#).

- `--exit-info[=flags], -T [flags]`

| | |
|----------------------------|----------------------------------|
| Command-Line Format | <code>--exit-info[=flags]</code> |
|----------------------------|----------------------------------|

| | | |
|-------------------------|-------------|---------|
| Permitted Values | Type | integer |
|-------------------------|-------------|---------|

This is a bitmask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking`

| | | |
|----------------------------|---------------------------------|--------------------|
| Command-Line Format | <code>--external-locking</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

Enable external locking (system locking), which is disabled by default. If you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

To disable external locking explicitly, use `--skip-external-locking`.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.11.5, “External Locking”](#).

- `--flush`

| | | |
|----------------------------|-------------------------|--------------------|
| Command-Line Format | <code>--flush</code> | |
| System Variable | Name | <code>flush</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#).

- `--gdb`

| | | |
|----------------------------|--------------------|--------------------|
| Command-Line Format | <code>--gdb</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See [Section 24.5, “Debugging and Porting MySQL”](#).

- `--general-log[={0|1}]`

| | | |
|----------------------------|----------------------------|--------------------------|
| Command-Line Format | <code>--general-log</code> | |
| System Variable | Name | <code>general_log</code> |
| | Variable Scope | Global |
| | Scope | 532 |

| | | |
|-------------------------|-------------------------|---------|
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | OFF |

Specify the initial general query log state. With no argument or an argument of 1, the `--general-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--ignore-db-dir=dir_name`

| | | |
|----------------------------|------------------------------|----------------|
| Introduced | 5.6.3 | |
| Command-Line Format | <code>--ignore-db-dir</code> | |
| Permitted Values | Type | directory name |

This option tells the server to ignore the given directory name for purposes of the `SHOW DATABASES` statement or `INFORMATION_SCHEMA` tables. For example, if a MySQL configuration locates the data directory at the root of a file system on Unix, the system might create a `lost+found` directory there that the server should ignore. Starting the server with `--ignore-db-dir=lost+found` causes that name not to be listed as a database.

To specify more than one name, use this option multiple times, once for each name. Specifying the option with an empty value (that is, as `--ignore-db-dir=`) resets the directory list to the empty list.

Instances of this option given at server startup are used to set the `ignore_db_dirs` system variable.

This option was added in MySQL 5.6.3.

- `--init-file=file_name`

| | | |
|----------------------------|------------------------------------|------------------------|
| Command-Line Format | <code>--init-file=file_name</code> | |
| System Variable | Name | <code>init_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

If the server is started with the `--bootstrap` option, it operates in bootstrap mode and some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers. See [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

- `--innodb-xxx`

Set an option for the InnoDB storage engine. The InnoDB options are listed in [Section 14.14, “InnoDB Startup Options and System Variables”](#).

- `--install [service_name]`

| | |
|----------------------------|---------------------------------------|
| Command-Line Format | <code>--install [service_name]</code> |
| Platform Specific | Windows |

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

Note

If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

- `--install-manual [service_name]`

| | |
|----------------------------|--|
| Command-Line Format | <code>--install-manual [service_name]</code> |
| Platform Specific | Windows |

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

Note

If the server is started with the `--defaults-file` and `--install-manual` options, `--install-manual` must be first.

- `--language=lang_name, -L lang_name`

| | | |
|----------------------------|--|--|
| Deprecated | 5.6.1, by <code>lc-messages-dir</code> | |
| Command-Line Format | <code>--language=name</code> | |
| System Variable | Name | <code>language</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |
| | Default | <code>/usr/local/mysql/share/mysql/english/</code> |

The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See [Section 10.2, “Setting the Error Message Language”](#).

`--lc-messages-dir` and `--lc-messages` should be used rather than `--language`, which is deprecated as of MySQL 5.6.1 and handled as an alias for `--lc-messages-dir`. The `--language` option will be removed in a future MySQL release.

- `--large-pages`

| | | |
|----------------------------|----------------------------|--------------------------|
| Command-Line Format | <code>--large-pages</code> | |
| System Variable | Name | <code>large_pages</code> |

| | | |
|---------------------------------|-------------------------|--------------------|
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Platform Specific | Linux | |
| Permitted Values (Linux) | Type | boolean |
| | Default | <code>FALSE</code> |

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL supports the Linux implementation of large page support (which is called HugeTLB in Linux). See [Section 8.12.4.2, “Enabling Large Page Support”](#). For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- `--lc-messages=locale_name`

| | | |
|----------------------------|---------------------------------|--------------------------|
| Command-Line Format | <code>--lc-messages=name</code> | |
| System Variable | Name | <code>lc_messages</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>en_US</code> |

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `--lc-messages-dir` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `--lc-messages-dir=dir_name`

| | | |
|----------------------------|---|------------------------------|
| Command-Line Format | <code>--lc-messages-dir=dir_name</code> | |
| System Variable | Name | <code>lc_messages_dir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The directory where error messages are located. The server uses the value together with the value of `--lc-messages` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `--local-service`

| | |
|----------------------------|------------------------------|
| Command-Line Format | <code>--local-service</code> |
|----------------------------|------------------------------|

(Windows only) A `--local-service` option following the service name causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

- `--log[=file_name], -l [file_name]`

| | | |
|----------------------------|--|---------------------|
| Deprecated | 5.1.29, by general-log | |
| Removed | 5.6.1 | |
| Command-Line Format | <code>--log[=file_name]</code> | |
| System Variable | Name | log |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | file name |

The `--log` option was removed in MySQL 5.6.1 (along with the `log` system variable). Instead, use the `--general-log` option to enable the general query log and the `--general_log_file=file_name` option to set the general query log file name.

- `--log-error[=file_name]`

| | | |
|----------------------------|--------------------------------------|---------------------------|
| Command-Line Format | <code>--log-error[=file_name]</code> | |
| System Variable | Name | log_error |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

Log errors and startup messages to this file. See [Section 5.4.2, “The Error Log”](#). If the file name has no extension, the server adds an extension of `.err`. If you omit the file name, the default log file on Unix and Unix-like systems is `host_name.err` in the data directory. The default on Windows is `host_name.err` in the data directory, unless the `--pid-file` option is specified. In that case, the default name is the PID file base name with a suffix of `.err` in the data directory.

- `--log-isam[=file_name]`

| | | |
|----------------------------|-------------------------------------|-----------|
| Command-Line Format | <code>--log-isam[=file_name]</code> | |
| Permitted Values | Type | file name |

Log all [MyISAM](#) changes to this file (used only when debugging [MyISAM](#)).

- `--log-output=value,...`

| | | |
|----------------------------|---------------------------------|--|
| Command-Line Format | <code>--log-output=value</code> | |
|----------------------------|---------------------------------|--|

| | | |
|-------------------------|-------------------------|-------------------------|
| System Variable | Name | <code>log_output</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | set |
| | Default | <code>FILE</code> |
| | Valid Values | <code>TABLE</code> |
| | | <code>FILE</code> |
| | | <code>NONE</code> |

This option determines the destination for general query log and slow query log output. The option value can be given as one or more of the words `TABLE`, `FILE`, or `NONE`. `TABLE` select logging to the `general_log` and `slow_log` tables in the `mysql` database as a destination. `FILE` selects logging to log files as a destination. `NONE` disables logging. If `NONE` is present in the option value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the `--general_log` and `--slow_query_log` options. For `FILE` logging, the `--general_log_file` and `--slow_query_log_file` options determine the log file location. For more information, see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

- `--log-queries-not-using-indexes`

| | | |
|----------------------------|--|--|
| Command-Line Format | <code>--log-queries-not-using-indexes</code> | |
| System Variable | Name | <code>log_queries_not_using_indexes</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See [Section 5.4.5, “The Slow Query Log”](#). This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- `--log-raw`

| | | |
|----------------------------|--------------------------------|------------------|
| Introduced | 5.6.3 | |
| Command-Line Format | <code>--log-raw[=value]</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

As of MySQL 5.6.3, passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be

suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

Before MySQL 5.6.3, passwords in statements are not rewritten and the general query log should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

This option was added in MySQL 5.6.3.

- `--log-short-format`

| | | |
|----------------------------|---------------------------------|--------------------|
| Command-Line Format | <code>--log-short-format</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

Log less information to the slow query log, if it has been activated.

- `--log-slow-admin-statements`

| | | |
|----------------------------|--|------------------|
| Removed | 5.6.11 | |
| Command-Line Format | <code>--log-slow-admin-statements</code> (<= 5.6.10) | |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

This command-line option was removed in MySQL 5.6.11 and replaced by the `log_slow_admin_statements` system variable. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- `--log-slow-queries[=file_name]`

| | | |
|----------------------------|--|-------------------------------|
| Deprecated | 5.1.29, by <code>slow-query-log</code> | |
| Removed | 5.6.1 | |
| Command-Line Format | <code>--log-slow-queries[=name]</code> | |
| System Variable | Name | <code>log_slow_queries</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |

The `--log-slow-queries` option was removed in MySQL 5.6.1 (along with the `log_slow_queries` system variable). Instead, use the `--slow_query_log` option to enable the slow query log and the `--slow_query_log_file=file_name` option to set the slow query log file name.

- `--log-tc=file_name`

| | | |
|----------------------------|---------------------------------|---------------------|
| Command-Line Format | <code>--log-tc=file_name</code> | |
| Permitted Values | Type | file name |
| | Default | <code>tc.log</code> |

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. This option is unused.

- `--log-tc-size=size`

| | | |
|--|------------------------------|-----------------------------------|
| Command-Line Format | <code>--log-tc-size=#</code> | |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | <code>24576</code> |
| | Max Value | <code>4294967295</code> |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | <code>24576</code> |
| | Max Value | <code>18446744073709551615</code> |

The size in bytes of the memory-mapped transaction coordinator log. The default size is 24KB.

- `--log-warnings[=level], -W [level]`

| | | |
|--|---------------------------------|---------------------------|
| Command-Line Format | <code>--log-warnings[=#]</code> | |
| System Variable (<= 5.6.3) | Name | <code>log_warnings</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| System Variable (>= 5.6.4) | Name | <code>log_warnings</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | <code>1</code> |
| | Min Value | <code>0</code> |
| | Max Value | <code>4294967295</code> |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | <code>1</code> |
| | Min Value | <code>0</code> |

| | | |
|--|------------------|----------------------|
| | Max Value | 18446744073709551615 |
|--|------------------|----------------------|

Print out warnings such as `Aborted connection...` to the error log. This option is enabled (1) by default. To disable it, use `--log-warnings=0`. Specifying the option without a *level* value increments the current value by 1. Enabling this option by setting it greater than 0 is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth. The server logs messages about statements that are unsafe for statement-based logging if `--log-warnings` is greater than 0.

- `--low-priority-updates`

| | | |
|----------------------------|-------------------------------------|-----------------------------------|
| Command-Line Format | <code>--low-priority-updates</code> | |
| System Variable | Name | <code>low_priority_updates</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

Give table-modifying operations (`INSERT`, `REPLACE`, `DELETE`, `UPDATE`) lower priority than selects. This can also be done using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`). See [Section 8.11.2, “Table Locking Issues”](#).

- `--min-examined-row-limit=number`

| | | |
|--|---|-------------------------------------|
| Command-Line Format | <code>--min-examined-row-limit=#</code> | |
| System Variable | Name | <code>min_examined_row_limit</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 4294967295 |

| | | |
|-------------------------------------|-----------|----------------------|
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 18446744073709551615 |

When this option is set, queries which examine fewer than *number* rows are not written to the slow query log. The default is 0.

- `--memlock`

| | | |
|---------------------|------------------------|--------------------|
| Command-Line Format | <code>--memlock</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris, most Linux distributions that use a 2.4 or higher kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

Important

Use of this option may require you to run the server as `root`, which, for reasons of security, is normally not a good idea. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

On Linux and perhaps other systems, you can avoid the need to run the server as `root` by changing the `limits.conf` file. See the notes regarding the memlock limit in [Section 8.12.4.2, “Enabling Large Page Support”](#).

You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N`

| | | |
|---------------------|------------------------------------|---------|
| Command-Line Format | <code>--myisam-block-size=#</code> | |
| Permitted Values | Type | integer |
| | Default | 1024 |

| | | |
|--|------------------|-------|
| | Min Value | 1024 |
| | Max Value | 16384 |

The block size to be used for [MyISAM](#) index pages.

- `--myisam-recover-options[=option[,option]...]`

| | | |
|----------------------------|--|-------------------------|
| Command-Line Format | <code>--myisam-recover-options[=name]</code> | |
| Permitted Values | Type | enumeration |
| | Default | OFF |
| | Valid Values | OFF |
| | | DEFAULT |
| | | BACKUP |
| | | FORCE |
| | | QUICK |

Set the [MyISAM](#) storage engine recovery mode. The option value is any combination of the values of [OFF](#), [DEFAULT](#), [BACKUP](#), [FORCE](#), or [QUICK](#). If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying [DEFAULT](#), and specifying with an explicit value of " " disables recovery (same as a value of [OFF](#)). If recovery is enabled, each time [mysqld](#) opens a [MyISAM](#) table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, [mysqld](#) runs a check on the table. If the table was corrupted, [mysqld](#) attempts to repair it.

The following options affect how the repair works.

| Option | Description |
|-------------------------|---|
| OFF | No recovery. |
| DEFAULT | Recovery without backup, forcing, or quick checking. |
| BACKUP | If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> . |
| FORCE | Run recovery even if we would lose more than one row from the <code>.MYD</code> file. |
| QUICK | Do not check the rows in the table if there are not any delete blocks. |

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options [BACKUP](#), [FORCE](#). This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See [Section 15.2.1, “MyISAM Startup Options”](#).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--old-alter-table`

| | | |
|----------------------------|--------------------------------|------------------------------|
| Command-Line Format | <code>--old-alter-table</code> | |
| System Variable | Name | <code>old_alter_table</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

When this option is given, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 13.1.7, “ALTER TABLE Syntax”](#).

- `--old-style-user-limits`

| | | |
|----------------------------|--------------------------------------|--------------------|
| Command-Line Format | <code>--old-style-user-limits</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See [Section 6.3.4, “Setting Account Resource Limits”](#).

- `--one-thread`

| | |
|----------------------------|---------------------------|
| Removed | 5.6.1 |
| Command-Line Format | <code>--one-thread</code> |

This option was removed in MySQL 5.6.1. Use `--thread_handling=no-threads` instead.

- `--open-files-limit=count`

| | | |
|---------------------------------------|-----------------------------------|-------------------------------|
| Command-Line Format | <code>--open-files-limit=#</code> | |
| System Variable | Name | <code>open_files_limit</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.7) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | | 543 |

| | | |
|------------------------------------|------------------|--------------------------------|
| | Max Value | platform dependent |
| Permitted Values (>= 5.6.8) | Type | integer |
| | Default | 5000, with possible adjustment |
| | Min Value | 0 |
| | Max Value | platform dependent |

Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld` gives you the error `Too many open files`. `mysqld` uses the option value to reserve descriptors with `setrlimit()`. Internally, the maximum value for this option is the maximum unsigned integer value, but the actual maximum is platform dependent. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

`mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` and `table_open_cache` to estimate whether more descriptors will be needed.

On Unix, the value cannot be set less than `ulimit -n`.

- `--partition[=value]`

| | | |
|----------------------------|-----------------------------|---------|
| Command-Line Format | <code>--partition</code> | |
| Disabled by | <code>skip-partition</code> | |
| Permitted Values | Type | boolean |
| | Default | ON |

Enables or disables user-defined partitioning support in the MySQL Server.

- `--performance-schema-xxx`

Configure a Performance Schema option. For details, see [Section 22.12, “Performance Schema Command Options”](#).

- `--pid-file=file_name`

| | | |
|----------------------------|-----------------------------------|-----------------------|
| Command-Line Format | <code>--pid-file=file_name</code> | |
| System Variable | Name | <code>pid_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The path name of the process ID file. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. This file is used by other programs such as `mysqld_safe` to determine the server's process ID.

- `--plugin-xxx`

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a `--plugin` prefix. Thus, the `--innodb_file_per_table` option for InnoDB can be specified as `--plugin-innodb_file_per_table`.

For boolean options that can be enabled or disabled, the `--skip` prefix and other alternative formats are supported as well (see [Section 4.2.5, “Program Option Modifiers”](#)). For example, `--skip-plugin-innodb_file_per_table` disables `innodb_file_per_table`.

The rationale for the `--plugin` prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be `--sql-mode`, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as `--plugin-sql-mode`. Use of the `--plugin` prefix for plugin options is recommended to avoid any question of ambiguity.

- `--plugin-load=plugin_list`

| | | |
|----------------------------|--|--------|
| Command-Line Format | <code>--plugin-load=plugin_list</code> | |
| Permitted Values | Type | string |

This option tells the server to load the named plugins at startup. If multiple `--plugin-load` options are given, only the last one is used. Additional plugins to load may be specified using `--plugin-load-add` options.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because otherwise semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugins` table and does not load plugins listed there. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup that cannot be loaded at runtime.

For additional information about plugin loading, see [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

- `--plugin-load-add=plugin_list`

| | | |
|----------------------------|--|--------|
| Introduced | 5.6.3 | |
| Command-Line Format | <code>--plugin-load-add=plugin_list</code> | |
| Permitted Values | Type | string |

This option complements the `--plugin-load` option. `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--plugin-load`. `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument. This option was added in MySQL 5.6.3.

`--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x:y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

For additional information about plugin loading, see [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

- `--port=port_num, -P port_num`

| | | |
|----------------------------|-------------------------|-------------------|
| Command-Line Format | <code>--port=#</code> | |
| System Variable | Name | <code>port</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 3306 |
| | Min Value | 0 |
| | Max Value | 65535 |

The port number to use when listening for TCP/IP connections. On Unix and Unix-like systems, the port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=num`

| | | |
|----------------------------|------------------------------------|---------|
| Command-Line Format | <code>--port-open-timeout=#</code> | |
| Permitted Values | Type | integer |
| | Default | 0 |

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--print-defaults`

Print the program name and all options that it gets from option files. This must be the first option on the command line if it is used, except that it may be used immediately after `--defaults-file` or `--defaults-extra-file`.

For additional information about this option, see [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--remove [service_name]`

| | |
|----------------------------|--------------------------------------|
| Command-Line Format | <code>--remove [service_name]</code> |
| Platform Specific | Windows |

(Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

- `--safe-mode`

| | |
|----------------------------|--------------------------|
| Deprecated | 5.5.26 |
| Removed | 5.6.6 |
| Command-Line Format | <code>--safe-mode</code> |

Skip some optimization stages. This option was removed in MySQL 5.6.6.

- `--safe-user-create`

| | | |
|----------------------------|---------------------------------|--------------------|
| Command-Line Format | <code>--safe-user-create</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

| | | |
|---------------------------------------|----------------------------|--------------------------|
| Command-Line Format | <code>--secure-auth</code> | |
| System Variable | Name | <code>secure_auth</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.4) | Type | boolean |
| | Default | <code>OFF</code> |
| Permitted Values (>= 5.6.5) | Type | boolean |
| | Default | <code>ON</code> |

This option causes the server to block connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format. Use it to prevent all use of passwords employing the old format (and hence insecure communication over the network). Before MySQL 5.6.5, this option is disabled by default. As of MySQL 5.6.5, it is enabled by default; to disable it, use `--skip-secure-auth`.

Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format. See [Section B.5.2.4, “Client does not support authentication protocol”](#).

The `mysql` client also has a `--secure-auth` option, which prevents connections to a server if the server requires a password in old format for the client account.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided. Pre-4.1 passwordss are deprecated and support for them will be removed in a future MySQL release. Consequently, disabling secure authentication using `--skip-secure-auth` is also deprecated.

- `--secure-file-priv=dir_name`

| | | |
|--|--|--------------------------------|
| Command-Line Format | <code>--secure-file-priv=dir_name</code> | |
| System Variable | Name | <code>secure_file_priv</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.33) | Type | string |
| | Default | <code>empty</code> |
| | Valid Values | <code>empty</code> |
| | | <code>dirname</code> |
| Permitted Values (>= 5.6.34) | Type | string |
| | Default | <code>platform specific</code> |

| | | |
|--|---------------------|---------|
| | Valid Values | empty |
| | | dirname |
| | | NULL |

This option sets the `secure_file_priv` system variable, which is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. For more information, see the description of `secure_file_priv`.

- `--shared-memory`

| | | |
|----------------------------|--------------------------------------|----------------------------|
| Command-Line Format | <code>--shared_memory[={0,1}]</code> | |
| System Variable | Name | <code>shared_memory</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Platform Specific | Windows | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

Enable shared-memory connections by local clients. This option is available only on Windows.

- `--shared-memory-base-name=name`

| | | |
|----------------------------|---|--------------------------------------|
| Command-Line Format | <code>--shared_memory_base_name=name</code> | |
| System Variable | Name | <code>shared_memory_base_name</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Platform Specific | Windows | |
| Permitted Values | Type | string |
| | Default | <code>MYSQL</code> |

The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- `--skip-concurrent-insert`

Turn off the ability to select and insert at the same time on `MyISAM` tables. (This is to be used only if you think you have found a bug in this feature.) See [Section 8.11.3, “Concurrent Inserts”](#).

- `--skip-event-scheduler`

| | |
|----------------------------|--|
| Command-Line Format | <code>--skip-event-scheduler</code> |
| | <code>--disable-event-scheduler</code> |

Turns the Event Scheduler `OFF`. This is not the same as disabling the Event Scheduler, which requires setting `--event-scheduler=DISABLED`; see [The `--event-scheduler` Option](#), for more information.

- `--skip-grant-tables`

This option causes the server to start without using the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server.

This option also causes the server to suppress during its startup sequence the loading of user-defined functions (UDFs), scheduled events, and plugins that were installed with the `INSTALL PLUGIN` statement. To cause plugins to be loaded anyway, use the `--plugin-load` option.

`FLUSH PRIVILEGES` might be executed implicitly by other actions performed after startup. For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- `--skip-host-cache`

Disable use of the internal host cache for faster name-to-IP resolution. In this case, the server performs a DNS lookup every time a client connects. See [Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”](#).

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache`, that does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

- `--skip-innodb`

Disable the `InnoDB` storage engine. In this case, because the default storage engine is `InnoDB`, the server will not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

As of MySQL 5.6.21, the `--skip-innodb` option is deprecated. Its use results in a warning. This option will be removed in a future MySQL release.

- `--skip-name-resolve`

Do not resolve host names when checking client connections. Use only IP addresses. If you use this option, all `Host` column values in the grant tables must be IP addresses or `localhost`. See [Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”](#).

Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=localhost`, `--host=127.0.0.1`, or `--host>:::1`.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option, so make sure that an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host>:::1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@':::1' IDENTIFIED BY 'root-password';
```

- `--skip-networking`

Do not listen for TCP/IP connections at all. All interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See [Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”](#).

- `--skip-partition`

| | |
|----------------------------|----------------------------------|
| Command-Line Format | <code>--skip-partition</code> |
| | <code>--disable-partition</code> |

Disables user-defined partitioning. Partitioned tables can be seen using `SHOW TABLES` or by querying the `INFORMATION_SCHEMA.TABLES` table, but cannot be created or modified, nor can data in such tables be accessed. All partition-specific columns in the `INFORMATION_SCHEMA.PARTITIONS` table display `NULL`.

Since `DROP TABLE` removes table definition (`.frm`) files, this statement works on partitioned tables even when partitioning is disabled using the option. The statement, however, does not remove `.par` files associated with partitioned tables in such cases. For this reason, you should avoid dropping partitioned tables with partitioning disabled, or take action to remove the orphaned `.par` files manually.

- `--ssl*`

Options that begin with `--ssl` specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See [Section 6.4.5, “Command Options for Secure Connections”](#).

- `--standalone`

| | |
|----------------------------|---------------------------|
| Command-Line Format | <code>--standalone</code> |
| Platform Specific | Windows |

Available on Windows only; instructs the MySQL server not to run as a service.

- `--super-large-pages`

| | | |
|-----------------------------------|----------------------------------|--------------------|
| Command-Line Format | <code>--super-large-pages</code> | |
| Platform Specific | Solaris | |
| Permitted Values (Solaris) | Type | boolean |
| | Default | <code>FALSE</code> |

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- `--symbolic-links`, `--skip-symbolic-links`

| | |
|----------------------------|-------------------------------|
| Command-Line Format | <code>--symbolic-links</code> |
|----------------------------|-------------------------------|

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links enables you to establish a symbolic link to a database directory by creating a `db_name.sym` file that contains the path to the real directory. See [Section 8.12.3.3, “Using Symbolic Links for Databases on Windows”](#).
- On Unix, enabling symbolic links means that you can link a `MyISAM` index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See [Section 8.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”](#).
- `--skip-show-database`

| | | |
|----------------------------|-----------------------------------|---------------------------------|
| Command-Line Format | <code>--skip-show-database</code> | |
| System Variable | Name | <code>skip_show_database</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |

This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See [Section 5.1.5, “Server System Variables”](#).

- `--skip-stack-trace`

| | |
|----------------------------|---------------------------------|
| Command-Line Format | <code>--skip-stack-trace</code> |
|----------------------------|---------------------------------|

Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See [Section 24.5, “Debugging and Porting MySQL”](#).

- `--skip-thread-priority`

| | |
|----------------------------|-------------------------------------|
| Deprecated | 5.1.29 |
| Removed | 5.6.1 |
| Command-Line Format | <code>--skip-thread-priority</code> |

Disable using thread priorities for faster response time. This option was unused and was removed in MySQL 5.6.1.

- `--slow-query-log[={0|1}]`

| | | |
|----------------------------|-------------------------------|-----------------------------|
| Command-Line Format | <code>--slow-query-log</code> | |
| System Variable | Name | <code>slow_query_log</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> 552 |

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--slow-start-timeout=timeout`

| | | |
|--------------------------------------|-------------------------------------|---------|
| Introduced | 5.6.5 | |
| Command-Line Format | <code>--slow-start-timeout=#</code> | |
| Permitted Values (Windows) | Type | integer |
| | Default | 15000 |

This option controls the Windows service control manager's service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- `--socket=path`

| | | |
|----------------------------|---|-----------------|
| Command-Line Format | <code>--socket={file_name pipe_name}</code> | |
| System Variable | Name | socket |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |
| | Default | /tmp/mysql.sock |

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]`

| | | |
|------------------------------------|------------------------------|----------------------------|
| Command-Line Format | <code>--sql-mode=name</code> | |
| System Variable | Name | sql_mode |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.5) | Type | set |
| | Default | '' |
| | Valid Values | ALLOW_INVALID_DATES |
| | | ANSI_QUOTES |
| | | ERROR_FOR_DIVISION_BY_ZERO |
| | | HIGH_NOT_PRECEDENCE |
| | | IGNORE_SPACE |

| | | | |
|-----------------------------|--------------|----------------------------|-------------------------|
| | | | NO_AUTO_CREATE_USER |
| | | | NO_AUTO_VALUE_ON_ZERO |
| | | | NO_BACKSLASH_ESCAPES |
| | | | NO_DIR_IN_CREATE |
| | | | NO_ENGINE_SUBSTITUTION |
| | | | NO_FIELD_OPTIONS |
| | | | NO_KEY_OPTIONS |
| | | | NO_TABLE_OPTIONS |
| | | | NO_UNSIGNED_SUBTRACTION |
| | | | NO_ZERO_DATE |
| | | | NO_ZERO_IN_DATE |
| | | | ONLY_FULL_GROUP_BY |
| | | | PAD_CHAR_TO_FULL_LENGTH |
| | | | PIPES_AS_CONCAT |
| | | | REAL_AS_FLOAT |
| | | | STRICT_ALL_TABLES |
| | | | STRICT_TRANS_TABLES |
| Permitted Values (>= 5.6.6) | Type | set | |
| | Default | NO_ENGINE_SUBSTITUTION | |
| | Valid Values | ALLOW_INVALID_DATES | |
| | | ANSI_QUOTES | |
| | | ERROR_FOR_DIVISION_BY_ZERO | |
| | | HIGH_NOT_PRECEDENCE | |
| | | IGNORE_SPACE | |
| | | NO_AUTO_CREATE_USER | |
| | | NO_AUTO_VALUE_ON_ZERO | |
| | | NO_BACKSLASH_ESCAPES | |
| | | NO_DIR_IN_CREATE | |
| | | NO_ENGINE_SUBSTITUTION | |
| | | NO_FIELD_OPTIONS | |
| | | NO_KEY_OPTIONS | |
| | | NO_TABLE_OPTIONS | |
| | | NO_UNSIGNED_SUBTRACTION | |
| | | NO_ZERO_DATE | |
| | | NO_ZERO_IN_DATE | |
| | | ONLY_FULL_GROUP_BY | |
| | | PAD_CHAR_TO_FULL_LENGTH | |
| | | PIPES_AS_CONCAT | |
| | | REAL_AS_FLOAT | |

| | | |
|--|--|---------------------|
| | | STRICT_ALL_TABLES |
| | | STRICT_TRANS_TABLES |

Set the SQL mode. Prior to MySQL 5.6.6, the default was '' (an empty string); beginning with MySQL 5.6.6, the default is `NO_ENGINE_SUBSTITUTION`. See [Section 5.1.8, “Server SQL Modes”](#).

Note

MySQL installation programs may configure the SQL mode during the installation process. For example, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file contains a line that sets the SQL mode; see [Section 4.4.3, “mysql_install_db — Initialize MySQL Data Directory”](#).

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `--sysdate-is-now`

| | | |
|----------------------------|-------------------------------|--------------------|
| Command-Line Format | <code>--sysdate-is-now</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

`SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes `SYSDATE()` to be an alias for `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in [Section 12.7, “Date and Time Functions”](#) and for `SET TIMESTAMP` in [Section 5.1.5, “Server System Variables”](#).

- `--tc-heuristic-recover={COMMIT|ROLLBACK}`

| | | |
|----------------------------|--|--|
| Command-Line Format | <code>--tc-heuristic-recover=name</code> | |
| Permitted Values | Type | enumeration |
| | Default | <code>COMMIT</code> |
| | Valid Values | <code>COMMIT</code> <code>ROLLBACK</code> |

The type of decision to use in the heuristic recovery process. To use this option, two or more storage engines that support [XA](#) transactions must be installed.

Prior to MySQL 5.7.8, the server interprets `--tc-heuristic-recover` option values incorrectly due to an off-by-one error (Bug #70860).

- `--temp-pool`

| | | |
|----------------------------|--------------------------|-------------------|
| Command-Line Format | <code>--temp-pool</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>TRUE</code> |

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating

many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is being allocated to the directory entry cache rather than to the disk cache. This option is ignored except on Linux.

- `--transaction-isolation=level`

| | | |
|----------------------------|---|-------------------------------|
| Command-Line Format | <code>--transaction-isolation=name</code> | |
| Permitted Values | Type | enumeration |
| | Default | <code>REPEATABLE-READ</code> |
| | Valid Values | <code>READ-UNCOMMITTED</code> |
| | | <code>READ-COMMITTED</code> |
| | | <code>REPEATABLE-READ</code> |
| | | <code>SERIALIZABLE</code> |

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `tx_isolation` system variable.

- `--transaction-read-only`

| | | |
|----------------------------|--------------------------------------|------------------|
| Introduced | 5.6.5 | |
| Command-Line Format | <code>--transaction-read-only</code> | |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

To set the default transaction access mode at runtime, use the `SET TRANSACTION` statement or set the `tx_read_only` system variable. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

This option was added in MySQL 5.6.5.

- `--tmpdir=dir_name, -t dir_name`

| | | |
|----------------------------|--------------------------------|---------------------|
| Command-Line Format | <code>--tmpdir=dir_name</code> | |
| System Variable | Name | <code>tmpdir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows. If the MySQL server is acting as a replication slave, you

should not set `--tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#). A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}, -u {user_name|user_id}`

| | | |
|----------------------------|--------------------------|--------|
| Command-Line Format | <code>--user=name</code> | |
| Permitted Values | Type | string |

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See [Section 6.1.1, “Security Guidelines”](#).

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--verbose, -v`

Use this option with the `--help` option for detailed help.

- `--version, -V`

Display version information and exit.

5.1.5 Server System Variables

The MySQL server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically at runtime using the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. Setting the global value of a system variable requires the `SUPER` privilege. For some system variables, setting the session value also requires the `SUPER` privilege; if so, it is indicated in the variable description. You can also use system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysql --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section includes a table that lists all system variables and following the table provides a description of each one. Variables with no version indicated are present in all MySQL 5.6 releases. For more information about manipulation of system variables, see [Section 5.1.6, “Using System Variables”](#).

Table 5.3 System Variable Summary

| Name | Cmd-Line | Option File | System Var | Var Scope | Dynamic |
|---|----------|-------------|------------|-----------|---------|
| audit_log_buffer_size | Yes | Yes | Yes | Global | No |
| audit_log_connection_policy | Yes | Yes | Yes | Global | Yes |
| audit_log_current_session | | | Yes | Both | No |
| audit_log_exclude_accounts | Yes | Yes | Yes | Global | Yes |
| audit_log_file | Yes | Yes | Yes | Global | No |
| audit_log_flush | | | Yes | Global | Yes |
| audit_log_format | Yes | Yes | Yes | Global | No |
| audit_log_include_accounts | Yes | Yes | Yes | Global | Yes |
| audit_log_policy | Yes | Yes | Yes | Global | Varies |
| audit_log_rotate_on_size | Yes | Yes | Yes | Global | Yes |
| audit_log_statement_policy | Yes | Yes | Yes | Global | Yes |
| audit_log_strategy | Yes | Yes | Yes | Global | No |
| auto_increment_increment | | | Yes | Both | Yes |
| auto_increment_offset | | | Yes | Both | Yes |
| autocommit | Yes | Yes | Yes | Both | Yes |
| automatic_sp_privileges | | | Yes | Global | Yes |
| avoid_temporal_upgrade | Yes | Yes | Yes | Global | Yes |
| back_log | | | Yes | Global | No |
| basedir | Yes | Yes | Yes | Global | No |
| big-tables | Yes | Yes | | | Yes |
| - Variable: big_tables | | | Yes | Both | Yes |
| bind-address | Yes | Yes | | | No |
| - Variable: bind_address | | | Yes | Global | No |
| binlog_cache_size | Yes | Yes | Yes | Global | Yes |
| binlog_checksum | | | Yes | Global | Yes |
| binlog_direct_non_transactional_updates | Yes | Yes | Yes | Both | Yes |
| binlog_error_action | Yes | Yes | Yes | Both | Yes |
| binlog-format | Yes | Yes | | | Yes |
| - Variable: binlog_format | | | Yes | Both | Yes |
| binlog_gtid_simple_recovery | Yes | Yes | Yes | Global | No |
| binlog_max_flush_queue_time | | | Yes | Global | Yes |

| Name | Cmd-Line | Option File | System Var | Var Scope | Dynamic |
|---|----------|-------------|------------|-----------|---------|
| binlog_order_commits | | | Yes | Global | Yes |
| binlog_row_image | Yes | Yes | Yes | Both | Yes |
| binlog_rows_query_log_events | | | Yes | Both | Yes |
| binlog_stmt_cache_size | Yes | Yes | Yes | Global | Yes |
| binlogging_impossible_mode | Yes | Yes | Yes | Both | Yes |
| block_encryption_mode | Yes | Yes | Yes | Both | Yes |
| bulk_insert_buffer_size | Yes | Yes | Yes | Both | Yes |
| character_set_client | | | Yes | Both | Yes |
| character_set_connection | | | Yes | Both | Yes |
| character_set_database^a | | | Yes | Both | Yes |
| character-set-filesystem | Yes | Yes | | | Yes |
| - Variable: character_set_filesystem | | | Yes | Both | Yes |

^aThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

^bThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- [Section 5.1.6, “Using System Variables”](#), discusses the syntax for setting and displaying system variable values.
- [Section 5.1.6.2, “Dynamic System Variables”](#), lists the variables that can be set at runtime.
- Information on tuning system variables can be found in [Section 5.1.1, “Configuring the Server”](#).
- [Section 14.14, “InnoDB Startup Options and System Variables”](#), lists [InnoDB](#) system variables.
- [NDB Cluster System Variables](#), lists system variables which are specific to MySQL Cluster.

- For information on server system variables specific to replication, see [Section 17.1.4, “Replication and Binary Logging Options and Variables”](#).

**Note**

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, before MySQL 5.6.2, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not. As of MySQL 5.6.2, boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case sensitive). See [Section 4.2.5, “Program Option Modifiers”](#).

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `authentication_windows_log_level`

| | | |
|----------------------------|---|---------|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--authentication_windows_log_level</code> | |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 4 |

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See [Section 6.5.1.6, “The Windows Native Authentication Plugin”](#).

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

| Value | Description |
|-------|---|
| 0 | No logging |
| 1 | Log only error messages |
| 2 | Log level 1 messages and warning messages |

| Value | Description |
|-------|--|
| 3 | Log level 2 messages and information notes |
| 4 | Log level 3 messages and debug messages |

This variable was added in MySQL 5.6.10.

- `authentication_windows_use_principal_name`

| | | |
|----------------------------|--|---------|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--authentication_windows_use_principal_name</code> | |
| Permitted Values | Type | boolean |
| | Default | ON |

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See [Section 6.5.1.6, “The Windows Native Authentication Plugin”](#).

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client in clear text. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which will happen primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

This variable was added in MySQL 5.6.10.

- `autocommit`

| | | |
|----------------------------|-------------------------------|-------------------------|
| Command-Line Format | <code>--autocommit[=#]</code> | |
| System Variable | Name | <code>autocommit</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | ON |

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

- `automatic_sp_privileges`

| | | |
|-------------------------|-------------------------|--------------------------------------|
| System Variable | Name | <code>automatic_sp_privileges</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>TRUE</code> |

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

See also [Section 20.2.2, “Stored Routines and MySQL Privileges”](#).

- `avoid_temporal_upgrade`

| | | |
|----------------------------|--|-------------------------------------|
| Introduced | 5.6.24 | |
| Deprecated | 5.6.24 | |
| Command-Line Format | <code>--avoid_temporal_upgrade={OFF ON}</code> | |
| System Variable | Name | <code>avoid_temporal_upgrade</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

This variable controls whether `ALTER TABLE` implicitly upgrades temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes `ALTER TABLE` not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable was added in MySQL 5.6.24. It is deprecated and will be removed in a future MySQL release.

- `back_log`

| | | |
|---------------------------------------|-------------------------|-----------------------|
| System Variable | Name | <code>back_log</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.5) | Type | integer |
| | Default | 50 |
| | Min Value | 1 |
| | Max Value | 65535 |
| Permitted Values (>= 5.6.6) | Type | integer |
| | Default | -1 (autosized) |
| | Min Value | 1 |
| | Max Value | 65535 |

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

As of MySQL 5.6.6, the default value is based on the following formula, capped to a limit of 900:

```
50 + (max_connections / 5)
```

Before 5.6.6, the default is 50.

- `basedir`

| | | |
|----------------------------|---------------------------------|----------------------|
| Command-Line Format | <code>--basedir=dir_name</code> | |
| System Variable | Name | <code>basedir</code> |
| | Variable Scope | Global |

| | | |
|-------------------------|-------------------------|----------------|
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The MySQL installation base directory. This variable can be set with the `--basedir` option. Relative path names for other variables usually are resolved relative to the base directory.

- `big_tables`

| | | |
|----------------------------|---------------------------|-------------------------|
| Command-Line Format | <code>--big-tables</code> | |
| System Variable | Name | <code>big_tables</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

- `bind_address`

| | | |
|------------------------------------|----------------------------------|---------------------------|
| Command-Line Format | <code>--bind-address=addr</code> | |
| System Variable (>= 5.6.1) | Name | <code>bind_address</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.5) | Type | string |
| | Default | <code>0.0.0.0</code> |
| Permitted Values (>= 5.6.6) | Type | string |
| | Default | <code>*</code> |

The value of the `--bind-address` option. This variable was added in MySQL 5.6.1.

- `block_encryption_mode`

| | | |
|----------------------------|--|------------------------------------|
| Introduced | 5.6.17 | |
| Command-Line Format | <code>--block_encryption_mode=#</code> | |
| System Variable | Name | <code>block_encryption_mode</code> |
| | Variable Scope | Global, Session |

| | | |
|-------------------------|-------------------------|--------------------------|
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>aes-128-ecb</code> |

This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for `AES_ENCRYPT()` and `AES_DECRYPT()`.

`block_encryption_mode` takes a value in `aes-keylen-mode` format, where `keylen` is the key length in bits and `mode` is the encryption mode. The value is not case sensitive. Permitted `keylen` values are 128, 192, and 256. Permitted encryption modes depend on whether MySQL was compiled using OpenSSL or yaSSL:

- For OpenSSL, permitted `mode` values are: `ECB`, `CBC`, `CFB1`, `CFB8`, `CFB128`, `OFB`
- For yaSSL, permitted `mode` values are: `ECB`, `CBC`

For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

```
SET block_encryption_mode = 'aes-256-cbc';
```

An error occurs for attempts to set `block_encryption_mode` to a value containing an unsupported key length or a mode that the SSL library does not support.

This variable was added in MySQL 5.6.17.

- `bulk_insert_buffer_size`

| | | |
|--|--|--------------------------------------|
| Command-Line Format | <code>--bulk_insert_buffer_size=#</code> | |
| System Variable | Name | <code>bulk_insert_buffer_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | <code>8388608</code> |
| | Min Value | 0 |
| | Max Value | <code>4294967295</code> |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | <code>8388608</code> |
| | Min Value | 0 |
| | Max Value | <code>18446744073709551615</code> |

MyISAM uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- `character_set_client`

| | | |
|-------------------------|-------------------------|-----------------------------------|
| System Variable | Name | <code>character_set_client</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also [Section 10.1.4, “Connection Character Sets and Collations”](#).) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

`ucs2`, `utf16`, `utf16le`, and `utf32` cannot be used as a client character set, which means that they also do not work for `SET NAMES` or `SET CHARACTER SET`.

- `character_set_connection`

| | | |
|-------------------------|-------------------------|---------------------------------------|
| System Variable | Name | <code>character_set_connection</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

The character set used for literals that do not have a character set introducer and for number-to-string conversion. For information about introducers, see [Section 10.1.3.8, “Character Set Introducers”](#).

- `character_set_database`

| | | |
|------------------------|-----------------------|-------------------------------------|
| System Variable | Name | <code>character_set_database</code> |
| | Variable Scope | Global, Session |

| | | |
|-------------------------|--|--------|
| | Dynamic Variable | Yes |
| Footnote | This option is dynamic, but only the server should set this information. You should not set the value of this variable manually. | |
| Permitted Values | Type | string |

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

- `character_set_filesystem`

| | | |
|----------------------------|--|---------------------------------------|
| Command-Line Format | <code>--character-set-filesystem=name</code> | |
| System Variable | Name | <code>character_set_filesystem</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>binary</code> |

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8'`.

- `character_set_results`

| | | |
|-------------------------|-------------------------|------------------------------------|
| System Variable | Name | <code>character_set_results</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

The character set used for returning query results such as result sets or error messages to the client.

- `character_set_server`

| | | |
|----------------------------|-------------------------------------|-----------------------------------|
| Command-Line Format | <code>--character-set-server</code> | |
| System Variable | Name | <code>character_set_server</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

| | | |
|--|----------------|---------------------|
| | Default | <code>latin1</code> |
|--|----------------|---------------------|

The server's default character set.

- `character_set_system`

| | | |
|-------------------------|-------------------------|-----------------------------------|
| System Variable | Name | <code>character_set_system</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |
| | Default | <code>utf8</code> |

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir`

| | | |
|----------------------------|--|---------------------------------|
| Command-Line Format | <code>--character-sets-dir=dir_name</code> | |
| System Variable | Name | <code>character_sets_dir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The directory where character sets are installed.

- `collation_connection`

| | | |
|-------------------------|-------------------------|-----------------------------------|
| System Variable | Name | <code>collation_connection</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

The collation of the connection character set.

- `collation_database`

| | | |
|-------------------------|--|---------------------------------|
| System Variable | Name | <code>collation_database</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Footnote | This option is dynamic, but only the server should set this information. You should not set the value of this variable manually. | |
| Permitted Values | Type | string |

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

- `collation_server`

| | | |
|----------------------------|---------------------------------|--------------------------------|
| Command-Line Format | <code>--collation-server</code> | |
| System Variable | Name | <code>collation_server</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>latin1_swedish_ci</code> |

The server's default collation.

- `completion_type`

| | | |
|----------------------------|----------------------------------|------------------------------|
| Command-Line Format | <code>--completion_type=#</code> | |
| System Variable | Name | <code>completion_type</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>NO_CHAIN</code> |
| | Valid Values | <code>NO_CHAIN</code> |
| | | <code>CHAIN</code> |
| | | <code>RELEASE</code> |
| | | <code>0</code> |
| | | <code>1</code> |
| | | <code>2</code> |

The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

| Value | Description |
|------------------------------|--|
| <code>NO_CHAIN</code> (or 0) | <code>COMMIT</code> and <code>ROLLBACK</code> are unaffected. This is the default value. |
| <code>CHAIN</code> (or 1) | <code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT AND CHAIN</code> and <code>ROLLBACK AND CHAIN</code> , respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.) |
| <code>RELEASE</code> (or 2) | <code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT RELEASE</code> and <code>ROLLBACK RELEASE</code> , respectively. (The server disconnects after terminating the transaction.) |

`completion_type` affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements listed in [Section 13.3.3, “Statements That Cause an Implicit Commit”](#). It also does not apply for `XA COMMIT`, `XA ROLLBACK`, or when `autocommit=1`.

- `concurrent_insert`

| | | |
|----------------------------|--------------------------------------|--------------------------------|
| Command-Line Format | <code>--concurrent_insert[=#]</code> | |
| System Variable | Name | <code>concurrent_insert</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>AUTO</code> |
| | Valid Values | <code>NEVER</code> |
| | | <code>AUTO</code> |
| | | <code>ALWAYS</code> |
| | | 0 |
| | | 1 |
| | | 2 |

If `AUTO` (the default), MySQL permits `INSERT` and `SELECT` statements to run concurrently for `MyISAM` tables that have no free blocks in the middle of the data file. If you start `mysqld` with `--skip-new`, this variable is set to `NEVER`.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

| Value | Description |
|----------------------------|---|
| <code>NEVER</code> (or 0) | Disables concurrent inserts |
| <code>AUTO</code> (or 1) | (Default) Enables concurrent insert for <code>MyISAM</code> tables that do not have holes |
| <code>ALWAYS</code> (or 2) | Enables concurrent inserts for all <code>MyISAM</code> tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole. |

See also [Section 8.11.3, “Concurrent Inserts”](#).

- `connect_timeout`

| | | |
|----------------------------|----------------------------------|------------------------------|
| Command-Line Format | <code>--connect_timeout=#</code> | |
| System Variable | Name | <code>connect_timeout</code> |
| | Variable Scope | Global |

| | | |
|-------------------------|-------------------------|----------|
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 10 |
| | Min Value | 2 |
| | Max Value | 31536000 |

The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`. The default value is 10 seconds.

Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form `Lost connection to MySQL server at 'XXX', system error: errno`.

- `core_file`

| | | |
|-------------------------|-------------------------|------------------------|
| Introduced | 5.6.2 | |
| System Variable | Name | <code>core_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | boolean |
| | Default | OFF |

Whether to write a core file if the server crashes. This variable is set by the `--core-file` option. It was added in MySQL 5.6.2.

- `datadir`

| | | |
|----------------------------|---------------------------------|----------------------|
| Command-Line Format | <code>--datadir=dir_name</code> | |
| System Variable | Name | <code>datadir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The MySQL data directory. This variable can be set with the `--datadir` option.

- `date_format`

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- `datetime_format`

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- `debug`

| | | |
|-----------------------------------|--------------------------------------|---|
| Command-Line Format | <code>--debug[=debug_options]</code> | |
| System Variable | Name | <code>debug</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (Unix) | Type | string |
| | Default | <code>d:t:i:o,/tmp/mysqlld.trace</code> |
| Permitted Values (Windows) | Type | string |
| | Default | <code>d:t:i:0,\mysqlld.trace</code> |

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime; the `SUPER` privilege is required, even for the session value.

Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| P:T     |
+-----+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+
```

For more information, see [Section 24.5.3, “The DBUG Package”](#).

- `debug_sync`

| | | |
|------------------------|-------------------------|-------------------------|
| System Variable | Name | <code>debug_sync</code> |
| | Variable Scope | Session |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|-------------|--------|
| Permitted Values | Type | string |
|-------------------------|-------------|--------|

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` CMake option (see [Section 2.9.4, “MySQL Source-Configuration Options”](#)). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where *N* is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, *N* becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set by users that have the `SUPER` privilege to control synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `default_storage_engine`

| | | |
|----------------------------|--|-------------------------------------|
| Command-Line Format | <code>--default-storage-engine=name</code> | |
| System Variable | Name | <code>default_storage_engine</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>InnoDB</code> |

The default storage engine. As of MySQL 5.6.3, this variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

`default_storage_engine` should be used in preference to `storage_engine`, which is deprecated.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `default_tmp_storage_engine`

| | | |
|----------------------------|--|---|
| Introduced | 5.6.3 | |
| Command-Line Format | <code>--default_tmp_storage_engine=name</code> | |
| System Variable | Name | <code>default_tmp_storage_engine</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |

| | | |
|--|----------------|--------|
| | Default | InnoDB |
|--|----------------|--------|

The default storage engine for [TEMPORARY](#) tables (created with [CREATE TEMPORARY TABLE](#)). To set the storage engine for permanent tables, set the [default_storage_engine](#) system variable.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and [TEMPORARY](#) tables to a different engine or the server will not start.

[default_tmp_storage_engine](#) was added in MySQL 5.6.3.

- [default_week_format](#)

| | | |
|----------------------------|---|-------------------------------------|
| Command-Line Format | --default_week_format=# | |
| System Variable | Name | default_week_format |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 7 |

The default mode value to use for the [WEEK\(\)](#) function. See [Section 12.7, “Date and Time Functions”](#).

- [delay_key_write](#)

| | | |
|----------------------------|--|---------------------------------|
| Command-Line Format | --delay-key-write[=name] | |
| System Variable | Name | delay_key_write |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | ON |
| | Valid Values | ON |
| | | OFF |
| | | ALL |

This option applies only to [MyISAM](#) tables. It can have one of the following values to affect handling of the [DELAY_KEY_WRITE](#) table option that can be used in [CREATE TABLE](#) statements.

| Option | Description |
|---------------------|--|
| OFF | DELAY_KEY_WRITE is ignored. |
| ON | MySQL honors any DELAY_KEY_WRITE option specified in CREATE TABLE statements. This is the default value. |

| Option | Description |
|---------------------|--|
| ALL | All new opened tables are treated as if they were created with the DELAY_KEY_WRITE option enabled. |

If [DELAY_KEY_WRITE](#) is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all [MyISAM](#) tables by starting the server with the [--myisam-recover-options](#) option (for example, [--myisam-recover-options=BACKUP,FORCE](#)). See [Section 5.1.4](#), “[Server Command Options](#)”, and [Section 15.2.1](#), “[MyISAM Startup Options](#)”.

Warning

If you enable external locking with [--external-locking](#), there is no protection against index corruption for tables that use delayed key writes.

- [delayed_insert_limit](#)

| | | |
|--|--|--------------------------------------|
| Deprecated | 5.6.7 | |
| Command-Line Format | --delayed_insert_limit=# | |
| System Variable | Name | delayed_insert_limit |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 100 |
| | Min Value | 1 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 100 |
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |

After inserting [delayed_insert_limit](#) delayed rows into a nontransactional table, the [INSERT DELAYED](#) handler thread checks whether there are any [SELECT](#) statements pending. If so, it permits them to execute before continuing to insert delayed rows.

As of MySQL 5.6.7, this system variable is deprecated (because [DELAYED](#) inserts are deprecated), and will be removed in a future release.

- [delayed_insert_timeout](#)

| | | |
|----------------------------|--|--|
| Deprecated | 5.6.7 | |
| Command-Line Format | --delayed_insert_timeout=# | |
| System Variable | Name | delayed_insert_timeout |

| | | |
|-------------------------|-------------------------|---------|
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 300 |

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `delayed_queue_size`

| | | |
|--|-------------------------------------|---------------------------------|
| Deprecated | 5.6.7 | |
| Command-Line Format | <code>--delayed_queue_size=#</code> | |
| System Variable | Name | <code>delayed_queue_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 1000 |
| | Min Value | 1 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 1000 |
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements for nontransactional tables. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `disconnect_on_expired_password`

| | | |
|----------------------------|---|---|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--disconnect_on_expired_password[=#]</code> | |
| System Variable | Name | <code>disconnect_on_expired_password</code> |

| | | |
|-------------------------|-------------------------|---------|
| | Variable Scope | Session |
| | Dynamic Variable | No |
| Permitted Values | Type | boolean |
| | Default | ON |

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expires passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.
- If the client does not indicate that it can handle expires passwords, the server handles the client according to the value of `disconnect_on_expired_password`:
 - If `disconnect_on_expired_password` is enabled, the server disconnects the client.
 - If `disconnect_on_expired_password` is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see [Section 6.3.6, “Password Expiration and Sandbox Mode”](#).

This variable was added in MySQL 5.6.10.

- `div_precision_increment`

| | | |
|----------------------------|--|--------------------------------------|
| Command-Line Format | <code>--div_precision_increment=#</code> | |
| System Variable | Name | <code>div_precision_increment</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 4 |
| | Min Value | 0 |
| | Max Value | 30 |

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7   |
+-----+
| 0.1429 |
+-----+
mysql> SET div_precision_increment = 12;
```

```
mysql> SELECT 1/7;
+-----+
| 1/7   |
+-----+
| 0.142857142857 |
+-----+
```

- [engine_condition_pushdown](#)

| | | |
|----------------------------|--|---|
| Deprecated | 5.5.3, by optimizer_switch | |
| Removed | 5.6.1 | |
| Command-Line Format | <code>--engine-condition-pushdown</code> | |
| System Variable | Name | engine_condition_pushdown |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | ON |

This variable was removed in MySQL 5.6.1. Use the [engine_condition_pushdown](#) flag of the [optimizer_switch](#) variable instead. See [Section 8.9.2, “Controlling Switchable Optimizations”](#).

- [end_markers_in_json](#)

| | | |
|-------------------------|-------------------------|-------------------------------------|
| Introduced | 5.6.5 | |
| System Variable | Name | end_markers_in_json |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | OFF |

Whether optimizer JSON output should add end markers. See [MySQL Internals: The end_markers_in_json System Variable](#).

- [eq_range_index_dive_limit](#)

| | | |
|-------------------------|-------------------------|---|
| Introduced | 5.6.5 | |
| System Variable | Name | eq_range_index_dive_limit |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 10 |
| | Min Value | 0 |

| | | |
|--|------------------|------------|
| | Max Value | 4294967295 |
|--|------------------|------------|

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up *col_name* values:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains *N* equality ranges. The optimizer can make row estimates using index dives or index statistics. If *eq_range_index_dive_limit* is greater than 0, the optimizer uses existing index statistics instead of index dives if there are *eq_range_index_dive_limit* or more equality ranges. Thus, to permit use of index dives for up to *N* equality ranges, set *eq_range_index_dive_limit* to *N* + 1. To disable use of index statistics and always use index dives regardless of *N*, set *eq_range_index_dive_limit* to 0.

For more information, see [Equality Range Optimization of Many-Valued Comparisons](#).

This variable was added in MySQL 5.6.5. Before 5.6.5, the optimizer makes row estimates using index dives in all cases.

To update table index statistics for best estimates, use [ANALYZE TABLE](#).

- *error_count*

The number of errors that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.5.18, “SHOW ERRORS Syntax”](#).

- *event_scheduler*

| | | |
|----------------------------|--|------------------------|
| Command-Line Format | <code>--event-scheduler[=value]</code> | |
| System Variable | Name | <i>event_scheduler</i> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | OFF |
| | Valid Values | ON |
| | | OFF |
| | | DISABLED |

This variable indicates the status of the Event Scheduler; possible values are *ON*, *OFF*, and *DISABLED*, with the default being *OFF*. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in the [Overview section of the Events chapter](#).

- *expire_logs_days*

| | |
|----------------------------|-----------------------------------|
| Command-Line Format | <code>--expire_logs_days=#</code> |
|----------------------------|-----------------------------------|

| | | |
|-------------------------|-------------------------|-------------------------------|
| System Variable | Name | <code>expire_logs_days</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 99 |

The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 5.4, “MySQL Server Logs”](#).

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

- `explicit_defaults_for_timestamp`

| | | |
|---------------------|--|--|
| Introduced | 5.6.6 | |
| Deprecated | 5.6.6 | |
| Command-Line Format | <code>--explicit_defaults_for_timestamp=#</code> | |
| System Variable | Name | <code>explicit_defaults_for_timestamp</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types:

- `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are assigned the `NOT NULL` attribute. (Columns of other data types, if not explicitly declared as `NOT NULL`, permit `NULL` values.) Setting such a column to `NULL` sets it to the current timestamp.
- The first `TIMESTAMP` column in a table, if not declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` clause, is automatically assigned the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.
- `TIMESTAMP` columns following the first one, if not declared with the `NULL` attribute or an explicit `DEFAULT` clause, are automatically assigned `DEFAULT '0000-00-00 00:00:00'` (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Those nonstandard behaviors remain the default for `TIMESTAMP` but as of MySQL 5.6.6 are deprecated and this warning appears at startup:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to turn off the nonstandard behaviors, enable the `explicit_defaults_for_timestamp` system variable at server startup. With this variable enabled, the server handles `TIMESTAMP` as follows instead:

- `TIMESTAMP` columns not explicitly declared as `NOT NULL` permit `NULL` values. Setting such a column to `NULL` sets it to `NULL`, not the current timestamp.
- No `TIMESTAMP` column is assigned the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes automatically. Those attributes must be explicitly specified.
- `TIMESTAMP` columns declared as `NOT NULL` and without an explicit `DEFAULT` clause are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is assigned the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.

Note

`explicit_defaults_for_timestamp` is itself deprecated because its only purpose is to permit control over now-deprecated `TIMESTAMP` behaviors that will be removed in a future MySQL release. When that removal occurs, `explicit_defaults_for_timestamp` will have no purpose and will be removed as well.

This variable was added in MySQL 5.6.6.

- `external_user`

| | | |
|-------------------------|-------------------------|----------------------------|
| System Variable | Name | <code>external_user</code> |
| | Variable Scope | Session |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See [Section 6.3.8, “Proxy Users”](#).

- `flush`

| | | |
|----------------------------|-------------------------|--------------------|
| Command-Line Format | <code>--flush</code> | |
| System Variable | Name | <code>flush</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|----------------|---------|
| Permitted Values | Type | boolean |
| | Default | OFF |

If **ON**, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#). This variable is set to **ON** if you start `mysqld` with the `--flush` option.

- `flush_time`

| | | |
|--|-----------------------------|-------------------------|
| Command-Line Format | <code>--flush_time=#</code> | |
| System Variable | Name | <code>flush_time</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| Permitted Values (Windows, <= 5.6.5) | Type | integer |
| | Default | 1800 |
| | Min Value | 0 |
| Permitted Values (Windows, >= 5.6.6) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources. The default is 0 except that before MySQL 5.6.6, the default is 1800 on Windows.

- `foreign_key_checks`

If set to 1 (the default), foreign key constraints for **InnoDB** tables are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an `ALTER TABLE` operation returns an error if a foreign key definition is incorrectly formed. For more information, see [Section 13.1.17.5, “Using FOREIGN KEY Constraints”](#).

Beginning with MySQL NDB Cluster 7.3.2, setting this variable has the same effect on **NDB** tables as it does for **InnoDB** tables—previously, the setting was ignored and all such checks were enforced (Bug #14095855). Typically you leave this setting enabled during normal operation, to enforce **referential integrity**.

Disabling foreign key checking can be useful for reloading such tables in an order different from that required by their parent/child relationships. See [Section 14.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

Note

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks=0` will not be verified for consistency.

Warning

With `foreign_key_checks=0`, dropping an index required by a foreign key constraint places the table in an inconsistent state and causes the foreign key check that occurs at table load to fail. To avoid this problem, remove the foreign key constraint before dropping the index (Bug #70260).

- `ft_boolean_syntax`

| | | |
|----------------------------|---------------------------------------|---|
| Command-Line Format | <code>--ft_boolean_syntax=name</code> | |
| System Variable | Name | <code>ft_boolean_syntax</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>+ -><() ~* : " "& </code> |

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See [Section 12.9.2, “Boolean Full-Text Searches”](#).

The default variable value is `'+ -><() ~* : " "& |'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to `:`, `&`, and `|`) are reserved for future extensions.
- `ft_max_word_len`

| | | |
|----------------------------|----------------------------------|------------------------------|
| Command-Line Format | <code>--ft_max_word_len=#</code> | |
| System Variable | Name | <code>ft_max_word_len</code> |
| | Variable Scope | Global |

| | | |
|-------------------------|-------------------------|---------|
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Min Value | 10 |

The maximum length of the word to be included in a [MyISAM FULLTEXT](#) index.

**Note**

[FULLTEXT](#) indexes on [MyISAM](#) tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- [ft_min_word_len](#)

| | | |
|----------------------------|----------------------------------|---------------------------------|
| Command-Line Format | <code>--ft_min_word_len=#</code> | |
| System Variable | Name | ft_min_word_len |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 4 |
| | Min Value | 1 |

The minimum length of the word to be included in a [MyISAM FULLTEXT](#) index.

**Note**

[FULLTEXT](#) indexes on [MyISAM](#) tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- [ft_query_expansion_limit](#)

| | | |
|----------------------------|---|--|
| Command-Line Format | <code>--ft_query_expansion_limit=#</code> | |
| System Variable | Name | ft_query_expansion_limit |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 20 |
| | Min Value | 0 |
| | Max Value | 1000 |

The number of top matches to use for full-text searches performed using [WITH QUERY EXPANSION](#).

- `ft_stopword_file`

| | | |
|----------------------------|---|-------------------------------|
| Command-Line Format | <code>--ft_stopword_file=file_name</code> | |
| System Variable | Name | <code>ft_stopword_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The file from which to read the list of stopwords for full-text searches on [MyISAM](#) tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string ('') disables stopword filtering. See also [Section 12.9.4, “Full-Text Stopwords”](#).

Note

[FULLTEXT](#) indexes on [MyISAM](#) tables must be rebuilt after changing this variable or the contents of the stopword file. Use `REPAIR TABLE tbl_name QUICK`.

- `general_log`

| | | |
|----------------------------|----------------------------|--------------------------|
| Command-Line Format | <code>--general-log</code> | |
| System Variable | Name | <code>general_log</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--general_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- `general_log_file`

| | | |
|----------------------------|---|-------------------------------|
| Command-Line Format | <code>--general-log-file=file_name</code> | |
| System Variable | Name | <code>general_log_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | file name |
| | Default | <code>host_name.log</code> |

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file` option.

- `group_concat_max_len`

| | | |
|--|---------------------------------------|-----------------------------------|
| Command-Line Format | <code>--group_concat_max_len=#</code> | |
| System Variable | Name | <code>group_concat_max_len</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 1024 |
| | Min Value | 4 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 1024 |
| | Min Value | 4 |
| | Max Value | 18446744073709551615 |

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- `have_compress`

`YES` if the `zlib` compression library is available to the server, `NO` if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- `have_crypt`

`YES` if the `crypt()` system call is available to the server, `NO` if not. If not, the `ENCRYPT()` function cannot be used.

- `have_csv`

`YES` if `mysqld` supports `CSV` tables, `NO` if not.

This variable was removed in MySQL 5.6.1. Use `SHOW ENGINES` instead.

- `have_dynamic_loading`

`YES` if `mysqld` supports dynamic loading of plugins, `NO` if not. If the value is `NO`, you cannot use options such as `--plugin-load` to load plugins at server startup, or the `INSTALL PLUGIN` statement to load plugins at runtime.

- `have_geometry`

`YES` if the server supports spatial data types, `NO` if not.

- `have_innodb`

`YES` if `mysqld` supports InnoDB tables. `DISABLED` if `--skip-innodb` is used.

This variable was removed in MySQL 5.6.1. Use `SHOW ENGINES` instead.

- `have_openssl`

This variable is an alias for `have_ssl`.

- `have_partitioning`

`YES` if `mysqld` supports partitioning.

This variable was removed in MySQL 5.6.1. Use `SHOW PLUGINS` instead. For more information, see [Chapter 19, Partitioning](#).

- `have_profiling`

`YES` if statement profiling capability is present, `NO` if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

This variable is deprecated in MySQL 5.6.8 and will be removed in a future MySQL release.

- `have_query_cache`

`YES` if `mysqld` supports the query cache, `NO` if not.

- `have_rtree_keys`

`YES` if `RTREE` indexes are available, `NO` if not. (These are used for spatial indexes in `MyISAM` tables.)

- `have_ssl`

`YES` if `mysqld` supports SSL connections, `NO` if not. `DISABLED` indicates that the server was compiled with SSL support, but was not started with the appropriate `--ssl-xxx` options. For more information, see [Section 6.4.2, “Building MySQL with Support for Secure Connections”](#).

- `have_symlink`

`YES` if symbolic link support is enabled, `NO` if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options, and on Windows for support of data directory symlinks. If the server is started with the `--skip-symbolic-links` option, the value is `DISABLED`.

- `host_cache_size`

| | | |
|---------------------------------------|-------------------------|------------------------------|
| Introduced | 5.6.5 | |
| System Variable | Name | <code>host_cache_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.7) | Type | integer |
| | Default | 128 604 |

| | | |
|---------------------------------------|------------------|----------------|
| Permitted Values (>= 5.6.8) | Min Value | 0 |
| | Max Value | 65536 |
| | Type | integer |
| | Default | -1 (autosized) |
| | Min Value | 0 |
| | Max Value | 65536 |
| | Type | integer |
| | Default | -1 (autosized) |

The size of the internal host cache (see [Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”](#)). Setting the size to 0 disables the host cache. Changing the cache size at runtime implicitly causes a `FLUSH HOSTS` operation to clear the host cache and truncate the `host_cache` table.

The default value is 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000. Before MySQL 5.6.8, the default is 128.

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache`, that does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

This variable was added in MySQL 5.6.5.

- `hostname`

| | | |
|-------------------------|-------------------------|-----------------------|
| System Variable | Name | <code>hostname</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The server sets this variable to the server host name at startup.

- `identity`

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- `ignore_db_dirs`

| | | |
|------------------------|-----------------------|-----------------------------|
| Introduced | 5.6.3 | |
| System Variable | Name | <code>ignore_db_dirs</code> |
| | Variable Scope | Global |
| | | 605 |

| | | |
|-------------------------|-------------------------|--------|
| | Dynamic Variable | No |
| Permitted Values | Type | string |

A comma-separated list of names that are not considered as database directories in the data directory. The value is set from any instances of `--ignore-db-dir` given at server startup.

- `init_connect`

| | | |
|----------------------------|----------------------------------|---------------------------|
| Command-Line Format | <code>--init-connect=name</code> | |
| System Variable | Name | <code>init_connect</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters. For example, each client session begins by default with autocommit mode enabled. For older servers (before MySQL 5.5.8), there is no global `autocommit` system variable to specify that autocommit should be disabled by default, but as a workaround `init_connect` can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The `init_connect` variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

For users that have the `SUPER` privilege, the content of `init_connect` is not executed. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

The server discards any result sets produced by statements in the value of `init_connect`.

- `init_file`

| | | |
|----------------------------|------------------------------------|------------------------|
| Command-Line Format | <code>--init-file=file_name</code> | |
| System Variable | Name | <code>init_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. For more information, see the description of `--init-file`.

- `innodb_xxx`

InnoDB system variables are listed in [Section 14.14, “InnoDB Startup Options and System Variables”](#). These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `interactive_timeout`

| | | |
|----------------------------|--------------------------------------|----------------------------------|
| Command-Line Format | <code>--interactive_timeout=#</code> | |
| System Variable | Name | <code>interactive_timeout</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 28800 |
| | Min Value | 1 |

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `join_buffer_size`

| | | |
|--|-----------------------------------|-------------------------------|
| Command-Line Format | <code>--join_buffer_size=#</code> | |
| System Variable | Name | <code>join_buffer_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (Windows, <= 5.6.5) | Type | integer |
| | Default | 131072 |
| | Min Value | 128 |
| | Max Value | 4294967295 |
| Permitted Values (Windows, >= 5.6.6) | Type | integer |

| | | |
|---|------------------|----------------------|
| | Default | 262144 |
| | Min Value | 128 |
| | Max Value | 4294967295 |
| Permitted Values (Other, 32-bit platforms, <= 5.6.5) | Type | integer |
| | Default | 131072 |
| | Min Value | 128 |
| | Max Value | 4294967295 |
| Permitted Values (Other, 32-bit platforms, >= 5.6.6) | Type | integer |
| | Default | 262144 |
| | Min Value | 128 |
| | Max Value | 4294967295 |
| Permitted Values (Other, 64-bit platforms, <= 5.6.5) | Type | integer |
| | Default | 131072 |
| | Min Value | 128 |
| | Max Value | 18446744073709547520 |
| Permitted Values (Other, 64-bit platforms, >= 5.6.6) | Type | integer |
| | Default | 262144 |
| | Min Value | 128 |
| | Max Value | 18446744073709547520 |

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

Unless Batched Key Access (BKA) is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access will be to the right hand table of a join operation, which can significantly improve performance.

The default is 256KB as of MySQL 5.6.6, 128KB before that. The maximum permissible setting for `join_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

For additional information about join buffering, see [Section 8.2.1.6, “Nested-Loop Join Algorithms”](#). For information about Batched Key Access, see [Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”](#).

- `keep_files_on_create`

| | | |
|----------------------------|---------------------------------------|-----------------------------------|
| Command-Line Format | <code>--keep_files_on_create=#</code> | |
| System Variable | Name | <code>keep_files_on_create</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` will not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

- `key_buffer_size`

| | | |
|--|----------------------------------|------------------------------|
| Command-Line Format | <code>--key_buffer_size=#</code> | |
| System Variable | Name | <code>key_buffer_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | <code>8388608</code> |
| | Min Value | <code>8</code> |
| | Max Value | <code>4294967295</code> |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | <code>8388608</code> |
| | Min Value | <code>8</code> |

| | | |
|--|------------------|----------------------|
| | Max Value | OS_PER_PROCESS_LIMIT |
|--|------------------|----------------------|

Index blocks for [MyISAM](#) tables are buffered and are shared by all threads. [key_buffer_size](#) is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for [key_buffer_size](#) is 4GB–1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the [MyISAM](#) storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to [MyISAM](#).

For even more speed when writing many rows at the same time, use [LOCK TABLES](#). See [Section 8.2.4.1, “Optimizing INSERT Statements”](#).

You can check the performance of the key buffer by issuing a [SHOW STATUS](#) statement and examining the [Key_read_requests](#), [Key_reads](#), [Key_write_requests](#), and [Key_writes](#) status variables. (See [Section 13.7.5, “SHOW Syntax”](#).) The [Key_reads/Key_read_requests](#) ratio should normally be less than 0.01. The [Key_writes/Key_write_requests](#) ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the [DELAY_KEY_WRITE](#) table option.

The fraction of the key buffer in use can be determined using [key_buffer_size](#) in conjunction with the [Key_blocks_unused](#) status variable and the buffer block size, which is available from the [key_cache_block_size](#) system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple [MyISAM](#) key caches. The size limit of 4GB applies to each cache individually, not as a group. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- [key_cache_age_threshold](#)

| | | |
|----------------------------|--|---|
| Command-Line Format | <code>--key_cache_age_threshold=#</code> | |
| System Variable | Name | key_cache_age_threshold |
| | Variable Scope | Global |

| | | |
|--|-------------------------|----------------------|
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 300 |
| | Min Value | 100 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 300 |
| | Min Value | 100 |
| | Max Value | 18446744073709551615 |

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- `key_cache_block_size`

| | | |
|----------------------------|---------------------------------------|-----------------------------------|
| Command-Line Format | <code>--key_cache_block_size=#</code> | |
| System Variable | Name | <code>key_cache_block_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 1024 |
| | Min Value | 512 |
| | Max Value | 16384 |

The size in bytes of blocks in the key cache. The default value is 1024. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- `key_cache_division_limit`

| | | |
|----------------------------|---|---------------------------------------|
| Command-Line Format | <code>--key_cache_division_limit=#</code> | |
| System Variable | Name | <code>key_cache_division_limit</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |

| | | |
|--|------------------|-----|
| | Default | 100 |
| | Min Value | 1 |
| | Max Value | 100 |

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See [Section 8.10.2, “The MyISAM Key Cache”](#).

- `large_files_support`

| | | |
|------------------------|-------------------------|----------------------------------|
| System Variable | Name | <code>large_files_support</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |

Whether `mysqld` was compiled with options for large file support.

- `large_pages`

| | | |
|---------------------------------|----------------------------|--------------------------|
| Command-Line Format | <code>--large-pages</code> | |
| System Variable | Name | <code>large_pages</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Platform Specific | Linux | |
| Permitted Values (Linux) | Type | boolean |
| | Default | <code>FALSE</code> |

Whether large page support is enabled (via the `--large-pages` option). See [Section 8.12.4.2, “Enabling Large Page Support”](#).

- `large_page_size`

| | | |
|---------------------------------|-------------------------|------------------------------|
| System Variable | Name | <code>large_page_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (Linux) | Type | integer |
| | Default | 0 |

If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 8.12.4.2, “Enabling Large Page Support”](#).

- `last_insert_id`

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_messages`

| | | |
|----------------------------|---------------------------------|--------------------------|
| Command-Line Format | <code>--lc-messages=name</code> | |
| System Variable | Name | <code>lc_messages</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |
| | Default | <code>en_US</code> |

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `lc_messages_dir`

| | | |
|----------------------------|---|------------------------------|
| Command-Line Format | <code>--lc-messages-dir=dir_name</code> | |
| System Variable | Name | <code>lc_messages_dir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `lc_time_names`

| | | |
|-------------------------|-------------------------|----------------------------|
| System Variable | Name | <code>lc_time_names</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting. For further information, see [Section 10.7, “MySQL Server Locale Support”](#).

- `license`

| | | |
|-------------------------|-------------------------|----------------------|
| System Variable | Name | <code>license</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |
| | Default | <code>GPL</code> |

The type of license the server has.

- `local_infile`

| | | |
|-------------------------|-------------------------|---------------------------|
| System Variable | Name | <code>local_infile</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>true</code> |

Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. If this variable is disabled, clients cannot use `LOCAL` in `LOAD DATA` statements. While the default for this variable is `true`, whether `LOAD DATA INFILE LOCAL` is actually permitted depends on how MySQL was compiled, as well as a number of settings on both the server and the client; see [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#), for details.

- `lock_wait_timeout`

| | | |
|----------------------------|------------------------------------|--------------------------------|
| Command-Line Format | <code>--lock_wait_timeout=#</code> | |
| System Variable | Name | <code>lock_wait_timeout</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | <code>31536000</code> |
| | Min Value | <code>1</code> |
| | Max Value | <code>31536000</code> |

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as `LOCK TABLES`, `FLUSH TABLES WITH READ LOCK`, and `HANDLER` statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by `GRANT` or `REVOKE` statements or table logging statements. The timeout does apply to system tables accessed directly, such as with `SELECT` or `UPDATE`.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the `lock_wait_timeout` value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

`lock_wait_timeout` does not apply to delayed inserts, which always execute with a timeout of 1 year. This is done to avoid unnecessary timeouts because a session that issues a delayed insert receives no notification of delayed insert timeouts.

- `locked_in_memory`

| | | |
|------------------------|-------------------------|-------------------------------|
| System Variable | Name | <code>locked_in_memory</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |

Whether `mysqld` was locked in memory with `--memlock`.

- `log`

| | | |
|----------------------------|-------------------------------------|------------------|
| Deprecated | 5.1.29, by <code>general-log</code> | |
| Removed | 5.6.1 | |
| Command-Line Format | <code>--log[=file_name]</code> | |
| System Variable | Name | <code>log</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | file name |

This variable removed in MySQL 5.6.1. Use `general_log` instead.

- `log_bin_trust_function_creators`

| | | |
|----------------------------|--|--|
| Command-Line Format | <code>--log-bin-trust-function-creators</code> | |
| System Variable | Name | <code>log_bin_trust_function_creators</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set

to 0 (the default), users are not permitted to create or alter stored functions unless they have the [SUPER](#) privilege in addition to the [CREATE ROUTINE](#) or [ALTER ROUTINE](#) privilege. A setting of 0 also enforces the restriction that a function must be declared with the [DETERMINISTIC](#) characteristic, or with the [READS SQL DATA](#) or [NO SQL](#) characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See [Section 20.7](#), “Binary Logging of Stored Programs”.

- [log_error](#)

| | | |
|----------------------------|--------------------------------------|---------------------------|
| Command-Line Format | <code>--log-error[=file_name]</code> | |
| System Variable | Name | log_error |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The location of the error log, or empty if the server is writing error message to the standard error output. See [Section 5.4.2](#), “The Error Log”.

- [log_output](#)

| | | |
|----------------------------|--------------------------------|----------------------------|
| Command-Line Format | <code>--log-output=name</code> | |
| System Variable | Name | log_output |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | set |
| | Default | FILE |
| | Valid Values | TABLE |
| | | FILE |
| | | NONE |

The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words [TABLE](#) (log to tables), [FILE](#) (log to files), or [NONE](#) (do not log to tables or files). The default value is [FILE](#). [NONE](#), if present, takes precedence over any other specifiers. If the value is [NONE](#) log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of [log_output](#) is not [NONE](#). For more information, see [Section 5.4.1](#), “Selecting General Query and Slow Query Log Output Destinations”.

- [log_queries_not_using_indexes](#)

| | | |
|----------------------------|--|---|
| Command-Line Format | <code>--log-queries-not-using-indexes</code> | |
| System Variable | Name | log_queries_not_using_indexes |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|----------------|---------|
| Permitted Values | Type | boolean |
| | Default | OFF |

Whether queries that do not use indexes are logged to the slow query log. See [Section 5.4.5, “The Slow Query Log”](#).

- `log_slow_admin_statements`

| | | |
|-------------------------|-------------------------|--|
| Introduced | 5.6.11 | |
| System Variable | Name | <code>log_slow_admin_statements</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | OFF |

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

This variable was added in MySQL 5.6.11 as a replacement for the `--log-slow-admin-statements` option. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- `log_slow_queries`

| | | |
|----------------------------|--|-------------------------------|
| Deprecated | 5.1.29, by <code>slow-query-log</code> | |
| Removed | 5.6.1 | |
| Command-Line Format | <code>--log-slow-queries[=name]</code> | |
| System Variable | Name | <code>log_slow_queries</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |

This variable was removed in MySQL 5.6.1. Use `slow_query_log` instead.

- `log_throttle_queries_not_using_indexes`

| | | |
|------------------------|-------------------------|---|
| Introduced | 5.6.5 | |
| System Variable | Name | <code>log_throttle_queries_not_using_indexes</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|----------------|---------|
| Permitted Values | Type | integer |
| | Default | 0 |

If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see [Section 5.4.5, “The Slow Query Log”](#).

This variable was added in MySQL 5.6.5.

- `log_warnings`

| | | |
|--|---------------------------------|---------------------------|
| Command-Line Format | <code>--log-warnings[=#]</code> | |
| System Variable (<= 5.6.3) | Name | <code>log_warnings</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| System Variable (>= 5.6.4) | Name | <code>log_warnings</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 1 |
| | Min Value | 0 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 1 |
| | Min Value | 0 |
| | Max Value | 18446744073709551615 |

Whether to produce additional warning messages to the error log. This variable is enabled (1) by default and can be disabled by setting it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1.

- `long_query_time`

| | | |
|----------------------------|----------------------------------|------------------------------|
| Command-Line Format | <code>--long_query_time=#</code> | |
| System Variable | Name | <code>long_query_time</code> |
| | Variable Scope | Global, Session |

| | | |
|-------------------------|-------------------------|---------|
| | Dynamic Variable | Yes |
| Permitted Values | Type | numeric |
| | Default | 10 |
| | Min Value | 0 |

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored. See [Section 5.4.5, “The Slow Query Log”](#).

- `low_priority_updates`

| | | |
|----------------------------|-------------------------------------|-----------------------------------|
| Command-Line Format | <code>--low-priority-updates</code> | |
| System Variable | Name | <code>low_priority_updates</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `lower_case_file_system`

| | | |
|-------------------------|-------------------------|-------------------------------------|
| System Variable | Name | <code>lower_case_file_system</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | boolean |

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case sensitive, `ON` means they are not case sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

| | | |
|----------------------------|---|-------------------------------------|
| Command-Line Format | <code>--lower_case_table_names[=#]</code> | |
| System Variable | Name | <code>lower_case_table_names</code> |

| | | |
|-------------------------|-------------------------|---------|
| Permitted Values | Variable Scope | Global |
| | Dynamic Variable | No |
| | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 2 |

If set to 0, table names are stored as specified and comparisons are case sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional information, see [Section 9.2.2, “Identifier Case Sensitivity”](#).

On Windows the default value is 1. On OS X, the default value is 2.

You should *not* set `lower_case_table_names` to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or OS X). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong `tbl_name` letter case. With `MyISAM`, accessing table names using different letter cases could cause index corruption.

As of MySQL 5.6.27, an error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

If you are using `InnoDB` tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable in MySQL 5.6 affects the behavior of replication filtering options with regard to case sensitivity. This is a change from previous versions of MySQL. (Bug #51639) See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

In previous versions of MySQL, using different settings for `lower_case_table_names` on replication masters and slaves could cause replication to fail when the slave used a case-sensitive file system. This issue is resolved in MySQL 5.6.1. For more information, see [Section 17.4.1.36, “Replication and Variables”](#).

- `max_allowed_packet`

| | | |
|---------------------------------------|-------------------------------------|---------------------------------|
| Command-Line Format | <code>--max_allowed_packet=#</code> | |
| System Variable | Name | <code>max_allowed_packet</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.5) | Type | integer |
| | Default | 1048576 |

| | | |
|------------------------------------|------------------|------------|
| Permitted Values (>= 5.6.6) | Min Value | 1024 |
| | Max Value | 1073741824 |
| | Type | integer |
| | Default | 4194304 |
| | Min Value | 1024 |
| | Max Value | 1073741824 |

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 4MB as of MySQL 5.6.6, 1MB before that.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server will not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

- `max_connect_errors`

| | | |
|--|-------------------------------------|---------------------------------|
| Command-Line Format | <code>--max_connect_errors=#</code> | |
| System Variable | Name | <code>max_connect_errors</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms, <= 5.6.5) | Type | integer |
| | Default | 10 |
| | Min Value | 1 |
| | Max Value | 4294967295 |

| | | |
|--|------------------|----------------------|
| Permitted Values (32-bit platforms, >= 5.6.6) | Type | integer |
| | Default | 100 |
| | Min Value | 1 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms, <= 5.6.5) | Type | integer |
| | Default | 10 |
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |
| Permitted Values (64-bit platforms, >= 5.6.6) | Type | integer |
| | Default | 100 |
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |

If more than this many successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. You can unblock blocked hosts by flushing the host cache. To do so, issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command. If a connection is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, flushing the host cache is the only way to unblock it. The default is 100 as of MySQL 5.6.6, 10 before that.

- `max_connections`

| | | |
|----------------------------|----------------------------------|------------------------------|
| Command-Line Format | <code>--max_connections=#</code> | |
| System Variable | Name | <code>max_connections</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 151 |
| | Min Value | 1 |
| | Max Value | 100000 |

The maximum permitted number of simultaneous client connections. By default, this is 151. See [Section B.5.2.7, “Too many connections”](#), for more information.

Increasing this value increases the number of file descriptors that `mysqld` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#), for comments on file descriptor limits.

Connections refused because the `max_connections` limit is reached increment the `Connection_errors_max_connections` status variable.

- `max_delayed_threads`

| | | |
|----------------------------|--------------------------------------|----------------------------------|
| Deprecated | 5.6.7 | |
| Command-Line Format | <code>--max_delayed_threads=#</code> | |
| System Variable | Name | <code>max_delayed_threads</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 20 |
| | Min Value | 0 |
| | Max Value | 16384 |

Do not start more than this number of threads to handle `INSERT DELAYED` statements for nontransactional tables. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute was not specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, this disables `DELAYED` entirely.

For the `SESSION` value of this variable, the only valid values are 0 or the `GLOBAL` value.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `max_digest_length`

| | | |
|----------------------------|------------------------------------|--------------------------------|
| Introduced | 5.6.24 | |
| Command-Line Format | <code>--max_digest_length=#</code> | |
| System Variable | Name | <code>max_digest_length</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 1024 |
| | Min Value | 0 |
| | Max Value | 1048576 |

The maximum number of bytes available for computing statement digests (see [Section 22.8](#), “Performance Schema Statement Digests”). Once this amount of space is used during digest computation for a statement, no further tokens from the parsed statement are collected or figure into the digest value. Statements that differ only after that many bytes of parsed statement tokens produce the same digest and are aggregated for digest statistics.

Decreasing the `max_digest_length` value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (`max_digest_length` bytes are allocated per session).

This variable was added in MySQL 5.6.24. Until 5.6.26, this variable applies to Performance Schema and to other server functions that use digests, such as MySQL Enterprise Firewall. As of 5.6.26, it no longer applies to Performance Schema; instead, use `performance_schema_max_digest_length`.

- `max_error_count`

| | | |
|----------------------------|----------------------------------|------------------------------|
| Command-Line Format | <code>--max_error_count=#</code> | |
| System Variable | Name | <code>max_error_count</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 64 |
| | Min Value | 0 |
| | Max Value | 65535 |

The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`.

- `max_heap_table_size`

| | | |
|--|--------------------------------------|----------------------------------|
| Command-Line Format | <code>--max_heap_table_size=#</code> | |
| System Variable | Name | <code>max_heap_table_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 16777216 |
| | Min Value | 16384 |
| | Max Value | 4294967295 |

| | | |
|--|------------------|---------------------|
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 16777216 |
| | Min Value | 16384 |
| | Max Value | 1844674407370954752 |

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

`max_heap_table_size` is not replicated. See [Section 17.4.1.22, “Replication and MEMORY Tables”](#), and [Section 17.4.1.36, “Replication and Variables”](#), for more information.

- `max_insert_delayed_threads`

| | | |
|-------------------------|-------------------------|---|
| Deprecated | 5.6.7 | |
| System Variable | Name | <code>max_insert_delayed_threads</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |

This variable is a synonym for `max_delayed_threads`.

As of MySQL 5.6.7, this system variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `max_join_size`

| | | |
|----------------------------|--------------------------------|----------------------------|
| Command-Line Format | <code>--max_join_size=#</code> | |
| System Variable | Name | <code>max_join_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 18446744073709551615 |
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

- `max_length_for_sort_data`

| | | |
|----------------------------|---|---------------------------------------|
| Command-Line Format | <code>--max_length_for_sort_data=#</code> | |
| System Variable | Name | <code>max_length_for_sort_data</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 1024 |
| | Min Value | 4 |
| | Max Value | 8388608 |

The cutoff on the size of index values that determines which `filesort` algorithm to use. See [Section 8.2.1.13, “ORDER BY Optimization”](#).

- `max_prepared_stmt_count`

| | | |
|----------------------------|--|--------------------------------------|
| Command-Line Format | <code>--max_prepared_stmt_count=#</code> | |
| System Variable | Name | <code>max_prepared_stmt_count</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 16382 |
| | Min Value | 0 |
| | Max Value | 1048576 |

This variable limits the total number of prepared statements in the server. (The sum of the number of prepared statements across all sessions.) It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of

statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- `max_relay_log_size`

| | | |
|----------------------------|-------------------------------------|---------------------------------|
| Command-Line Format | <code>--max_relay_log_size=#</code> | |
| System Variable | Name | <code>max_relay_log_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 1073741824 |

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See [Section 17.2.1, “Replication Implementation Details”](#).

- `max_seeks_for_key`

| | | |
|--|------------------------------------|--------------------------------|
| Command-Line Format | <code>--max_seeks_for_key=#</code> | |
| System Variable | Name | <code>max_seeks_for_key</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 4294967295 |
| | Min Value | 1 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 18446744073709551615 |
| | Min Value | 1 |

| | | |
|--|------------------|----------------------|
| | Max Value | 18446744073709551615 |
|--|------------------|----------------------|

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 13.7.5.23, “SHOW INDEX Syntax”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

| | | |
|----------------------------|----------------------------------|------------------------------|
| Command-Line Format | <code>--max_sort_length=#</code> | |
| System Variable | Name | <code>max_sort_length</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 1024 |
| | Min Value | 4 |
| | Max Value | 8388608 |

The number of bytes to use when sorting data values. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Consequently, values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations.

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see [Section 8.2.1.13, “ORDER BY Optimization”](#)

- `max_sp_recursion_depth`

| | | |
|----------------------------|---|-------------------------------------|
| Command-Line Format | <code>--max_sp_recursion_depth[=#]</code> | |
| System Variable | Name | <code>max_sp_recursion_depth</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Max Value | 255 |

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_tmp_tables`

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- `max_user_connections`

| | | |
|----------------------------|---------------------------------------|-----------------------------------|
| Command-Line Format | <code>--max_user_connections=#</code> | |
| System Variable | Name | <code>max_user_connections</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 4294967295 |

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.
- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `GRANT` statement. See [Section 6.3.4, “Setting Account Resource Limits”](#), and [Section 13.7.1.4, “GRANT Syntax”](#).

- `max_write_lock_count`

| | | |
|--|---------------------------------------|-----------------------------------|
| Command-Line Format | <code>--max_write_lock_count=#</code> | |
| System Variable | Name | <code>max_write_lock_count</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 4294967295 |

| | | |
|--|------------------|----------------------|
| Permitted Values (64-bit platforms) | Min Value | 1 |
| | Max Value | 4294967295 |
| | Type | integer |
| | Default | 18446744073709551615 |
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |

After this many write locks, permit some pending read lock requests to be processed in between.

- `metadata_locks_cache_size`

| | | |
|-------------------------|-------------------------|--|
| Introduced | 5.6.4 | |
| System Variable | Name | <code>metadata_locks_cache_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 1024 |
| | Min Value | 1 |
| | Max Value | 1048576 |

The size of the metadata locks cache. The server uses this cache to avoid creation and destruction of synchronization objects. This is particularly helpful on systems where such operations are expensive, such as Windows XP. This variable was added in MySQL 5.6.4.

- `metadata_locks_hash_instances`

| | | |
|-------------------------|-------------------------|--|
| Introduced | 5.6.8 | |
| System Variable | Name | <code>metadata_locks_hash_instances</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 8 |
| | Min Value | 1 |
| | Max Value | 1024 |

The set of metadata locks can be partitioned into separate hashes to permit connections accessing different objects to use different locking hashes and reduce contention. The `metadata_locks_hash_instances` system variable specifies the number of hashes (default 8). This variable was added in MySQL 5.6.8.

- `min_examined_row_limit`

| | | |
|--|---|-------------------------------------|
| Command-Line Format | <code>--min-examined-row-limit=#</code> | |
| System Variable | Name | <code>min_examined_row_limit</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 18446744073709551615 |

Queries that examine fewer than this number of rows are not logged to the slow query log.

- `multi_range_count`

| | | |
|----------------------------|------------------------------------|--------------------------------|
| Deprecated | 5.6.7 | |
| Command-Line Format | <code>--multi_range_count=#</code> | |
| System Variable | Name | <code>multi_range_count</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 256 |
| | Min Value | 1 |
| | Max Value | 4294967295 |

This variable has no effect. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- `myisam_data_pointer_size`

| | | |
|----------------------------|---|---------------------------------------|
| Command-Line Format | <code>--myisam_data_pointer_size=#</code> | |
| System Variable | Name | <code>myisam_data_pointer_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 6 |
| | Min Value | 2 |
| | Max Value | 7 |

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section B.5.2.12, “The table is full”](#).

- `myisam_max_sort_file_size`

| | | |
|--|--|--|
| Command-Line Format | <code>--myisam_max_sort_file_size=#</code> | |
| System Variable | Name | <code>myisam_max_sort_file_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 2147483648 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 9223372036854775807 |

The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If `MyISAM` index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size`

| | | |
|----------------------------|-----------------------------------|-------------------------------|
| Command-Line Format | <code>--myisam_mmap_size=#</code> | |
| System Variable | Name | <code>myisam_mmap_size</code> |
| | Variable Scope | Global |

| | | |
|--|-------------------------|----------------------|
| | Dynamic Variable | No |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 4294967295 |
| | Min Value | 7 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 18446744073709551615 |
| | Min Value | 7 |
| | Max Value | 18446744073709551615 |

The maximum amount of memory to use for memory mapping compressed [MyISAM](#) files. If many compressed [MyISAM](#) tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- [myisam_recover_options](#)

| | | |
|------------------------|-------------------------|--|
| System Variable | Name | myisam_recover_options |
| | Variable Scope | Global |
| | Dynamic Variable | No |

The value of the `--myisam-recover-options` option. See [Section 5.1.4, “Server Command Options”](#).

- [myisam_repair_threads](#)

| | | |
|--|--|---------------------------------------|
| Command-Line Format | <code>--myisam_repair_threads=#</code> | |
| System Variable | Name | myisam_repair_threads |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 1 |
| | Min Value | 1 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 1 |

| | | |
|--|------------------|----------------------|
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |

If this value is greater than 1, [MyISAM](#) table indexes are created in parallel (each index in its own thread) during the [Repair by sorting](#) process. The default value is 1.

**Note**

Multi-threaded repair is still *beta-quality* code.

- [myisam_sort_buffer_size](#)

| | | |
|--|--|---|
| Command-Line Format | <code>--myisam_sort_buffer_size=#</code> | |
| System Variable | Name | myisam_sort_buffer_size |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (Windows, 32-bit platforms) | Type | integer |
| | Default | 8388608 |
| | Min Value | 4096 |
| | Max Value | 4294967295 |
| Permitted Values (Windows, 64-bit platforms, ≤ 5.6.4) | Type | integer |
| | Default | 8388608 |
| | Min Value | 4096 |
| | Max Value | 4294967295 |
| Permitted Values (Windows, 64-bit platforms, ≥ 5.6.5) | Type | integer |
| | Default | 8388608 |
| | Min Value | 4096 |
| | Max Value | 18446744073709551615 |
| Permitted Values (Other, 32-bit platforms) | Type | integer |
| | Default | 8388608 |
| | Min Value | 4096 |
| | Max Value | 4294967295 |

| | | |
|---|------------------|----------------------|
| Permitted Values (Other, 64-bit platforms) | Type | integer |
| | Default | 8388608 |
| | Min Value | 4096 |
| | Max Value | 18446744073709551615 |

The size of the buffer that is allocated when sorting [MyISAM](#) indexes during a [REPAIR TABLE](#) or when creating indexes with [CREATE INDEX](#) or [ALTER TABLE](#).

The maximum permissible setting for [mysam_sort_buffer_size](#) is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows prior to MySQL 5.6.5, for which large values are truncated to 4GB-1 with a warning).

- [mysam_stats_method](#)

| | | |
|----------------------------|--|------------------------------------|
| Command-Line Format | <code>--mysam_stats_method=name</code> | |
| System Variable | Name | mysam_stats_method |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | nulls_unequal |
| | Valid Values | nulls_equal |
| | | nulls_unequal |
| | | nulls_ignored |

How the server treats [NULL](#) values when collecting statistics about the distribution of index values for [MyISAM](#) tables. This variable has three possible values, [nulls_equal](#), [nulls_unequal](#), and [nulls_ignored](#). For [nulls_equal](#), all [NULL](#) index values are considered equal and form a single value group that has a size equal to the number of [NULL](#) values. For [nulls_unequal](#), [NULL](#) values are considered unequal, and each [NULL](#) forms a distinct value group of size 1. For [nulls_ignored](#), [NULL](#) values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- [mysam_use_mmap](#)

| | | |
|----------------------------|-------------------------------|--------------------------------|
| Command-Line Format | <code>--mysam_use_mmap</code> | |
| System Variable | Name | mysam_use_mmap |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | OFF |

Use memory mapping for reading and writing [MyISAM](#) tables.

- [named_pipe](#)

| | | |
|--------------------------------------|-------------------------|----------------------------|
| System Variable | Name | named_pipe |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Platform Specific | Windows | |
| Permitted Values (Windows) | Type | boolean |
| | Default | OFF |

(Windows only.) Indicates whether the server supports connections over named pipes.

- [net_buffer_length](#)

| | | |
|----------------------------|---------------------------------------|-----------------------------------|
| Command-Line Format | --net_buffer_length=# | |
| System Variable | Name | net_buffer_length |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 16384 |
| | Min Value | 1024 |
| | Max Value | 1048576 |

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by [net_buffer_length](#) but are dynamically enlarged up to [max_allowed_packet](#) bytes as needed. The result buffer shrinks to [net_buffer_length](#) after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which [net_buffer_length](#) can be set is 1MB.

The session value of this variable is read only.

- [net_read_timeout](#)

| | | |
|----------------------------|--------------------------------------|----------------------------------|
| Command-Line Format | --net_read_timeout=# | |
| System Variable | Name | net_read_timeout |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|------------------|---------|
| Permitted Values | Type | integer |
| | Default | 30 |
| | Min Value | 1 |

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- `net_retry_count`

| | | |
|--|----------------------------------|------------------------------|
| Command-Line Format | <code>--net_retry_count=#</code> | |
| System Variable | Name | <code>net_retry_count</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 10 |
| | Min Value | 1 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 10 |
| | Min Value | 1 |
| | Max Value | 18446744073709551615 |

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

| | | |
|----------------------------|------------------------------------|--------------------------------|
| Command-Line Format | <code>--net_write_timeout=#</code> | |
| System Variable | Name | <code>net_write_timeout</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 60 |
| | Min Value | 1 |

The number of seconds to wait for a block to be written to a connection before aborting the write. See also [net_read_timeout](#).

- [new](#)

| | | |
|----------------------------|--------------------------|-----------------------|
| Command-Line Format | --new | |
| System Variable | Name | new |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Disabled by | skip-new | |
| Permitted Values | Type | boolean |
| | Default | FALSE |

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always [OFF](#).

In MySQL Cluster, setting this variable to [ON](#) makes it possible to employ partitioning types other than [KEY](#) or [LINEAR KEY](#) with [NDB](#) tables. *This feature is experimental only, and not supported in production.* For additional information, see [User-defined partitioning and the NDB storage engine \(MySQL Cluster\)](#).

- [old](#)

| | | |
|----------------------------|-------------------------|---------------------|
| Command-Line Format | --old | |
| System Variable | Name | old |
| | Variable Scope | Global |
| | Dynamic Variable | No |

[old](#) is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When [old](#) is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no [FOR](#) clause apply only to how indexes are used for row retrieval and not to resolution of [ORDER BY](#) or [GROUP BY](#) clauses. (See [Section 8.9.3, “Index Hints”](#).) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- [old_alter_table](#)

| | | |
|----------------------------|-----------------------------------|---------------------------------|
| Command-Line Format | --old-alter-table | |
| System Variable | Name | old_alter_table |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |

| | | |
|--|----------------|-----|
| | Default | OFF |
|--|----------------|-----|

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 13.1.7, “ALTER TABLE Syntax”](#).

- `old_passwords`

| | | |
|---------------------------------------|-------------------------|----------------------------|
| System Variable | Name | <code>old_passwords</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.5) | Type | boolean |
| | Default | 0 |
| Permitted Values (>= 5.6.6) | Type | enumeration |
| | Default | 0 |
| | Valid Values | 0 |
| | | 1 |
| | | 2 |

This variable controls the password hashing method used by the `PASSWORD()` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method. These values are permitted as of MySQL 5.6.6. Before 5.6.6, the permitted values are 0 (or `OFF`) and 1 (or `ON`).

| Value | Password Hashing Method | Associated Authentication Plugin |
|-------|--------------------------|------------------------------------|
| 0 | MySQL 4.1 native hashing | <code>mysql_native_password</code> |
| 1 | Pre-4.1 (“old”) hashing | <code>mysql_old_password</code> |
| 2 | SHA-256 hashing | <code>sha256_password</code> |

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them will be removed in a future MySQL release. Consequently, `old_passwords=1`, which causes `PASSWORD()` to generate pre-4.1 password hashes, is also deprecated. For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the `mysql_old_password` Plugin”](#).

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

If you set `old_passwords=2`, follow the instructions for using the `sha256_password` plugin at [Section 6.5.1.4, “The SHA-256 Authentication Plugin”](#).

As of MySQL 5.6.6, the server sets the global `old_passwords` value during startup to be consistent with the password hashing method required by the default authentication plugin. The default plugin is `mysql_native_password` unless the `--default-authentication-plugin` option is set otherwise.

As of MySQL 5.6.10, when a client successfully connects to the server, the server sets the session `old_passwords` value appropriately for the account authentication method. For example, if the account uses the `sha256_password` authentication plugin, the server sets `old_passwords=2`.

For additional information about authentication plugins and hashing formats, see [Section 6.3.7, “Pluggable Authentication”](#), and [Section 6.1.2.4, “Password Hashing in MySQL”](#).

- `open_files_limit`

| | | |
|---------------------------------------|-----------------------------------|--------------------------------|
| Command-Line Format | <code>--open-files-limit=#</code> | |
| System Variable | Name | <code>open_files_limit</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.7) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | platform dependent |
| Permitted Values (>= 5.6.8) | Type | integer |
| | Default | 5000, with possible adjustment |
| | Min Value | 0 |
| | Max Value | platform dependent |

The number of files that the operating system permits `mysqld` to open. The value of this variable at runtime is the real value permitted by the system and might be different from the value you specify at server startup. The value is 0 on systems where MySQL cannot change the number of open files.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

```

1) 10 + max_connections + (table_open_cache * 2)
2) max_connections * 5
3) open_files_limit value specified at startup, 5000 if none

```

The server attempts to obtain the number of file descriptors using the maximum of those three values. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system will permit.

- `optimizer_join_cache_level`

| | | |
|----------------------------|---|---|
| Introduced | 5.6.1 | |
| Removed | 5.6.3 | |
| Command-Line Format | <code>--optimizer_join_cache_level=#</code> | |
| System Variable | Name | <code>optimizer_join_cache_level</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 4 |
| | Min Value | 0 |
| | Max Value | 4 |

Before MySQL 5.6.3, this variable is used for join buffer management. It controls how join buffers are used for join operations. As of MySQL 5.6.3, it is removed and the `optimizer_switch` variable is used instead. See [Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”](#).

The following table shows the permissible `optimizer_join_cache_level` values.

| Option | Description |
|--------|--|
| 0 | No join buffer is used for any join operation. This setting can be useful for assessing baseline join performance in comparison to performance with nonzero values that enable use of join buffering. |
| 1 | This is the default value. Join buffers are employed only for inner joins that are executed by the original Block Nested-Loop (BNL) join algorithm. When this algorithm is applied, rows of the inner table are accessed through a table scan, a plain index scan, or a range index scan. |
| 2 | The server employs an incremental join buffer for a join operation if its first operand is produced by a join operation that uses a join buffer itself. |
| 3 | The BNL algorithm is used for outer join operations with one inner table and for inner joins. |
| 4 | The BNL algorithm uses incremental buffers for inner tables. In this case, the BNL algorithm can be used for nested outer joins (outer joins with several inner tables). Such an operation can be executed only if incremental join buffers are used to join all inner tables but the first one. |

- `optimizer_prune_level`

| | | |
|----------------------------|--|------------------------------------|
| Command-Line Format | <code>--optimizer_prune_level[=#]</code> | |
| System Variable | Name | <code>optimizer_prune_level</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|----------------|---------|
| Permitted Values | Type | boolean |
| | Default | 1 |

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

| | | |
|----------------------------|---|-------------------------------------|
| Command-Line Format | <code>--optimizer_search_depth[=#]</code> | |
| System Variable | Name | <code>optimizer_search_depth</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 62 |
| | Min Value | 0 |
| | Max Value | 62 |

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- `optimizer_switch`

| | | |
|--|---------------------------------------|---|
| Command-Line Format | <code>--optimizer_switch=value</code> | |
| System Variable | Name | <code>optimizer_switch</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (5.6.0) | Type | set |
| | Valid Values | <code>engine_condition_pushdown={on off}</code> |
| | | <code>index_merge={on off}</code> |
| | | <code>index_merge_intersection={on off}</code> |
| | | <code>index_merge_sort_union={on off}</code> |
| | | <code>index_merge_union={on off}</code> |
| Permitted Values (>= 5.6.1, <= 5.6.2) | Type | set |
| | Valid Values | <code>engine_condition_pushdown={on off}</code> |
| | | <code>index_condition_pushdown={on off}</code> |

| | | |
|--|---------------------|------------------------------------|
| | | index_merge={on off} |
| | | index_merge_intersection={on off} |
| | | index_merge_sort_union={on off} |
| | | index_merge_union={on off} |
| | | mrr={on off} |
| | | mrr_cost_based={on off} |
| Permitted Values (>= 5.6.3, <= 5.6.4) | Type | set |
| | Valid Values | batched_key_access={on off} |
| | | block_nested_loop={on off} |
| | | engine_condition_pushdown={on off} |
| | | index_condition_pushdown={on off} |
| | | index_merge={on off} |
| | | index_merge_intersection={on off} |
| | | index_merge_sort_union={on off} |
| | | index_merge_union={on off} |
| | | mrr={on off} |
| | | mrr_cost_based={on off} |
| Permitted Values (>= 5.6.5, <= 5.6.6) | Type | set |
| | Valid Values | batched_key_access={on off} |
| | | block_nested_loop={on off} |
| | | engine_condition_pushdown={on off} |
| | | firstmatch={on off} |
| | | index_condition_pushdown={on off} |
| | | index_merge={on off} |
| | | index_merge_intersection={on off} |
| | | index_merge_sort_union={on off} |
| | | index_merge_union={on off} |
| | | loosescan={on off} |
| | | materialization={on off} |
| | | mrr={on off} |
| | | mrr_cost_based={on off} |
| | | semijoin={on off} |
| Permitted Values (>= 5.6.7, <= 5.6.8) | Type | set |
| | Valid Values | batched_key_access={on off} |
| | | block_nested_loop={on off} |
| | | engine_condition_pushdown={on off} |
| | | firstmatch={on off} |
| | | index_condition_pushdown={on off} |
| | | index_merge={on off} |

| | | |
|---------------------------------------|---------------------|--|
| | | index_merge_intersection={on off} |
| | | index_merge_sort_union={on off} |
| | | index_merge_union={on off} |
| | | loosescan={on off} |
| | | materialization={on off} |
| | | mrr={on off} |
| | | mrr_cost_based={on off} |
| | | semijoin={on off} |
| | | subquery_materialization_cost_based={on off} |
| Permitted Values (>= 5.6.9) | Type | set |
| | Valid Values | batched_key_access={on off} |
| | | block_nested_loop={on off} |
| | | engine_condition_pushdown={on off} |
| | | firstmatch={on off} |
| | | index_condition_pushdown={on off} |
| | | index_merge={on off} |
| | | index_merge_intersection={on off} |
| | | index_merge_sort_union={on off} |
| | | index_merge_union={on off} |
| | | loosescan={on off} |
| | | materialization={on off} |
| | | mrr={on off} |
| | | mrr_cost_based={on off} |
| | | semijoin={on off} |
| | | subquery_materialization_cost_based={on off} |
| | | use_index_extensions={on off} |

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
```

```
use_index_extensions=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 8.9.2, “Controlling Switchable Optimizations”](#).

- `optimizer_trace`

| | | |
|-------------------------|-------------------------|------------------------------|
| Introduced | 5.6.3 | |
| System Variable | Name | <code>optimizer_trace</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

This variable controls optimizer tracing. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_features`

| | | |
|-------------------------|-------------------------|---------------------------------------|
| Introduced | 5.6.3 | |
| System Variable | Name | <code>optimizer_trace_features</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

This variable enables or disables selected optimizer tracing features. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_limit`

| | | |
|-------------------------|-------------------------|------------------------------------|
| Introduced | 5.6.3 | |
| System Variable | Name | <code>optimizer_trace_limit</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 1 |

The maximum number of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_max_mem_size`

| | | |
|------------------------|-------------|---|
| Introduced | 5.6.3 | |
| System Variable | Name | <code>optimizer_trace_max_mem_size</code> |

| | | |
|-------------------------|-------------------------|-----------------|
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 16384 |

The maximum cumulative size of stored optimizer traces. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_offset`

| | | |
|-------------------------|-------------------------|-------------------------------------|
| Introduced | 5.6.3 | |
| System Variable | Name | <code>optimizer_trace_offset</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | -1 |

The offset of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `performance_schema_xxx`

Performance Schema system variables are listed in [Section 22.13, “Performance Schema System Variables”](#). These variables may be used to configure Performance Schema operation.

- `pid_file`

| | | |
|----------------------------|-----------------------------------|-----------------------|
| Command-Line Format | <code>--pid-file=file_name</code> | |
| System Variable | Name | <code>pid_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The path name of the process ID (PID) file. This variable can be set with the `--pid-file` option.

- `plugin_dir`

| | | |
|----------------------------|------------------------------------|-------------------------|
| Command-Line Format | <code>--plugin_dir=dir_name</code> | |
| System Variable | Name | <code>plugin_dir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

| | | |
|--|----------------|---------------------------------|
| | Default | <code>BASEDIR/lib/plugin</code> |
|--|----------------|---------------------------------|

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

- `port`

| | | |
|----------------------------|-------------------------|--------------------|
| Command-Line Format | <code>--port=#</code> | |
| System Variable | Name | <code>port</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | <code>3306</code> |
| | Min Value | <code>0</code> |
| | Max Value | <code>65535</code> |

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

| | | |
|----------------------------|--------------------------------------|----------------------------------|
| Command-Line Format | <code>--preload_buffer_size=#</code> | |
| System Variable | Name | <code>preload_buffer_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | <code>32768</code> |
| | Min Value | <code>1024</code> |
| | Max Value | <code>1073741824</code> |

The size of the buffer that is allocated when preloading indexes.

- `profiling`

If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

This variable is deprecated in MySQL 5.6.8 and will be removed in a future MySQL release.

- `profiling_history_size`

The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

This variable is deprecated in MySQL 5.6.8 and will be removed in a future MySQL release.

- `protocol_version`

| | | |
|-------------------------|-------------------------|-------------------------------|
| System Variable | Name | <code>protocol_version</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |

The version of the client/server protocol used by the MySQL server.

- `proxy_user`

| | | |
|-------------------------|-------------------------|-------------------------|
| System Variable | Name | <code>proxy_user</code> |
| | Variable Scope | Session |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See [Section 6.3.8, “Proxy Users”](#).

- `pseudo_slave_mode`

| | | |
|-------------------------|-------------------------|--------------------------------|
| Introduced | 5.6.10 | |
| System Variable | Name | <code>pseudo_slave_mode</code> |
| | Variable Scope | Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |

This variable is for internal server use. It was added in MySQL 5.6.10.

- `pseudo_thread_id`

| | | |
|------------------------|-----------------------|-------------------------------|
| System Variable | Name | <code>pseudo_thread_id</code> |
| | Variable Scope | Session |

| | | |
|-------------------------|-------------------------|---------|
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |

This variable is for internal server use.

- `query_alloc_block_size`

| | | |
|--|---|-------------------------------------|
| Command-Line Format | <code>--query_alloc_block_size=#</code> | |
| System Variable | Name | <code>query_alloc_block_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 8192 |
| | Min Value | 1024 |
| | Max Value | 4294967295 |
| | Block Size | 1024 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 8192 |
| | Min Value | 1024 |
| | Max Value | 18446744073709551615 |
| | Block Size | 1024 |

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- `query_cache_limit`

| | | |
|--|------------------------------------|--------------------------------|
| Command-Line Format | <code>--query_cache_limit=#</code> | |
| System Variable | Name | <code>query_cache_limit</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 1048576 |
| | Min Value | 0 |

| | | |
|--|------------------|----------------------|
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 1048576 |
| | Min Value | 0 |
| | Max Value | 18446744073709551615 |

Do not cache results that are larger than this number of bytes. The default value is 1MB.

- [query_cache_min_res_unit](#)

| | | |
|--|---|--|
| Command-Line Format | <code>--query_cache_min_res_unit=#</code> | |
| System Variable | Name | query_cache_min_res_unit |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 4096 |
| | Min Value | 512 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 4096 |
| | Min Value | 512 |
| | Max Value | 18446744073709551615 |

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in [Section 8.10.3.3, “Query Cache Configuration”](#).

- [query_cache_size](#)

| | | |
|--|-----------------------------------|----------------------------------|
| Command-Line Format | <code>--query_cache_size=#</code> | |
| System Variable | Name | query_cache_size |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms, <= 5.6.7) | Type | integer |
| | Default | 0 |

| | | |
|--|------------------|----------------------|
| | Min Value | 0 |
| | Max Value | 4294967295 |
| Permitted Values (32-bit platforms, >= 5.6.8) | Type | integer |
| | Default | 1048576 |
| | Min Value | 0 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms, <= 5.6.7) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 18446744073709551615 |
| Permitted Values (64-bit platforms, >= 5.6.8) | Type | integer |
| | Default | 1048576 |
| | Min Value | 0 |
| | Max Value | 18446744073709551615 |

The amount of memory allocated for caching query results. By default, the query cache is disabled. This is achieved using a default value of 1M, with a default for `query_cache_type` of 0. (Before MySQL 5.6.8, the default size is 0, with a default `query_cache_type` of 1. To reduce overhead significantly if you set the size to 0, you should also start the server with `query_cache_type=0` if you will not be using the query cache.)

The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. For nonzero values of `query_cache_size`, that many bytes of memory are allocated even if `query_cache_type=0`. See [Section 8.10.3.3, “Query Cache Configuration”](#), for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` too small, a warning will occur, as described in [Section 8.10.3.3, “Query Cache Configuration”](#).

- `query_cache_type`

| | | |
|------------------------------------|-----------------------------------|-------------------------------|
| Command-Line Format | <code>--query_cache_type=#</code> | |
| System Variable | Name | <code>query_cache_type</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.7) | Type | enumeration |
| | Default | 1 |

| | | |
|---------------------------------------|---------------------|-------------|
| | Valid Values | 0 |
| | | 1 |
| | | 2 |
| Permitted Values (>= 5.6.8) | Type | enumeration |
| | Default | 0 |
| | Valid Values | 0 |
| | | 1 |
| | | 2 |

Set the query cache type. Setting the [GLOBAL](#) value sets the type for all clients that connect thereafter. Individual clients can set the [SESSION](#) value to affect their own use of the query cache. Possible values are shown in the following table.

| Option | Description |
|-----------------------------|--|
| 0 or OFF | Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set query_cache_size to 0. |
| 1 or ON | Cache all cacheable query results except for those that begin with SELECT SQL_NO_CACHE . |
| 2 or DEMAND | Cache results only for cacheable queries that begin with SELECT SQL_CACHE . |

This variable defaults to [OFF](#) as of MySQL 5.6.8, [ON](#) before that.

If the server is started with [query_cache_type](#) set to 0, it does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

- [query_cache_wlock_invalidate](#)

| | | |
|----------------------------|--|--|
| Command-Line Format | --query_cache_wlock_invalidate | |
| System Variable | Name | query_cache_wlock_invalidate |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | FALSE |

Normally, when one client acquires a [WRITE](#) lock on a [MyISAM](#) table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a [WRITE](#) lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- [query_prealloc_size](#)

| | | |
|----------------------------|---|-------------------------------------|
| Command-Line Format | --query_prealloc_size=# | |
| System Variable | Name | query_prealloc_size |

| | | |
|--|-------------------------|----------------------|
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 8192 |
| | Min Value | 8192 |
| | Max Value | 4294967295 |
| | Block Size | 1024 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 8192 |
| | Min Value | 8192 |
| | Max Value | 18446744073709551615 |
| | Block Size | 1024 |

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- `rand_seed1`

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- `rand_seed2`

See the description for `rand_seed1`.

- `range_alloc_block_size`

| | | |
|----------------------------|---|-------------------------------------|
| Command-Line Format | <code>--range_alloc_block_size=#</code> | |
| System Variable | Name | <code>range_alloc_block_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |

| | | |
|--|-------------------|----------------------|
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 4096 |
| | Min Value | 4096 |
| | Max Value | 4294967295 |
| | Block Size | 1024 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 4096 |
| | Min Value | 4096 |
| | Max Value | 18446744073709551615 |
| | Block Size | 1024 |

The size of blocks that are allocated when doing range optimization.

- `read_buffer_size`

| | | |
|----------------------------|-----------------------------------|-------------------------------|
| Command-Line Format | <code>--read_buffer_size=#</code> | |
| System Variable | Name | <code>read_buffer_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 131072 |
| | Min Value | 8200 |
| | Max Value | 2147479552 |

Each thread that does a sequential scan for a `MyISAM` table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all storage engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for `ORDER BY`.
- For bulk insert into partitions.
- For caching results of nested queries.

and in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

The maximum permissible setting for `read_buffer_size` is 2GB.

For more information about memory use during different operations, see [Section 8.12.4.1, “How MySQL Uses Memory”](#).

- `read_only`

| | | |
|----------------------------|--------------------------|------------------------|
| Command-Line Format | <code>--read_only</code> | |
| System Variable | Name | <code>read_only</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

When the `read_only` system variable is enabled, the server permits no client updates except from users who have the `SUPER` privilege. This variable is disabled by default.

Even with `read_only` enabled, the server permits these operations:

- Updates performed by slave threads, if the server is a replication slave. In replication setups, it can be useful to enable `read_only` on slave servers to ensure that slaves accept updates only from the master server and not from clients.
- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only replication slaves can be performed with `mysqlcheck --all-databases --analyze`.
- Operations on `TEMPORARY` tables.
- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`; see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

`read_only` exists only as a `GLOBAL` variable, so changes to its value require the `SUPER` privilege. Changes to `read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

The following conditions apply to attempts to enable `read_only`:

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.
- The attempt blocks while other clients hold explicit table locks or have pending transactions, until the locks are released and the transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.

- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.
- `read_rnd_buffer_size`

| | | |
|----------------------------|---------------------------------------|-----------------------------------|
| Command-Line Format | <code>--read_rnd_buffer_size=#</code> | |
| System Variable | Name | <code>read_rnd_buffer_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 262144 |
| | Min Value | 1 |
| | Max Value | 2147483647 |

This variable is used for reads from [MyISAM](#) tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a [MyISAM](#) table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 8.2.1.13, “ORDER BY Optimization”](#). Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

The maximum permissible setting for `read_rnd_buffer_size` is 2GB.

For more information about memory use during different operations, see [Section 8.12.4.1, “How MySQL Uses Memory”](#). For information about Multi-Range Read optimization, see [Section 8.2.1.10, “Multi-Range Read Optimization”](#).

- `relay_log_purge`

| | | |
|----------------------------|--------------------------------|------------------------------|
| Command-Line Format | <code>--relay_log_purge</code> | |
| System Variable | Name | <code>relay_log_purge</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>TRUE</code> |

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_space_limit`

| | | |
|--|--|------------------------------------|
| Command-Line Format | <code>--relay_log_space_limit=#</code> | |
| System Variable | Name | <code>relay_log_space_limit</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 4294967295 |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 18446744073709551615 |

The maximum amount of space to use for all relay logs.

- `report_host`

| | | |
|----------------------------|--------------------------------------|--------------------------|
| Command-Line Format | <code>--report-host=host_name</code> | |
| System Variable | Name | <code>report_host</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The value of the `--report-host` option.

- `report_password`

| | | |
|----------------------------|-------------------------------------|------------------------------|
| Command-Line Format | <code>--report-password=name</code> | |
| System Variable | Name | <code>report_password</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The value of the `--report-password` option. Not the same as the password used for the MySQL replication user account.

- `report_port`

| | | |
|---------------------------------------|------------------------------|---------------------------|
| Command-Line Format | <code>--report-port=#</code> | |
| System Variable | Name | <code>report_port</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.4) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 65535 |
| Permitted Values (>= 5.6.5) | Type | integer |
| | Default | <code>[slave_port]</code> |
| | Min Value | 0 |
| | Max Value | 65535 |

The value of the `--report-port` option.

- `report_user`

| | | |
|----------------------------|---------------------------------|--------------------------|
| Command-Line Format | <code>--report-user=name</code> | |
| System Variable | Name | <code>report_user</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The value of the `--report-user` option. Not the same as the name for the MySQL replication user account.

- `rpl_semi_sync_master_enabled`

| | | |
|-------------------------|-------------------------|---|
| System Variable | Name | <code>rpl_semi_sync_master_enabled</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to **ON** or **OFF** (or 1 or 0), respectively. The default is **OFF**.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_timeout`

| | | |
|-------------------------|-------------------------|---|
| System Variable | Name | <code>rpl_semi_sync_master_timeout</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 10000 |

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_trace_level`

| | | |
|-------------------------|-------------------------|---|
| System Variable | Name | <code>rpl_semi_sync_master_trace_level</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 32 |

The semisynchronous replication debug trace level on the master. Four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave`

| | | |
|------------------------|-------------------------|---|
| System Variable | Name | <code>rpl_semi_sync_master_wait_no_slave</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|----------------|---------|
| Permitted Values | Type | boolean |
| | Default | ON |

With semisynchronous replication, for each transaction, the master waits until timeout for acknowledgment of receipt from some semisynchronous slave. If no response occurs during this period, the master reverts to normal replication. This variable controls whether the master waits for the timeout to expire before reverting to normal replication even if the slave count drops to zero during the timeout period.

If the value is [ON](#) (the default), it is permissible for the slave count to drop to zero during the timeout period (for example, if slaves disconnect). The master still waits for the timeout, so as long as some slave reconnects and acknowledges the transaction within the timeout interval, semisynchronous replication continues.

If the value is [OFF](#), the master reverts to normal replication if the slave count drops to zero during the timeout period.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- [rpl_semi_sync_slave_enabled](#)

| | | |
|-------------------------|-------------------------|---|
| System Variable | Name | rpl_semi_sync_slave_enabled |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | OFF |

Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to [ON](#) or [OFF](#) (or 1 or 0), respectively. The default is [OFF](#).

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [rpl_semi_sync_slave_trace_level](#)

| | | |
|-------------------------|-------------------------|---|
| System Variable | Name | rpl_semi_sync_slave_trace_level |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 32 |

The semisynchronous replication debug trace level on the slave. See [rpl_semi_sync_master_trace_level](#) for the permissible values.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [secure_auth](#)

| | | |
|---------------------------------------|----------------------------|--------------------------|
| Command-Line Format | <code>--secure-auth</code> | |
| System Variable | Name | <code>secure_auth</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.4) | Type | boolean |
| | Default | <code>OFF</code> |
| Permitted Values (>= 5.6.5) | Type | boolean |
| | Default | <code>ON</code> |

If this variable is enabled, the server blocks connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format.

Enable this variable to prevent all use of passwords employing the old format (and hence insecure communication over the network). Before MySQL 5.6.5, this variable is disabled by default. As of MySQL 5.6.5, it is enabled by default.

Server startup fails with an error if this variable is enabled and the privilege tables are in pre-4.1 format. See [Section B.5.2.4, “Client does not support authentication protocol”](#).

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them will be removed in a future MySQL release. Consequently, disabling `secure_auth` is also deprecated.

- `secure_file_priv`

| | | |
|--|--|---|
| Command-Line Format | <code>--secure-file-priv=dir_name</code> | |
| System Variable | Name | <code>secure_file_priv</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (<= 5.6.33) | Type | string |
| | Default | <code>empty</code> |
| | Valid Values | <code>empty</code> <code>dirname</code> |
| Permitted Values (>= 5.6.34) | Type | string |
| | Default | <code>platform specific</code> |
| | Valid Values | <code>empty</code> <code>dirname</code> <code>NULL</code> |

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.
- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server will not create it.
- If set to `NULL`, the server disables import and export operations. This value is permitted as of MySQL 5.6.34.

Before MySQL 5.6.34, this variable is empty by default. As of 5.6.34, the default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR` CMake option.

| <code>INSTALL_LAYOUT</code> Value | Default <code>secure_file_priv</code> Value |
|-----------------------------------|---|
| STANDALONE, WIN | NULL |
| DEB, RPM, SLES, SVR4 | /var/lib/mysql-files |
| Otherwise | mysql-files under the <code>CMAKE_INSTALL_PREFIX</code> value |

To set the default `secure_file_priv` value for the `libmysqld` embedded server, use the `INSTALL_SECURE_FILE_PRIV_EMBEDDEDIR` CMake option. The default value for this option is `NULL`.

As of MySQL 5.6.34, the server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-`NULL` value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.

- `server_id`

| | | |
|----------------------------|----------------------------|------------------------|
| Command-Line Format | <code>--server-id=#</code> | |
| System Variable | Name | <code>server_id</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 4294967295 |

The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` option. For each server participating in replication, you should pick a positive integer in the range from 1 to $2^{32} - 1$ to act as that server's ID.

- `sha256_password_private_key_path`

| | | |
|-------------------------|-------------------------|---|
| Introduced | 5.6.6 | |
| System Variable | Name | <code>sha256_password_private_key_path</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |
| | Default | <code>private_key.pem</code> |

This variable is available if MySQL was compiled using OpenSSL (see [Section 6.4.1, “OpenSSL Versus yaSSL”](#)). Its value is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, including instructions for creating the RSA key files, see [Section 6.5.1.4, “The SHA-256 Authentication Plugin”](#).

This variable was added in MySQL 5.6.6.

- `sha256_password_public_key_path`

| | | |
|-------------------------|-------------------------|--|
| Introduced | 5.6.6 | |
| System Variable | Name | <code>sha256_password_public_key_path</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |
| | Default | <code>public_key.pem</code> |

This variable is available if MySQL was compiled using OpenSSL (see [Section 6.4.1, “OpenSSL Versus yaSSL”](#)). Its value is the path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including instructions for creating the RSA key files and how clients specify the RSA public key, see [Section 6.5.1.4, “The SHA-256 Authentication Plugin”](#).

This variable was added in MySQL 5.6.6.

- `shared_memory`

| | | |
|----------------------------|--------------------------------------|----------------------------|
| Command-Line Format | <code>--shared_memory[={0,1}]</code> | |
| System Variable | Name | <code>shared_memory</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Platform Specific | Windows | |
| Permitted Values | Type | boolean |
| | Default | <code>FALSE</code> |

(Windows only.) Whether the server permits shared-memory connections.

- `shared_memory_base_name`

| | | |
|----------------------------|---|--------------------------------------|
| Command-Line Format | <code>--shared_memory_base_name=name</code> | |
| System Variable | Name | <code>shared_memory_base_name</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Platform Specific | Windows | |
| Permitted Values | Type | string |
| | Default | <code>MYSQL</code> |

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- `show_old_temporals`

| | | |
|----------------------------|--|---------------------------------|
| Introduced | 5.6.24 | |
| Deprecated | 5.6.24 | |
| Command-Line Format | <code>--show_old_temporals={OFF ON}</code> | |
| System Variable | Name | <code>show_old_temporals</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Whether `SHOW CREATE TABLE` output includes comments to flag temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). This variable is disabled by default. If enabled, `SHOW CREATE TABLE` output looks like this:

```
CREATE TABLE `mytbl` (
```

```
`ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,
`dt` datetime /* 5.5 binary format */ DEFAULT NULL,
`t` time /* 5.5 binary format */ DEFAULT NULL
) DEFAULT CHARSET=latin1
```

Output for the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` table is affected similarly.

This variable was added in MySQL 5.6.24. It is deprecated and will be removed in a future MySQL release.

- `skip_external_locking`

| | | |
|----------------------------|--------------------------------------|------------------------------------|
| Command-Line Format | <code>--skip-external-locking</code> | |
| System Variable | Name | <code>skip_external_locking</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | boolean |
| | Default | <code>ON</code> |

This is `OFF` if `mysqld` uses external locking (system locking), `ON` if external locking is disabled. This affects only `MyISAM` table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking is disabled by default.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.11.5, “External Locking”](#).

- `skip_name_resolve`

| | | |
|----------------------------|----------------------------------|--------------------------------|
| Command-Line Format | <code>--skip-name-resolve</code> | |
| System Variable | Name | <code>skip_name_resolve</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

This variable is set from the value of the `--skip-name-resolve` option. If it is `OFF`, `mysqld` resolves host names when checking client connections. If it is `ON`, `mysqld` uses only IP numbers; in this case, all `Host` column values in the grant tables must be IP addresses or `localhost`. See [Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”](#).

- `skip_networking`

| | | |
|----------------------------|--------------------------------|------------------------------|
| Command-Line Format | <code>--skip-networking</code> | |
| System Variable | Name | <code>skip_networking</code> |

| | | |
|--|-------------------------|--------|
| | Variable Scope | Global |
| | Dynamic Variable | No |

This is `ON` if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. This variable can be set to `ON` with the `--skip-networking` option.

- `skip_show_database`

| | | |
|----------------------------|-----------------------------------|---------------------------------|
| Command-Line Format | <code>--skip-show-database</code> | |
| System Variable | Name | <code>skip_show_database</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege. (Note that *any* global privilege is considered a privilege for the database.)

- `slow_launch_time`

| | | |
|----------------------------|-----------------------------------|-------------------------------|
| Command-Line Format | <code>--slow_launch_time=#</code> | |
| System Variable | Name | <code>slow_launch_time</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 2 |

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `slow_query_log`

| | | |
|----------------------------|-------------------------------|-----------------------------|
| Command-Line Format | <code>--slow-query-log</code> | |
| System Variable | Name | <code>slow_query_log</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|----------------|------------------|
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--slow_query_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See [Section 5.4.5, “The Slow Query Log”](#).

- `slow_query_log_file`

| | | |
|----------------------------|--|----------------------------------|
| Command-Line Format | <code>--slow-query-log-file=file_name</code> | |
| System Variable | Name | <code>slow_query_log_file</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | file name |
| | Default | <code>host_name-slow.log</code> |

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- `socket`

| | | |
|----------------------------|---|------------------------------|
| Command-Line Format | <code>--socket={file_name pipe_name}</code> | |
| System Variable | Name | <code>socket</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |
| | Default | <code>/tmp/mysql.sock</code> |

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- `sort_buffer_size`

| | | |
|----------------------------|-----------------------------------|-------------------------------|
| Command-Line Format | <code>--sort_buffer_size=#</code> | |
| System Variable | Name | <code>sort_buffer_size</code> |
| | Variable Scope | Global, Session |
| | Default | 667 |

| | Dynamic Variable | Yes |
|---|------------------|----------------------|
| Permitted Values (Windows, <= 5.6.3) | Type | integer |
| | Default | 2097144 |
| | Min Value | 32768 |
| | Max Value | 4294967295 |
| Permitted Values (Windows, >= 5.6.4) | Type | integer |
| | Default | 262144 |
| | Min Value | 32768 |
| | Max Value | 4294967295 |
| Permitted Values (Other, 32-bit platforms, <= 5.6.3) | Type | integer |
| | Default | 2097144 |
| | Min Value | 32768 |
| | Max Value | 4294967295 |
| Permitted Values (Other, 32-bit platforms, >= 5.6.4) | Type | integer |
| | Default | 262144 |
| | Min Value | 32768 |
| | Max Value | 4294967295 |
| Permitted Values (Other, 64-bit platforms, <= 5.6.3) | Type | integer |
| | Default | 2097144 |
| | Min Value | 32768 |
| | Max Value | 18446744073709551615 |
| Permitted Values (Other, 64-bit platforms, >= 5.6.4) | Type | integer |
| | Default | 262144 |
| | Min Value | 32768 |
| | Max Value | 18446744073709551615 |

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see [Section 8.2.1.13, “ORDER BY Optimization”](#)

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

As of MySQL 5.6.4, the optimizer tries to work out how much space is needed but can allocate more, up to the limit. Before MySQL 5.6.4, the optimizer allocates the entire buffer even if it is not all needed. In either case, setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

- `sql_auto_is_null`

| | | |
|-------------------------|-------------------------|-------------------------------|
| System Variable | Name | <code>sql_auto_is_null</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | 0 |

If this variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 12.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See [Obtaining Auto-Increment Values](#). This behavior can be disabled by setting `sql_auto_is_null` to 0.

The default value of `sql_auto_is_null` is 0.

- `sql_big_selects`

| | | |
|-------------------------|-------------------------|------------------------------|
| System Variable | Name | <code>sql_big_selects</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | 1 |

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to 0.

- `sql_buffer_result`

| | | |
|-------------------------|-------------------------|--------------------------------|
| System Variable | Name | <code>sql_buffer_result</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | 0 |

If set to 1, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `sql_log_bin`

| | | |
|-------------------------|-------------------------|--------------------------|
| System Variable | Name | <code>sql_log_bin</code> |
| | Variable Scope | Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |

This variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` privilege to set this variable.

Setting this variable to 0 prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that, even when binary logging is later enabled once again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime—in effect, those transactions are lost.

In MySQL 5.6, it is not possible to set `@@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

- `sql_log_off`

| | | |
|------------------------|-------------------------|--------------------------|
| System Variable | Name | <code>sql_log_off</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |

| | | |
|-------------------------|----------------|---------|
| Permitted Values | Type | boolean |
| | Default | 0 |

This variable controls whether logging to the general query log is done. The default value is 0 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the [SUPER](#) privilege to set this option. The default value is 0.

- [sql_mode](#)

| | | |
|---------------------------------------|------------------------------|--|
| Command-Line Format | <code>--sql-mode=name</code> | |
| System Variable | Name | sql_mode |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.5) | Type | set |
| | Default | '' |
| | Valid Values | ALLOW_INVALID_DATES |
| | | ANSI_QUOTES |
| | | ERROR_FOR_DIVISION_BY_ZERO |
| | | HIGH_NOT_PRECEDENCE |
| | | IGNORE_SPACE |
| | | NO_AUTO_CREATE_USER |
| | | NO_AUTO_VALUE_ON_ZERO |
| | | NO_BACKSLASH_ESCAPES |
| | | NO_DIR_IN_CREATE |
| | | NO_ENGINE_SUBSTITUTION |
| | | NO_FIELD_OPTIONS |
| | | NO_KEY_OPTIONS |
| | | NO_TABLE_OPTIONS |
| | | NO_UNSIGNED_SUBTRACTION |
| | | NO_ZERO_DATE |
| | | NO_ZERO_IN_DATE |
| | | ONLY_FULL_GROUP_BY |
| | | PAD_CHAR_TO_FULL_LENGTH |
| | | PIPES_AS_CONCAT |
| | | REAL_AS_FLOAT |
| | | STRICT_ALL_TABLES |
| | | STRICT_TRANS_TABLES |
| Permitted Values (>= 5.6.6) | Type | set |
| | Default | NO_ENGINE_SUBSTITUTION |

| | | |
|--|---------------------|----------------------------|
| | Valid Values | ALLOW_INVALID_DATES |
| | | ANSI_QUOTES |
| | | ERROR_FOR_DIVISION_BY_ZERO |
| | | HIGH_NOT_PRECEDENCE |
| | | IGNORE_SPACE |
| | | NO_AUTO_CREATE_USER |
| | | NO_AUTO_VALUE_ON_ZERO |
| | | NO_BACKSLASH_ESCAPES |
| | | NO_DIR_IN_CREATE |
| | | NO_ENGINE_SUBSTITUTION |
| | | NO_FIELD_OPTIONS |
| | | NO_KEY_OPTIONS |
| | | NO_TABLE_OPTIONS |
| | | NO_UNSIGNED_SUBTRACTION |
| | | NO_ZERO_DATE |
| | | NO_ZERO_IN_DATE |
| | | ONLY_FULL_GROUP_BY |
| | | PAD_CHAR_TO_FULL_LENGTH |
| | | PIPES_AS_CONCAT |
| | | REAL_AS_FLOAT |
| | | STRICT_ALL_TABLES |
| | | STRICT_TRANS_TABLES |

The current server SQL mode, which can be set dynamically. The default as of MySQL 5.6.6 is `NO_ENGINE_SUBSTITUTION`; previously it was an empty string. For details, see [Section 5.1.8, “Server SQL Modes”](#).

Note

MySQL installation programs may configure the SQL mode during the installation process. For example, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file contains a line that sets the SQL mode; see [Section 4.4.3, “mysql_install_db — Initialize MySQL Data Directory”](#).

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `sql_notes`

If set to 1 (the default), warnings of `Note` level increment `warning_count` and the server records them. If set to 0, `Note` warnings do not increment `warning_count` and the server does not record them. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `sql_quote_show_create`

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 13.7.5.12, “SHOW CREATE TABLE Syntax”](#), and [Section 13.7.5.8, “SHOW CREATE DATABASE Syntax”](#).

- `sql_safe_updates`

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. (Specifically, `UPDATE` statements must have a `WHERE` clause that uses a key or a `LIMIT` clause, or both. `DELETE` statements must have both.) This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- `sql_select_limit`

| | | |
|-------------------------|-------------------------|-------------------------------|
| System Variable | Name | <code>sql_select_limit</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are $(2^{32})-1$ or $(2^{64})-1$. If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- `sql_warnings`

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `ssl_ca`

| | | |
|----------------------------|---------------------------------|---------------------|
| Command-Line Format | <code>--ssl-ca=file_name</code> | |
| System Variable | Name | <code>ssl_ca</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The path to a file with a list of trusted SSL CAs.

- `ssl_capath`

| | | |
|----------------------------|------------------------------------|-------------------------|
| Command-Line Format | <code>--ssl-capath=dir_name</code> | |
| System Variable | Name | <code>ssl_capath</code> |

| | | |
|-------------------------|-------------------------|----------------|
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `ssl_cert`

| | | |
|----------------------------|-----------------------------------|-----------------------|
| Command-Line Format | <code>--ssl-cert=file_name</code> | |
| System Variable | Name | <code>ssl_cert</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The name of the SSL certificate file to use for establishing a secure connection.

- `ssl_cipher`

| | | |
|----------------------------|--------------------------------|-------------------------|
| Command-Line Format | <code>--ssl-cipher=name</code> | |
| System Variable | Name | <code>ssl_cipher</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

A list of permissible ciphers to use for SSL encryption.

- `ssl_crl`

| | | |
|----------------------------|----------------------------------|----------------------|
| Introduced | 5.6.3 | |
| Command-Line Format | <code>--ssl-crl=file_name</code> | |
| System Variable | Name | <code>ssl_crl</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The path to a file containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled using OpenSSL (but not yaSSL). See [Section 6.4.1, “OpenSSL Versus yaSSL”](#).

This variable was added in MySQL 5.6.3.

- `ssl_crlpath`

| | | |
|----------------------------|-------------------------------------|--------------------------|
| Introduced | 5.6.3 | |
| Command-Line Format | <code>--ssl-crlpath=dir_name</code> | |
| System Variable | Name | <code>ssl_crlpath</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The path to a directory that contains files containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled using OpenSSL (but not yaSSL). See [Section 6.4.1, “OpenSSL Versus yaSSL”](#).

This variable was added in MySQL 5.6.3.

- `ssl_key`

| | | |
|----------------------------|----------------------------------|----------------------|
| Command-Line Format | <code>--ssl-key=file_name</code> | |
| System Variable | Name | <code>ssl_key</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | file name |

The name of the SSL key file to use for establishing a secure connection.

- `storage_engine`

| | | |
|-------------------------|-------------------------|-----------------------------|
| System Variable | Name | <code>storage_engine</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>InnoDB</code> |

The default storage engine (table type). To set the storage engine at server startup, use the `--default-storage-engine` option. See [Section 5.1.4, “Server Command Options”](#).

This variable is deprecated. Use `default_storage_engine` instead.

- `stored_program_cache`

| | | |
|----------------------------|---------------------------------------|-----------------------------------|
| Introduced | 5.6.5 | |
| Command-Line Format | <code>--stored-program-cache=#</code> | |
| System Variable | Name | <code>stored_program_cache</code> |

| | | |
|-------------------------|-------------------------|---------|
| Permitted Values | Variable Scope | Global |
| | Dynamic Variable | Yes |
| | Type | integer |
| | Default | 256 |
| | Min Value | 256 |
| | Max Value | 524288 |

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

- `sync_frm`

| | | |
|----------------------------|-------------------------|-----------------------|
| Command-Line Format | <code>--sync_frm</code> | |
| System Variable | Name | <code>sync_frm</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | TRUE |

If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- `system_time_zone`

| | | |
|-------------------------|-------------------------|-------------------------------|
| System Variable | Name | <code>system_time_zone</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 10.6, “MySQL Server Time Zone Support”](#).

- `table_definition_cache`

| | | |
|---------------------------------------|-------------------------|-------------------------------------|
| System Variable | Name | <code>table_definition_cache</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.7) | Type | integer |
| | Default | 400 |
| | Min Value | 400 |
| | Max Value | 524288 |
| Permitted Values (>= 5.6.8) | Type | integer |
| | Default | -1 (autosized) |
| | Min Value | 400 |
| | Max Value | 524288 |

The number of table definitions (from `.frm` files) that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

```
400 + (table_open_cache / 2)
```

Before MySQL 5.6.8, the default is 400.

For `InnoDB`, `table_definition_cache` acts as a soft limit for the number of open table instances in the `InnoDB` data dictionary cache. If the number of open table instances exceeds the `table_definition_cache` setting, the LRU mechanism begins to mark table instances for eviction and eventually removes them from the data dictionary cache. The limit helps address situations in which significant amounts of memory would be used to cache rarely used table instances until the next server restart. The number of table instances with cached metadata could be higher than the limit defined by `table_definition_cache`, because `InnoDB` system table instances and parent and child table instances with foreign key relationships are not placed on the LRU list and are not subject to eviction from memory.

Additionally, `table_definition_cache` defines a soft limit for the number of `InnoDB` file-per-table tablespaces that can be open at one time, which is also controlled by `innodb_open_files`. If both `table_definition_cache` and `innodb_open_files` are set, the highest setting is used. If neither variable is set, `table_definition_cache`, which has a higher default value, is used. If the number of open tablespace file handles exceeds the limit defined by `table_definition_cache` or

[innodb_open_files](#), the LRU mechanism searches the tablespace file LRU list for files that are fully flushed and are not currently being extended. This process is performed each time a new tablespace is opened. If there are no “inactive” tablespaces, no tablespace files are closed.

- [table_open_cache](#)

| | | |
|---------------------------------------|-------------------------|----------------------------------|
| System Variable | Name | table_open_cache |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.7) | Type | integer |
| | Default | 400 |
| | Min Value | 1 |
| | Max Value | 524288 |
| Permitted Values (>= 5.6.8) | Type | integer |
| | Default | 2000 |
| | Min Value | 1 |
| | Max Value | 524288 |

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See [Section 5.1.7, “Server Status Variables”](#). If the value of `Opened_tables` is large and you do not use `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` variable. For more information about the table cache, see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

- [table_open_cache_instances](#)

| | | |
|-------------------------|-------------------------|--|
| Introduced | 5.6.6 | |
| System Variable | Name | table_open_cache_instances |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 1 |
| | Min Value | 1 |
| | Max Value | 64 |

The number of open tables cache instances (default 1). To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size

`table_open_cache` / `table_open_cache_instances` . A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

This variable was added in MySQL 5.6.6.

- `thread_cache_size`

| | | |
|---------------------------------------|------------------------------------|--------------------------------|
| Command-Line Format | <code>--thread_cache_size=#</code> | |
| System Variable | Name | <code>thread_cache_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values (<= 5.6.7) | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 16384 |
| Permitted Values (>= 5.6.8) | Type | integer |
| | Default | -1 (autosized) |
| | Min Value | 0 |
| | Max Value | 16384 |

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see [Section 5.1.7, “Server Status Variables”](#).

The default value is based on the following formula, capped to a limit of 100:

```
8 + (max_connections / 100)
```

Before MySQL 5.6.8, the default is 0.

- `thread_concurrency`

| | |
|-------------------|-------|
| Deprecated | 5.6.1 |
|-------------------|-------|

| | | |
|----------------------------|-------------------------------------|---------------------------------|
| Command-Line Format | <code>--thread_concurrency=#</code> | |
| System Variable | Name | <code>thread_concurrency</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 10 |
| | Min Value | 1 |
| | Max Value | 512 |

This variable is specific to Solaris 8 and earlier systems, for which `mysqld` invokes the `thr_setconcurrency()` function with the variable value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time. Current Solaris versions document this as having no effect.

This variable is deprecated as of MySQL 5.6.1 and is removed in MySQL 5.7. You should remove this from MySQL configuration files whenever you see it unless they are for Solaris 8 or earlier.

- `thread_handling`

| | | |
|----------------------------|-------------------------------------|--|
| Command-Line Format | <code>--thread_handling=name</code> | |
| System Variable | Name | <code>thread_handling</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | enumeration |
| | Default | <code>one-thread-per-connection</code> |
| | Valid Values | <code>no-threads</code> |
| | | <code>one-thread-per-connection</code> |
| | | <code>dynamically-loaded</code> |

The thread-handling model used by the server for connection threads. The permissible values are `no-threads` (the server uses a single thread to handle one connection) and `one-thread-per-connection` (the server uses one thread to handle each client connection). `no-threads` is useful for debugging under Linux; see [Section 24.5, “Debugging and Porting MySQL”](#).

If the thread pool plugin is enabled, the server sets the `thread_handling` value to `dynamically-loaded`. See [Section 5.5.4.2, “Thread Pool Installation”](#).

- `thread_pool_algorithm`

| | | |
|----------------------------|--|------------------------------------|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--thread_pool_algorithm=#</code> | |
| System Variable | Name | <code>thread_pool_algorithm</code> |

| | | |
|-------------------------|-------------------------|---------|
| Permitted Values | Variable Scope | Global |
| | Dynamic Variable | No |
| | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 1 |

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.
- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 5.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_high_priority_connection`

| | | |
|----------------------------|---|---|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--thread_pool_high_priority_connection=#</code> | |
| System Variable | Name | <code>thread_pool_high_priority_connection</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 1 |

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 5.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_max_unused_threads`

| | |
|-------------------|--------|
| Introduced | 5.6.10 |
|-------------------|--------|

| | | |
|----------------------------|---|---|
| Command-Line Format | <code>--thread_pool_max_unused_threads=#</code> | |
| System Variable | Name | <code>thread_pool_max_unused_threads</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 0 |
| | Min Value | 0 |
| | Max Value | 4096 |

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of *N* where *N* is greater than 0 means 1 consumer thread and *N*−1 reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 5.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_prio_kickup_timer`

| | | |
|----------------------------|--|--|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--thread_pool_prio_kickup_timer=#</code> | |
| System Variable | Name | <code>thread_pool_prio_kickup_timer</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 1000 |
| | Min Value | 0 |
| | Max Value | 4294967294 |

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second). The range of values is 0 to $2^{32} - 2$.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 5.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_size`

| | | |
|----------------------------|-----------------------------------|-------------------------------|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--thread_pool_size=#</code> | |
| System Variable | Name | <code>thread_pool_size</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | integer |
| | Default | 16 |
| | Min Value | 1 |
| | Max Value | 64 |

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. The default value is 16, with a range from 1 to 64 of permissible values. If a value outside this range is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 5.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_stall_limit`

| | | |
|----------------------------|--|--------------------------------------|
| Introduced | 5.6.10 | |
| Command-Line Format | <code>--thread_pool_stall_limit=#</code> | |
| System Variable | Name | <code>thread_pool_stall_limit</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | 6 |
| | Min Value | 4 |
| | Max Value | 600 |

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so a value of 6 (the default) means 60ms. The range of values is 4 to 600 (40ms to 6s). Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable was added in MySQL 5.6.10. It is available only if the thread pool plugin is enabled. See [Section 5.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_stack`

| | | |
|--|-------------------------------|-----------------------------------|
| Command-Line Format | <code>--thread_stack=#</code> | |
| System Variable | Name | <code>thread_stack</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values (32-bit platforms) | Type | integer |
| | Default | <code>196608</code> |
| | Min Value | <code>131072</code> |
| | Max Value | <code>4294967295</code> |
| | Block Size | <code>1024</code> |
| Permitted Values (64-bit platforms) | Type | integer |
| | Default | <code>262144</code> |
| | Min Value | <code>131072</code> |
| | Max Value | <code>18446744073709551615</code> |
| | Block Size | <code>1024</code> |

The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. See [Section 8.13.2, “The MySQL Benchmark Suite”](#). The default of 192KB (256KB for 64-bit systems) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format`

This variable is unused. It is deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release.

- `time_zone`

| | | |
|-------------------------|-------------------------|------------------------|
| System Variable | Name | <code>time_zone</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | string |

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is `'SYSTEM'` (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See [Section 10.6, “MySQL Server Time Zone Support”](#).

- `timed_mutexes`

| | | |
|----------------------------|------------------------------|----------------------------|
| Deprecated | 5.6.20 | |
| Command-Line Format | <code>--timed_mutexes</code> | |
| System Variable | Name | <code>timed_mutexes</code> |
| | Variable Scope | Global |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

This variable is deprecated; it has no use. It will be removed in a future MySQL release.

- `timestamp`

| | | |
|-------------------------|-------------------------|------------------------|
| System Variable | Name | <code>timestamp</code> |
| | Variable Scope | Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | numeric |

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`, not a value in `'YYYY-MM-DD hh:mm:ss'` format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed.

As of MySQL 5.6.4, `timestamp` is a `DOUBLE` rather than `BIGINT` because its value includes a microseconds part.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that `timestamp` settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET timestamp` affects both functions.

- `tmp_table_size`

| | | |
|----------------------------|---------------------------------|-----------------------------------|
| Command-Line Format | <code>--tmp_table_size=#</code> | |
| System Variable | Name | <code>tmp_table_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | integer |
| | Default | <code>16777216</code> |
| | Min Value | <code>1024</code> |
| | Max Value | <code>18446744073709551615</code> |

The maximum size of internal in-memory temporary tables. This variable does not apply to user-created `MEMORY` tables.

The actual limit is determined from whichever of the values of `tmp_table_size` and `max_heap_table_size` is smaller. If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk `MyISAM` table. Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- `tmpdir`

| | | |
|----------------------------|--------------------------------|---------------------|
| Command-Line Format | <code>--tmpdir=dir_name</code> | |
| System Variable | Name | <code>tmpdir</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | directory name |

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. You can set the slave's temporary directory using the `slave_load_tmpdir`

variable. In that case, the slave will not use the general `tmpdir` value and you can set `tmpdir` to a nonpermanent location.

- `transaction_alloc_block_size`

| | | |
|---|---|---|
| Command-Line Format | <code>--transaction_alloc_block_size=#</code> | |
| System Variable | Name | <code>transaction_alloc_block_size</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (>= 5.6.24) | Type | integer |
| | Default | 8192 |
| | Min Value | 1024 |
| | Max Value | 131072 |
| | Block Size | 1024 |
| Permitted Values (32-bit platforms, <= 5.6.23) | Type | integer |
| | Default | 8192 |
| | Min Value | 1024 |
| | Max Value | 4294967295 |
| | Block Size | 1024 |
| Permitted Values (64-bit platforms, <= 5.6.23) | Type | integer |
| | Default | 8192 |
| | Min Value | 1024 |
| | Max Value | 18446744073709551615 |
| | Block Size | 1024 |

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_prealloc_size`

| | | |
|----------------------------|--|--|
| Command-Line Format | <code>--transaction_prealloc_size=#</code> | |
| System Variable | Name | <code>transaction_prealloc_size</code> |
| | Variable Scope | Global, Session |

| | | |
|---|-------------------------|----------------------|
| | Dynamic Variable | Yes |
| Permitted Values (>= 5.6.24) | Type | integer |
| | Default | 4096 |
| | Min Value | 1024 |
| | Max Value | 131072 |
| | Block Size | 1024 |
| Permitted Values (32-bit platforms, <= 5.6.23) | Type | integer |
| | Default | 4096 |
| | Min Value | 1024 |
| | Max Value | 4294967295 |
| | Block Size | 1024 |
| Permitted Values (64-bit platforms, <= 5.6.23) | Type | integer |
| | Default | 4096 |
| | Min Value | 1024 |
| | Max Value | 18446744073709551615 |
| | Block Size | 1024 |

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `tx_isolation`

| | | |
|-------------------------|-------------------------|------------------------------|
| System Variable | Name | <code>tx_isolation</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | enumeration |
| | Default | <code>REPEATABLE-READ</code> |

| | | |
|--|---------------------|------------------|
| | Valid Values | READ-UNCOMMITTED |
| | | READ-COMMITTED |
| | | REPEATABLE-READ |
| | | SERIALIZABLE |

The default transaction isolation level. Defaults to `REPEATABLE-READ`.

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#). If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

Any unique prefix of a valid value may be used to set the value of this variable.

The default transaction isolation level can also be set at startup using the `--transaction-isolation` server option.

- `tx_read_only`

| | | |
|-------------------------|-------------------------|---------------------------|
| Introduced | 5.6.5 | |
| System Variable | Name | <code>tx_read_only</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>OFF</code> |

The default transaction access mode. The value can be `OFF` (read/write, the default) or `ON` (read only).

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

To set the default transaction access mode at startup, use the `--transaction-read-only` server option.

This variable was added in MySQL 5.6.5.

- `unique_checks`

| | | |
|-------------------------|-------------------------|----------------------------|
| System Variable | Name | <code>unique_checks</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | <code>1</code> |

If set to 1 (the default), uniqueness checks for secondary indexes in [InnoDB](#) tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to [InnoDB](#).

Setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- [updatable_views_with_limit](#)

| | | |
|----------------------------|---|--|
| Command-Line Format | <code>--updatable_views_with_limit=#</code> | |
| System Variable | Name | updatable_views_with_limit |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values | Type | boolean |
| | Default | 1 |

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a [LIMIT](#) clause. (Such updates often are generated by GUI tools.) An update is an [UPDATE](#) or [DELETE](#) statement. Primary key here means a [PRIMARY KEY](#), or a [UNIQUE](#) index in which no column can contain [NULL](#).

The variable can have two values:

- [1](#) or [YES](#): Issue a warning only (not an error message). This is the default value.
- [0](#) or [NO](#): Prohibit the update.

- [validate_password_xxx](#)

The [validate_password](#) plugin implements a set of system variables having names of the form [validate_password_xxx](#). These variables affect password testing by that plugin; see [Section 6.5.3.2](#), “Password Validation Plugin Options and Variables”.

- [validate_user_plugins](#)

| | | |
|-------------------------|-------------------------|---------------------------------------|
| Introduced | 5.6.11 | |
| System Variable | Name | validate_user_plugins |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | boolean |
| | Default | ON |

If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.

- The account requires the `sha256_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by this plugin.

Enabling `validate_user_plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

This variable was added in MySQL 5.6.11.

- `version`

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-log` indicates that one or more of the general log, slow query log, or binary log are enabled. `-debug` indicates that the server was built with debugging support enabled.

- `version_comment`

| | | |
|-------------------------|-------------------------|------------------------------|
| System Variable | Name | <code>version_comment</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The `CMake` configuration program has a `COMPILATION_COMMENT` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- `version_compile_machine`

| | | |
|-------------------------|-------------------------|--------------------------------------|
| System Variable | Name | <code>version_compile_machine</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The type of the server binary.

- `version_compile_os`

| | | |
|-------------------------|-------------------------|---------------------------------|
| System Variable | Name | <code>version_compile_os</code> |
| | Variable Scope | Global |
| | Dynamic Variable | No |
| Permitted Values | Type | string |

The type of operating system on which MySQL was built.

- `wait_timeout`

| | | |
|-----------------------------------|-------------------------------|---------------------------|
| Command-Line Format | <code>--wait_timeout=#</code> | |
| System Variable | Name | <code>wait_timeout</code> |
| | Variable Scope | Global, Session |
| | Dynamic Variable | Yes |
| Permitted Values (Windows) | Type | integer |
| | Default | 28800 |
| | Min Value | 1 |
| | Max Value | 2147483 |
| Permitted Values (Other) | Type | integer |
| | Default | 28800 |
| | Min Value | 1 |
| | Max Value | 31536000 |

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

5.1.6 Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. [Section 5.1.5, “Server System Variables”](#), describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See [Section 4.2.3, “Specifying Program Options”](#).)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables.

For example, a client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024 , 1024^2 or 1024^3 ; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `query_cache_size` from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see [Section 5.1.6.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier:

- To indicate that a variable is a global variable, precede its name by the `GLOBAL` keyword or the `@@global.` qualifier:

```
SET GLOBAL max_connections = 1000;
SET @@global.max_connections = 1000;
```

The `SUPER` privilege is required to set global variables.

- To indicate that a variable is a session variable, precede its name by the `SESSION` keyword or either the `@@session.` or `@@` qualifier:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

Setting a session variable normally requires no special privilege, although there are exceptions that require the `SUPER` privilege (such as `sql_log_bin`). A client can change its own session variables, but not those of any other client.

- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable.
- An error occurs under these circumstances:

- Use of `SET GLOBAL` (or `@@global.`) when setting a variable that has only a session value:

```
mysql> SET GLOBAL sql_log_bin = ON;
ERROR 1231 (42000): Variable 'sql_log_bin' can't be
set to the value of 'ON'
```

- Omission of `GLOBAL` (or `@@global.`) when setting a variable that has only a global value:

```
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- Use of `SET SESSION` (or `@@SESSION.`) when setting a variable that has only a global value:

```
mysql> SET SESSION max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

The preceding modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following assignments that have no modifier specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@global.sort_buffer_size = 1000000, @@local.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any current client sessions (not even the session within which the `SET GLOBAL` statement occurred).

To make a global system variable setting permanent so that it applies across server restarts, you should also set it in an option file.

To set a `GLOBAL` value to the compiled-in MySQL default value or a `SESSION` variable to the current corresponding `GLOBAL` value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```
SET @@session.max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

It is not permitted to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables. This results in an error for user-defined variables, and also for parameters or local variables as of MySQL 5.6.6.

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

For a reference to a system variable in an expression as `@@var_name` (rather than with `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
```

| Variable_name | Value |
|--------------------------|--------------|
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
| automatic_sp_privileges | ON |
| back_log | 50 |
| basedir | /home/mysql/ |
| binlog_cache_size | 32768 |
| bulk_insert_buffer_size | 8388608 |
| character_set_client | latin1 |
| character_set_connection | latin1 |
| character_set_database | latin1 |

| | | |
|---------------------------------|-----------------------------------|--|
| character_set_results | latin1 | |
| character_set_server | latin1 | |
| character_set_system | utf8 | |
| character_sets_dir | /home/mysql/share/mysql/charsets/ | |
| collation_connection | latin1_swedish_ci | |
| collation_database | latin1_swedish_ci | |
| collation_server | latin1_swedish_ci | |
| ... | | |
| innodb_additional_mem_pool_size | 1048576 | |

| innodb_buffer_pool_size | 8388608 | |
| innodb_checksums | ON | |
| innodb_commit_concurrency | 0 | |
| innodb_concurrency_tickets | 500 | |
| innodb_data_file_path | ibdata1:10M:autoextend | |
| innodb_data_home_dir | | |
| ... | | |
| version | 5.1.6-alpha-log | |
| version_comment | Source distribution | |
| version_compile_machine | i686 | |
| version_compile_os | suse-linux | |
| wait_timeout | 28800 | |
| +-----+-----+-----+ | | |

With a [LIKE](#) clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the [%](#) wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because [_](#) is a wildcard that matches any single character, you should escape it as [_](#) to match it literally. In practice, this is rarely necessary.

For [SHOW VARIABLES](#), if you specify neither [GLOBAL](#) nor [SESSION](#), MySQL returns [SESSION](#) values.

The reason for requiring the [GLOBAL](#) keyword when setting [GLOBAL](#)-only variables but not when retrieving them is to prevent problems in the future:

- Were we to remove a [SESSION](#) variable that has the same name as a [GLOBAL](#) variable, a client with the [SUPER](#) privilege might accidentally change the [GLOBAL](#) variable rather than just the [SESSION](#) variable for its own connection.
- Were we to add a [SESSION](#) variable with the same name as a [GLOBAL](#) variable, a client that intends to change the [GLOBAL](#) variable might find only its own [SESSION](#) variable changed.

5.1.6.1 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 8.10.2, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]  
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \  
        --extra_cache.key_buffer_size=128K \  
        --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \  
        --hot_cache.key_buffer_size=2M \  
        --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;  
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

5.1.6.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also obtain their values using `SELECT`. See [Section 5.1.6, “Using System Variables”](#).

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOBAL` or `SESSION` (or both) apply. The table also lists session options that can be set with the `SET` statement. [Section 5.1.5, “Server System Variables”](#), discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system

variables, the first enumeration value corresponds to 0. This differs from [ENUM](#) columns, for which the first enumeration value corresponds to 1.

Table 5.4 Dynamic Variable Summary

| Variable Name | Variable Type | Variable Scope |
|---|---------------|------------------|
| audit_log_connection_policy | enumeration | GLOBAL |
| audit_log_exclude_accounts | string | GLOBAL |
| audit_log_flush | boolean | GLOBAL |
| audit_log_include_accounts | string | GLOBAL |
| audit_log_policy | enumeration | GLOBAL |
| audit_log_rotate_on_size | integer | GLOBAL |
| audit_log_statement_policy | enumeration | GLOBAL |
| auto_increment_increment | integer | GLOBAL SESSION |
| auto_increment_offset | integer | GLOBAL SESSION |
| autocommit | boolean | GLOBAL SESSION |
| automatic_sp_privileges | boolean | GLOBAL |
| avoid_temporal_upgrade | boolean | GLOBAL |
| big_tables | boolean | GLOBAL SESSION |
| binlog_cache_size | integer | GLOBAL |
| binlog_checksum | string | GLOBAL |
| binlog_direct_non_transactional_updates | boolean | GLOBAL SESSION |
| binlog_error_action | enumeration | GLOBAL SESSION |
| binlog_format | enumeration | GLOBAL SESSION |
| binlog_max_flush_queue_time | integer | GLOBAL |
| binlog_order_commits | boolean | GLOBAL |
| binlog_row_image=image_type | enumeration | GLOBAL SESSION |
| binlog_rows_query_log_events | boolean | GLOBAL SESSION |
| binlog_stmt_cache_size | integer | GLOBAL |
| binlogging_impossible_mode | enumeration | GLOBAL SESSION |
| block_encryption_mode | string | GLOBAL SESSION |
| bulk_insert_buffer_size | integer | GLOBAL SESSION |
| character_set_client | string | GLOBAL SESSION |
| character_set_connection | string | GLOBAL SESSION |
| character_set_database | string | GLOBAL SESSION |
| character_set_filesystem | string | GLOBAL SESSION |
| character_set_results | string | GLOBAL SESSION |
| character_set_server | string | GLOBAL SESSION |
| collation_connection | string | GLOBAL SESSION |
| collation_database | string | GLOBAL SESSION |
| collation_server | string | GLOBAL SESSION |

| Variable Name | Variable Type | Variable Scope |
|---|---------------|------------------|
| completion_type | enumeration | GLOBAL SESSION |
| concurrent_insert | enumeration | GLOBAL |
| connect_timeout | integer | GLOBAL |
| connection_control_failed_connections_threshold | integer | GLOBAL |
| connection_control_max_connection_delay | integer | GLOBAL |
| connection_control_min_connection_delay | integer | GLOBAL |
| debug | string | GLOBAL SESSION |
| debug_sync | string | SESSION |
| default_storage_engine | enumeration | GLOBAL SESSION |
| default_tmp_storage_engine | enumeration | GLOBAL SESSION |
| default_week_format | integer | GLOBAL SESSION |
| delay_key_write | enumeration | GLOBAL |
| delayed_insert_limit | integer | GLOBAL |
| delayed_insert_timeout | integer | GLOBAL |
| delayed_queue_size | integer | GLOBAL |
| div_precision_increment | integer | GLOBAL SESSION |
| end_markers_in_json | boolean | GLOBAL SESSION |
| engine_condition_pushdown | boolean | GLOBAL SESSION |
| eq_range_index_dive_limit | integer | GLOBAL SESSION |
| event_scheduler | enumeration | GLOBAL |
| expire_logs_days | integer | GLOBAL |

5.1.7 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 13.7.5.36, “SHOW STATUS Syntax”](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
```

| Variable_name | Value |
|------------------|------------|
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
| ... | |
| Connections | 30023 |

| | | |
|-------------------------|---------|--|
| Created_tmp_disk_tables | 0 | |
| Created_tmp_files | 3 | |
| Created_tmp_tables | 2 | |
| ... | | |
| Threads_created | 217 | |
| Threads_running | 88 | |
| Uptime | 1389872 | |
| +-----+-----+ | | |

Several status variables provide statement counts. To determine the number of statements executed, use these relationships:

```
SUM(Com_xxx) + Qcache_hits
= Questions + statements executed within stored programs
= Queries
```

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The following table lists all available server status variables:

Table 5.5 Status Variable Summary

| Variable Name | Variable Type | Variable Scope |
|-------------------------------|---------------|------------------|
| Aborted_clients | integer | GLOBAL |
| Aborted_connects | integer | GLOBAL |
| Audit_log_current_size | integer | GLOBAL |
| Audit_log_event_max_drop_size | integer | GLOBAL |
| Audit_log_events | integer | GLOBAL |

The status variables have the following meanings. For meanings of status variables specific to MySQL Cluster, see [NDB Cluster Status Variables](#).

- `Aborted_clients`

The number of connections that were aborted because the client died without closing the connection properly. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

- `Aborted_connects`

The number of failed attempts to connect to the MySQL server. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

For additional connection-related information, check the `Connection_errors_xxx` status variables and the `host_cache` table.

- `Binlog_cache_disk_use`

The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- `Binlog_cache_use`

The number of transactions that used the binary log cache.

- `Binlog_stmt_cache_disk_use`

The number of nontransaction statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- `Binlog_stmt_cache_use`

The number of nontransactional statements that used the binary log statement cache.

- `Bytes_received`

The number of bytes received from all clients.

- `Bytes_sent`

The number of bytes sent to all clients.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See [Section 8.10.3.4, “Query Cache Status and Maintenance”](#).

The discussion at the beginning of this section indicates how to relate these statement-counting status variables to other such variables.

All of the `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_xxx` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

- `Compression`

Whether the client connection uses compression in the client/server protocol.

- `Connection_errors_xxx`

These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see [Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”](#)), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). These variables were added in MySQL 5.6.5.

- `Connection_errors_accept`

The number of errors that occurred during calls to `accept()` on the listening port.

- `Connection_errors_internal`

The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

- `Connection_errors_max_connections`

The number of connections refused because the server `max_connections` limit was reached.

- `Connection_errors_peer_addr`

The number of errors that occurred while searching for connecting client IP addresses.

- `Connection_errors_select`

The number of errors that occurred during calls to `select()` or `poll()` on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- `Connection_errors_tcpwrap`

The number of connections refused by the `libwrap` library.

- `Connections`

The number of connection attempts (successful or not) to the MySQL server.

- `Created_tmp_disk_tables`

The number of internal on-disk temporary tables created by the server while executing statements.

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` and `max_heap_table_size` values. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` or `max_heap_table_size` value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

- `Created_tmp_files`

How many temporary files `mysqld` has created.

- `Created_tmp_tables`

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- `Delayed_errors`

The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

As of MySQL 5.6.7, this status variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `Delayed_insert_threads`

The number of `INSERT DELAYED` handler threads in use for nontransactional tables.

As of MySQL 5.6.7, this status variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `Delayed_writes`

The number of `INSERT DELAYED` rows written to nontransactional tables.

As of MySQL 5.6.7, this status variable is deprecated (because `DELAYED` inserts are deprecated), and will be removed in a future release.

- `Flush_commands`

The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `Handler_commit`

The number of internal `COMMIT` statements.

- `Handler_delete`

The number of times that rows have been deleted from tables.

- `Handler_external_lock`

The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked. This variable was added in MySQL 5.6.2.

- `Handler_mrr_init`

The number of times the server uses a storage engine's own Multi-Range Read implementation for table access. This variable was added in MySQL 5.6.1.

- `Handler_prepare`

A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.

- `Handler_read_key`

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_last`

The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests. This variable was added in MySQL 5.6.1.

- `Handler_read_next`

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- `Handler_read_rnd_next`

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

The number of requests for a storage engine to perform a rollback operation.

- `Handler_savepoint`

The number of requests for a storage engine to place a savepoint.

- `Handler_savepoint_rollback`

The number of requests for a storage engine to roll back to a savepoint.

- `Handler_update`

The number of requests to update a row in a table.

- `Handler_write`

The number of requests to insert a row in a table.

- `Innodb_available_undo_logs`

The total number of available [InnoDB rollback segments](#). Supplements the `innodb_undo_logs` system variable, which defines the number of active rollback segments.

- `Innodb_buffer_pool_dump_status`

The progress of an operation to record the [pages](#) held in the [InnoDB buffer pool](#), triggered by the setting of `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

For related information and examples, see [Section 14.6.3.7, “Saving and Restoring the Buffer Pool State”](#).

- `Innodb_buffer_pool_load_status`

The progress of an operation to [warm up](#) the [InnoDB buffer pool](#) by reading in a set of [pages](#) corresponding to an earlier point in time, triggered by the setting of `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`. If the operation introduces too much overhead, you can cancel it by setting `innodb_buffer_pool_load_abort`.

For related information and examples, see [Section 14.6.3.7, “Saving and Restoring the Buffer Pool State”](#).

- `Innodb_buffer_pool_bytes_data`

The total number of bytes in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. For more accurate memory usage calculations than with

`Innodb_buffer_pool_pages_data`, when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_data`

The number of [pages](#) in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. When using [compressed tables](#), the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- `Innodb_buffer_pool_bytes_dirty`

The total current number of bytes held in [dirty pages](#) in the [InnoDB buffer pool](#). For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_dirty`

The current number of [dirty pages](#) in the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_flushed`

The number of requests to [flush pages](#) from the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_free`

The number of free [pages](#) in the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_latched`

The number of latched [pages](#) in the [InnoDB buffer pool](#). These are pages currently being read or written, or that cannot be [flushed](#) or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- `Innodb_buffer_pool_pages_misc`

The number of [pages](#) in the [InnoDB buffer pool](#) that are busy because they have been allocated for administrative overhead, such as [row locks](#) or the [adaptive hash index](#). This value can also be calculated as `Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data`. When using [compressed tables](#), `Innodb_buffer_pool_pages_misc` may report an out-of-bounds value (Bug #59550).

- `Innodb_buffer_pool_pages_total`

The total size of the [InnoDB buffer pool](#), in [pages](#). When using [compressed tables](#), the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550)

- `Innodb_buffer_pool_read_ahead`

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread.

- `Innodb_buffer_pool_read_ahead_evicted`

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread that were subsequently [evicted](#) without having been accessed by queries.

- `Innodb_buffer_pool_read_ahead_rnd`

The number of “random” read-aheads initiated by [InnoDB](#). This happens when a query scans a large portion of a table but in random order.

- [Innodb_buffer_pool_read_requests](#)

The number of logical read requests.

- [Innodb_buffer_pool_reads](#)

The number of logical reads that [InnoDB](#) could not satisfy from the [buffer pool](#), and had to read directly from disk.

- [Innodb_buffer_pool_wait_free](#)

Normally, writes to the [InnoDB buffer pool](#) happen in the background. When [InnoDB](#) needs to read or create a [page](#) and no clean pages are available, [InnoDB](#) flushes some [dirty pages](#) first and waits for that operation to finish. This counter counts instances of these waits. If [innodb_buffer_pool_size](#) has been set properly, this value should be small.

- [Innodb_buffer_pool_write_requests](#)

The number of writes done to the [InnoDB buffer pool](#).

- [Innodb_data_fsyncs](#)

The number of `fsync()` operations so far. The frequency of `fsync()` calls is influenced by the setting of the [innodb_flush_method](#) configuration option.

- [Innodb_data_pending_fsyncs](#)

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the [innodb_flush_method](#) configuration option.

- [Innodb_data_pending_reads](#)

The current number of pending reads.

- [Innodb_data_pending_writes](#)

The current number of pending writes.

- [Innodb_data_read](#)

The amount of data read since the server was started (in bytes).

- [Innodb_data_reads](#)

The total number of data reads (OS file reads).

- [Innodb_data_writes](#)

The total number of data writes.

- [Innodb_data_written](#)

The amount of data written so far, in bytes.

- [Innodb_dblwr_pages_written](#)

The number of [pages](#) that have been written to the [doublewrite buffer](#). See [Section 14.12.1, “InnoDB Disk I/O”](#).

- [InnoDB_dblwr_writes](#)

The number of doublewrite operations that have been performed. See [Section 14.12.1, “InnoDB Disk I/O”](#).

- [InnoDB_have_atomic_builtins](#)

Indicates whether the server was built with [atomic instructions](#).

- [InnoDB_log_waits](#)

The number of times that the [log buffer](#) was too small and a [wait](#) was required for it to be [flushed](#) before continuing.

- [InnoDB_log_write_requests](#)

The number of write requests for the [InnoDB redo log](#).

- [InnoDB_log_writes](#)

The number of physical writes to the [InnoDB redo log](#) file.

- [InnoDB_num_open_files](#)

The number of files [InnoDB](#) currently holds open.

- [InnoDB_os_log_fsyncs](#)

The number of `fsync()` writes done to the [InnoDB redo log](#) files.

- [InnoDB_os_log_pending_fsyncs](#)

The number of pending `fsync()` operations for the [InnoDB redo log](#) files.

- [InnoDB_os_log_pending_writes](#)

The number of pending writes to the [InnoDB redo log](#) files.

- [InnoDB_os_log_written](#)

The number of bytes written to the [InnoDB redo log](#) files.

- [InnoDB_page_size](#)

[InnoDB](#) page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- [InnoDB_pages_created](#)

The number of pages created by operations on [InnoDB](#) tables.

- [InnoDB_pages_read](#)

The number of pages read from the [InnoDB](#) buffer pool by operations on [InnoDB](#) tables.

- [InnoDB_pages_written](#)

The number of pages written by operations on [InnoDB](#) tables.

- [Innodb_row_lock_current_waits](#)

The number of [row locks](#) currently being waited for by operations on [InnoDB](#) tables.

- [Innodb_row_lock_time](#)

The total time spent in acquiring [row locks](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb_row_lock_time_avg](#)

The average time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb_row_lock_time_max](#)

The maximum time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb_row_lock_waits](#)

The number of times operations on [InnoDB](#) tables had to wait for a [row lock](#).

- [Innodb_rows_deleted](#)

The number of rows deleted from [InnoDB](#) tables.

- [Innodb_rows_inserted](#)

The number of rows inserted into [InnoDB](#) tables.

- [Innodb_rows_read](#)

The number of rows read from [InnoDB](#) tables.

- [Innodb_rows_updated](#)

The number of rows updated in [InnoDB](#) tables.

- [Innodb_truncated_status_writes](#)

The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- [Key_blocks_not_flushed](#)

The number of key blocks in the [MyISAM](#) key cache that have changed but have not yet been flushed to disk.

- [Key_blocks_unused](#)

The number of unused blocks in the [MyISAM](#) key cache. You can use this value to determine how much of the key cache is in use; see the discussion of [key_buffer_size](#) in [Section 5.1.5, “Server System Variables”](#).

- [Key_blocks_used](#)

The number of used blocks in the [MyISAM](#) key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- [Key_read_requests](#)

The number of requests to read a key block from the [MyISAM](#) key cache.

- [Key_reads](#)

The number of physical reads of a key block from disk into the [MyISAM](#) key cache. If [Key_reads](#) is large, then your [key_buffer_size](#) value is probably too small. The cache miss rate can be calculated as $\text{Key_reads} / \text{Key_read_requests}$.

- [Key_write_requests](#)

The number of requests to write a key block to the [MyISAM](#) key cache.

- [Key_writes](#)

The number of physical writes of a key block from the [MyISAM](#) key cache to disk.

- [Last_query_cost](#)

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. [Last_query_cost](#) has session scope.

The [Last_query_cost](#) value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or [UNION](#). For the latter, the value is set to 0.

- [Last_query_partial_plans](#)

The number of iterations the query optimizer made in execution plan construction for the previous query. [Last_query_cost](#) has session scope. This variable was added in MySQL 5.6.5.

- [Max_used_connections](#)

The maximum number of connections that have been in use simultaneously since the server started.

- [Not_flushed_delayed_rows](#)

The number of rows waiting to be written to nontransactional tables in [INSERT DELAYED](#) queues.

As of MySQL 5.6.7, this status variable is deprecated (because [DELAYED](#) inserts are deprecated), and will be removed in a future release.

- [Open_files](#)

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- [Open_streams](#)

The number of streams that are open (used mainly for logging).

- [Open_table_definitions](#)

The number of cached [.frm](#) files.

- [Open_tables](#)

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

The number of `.frm` files that have been cached.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Performance_schema_xxx`

Performance Schema status variables are listed in [Section 22.14, “Performance Schema Status Variables”](#). These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Qcache_free_blocks`

The number of free memory blocks in the query cache.

- `Qcache_free_memory`

The amount of free memory for the query cache.

- `Qcache_hits`

The number of query cache hits.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Qcache_inserts`

The number of queries added to the query cache.

- `Qcache_lowmem_prunes`

The number of queries that were deleted from the query cache because of low memory.

- `Qcache_not_cached`

The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` setting).

- `Qcache_queries_in_cache`

The number of queries registered in the query cache.

- `Qcache_total_blocks`

The total number of blocks in the query cache.

- `Queries`

The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Questions`

The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time`

The average time in microseconds the master waited for a slave reply.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time`

The total time in microseconds the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits`

The total number of times the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times`

The number of times the master turned off semisynchronous replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is **ON** if the plugin has been enabled and a commit acknowledgment has occurred. It is **OFF** if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_timefunc_failures`

The number of times the master failed when calling time functions such as `gettimeofday()`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_avg_wait_time`

The average time in microseconds the master waited for each transaction.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_wait_time`

The total time in microseconds the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_waits`

The total number of times the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_pos_backtraverse`

The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_sessions`

The number of sessions currently waiting for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is **ON** if the plugin has been enabled and the slave I/O thread is running, **OFF** otherwise.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- `Rsa_public_key`

This variable is available if MySQL was using OpenSSL (see [Section 6.4.1, “OpenSSL Versus yaSSL”](#)). Its value is the RSA public key value used by the `sha256_password` authentication plugin. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables. The value of `Rsa_public_key` comes from the latter file.

For information about `sha256_password`, see [Section 6.5.1.4, “The SHA-256 Authentication Plugin”](#).

This variable was added in MySQL 5.6.6.

- `Select_full_join`

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

The number of joins that did a full scan of the first table.

- `Slave_heartbeat_period`

Shows the replication heartbeat interval (in seconds) on a replication slave.

- `Slave_last_heartbeat`

Shows when the most recent heartbeat signal was received by a replication slave, as a `TIMESTAMP` value.

- `Slave_open_temp_tables`

The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see [Section 17.4.1.23, “Replication and Temporary Tables”](#).

- `Slave_received_heartbeats`

This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

- `Slave_retried_transactions`

The total number of times since startup that the replication slave SQL thread has retried transactions.

- `Slave_running`

This is `ON` if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

- `Slow_launch_threads`

The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see [Section 5.4.5, “The Slow Query Log”](#).

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

The number of negotiates needed to establish the connection.

- `Ssl_accepts`

The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

The number of callback cache hits.

- `Ssl_cipher`

The current encryption cipher (empty for unencrypted connections).

- `Ssl_cipher_list`

The list of possible SSL ciphers (empty for non-SSL connections).

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled master.

- `Ssl_connect_renegotiates`

The number of negotiates needed to establish the connection to an SSL-enabled master.

- `Ssl_ctx_verify_depth`

The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

The SSL context verification mode.

- `Ssl_default_timeout`

The default SSL timeout.

- `Ssl_finished_accepts`

The number of successful SSL connections to the server.

- `Ssl_finished_connects`

The number of successful slave connections to an SSL-enabled master.

- `Ssl_server_not_after`

The last date for which the SSL certificate is valid. This variable was added in MySQL 5.6.3.

To check SSL certificate expiration information, use this statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| Ssl_server_not_after | Apr 28 14:16:39 2025 GMT |
| Ssl_server_not_before | May 1 14:16:39 2015 GMT |
+-----+-----+
```

In MySQL 5.6, the value is empty unless the connection uses SSL.

- `Ssl_server_not_before`

The first date for which the SSL certificate is valid. This variable was added in MySQL 5.6.3.

In MySQL 5.6, the value is empty unless the connection uses SSL.

- `Ssl_session_cache_hits`

The number of SSL session cache hits.

- `Ssl_session_cache_misses`

The number of SSL session cache misses.

- `Ssl_session_cache_mode`

The SSL session cache mode.

- `Ssl_session_cache_overflows`

The number of SSL session cache overflows.

- `Ssl_session_cache_size`

The SSL session cache size.

- `Ssl_session_cache_timeouts`

The number of SSL session cache timeouts.

- `Ssl_sessions_reused`

How many SSL connections were reused from the cache.

- `Ssl_used_session_cache_entries`

How many SSL session cache entries were used.

- `Ssl_verify_depth`

The verification depth for replication SSL connections.

- `Ssl_verify_mode`

The verification mode for replication SSL connections.

- `Ssl_version`

The SSL protocol version of the connection; for example, TLSv1. If the connection is not encrypted, the value is empty.

- `Table_locks_immediate`

The number of times that a request for a table lock could be granted immediately.

- `Table_locks_waited`

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- `Table_open_cache_hits`

The number of hits for open tables cache lookups. This variable was added in MySQL 5.6.6.

- `Table_open_cache_misses`

The number of misses for open tables cache lookups. This variable was added in MySQL 5.6.6.

- `Table_open_cache_overflows`

The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache / table_open_cache_instances`. This variable was added in MySQL 5.6.6.

- `Tc_log_max_pages_used`

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (`InnoDB` is the only applicable engine.)

- [Tc_log_page_size](#)

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for [Tc_log_max_pages_used](#).

- [Tc_log_page_waits](#)

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- [Threads_cached](#)

The number of threads in the thread cache.

- [Threads_connected](#)

The number of currently open connections.

- [Threads_created](#)

The number of threads created to handle connections. If [Threads_created](#) is big, you may want to increase the [thread_cache_size](#) value. The cache miss rate can be calculated as [Threads_created/Connections](#).

- [Threads_running](#)

The number of threads that are not sleeping.

- [Uptime](#)

The number of seconds that the server has been up.

- [Uptime_since_flush_status](#)

The number of seconds since the most recent `FLUSH STATUS` statement.

5.1.8 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the [sql_mode](#) system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- [Setting the SQL Mode](#)
- [The Most Important SQL Modes](#)
- [Full List of SQL Modes](#)
- [Combination SQL Modes](#)
- [Strict SQL Mode](#)

For answers to questions often asked about server SQL modes in MySQL, see [Section A.3, “MySQL 5.6 FAQ: Server SQL Mode”](#).

When working with [InnoDB](#) tables, consider also the `innodb_strict_mode` system variable. It enables additional error checks for [InnoDB](#) tables.

Setting the SQL Mode

The default SQL mode in MySQL 5.6.6 and later is `NO_ENGINE_SUBSTITUTION`; in MySQL 5.6.5 and earlier, it was empty (no modes set).

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

Note

MySQL installation programs may configure the SQL mode during the installation process. For example, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file contains a line that sets the SQL mode; see [Section 4.4.3, “mysql_install_db — Initialize MySQL Data Directory”](#).

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` value, use the following statements:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

Important

SQL mode and user-defined partitioning. Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and on the slave.

See [Section 19.6, “Restrictions and Limitations on Partitioning”](#), for more information.

The Most Important SQL Modes

The most important `sql_mode` values are probably these:

- `ANSI`

This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special [combination modes](#) listed at the end of this section.

- `STRICT_TRANS_TABLES`

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

- `TRADITIONAL`

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special [combination modes](#) listed at the end of this section.

Note

The `INSERT` or `UPDATE` aborts as soon as the error is noticed. This may not be what you want if you are using a nontransactional storage engine, because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` enabled.

Full List of SQL Modes

The following list describes all supported SQL modes:

- `ALLOW_INVALID_DATES`

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to `DATE` and `DATETIME` columns. It does not apply `TIMESTAMP` columns, which always require a valid date.

The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

- `ANSI_QUOTES`

Treat `"` as an identifier quote character (like the ``` quote character) and not as a string quote character. You can still use ``` to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings, because it is interpreted as an identifier.

- `ERROR_FOR_DIVISION_BY_ZERO`

The `ERROR_FOR_DIVISION_BY_ZERO` mode affects handling of division by zero, which includes `MOD(N, 0)`. For data-change operations (`INSERT`, `UPDATE`), its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If this mode is enabled, division by zero inserts `NULL` and produces a warning.
- If this mode and strict mode are enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

As of MySQL 5.6.17, `ERROR_FOR_DIVISION_BY_ZERO` is deprecated and setting the `sql_mode` value to include it generates a warning.

- `HIGH_NOT_PRECEDENCE`

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 1
```

- `IGNORE_SPACE`

Permit spaces between a function name and the `(` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 9.2, “Schema Object Names”](#). For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

For further discussion of `IGNORE_SPACE`, see [Section 9.2.4, “Function Name Parsing and Resolution”](#).

- `NO_AUTO_CREATE_USER`

Prevent the `GRANT` statement from automatically creating new users if it would otherwise do so, unless authentication information is specified. The statement must specify a nonempty password using `IDENTIFIED BY` or an authentication plugin using `IDENTIFIED WITH`.

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. `mysqldump` now automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`, to avoid this problem.

- `NO_BACKSLASH_ESCAPES`

Disable the use of the backslash character (`\`) as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- `NO_DIR_IN_CREATE`

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers.

- `NO_ENGINE_SUBSTITUTION`

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_FIELD_OPTIONS`

Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_KEY_OPTIONS`

Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_TABLE_OPTIONS`

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_UNSIGNED_SUBTRACTION`

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21) unsigned | NO   |     | 0        |       |
+-----+-----+-----+-----+-----+-----+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21)          | NO   |     | 0        |       |
+-----+-----+-----+-----+-----+-----+
```

This means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 12.10, “Cast Functions and Operators”](#).

- `NO_ZERO_DATE`

The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
- If this mode is enabled, `'0000-00-00'` is permitted and inserts produce a warning.

- If this mode and strict mode are enabled, '0000-00-00' is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, '0000-00-00' is permitted and inserts produce a warning.

As of MySQL 5.6.17, `NO_ZERO_DATE` is deprecated and setting the `sql_mode` value to include it generates a warning.

- `NO_ZERO_IN_DATE`

The `NO_ZERO_IN_DATE` mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as '2010-00-01' or '2010-01-00', but not '0000-00-00'. To control whether the server permits '0000-00-00', use the `NO_ZERO_DATE` mode.) The effect of `NO_ZERO_IN_DATE` also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If this mode is enabled, dates with zero parts are inserted as '0000-00-00' and produce a warning.
- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as '0000-00-00' and produce a warning.

As of MySQL 5.6.17, `NO_ZERO_IN_DATE` is deprecated and setting the `sql_mode` value to include it generates a warning.

- `ONLY_FULL_GROUP_BY`

Reject queries for which the select list, `HAVING` condition, or (as of MySQL 5.6.5) `ORDER` list refer to nonaggregated columns that are not named in the `GROUP BY` clause.

A MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. Enabling `ONLY_FULL_GROUP_BY` disables this extension, thus requiring the `HAVING` clause to be written using unaliased expressions.

For additional discussion and examples, see [Section 12.18.3, “MySQL Handling of GROUP BY”](#).

- `PAD_CHAR_TO_FULL_LENGTH`

By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1    | CHAR_LENGTH(c1) |
+-----+-----+
```

```

| xy |          2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1      | CHAR_LENGTH(c1) |
+-----+-----+
| xy      |          10     |
+-----+-----+
1 row in set (0.00 sec)

```

- [PIPES_AS_CONCAT](#)

Treat `||` as a string concatenation operator (same as [CONCAT\(\)](#)) rather than as a synonym for [OR](#).

- [REAL_AS_FLOAT](#)

Treat [REAL](#) as a synonym for [FLOAT](#). By default, MySQL treats [REAL](#) as a synonym for [DOUBLE](#).

- [STRICT_ALL_TABLES](#)

Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see [Strict SQL Mode](#).

- [STRICT_TRANS_TABLES](#)

Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see [Strict SQL Mode](#).

Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- [ANSI](#)

Equivalent to [REAL_AS_FLOAT](#), [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#).

[ANSI](#) mode also causes the server to return an error for queries where a set function [S](#) with an outer reference [S\(outer_ref\)](#) cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, [MAX\(t1.b\)](#) cannot be aggregated in the outer query because it appears in the [WHERE](#) clause of that query. Standard SQL requires an error in this situation. If [ANSI](#) mode is not enabled, the server treats [S\(outer_ref\)](#) in such queries the same way that it would interpret [S\(const\)](#).

See [Section 1.7, “MySQL Standards Compliance”](#).

- [DB2](#)

Equivalent to [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#), [NO_KEY_OPTIONS](#), [NO_TABLE_OPTIONS](#), [NO_FIELD_OPTIONS](#).

- [MAXDB](#)

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `MSSQL`

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MYSQL323`

Equivalent to `MYSQL323`, `HIGH_NOT_PRECEDENCE`. This means `HIGH_NOT_PRECEDENCE` plus some `SHOW CREATE TABLE` behaviors specific to `MYSQL323`:

- `TIMESTAMP` column display does not include `DEFAULT` or `ON UPDATE` attributes that were introduced in MySQL 4.1.
- String column display does not include character set and collation attributes that were introduced in MySQL 4.1. For `CHAR` and `VARCHAR` columns, if the collation is binary, `BINARY` is appended to the column type.
- The `ENGINE=engine_name` table option displays as `TYPE=engine+name`.
- For `MEMORY` tables, the storage engine is displayed as `HEAP`.

- `MYSQL40`

Equivalent to `MYSQL40`, `HIGH_NOT_PRECEDENCE`. This means `HIGH_NOT_PRECEDENCE` plus some behaviors specific to `MYSQL40`. These are the same as for `MYSQL323`, except that `SHOW CREATE TABLE` does not display `HEAP` as the storage engine for `MEMORY` tables.

- `ORACLE`

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `POSTGRESQL`

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `TRADITIONAL`

Equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`.

Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as `INSERT` or `UPDATE`. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.) Strict mode also affects DDL statements such as `CREATE TABLE`.

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#)). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

As of MySQL 5.6.11, strict mode produces an error for attempts to create a key that exceeds the maximum key length. Previously, this resulted in a warning and truncation of the key to the maximum key length (the same as when strict mode is not enabled).

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See [Section 5.1.5, “Server System Variables”](#).)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
- For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
- For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in [Section 11.6, “Data Type Default Values”](#).

Strict mode also affects handling of division by zero, zero dates, and zeros in dates, in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes. For details, see the descriptions of those modes.

5.1.9 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
shell> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See [Section 5.1.9.1, “Verifying System Support for IPv6”](#).
- As of MySQL 5.6.6, the default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. Before 5.6.6, the default is to permit only IPv4 connections. To change the default configuration, start the server with an appropriate `--bind-address` option. See [Section 5.1.5, “Server System Variables”](#).

- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See [Section 6.2.3, “Specifying Account Names”](#). IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```
mysql> CREATE USER 'bill'@':::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@':::1';
```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See [Section 12.19, “Miscellaneous Functions”](#).

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

5.1.9.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- [Windows](#)
- [Gentoo Linux](#)
- [Ubuntu Linux](#)
- [Linux \(Generic\)](#)
- [OS X](#)

5.1.9.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, use the `--bind-address=addr` option at server startup, where `addr` is an IPv4 or IPv6 address or a host name. (IPv6 addresses are not supported before MySQL 5.5.3.) If `addr` is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is permitted (and is the default) as of MySQL 5.6.6.

- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces. This is the default before MySQL 5.6.6.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

5.1.9.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = *    # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to `::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#).

2. As an administrator, connect to the server and create an account for a local user who will connect from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see [Section 6.2.3, “Specifying Account Names”](#). In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:  ::1 via TCP/IP
...
```

```
mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| ipv6user@::1   | ::             |
+-----+-----+
```

5.1.9.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by [IANA](#) for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see [Section 5.1.9.5, “Obtaining an IPv6 Address from a Broker”](#).

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = *      # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to `2001:db8:0:f101::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#).

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who will connect from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection: 2001:db8:0:f101::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| remoteipv6user@2001:db8:0:f101::2 | ::             |
+-----+-----+
```

5.1.9.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The [Wikipedia IPv6 Tunnel Broker page](#) lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `--bind-address` option to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind-address = *    # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#). In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
shell> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser
passwd=gogopass
```

5. Start `gogoc`:

```
shell> /etc/init.d/gogoc start
```

To start `gogoc` each time your system boots, execute this command:

```
shell> rc-update add gogoc default
```

6. Use `ping6` to try to ping a host:

```
shell> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
shell> ifconfig tun
```

5.1.10 Server-Side Help

MySQL Server supports a `HELP` statement that returns information from the MySQL Reference manual (see [Section 13.8.3, “HELP Syntax”](#)). Several tables in the `mysql` system database contain the information needed to support this statement (see [Section 5.3, “The mysql System Database”](#)). The proper operation of this statement requires that these help tables be initialized, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table content initialization occurs when you initialize the data directory (see [Section 2.10.1, “Initializing the Data Directory”](#)). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, help table content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from <http://dev.mysql.com/doc/index-other.html>. After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Git and a MySQL development source tree, you must use a downloaded copy of the `fill_help_tables.sql` file because the source tree contains only a “stub” version.

Note

For a server that participates in replication, the help table content upgrade process involves multiple servers. For details, see [Section 17.4.1.29, “Replication of Server-Side Help Tables”](#).

5.1.11 Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- `SIGTERM` causes the server to shut down.
- `SIGHUP` causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. The server also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
Buffer_size:      8388600
Block_size:       1024
Division_limit:   100
```

```

Age_limit:          300
blocks used:         0
not flushed:         0
w_requests:          0
writes:              0
r_requests:          0
reads:               0

handler status:
read_key:            0
read_next:           0
read_rnd             0
read_first:          1
write:               0
delete               0
update:              0

Table status:
Opened tables:        5
Open tables:          0
Open files:           7
Open streams:         0

Alarm status:
Active alarms:        1
Max used alarms:      2
Next alarm time:      67

```

5.1.12 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle

connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see [Section 13.7.6.4, “KILL Syntax”](#), in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

For threads that have an open transaction, the transaction is rolled back.

**Note**

If a thread is updating a nontransactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated because the operation can terminate before completion.

If the server is a master replication server, it treats threads associated with currently connected slaves like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. See also [Section 13.4.2.6, “STOP SLAVE Syntax”](#). Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

**Note**

To guarantee crash safety on the slave, you must run the slave with `--relay-log-recovery` enabled.

See also [Section 17.2.2, “Replication Relay and Status Logs”](#).

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. `InnoDB` flushes its buffer pool to disk (unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads. `MyISAM` flushes any pending index writes for a table.

6. The server exits.

5.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:
 - The `mysql` directory corresponds to the `mysql` system database, which contains information required by the MySQL server as it runs. See [Section 5.3, “The mysql System Database”](#).
 - The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See [Chapter 22, MySQL Performance Schema](#).

- The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to MySQL Cluster (present only for installations built to include MySQL Cluster). See [Section 18.5.10](#), “The `ndbinfo` NDB Cluster Information Database”.

Other subdirectories correspond to databases created by users or applications.

**Note**

`INFORMATION_SCHEMA` is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See [Section 5.4](#), “MySQL Server Logs”.
- `InnoDB` tablespace and log files. See [Chapter 14](#), *The InnoDB Storage Engine*.
- The server process ID file (while the server is running).

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

5.3 The mysql System Database

The `mysql` database is the system database. It contains tables that store information required by the MySQL server as it runs.

Tables in the `mysql` database fall into these categories:

- [Grant System Tables](#)
- [Object Information System Tables](#)
- [Log System Tables](#)
- [Server-Side Help System Tables](#)
- [Time Zone System Tables](#)
- [Replication System Tables](#)
- [Optimizer System Tables](#)
- [Miscellaneous System Tables](#)

The remainder of this section enumerates the tables in each category, with cross references for additional information. System tables use the `MyISAM` storage engine unless otherwise indicated.

Grant System Tables

These system tables contain grant information about user accounts and the privileges held by them:

- `user`: User accounts, global privileges, and other non-privilege columns.
- `db`: Database-level privileges.
- `host`: Obsolete. MySQL install operations do not create this table as of MySQL 5.6.7.
- `tables_priv`: Table-level privileges.

- `columns_priv`: Column-level privileges.
- `procs_priv`: Stored procedure and function privileges.
- `proxies_priv`: Proxy-user privileges.

For more information about the structure, contents, and purpose of the grant tables, see [Section 6.2.2, “Grant Tables”](#).

Object Information System Tables

These system tables contain information about stored programs, user-defined functions, and server-side plugins:

- `event`: Information about Event Scheduler events. See [Section 20.4, “Using the Event Scheduler”](#). The server loads events listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.
- `func`: Information about user-defined functions (UDFs). See [Section 24.4, “Adding New Functions to MySQL”](#). The server loads UDFs listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.
- `plugin`: Information about server-side plugins. See [Section 5.5.2, “Installing and Uninstalling Plugins”](#), and [Section 24.2, “The MySQL Plugin API”](#). The server loads plugins listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.
- `proc`: Information about stored procedures and functions. See [Section 20.2, “Using Stored Routines \(Procedures and Functions\)”](#).

Log System Tables

The server uses these system tables for logging:

- `general_log`: The general query log table.
- `slow_log`: The slow query log table.

Log tables use the `CSV` storage engine.

For more information, see [Section 5.4, “MySQL Server Logs”](#).

Server-Side Help System Tables

These system tables contain server-side help information:

- `help_category`: Information about help categories.
- `help_keyword`: Keywords associated with help topics.
- `help_relation`: Mappings between help keywords and topics.
- `help_topic`: Help topic contents.

For more information, see [Section 5.1.10, “Server-Side Help”](#).

Time Zone System Tables

These system tables contain time zone information:

- `time_zone`: Time zone IDs and whether they use leap seconds.

- `time_zone_leap_second`: When leap seconds occur.
- `time_zone_name`: Mappings between time zone IDs and names.
- `time_zone_transition`, `time_zone_transition_type`: Time zone descriptions.

For more information, see [Section 10.6, “MySQL Server Time Zone Support”](#).

Replication System Tables

The server uses these system tables to support replication:

- `ndb_binlog_index`: Binary log information for MySQL Cluster replication. See [Section 18.6.4, “NDB Cluster Replication Schema and Tables”](#).
- `slave_master_info`, `slave_relay_log_info`, `slave_worker_info`: Used to store replication information on slave servers. See [Section 17.2.2, “Replication Relay and Status Logs”](#).

These tables use the `InnoDB` storage engine as of MySQL 5.6.6, `MyISAM` before that.

Optimizer System Tables

The `innodb_index_stats` and `innodb_table_stats` system tables are used for `InnoDB` persistent optimizer statistics. See [Section 14.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

These tables use the `InnoDB` storage engine.

Miscellaneous System Tables

Other system tables do not fall into the preceding categories:

- `firewall_users`, `firewall_whitelist`: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See [Section 6.5.5, “MySQL Enterprise Firewall”](#).
- `servers`: Used by the `FEDERATED` storage engine. See [Section 15.8.2.2, “Creating a FEDERATED Table Using CREATE SERVER”](#).

5.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

| Log Type | Information Written to Log |
|------------------------|---|
| Error log | Problems encountered starting, running, or stopping <code>mysqld</code> |
| General query log | Established client connections and statements received from clients |
| Binary log | Statements that change data (also used for replication) |
| Relay log | Data changes received from a replication master server |
| Slow query log | Queries that took more than <code>long_query_time</code> seconds to execute |
| DDL log (metadata log) | Metadata operations performed by DDL statements |

By default, no logs are enabled, except the error log on Windows. (The DDL log is always created when required, and has no user-configurable options; see [Section 5.4.6, “The DDL Log”](#).) The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log

flushing occurs when you issue a `FLUSH LOGS` statement; execute `mysqladmin` with a `flush-logs` or `refresh` argument; or execute `mysqldump` with a `--flush-logs` or `--master-data` option. See [Section 13.7.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#), [Section 5.4.3, “The General Query Log”](#), and [Section 5.4.5, “The Slow Query Log”](#).

The relay log is used only on slave replication servers, to hold data changes from the master server that must also be made on the slave. For discussion of relay log contents and configuration, see [Section 17.2.2.1, “The Slave Relay Log”](#).

For information about log maintenance operations such as expiration of old log files, see [Section 5.4.7, “Server Log Maintenance”](#).

For information about keeping logs secure, see [Section 6.1.2.3, “Passwords and Logging”](#).

5.4.1 Selecting General Query and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` database. Either or both destinations can be selected.

Log control at server startup. The `--log-output` option specifies the destination for log output. This option does not in itself enable the logs. Its syntax is `--log-output[=value,...]`:

- If `--log-output` is given with a value, the value should be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.
- If `--log-output` is omitted, the default logging destination is `FILE`.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log-output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log-output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.
- To write slow query log entries only to the log file, use `--log-output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. (In this case, because the default log destination is `FILE`, you could omit the `--log-output` option.)

Log control at runtime. The system variables associated with log tables and files enable runtime control over logging:

- The global `log_output` system variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The global `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The global `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.
- To disable or enable general query logging for the current connection, set the session `sql_log_off` variable to `ON` or `OFF`.

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.
- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@global.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.

- [RENAME TABLE](#) is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- [CHECK TABLE](#) is a valid operation on a log table.
- [LOCK TABLES](#) cannot be used on a log table.
- [INSERT](#), [DELETE](#), and [UPDATE](#) cannot be used on a log table. These operations are permitted only internally to the server itself.
- [FLUSH TABLES WITH READ LOCK](#) and the state of the [read_only](#) system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers. (Prior to MySQL 5.6.9, this was not always enforced correctly. See Bug #14741537.)
- To flush the log tables or log files, use [FLUSH TABLES](#) or [FLUSH LOGS](#), respectively.
- Partitioning of log tables is not permitted.
- Before MySQL 5.6.6, [mysqldump](#) does not dump the [general_log](#) or [slow_query_log](#) tables for dumps of the [mysql](#) database. As of 5.6.6, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

5.4.2 The Error Log

The error log contains information about [mysqld](#) startup and shutdown times, progress notes that occur during startup and shutdown, and critical errors that occur while the server is running. If [mysqld](#) notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if [mysqld](#) exits abnormally. The trace can be used to determine where [mysqld](#) exited. See [Section 24.5, “Debugging and Porting MySQL”](#).

Interpretation of error logging options differs somewhat for Windows and Unix systems, so be sure to use the information appropriate to your system.

[mysqld_safe](#) may write messages to the error log if it is used to start [mysqld](#). For example, when [mysqld_safe](#) notices abnormal [mysqld](#) exits, it restarts [mysqld](#) and writes a [mysqld restarted](#) message to the error log.

In the following discussion, “console” means [stderr](#), the standard error output. This is your terminal or console window unless the standard error output has been redirected. (For example, if invoked with the [--syslog](#) option, [mysqld_safe](#) arranges for the server's [stderr](#) to be sent to [syslog](#), as described later.)

- [Error Logging on Windows](#)
- [Error Logging on Unix and Unix-Like Systems](#)
- [Using Syslog for the Error Log](#)
- [Error Log Verbosity](#)
- [Flushing and Renaming the Error Log File](#)

Error Logging on Windows

On Windows, the `--log-error`, `--pid-file`, and `--console` options affect error logging:

- Without `--log-error`, `mysqld` writes error messages to the default log file.
- With `--log-error[=file_name]`, `mysqld` writes error messages to an error log file. If no file is named, `mysqld` writes to the default log file. If a file is named, `mysqld` writes to it, creating it in the data directory unless an absolute path name is given to specify a different directory.
- The default log file is `host_name.err` in the data directory, unless the `--pid-file` option is specified. In that case, the default name is the PID file base name with a suffix of `.err` in the data directory. This default is used if `--log-error` is not given, or is given without naming a log file.
- With `--console`, `mysqld` writes error messages to the console, unless `--log-error` is also given. If both options are present, `--console` is ignored and has no effect. Their order does not matter: `--log-error` takes precedence and error messages go to a log file.

In addition, on Windows, the server by default writes events and error messages to the Windows Event Log within the Application log.

- Entries marked as `Error`, `Warning`, and `Note` are written to the Event Log, but not informational messages such as information statements from individual storage engines.
- These log entries have a source of `MySQL`.
- You cannot disable writing information to the Windows Event Log.

If the server writes error output to a file, the `log_error` system variable indicates the error log file name.

Error Logging on Unix and Unix-Like Systems

On Unix and Unix-like systems, `mysqld` writes error log messages as follows:

- Without `--log-error`, `mysqld` writes error messages to the console.
- With `--log-error[=file_name]`, `mysqld` writes error messages to an error log file. If no file is named, `mysqld` writes to the default log file. If a file is named, `mysqld` writes to it, creating it in the data directory unless an absolute path name is given to specify a different directory.

Note

It is common for Yum or APT package installations to configure the error log location to be under `/var/log` with an entry like `log-error=/var/log/mysqld.log` in a server configuration file; removing the file name from the entry causes the default log file to be used.

- The default log file is `host_name.err` in the data directory. This default is used if `--log-error` is given without naming a log file.

If the server writes error output to a file, the `log_error` system variable indicates the error log file name.

If you specify `--log-error` in an option file in a `[mysqld]`, `[server]`, or `[mysqld_safe]` section, `mysqld_safe` finds and uses the option.

Using Syslog for the Error Log

If you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for `mysqld` to write error messages to a log file or to `syslog`. `mysqld_safe` has three error-logging options, `--syslog`, `--skip-syslog`,

and `--log-error`. The default with no logging options or with `--skip-syslog` is to use the default log file. To explicitly specify use of an error log file, specify `--log-error=file_name` to `mysqld_safe`, and `mysqld_safe` will arrange for `mysqld` to write messages to a log file. To use `syslog` instead, specify the `--syslog` option.

Error Log Verbosity

The `--log-warnings` option or `log_warnings` system variable controls warning logging to the error log. The default value is enabled (1). To disable warning logging, set `--log-warnings` or `log_warnings` to 0. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

Flushing and Renaming the Error Log File

If you flush the logs using `FLUSH LOGS` or `mysqladmin flush-logs` and `mysqld` is writing the error log to a file (for example, if it was started with the `--log-error` option), the server closes and reopens the log file. To rename the file, do so manually before flushing. Flushing the logs then reopens a new file with the original file name. For example, to rename the file and create a new one, use the following commands (assuming a log file name of `host_name.err`):

```
shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

If the location of the error file is not writable by the server, the log-flushing operation will fail to create a new log file. For example, on Linux, the server might write the error log as `/var/log/mysqld.log`, where `/var/log` is owned by `root` and not writable by `mysqld`. For information about handling this case, see [Section 5.4.7, “Server Log Maintenance”](#).

If the server is not writing to a named file, no error log renaming occurs when the logs are flushed.

5.4.3 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication master server, statements received by its slaves are written to the query log of each slave. Statements are written to the query log of the master server if a client reads events with the `mysqlbinlog` utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log[={0|1}]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use `--log-output` (as described in [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally; for example, from the command line. Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

As of MySQL 5.6.3, passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

Before MySQL 5.6.3, passwords in statements are not rewritten and the general query log should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

One implication of the introduction of password rewriting in MySQL 5.6.3 is that statements that cannot be parsed (due, for example, to syntax errors) are no longer written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting. For example, the following statement is logged as shown because a password hash value is expected:

```
CREATE USER 'user1'@'localhost' IDENTIFIED BY PASSWORD 'not-so-secret';
```

5.4.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a master replication server provides a record of the data changes to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 17.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See [Section 5.4.3, “The General Query Log”](#).

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

Beginning with MySQL 5.6.2, the binary log is resilient to unexpected halts. Only complete events or transactions are logged or read back. See [Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”](#).

As of MySQL 5.6.3, passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. Before MySQL 5.6.3, passwords in statements are not rewritten and the binary log should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see [Section 17.1.4.4, “Binary Log Options and Variables”](#).

To enable the binary log, start the server with the `--log-bin[=base_name]` option. If no `base_name` value is given, the default name is the value of the `pid-file` option (which by default is the name of host machine) followed by `-bin`. If the base name is given, the server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. It is recommended that you specify a base name explicitly rather than using the default of the host name; see [Section B.5.7, “Known Issues in MySQL”](#), for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The

server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically after the current log's size reaches `max_binlog_size`. A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of all used binary log files. By default, this has the same base name as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

A client that has the `SUPER` privilege can disable binary logging of its own statements by using a `SET sql_log_bin=0` statement. See [Section 5.1.5, “Server System Variables”](#).

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the master uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` system variable. The slave I/O thread also verifies events received from the master. You can cause the slave SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see [Section 5.4.4.1, “Binary Logging Formats”](#). For detailed information about the format of the binary log, see [MySQL Internals: The Binary Log](#).

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see [Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

A replication slave server by default does not write to its own binary log any data modifications that are received from the replication master. To log these modifications, start the slave with the `--log-slave-updates` option in addition to the `--log-bin` option (see [Section 17.1.4.3, “Replication Slave Options and Variables”](#)). This is done when a slave is also to act as a master to other slaves in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See [Section 13.7.6.6, “RESET Syntax”](#), and [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

If you are using replication, you should not delete old binary log files on the master until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#). For more information about the binary log and recovery operations, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See [Section 17.4.1, “Replication Features and Issues”](#).

Binary logging for stored programs is done as described in [Section 20.7, “Binary Logging of Stored Programs”](#).

The binary log format differs in MySQL 5.6 from previous versions of MySQL, due to enhancements in replication. See [Section 17.4.2, “Replication Compatibility Between MySQL Versions”](#).

Writes to the binary log file and binary log index file are handled in the same way as writes to `MyISAM` tables. See [Section B.5.3.4, “How MySQL Handles a Full Disk”](#).

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, use the `sync_binlog` system variable to synchronize the binary log to disk after every `N` commit groups. See [Section 5.1.5, “Server System Variables”](#). The safest value for `sync_binlog` is 1, but this is also the slowest. Even with `sync_binlog` set to 1, there is still the chance of inconsistency between the table content and binary log content in case of a crash.

For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes many prepared transactions to the binary log in sequence, synchronizes the binary log, and then

commits this transaction into [InnoDB](#). If the server crashes between those two operations, the transaction is rolled back by [InnoDB](#) at restart but still exists in the binary log. Such an issue is resolved assuming `--innodb_support_xa` is set to 1, the default. Although this option is related to the support of XA transactions in [InnoDB](#), it also ensures that the binary log and [InnoDB](#) data files are synchronized. For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the [InnoDB](#) logs to disk before committing the transaction. The [InnoDB](#) logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server scans the latest binary log file to collect transaction `xid` values and calculate the last valid position in the binary log file. The MySQL server then tells [InnoDB](#) to complete any prepared transactions that were successfully written to the to the binary log, and truncates the binary log to the last valid position. This ensures that the binary log reflects the exact data of [InnoDB](#) tables, and therefore the slave remains in synchrony with the master because it does not receive a statement which has been rolled back.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed [InnoDB](#) transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

The session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- `sql_mode` (except that the `NO_DIR_IN_CREATE` mode is not replicated; see [Section 17.4.1.36](#), “Replication and Variables”)
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

5.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.
- In *row-based logging*, the master writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.
- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

In MySQL 5.6, the default binary logging format is `STATEMENT`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a master and slave which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, `Statement may not be safe to log in statement format`.

You can avoid these issues by using MySQL's row-based replication instead.

5.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- `STATEMENT` causes logging to be statement based.
- `ROW` causes logging to be row based.
- `MIXED` causes logging to use mixed format.

In MySQL 5.6, the default binary logging format is `STATEMENT`.

The logging format also can be switched at runtime. To specify the format globally for all clients, set the global value of the `binlog_format` system variable:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Note

Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication master does not cause a slave to change its logging format to match. (When using `STATEMENT` mode, the `binlog_format` system variable is not replicated; when using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the slave.) Changing the binary logging format on the master while replication is ongoing, or without also changing it on the slave can cause replication to fail with errors such as `Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.'`

To change the global or session `binlog_format` value, you must have the `SUPER` privilege.

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger
- If the `NDB` storage engine is enabled
- If the session is currently in row-based replication mode and has open temporary tables

Trying to switch the format in any of these cases results in an error.

If you are using `InnoDB` tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is *possible* to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because `InnoDB` can no longer perform inserts.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` function.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192; prior to MySQL 5.6.6, this was 1024.

Warning

When using *statement-based logging* for replication, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see [Section B.5.7, “Known Issues in MySQL”](#).

For information about logs kept by replication slaves, see [Section 17.2.2, “Replication Relay and Status Logs”](#).

5.4.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see [Section 17.4.1.1, “Replication and AUTO_INCREMENT”](#).

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.
- When a call to a UDF is involved.
- When any `INSERT DELAYED` is executed for a nontransactional table.
- If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped.

This is true whether or not any temporary tables are actually logged.

Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)
- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)
- When a statement refers to one or more system variables. (Bug #31168)

Exception. The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`

- `time_zone`
- `timestamp`
- `unique_checks`

For information about determining system variable scope, see [Section 5.1.6, “Using System Variables”](#).

For information about how replication treats `sql_mode`, see [Section 17.4.1.36, “Replication and Variables”](#).

- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` function is used. (Bug #39701)

Note

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

| Storage Engine | Row Logging Supported | Statement Logging Supported |
|------------------------|-----------------------|---|
| <code>ARCHIVE</code> | Yes | Yes |
| <code>BLACKHOLE</code> | Yes | Yes |
| <code>CSV</code> | Yes | Yes |
| <code>EXAMPLE</code> | Yes | No |
| <code>FEDERATED</code> | Yes | Yes |
| <code>HEAP</code> | Yes | Yes |
| <code>InnoDB</code> | Yes | Yes when the transaction isolation level is <code>REPEATABLE READ</code> or <code>SERIALIZABLE</code> ; No otherwise. |
| <code>MyISAM</code> | Yes | Yes |
| <code>MERGE</code> | Yes | Yes |
| <code>NDB</code> | Yes | No |

Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format (`STATEMENT`, `ROW`, or `MIXED`), and

the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using `ROW` format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table, where **SLC** stands for “statement-logging capable” and **RLC** stands for “row-logging capable”.

| Condition | | | | Action | |
|-----------|---------------|-----|-----|--|-----------|
| Type | binlog_format | SLC | RLC | Error / Warning | Logged as |
| * | * | No | No | Error: Cannot execute statement: Binary logging is impossible since at least one engine is involved that is both row-incapable and statement-incapable. | – |
| Safe | STATEMENT | Yes | No | – | STATEMENT |
| Safe | MIXED | Yes | No | – | STATEMENT |
| Safe | ROW | Yes | No | Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = ROW and at least one table uses a storage engine that is not capable of row-based logging. | – |
| Unsafe | STATEMENT | Yes | No | Warning: Unsafe statement binlogged in statement format, since BINLOG_FORMAT = STATEMENT | STATEMENT |
| Unsafe | MIXED | Yes | No | Error: Cannot execute statement: Binary logging of an unsafe statement is impossible when the storage engine is limited to statement-based logging, even if BINLOG_FORMAT = MIXED. | – |

| Condition | | | | Action | |
|---------------|---------------|-----|-----|--|-----------|
| Type | binlog_format | SLC | RLC | Error / Warning | Logged as |

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

5.4.4.4 Logging Format for Changes to mysql Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA INFILE`, `SELECT`, and `TRUNCATE TABLE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

5.4.5 The Slow Query Log

The slow query log consists of SQL statements that took more than `long_query_time` seconds to execute and required at least `min_examined_row_limit` rows to be examined. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `log_slow_admin_statements` and `log_queries_not_using_indexes`, as described later.

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log[={0|1}]`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use `--log-output` (as described in [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the slow query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

The server writes less information to the slow query log if you use the `--log-short-format` option.

To include slow administrative statements in the statements written to the slow query log, use the `log_slow_admin_statements` system variable. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. When such queries are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

The server does not write queries handled by the query cache to the slow query log, nor queries that would not benefit from the presence of an index because the table has zero rows or one row.

By default, a replication slave does not write replicated queries to the slow query log. To change this, use the `log_slow_slave_statements` system variable.

As of MySQL 5.6.3, passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. Before MySQL 5.6.3, passwords in statements are not rewritten and the slow query log should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process a slow query log file using the `mysqldumpslow` command to summarize the queries that appear in the log. See [Section 4.6.9, “mysqldumpslow — Summarize Slow Query Log Files”](#).

5.4.6 The DDL Log

The DDL log, or metadata log, records metadata operations generated by data definition statements such as `DROP TABLE` and `ALTER TABLE`. MySQL uses this log to recover from crashes occurring in the middle of a metadata operation. When executing the statement `DROP TABLE t1, t2`, we need to ensure that both `t1` and `t2` are dropped, and that each table drop is complete. Another example of this type of SQL statement is `ALTER TABLE t3 DROP PARTITION p2`, where we must make certain that the partition is completely dropped and that its definition is removed from the list of partitions for table `t3`.

A record of metadata operations such as those just described are written to the file `ddl_log.log`, in the MySQL data directory. This is a binary file; it is not intended to be human-readable, and you should not attempt to modify its contents in any way.

`ddl_log.log` is not created until it is actually needed for recording metadata statements, and is removed following a successful start of `mysqld`. Thus, it is possible for this file not to be present on a MySQL server that is functioning in a completely normal manner.

Currently, `ddl_log.log` can hold up to 1048573 entries, equivalent 4 GB in size. Once this limit is exceeded, you must rename or remove the file before it is possible to execute any additional DDL statements. This is a known issue which we are working to resolve (Bug #83708).

There are no user-configurable server options or variables associated with this file.

5.4.7 Server Log Maintenance

As described in [Section 5.4, “MySQL Server Logs”](#), MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See [Section 7.2, “Database Backup Methods”](#).

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.5, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#)).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See [Section 13.7.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`).

A log-flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.
- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If the server was started with the `--log-error` option to cause the error log to be written to a file, the server closes and reopens the log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current log files before flushing them. At flush time, the server opens new log files with the original names. For example, if the general and slow query log files are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

A similar strategy can be used to back up the error log file, if there is one.

You can rename the general query log or slow query log at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally; for example, from the command line. Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

Note

For the server to recreate a given log file after you have renamed the file externally, the file location must be writable by the server. This may not always be the case. For example, on Linux, the server might write the error log as `/var/log/`

`mysqld.log`, where `/var/log` is owned by `root` and not writable by `mysqld`. In this case, the log-flushing operation will fail to create a new log file.

To handle this situation, you must manually create the new log file with the proper ownership after renaming the original log file. For example, execute these commands as `root`:

```
shell> mv /var/log/mysqld.log /var/log/mysqld.log.old
shell> install -omysql -gmysql -m0644 /dev/null /var/log/mysqld.log
```

5.5 MySQL Server Plugins

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The components supported by this interface include, but are not limited to, storage engines, `INFORMATION_SCHEMA` tables, full-text parser plugins, partitioning support, and server extensions.

5.5.1 Server Plugins Available

MySQL distributions include several plugins that implement server extensions:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See [Section 6.3.7, “Pluggable Authentication”](#).
- A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See [Section 6.5.2, “The Connection-Control Plugin”](#).
- A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See [Section 6.5.3, “The Password Validation Plugin”](#).
- Semisynchronous replication plugins implement an interface to replication capabilities that permit the master to proceed as long as at least one slave has responded to each transaction. See [Section 17.3.9, “Semisynchronous Replication”](#).
- MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 5.5.4, “MySQL Enterprise Thread Pool”](#).
- MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See [Section 6.5.4, “MySQL Enterprise Audit”](#).
- MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. See [Section 6.5.5, “MySQL Enterprise Firewall”](#).

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see [Section 24.2, “The MySQL Plugin API”](#).

5.5.2 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

- [Installing plugins](#)

- [Controlling plugin activation state](#)
- [Uninstalling plugins](#)

While a plugin is loaded, information about it is available at runtime from the `INFORMATION_SCHEMA.PLUGINS` table and the `SHOW PLUGINS` statement. See [Section 5.5.3](#), “Obtaining Server Plugin Information”.

Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, *plugin_name* stands for a plugin name such as `innodb`, `csv`, or `validate_password`.

Built-in plugins:

A built-in plugin is known by the server automatically. Normally, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the `--plugin_name[=activation_state]` option.

Plugins registered in the `mysql.plugin` system table:

The `mysql.plugin` table serves as a registry of plugins (other than built-in plugins, which need not be registered). At startup, the server loads each plugin listed in the table. Normally, for a plugin loaded from the `mysql.plugin` table, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugin` table and does not load the plugins listed there.

Plugins named with command-line options:

A plugin located in a plugin library file can be loaded at server startup with the `--plugin-load` or `--plugin-load-add` option. Normally, for a plugin loaded at startup, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The value of each plugin-loading option is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each *name* is the name of a plugin to load, and *plugin_library* is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load` or `--plugin-load-add` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load` and `--plugin-load-add` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load` and `--plugin-load-add` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup.
- The argument format is the same as for `--plugin-load`, but `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.
- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.

For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

Plugins installed with the `INSTALL PLUGIN` statement:

A plugin located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

The plugin library file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

Example: The `--plugin-load` option installs a plugin at server startup. To install a plugin named `myplugin` from a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The plugin is listed in the `mysql.plugin` table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using `INSTALL PLUGIN` produce an error:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically
installable. You have to stop the server to install it.
```

In this case, you must use `--plugin-load` or `--plugin-load-add`.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, use `--plugin-load` or `--plugin-load-add` rather than `INSTALL PLUGIN`.

If a plugin is named both using a `--plugin-load` or `--plugin-load-add` option and (as a result of an earlier `INSTALL PLUGIN` statement) in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load` option or is registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a `--plugin_name=[activation_state]` startup option, where *plugin_name* is the name of the plugin to affect, such as `innodb`, `csv`, or `validate_password`. As with other options, dashes and underscores are interchangeable in option names. Also, activation state values are not case sensitive. For example, `--my_plugin=ON` and `--my-plugin=on` are equivalent.

- `--plugin_name=OFF`

Tells the server to disable the plugin. This may not be possible for certain built-in plugins, such as `mysql_native_password`.

- `--plugin_name[=ON]`

Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`

Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`

Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but failed to initialize, aspects of server operation that require the plugin will change. For example, if the plugin

implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable InnoDB, other `innodb_XXX` options likely will need to be omitted at startup. In addition, because InnoDB is the default storage engine, it will not start unless you specify another available storage engine with `--default_storage_engine`. As of MySQL 5.6.3, you must also set `--default_tmp_storage_engine`.

Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` table, if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server will not load the plugin automatically for subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.
- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove any options related to the plugin from the `my.cnf` file.
2. Restart the server.
3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

5.5.3 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```
mysql> SELECT * FROM information_schema.PLUGINS\G
***** 1. row *****
      PLUGIN_NAME: binlog
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
      PLUGIN_AUTHOR: MySQL AB
```

```

    PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
    PLUGIN_LICENSE: GPL
    LOAD_OPTION: FORCE
...
***** 10. row *****
    PLUGIN_NAME: InnoDB
    PLUGIN_VERSION: 1.0
    PLUGIN_STATUS: ACTIVE
    PLUGIN_TYPE: STORAGE ENGINE
    PLUGIN_TYPE_VERSION: 50158.0
    PLUGIN_LIBRARY: ha_innodb_plugin.so
    PLUGIN_LIBRARY_VERSION: 1.0
    PLUGIN_AUTHOR: Innobase Oy
    PLUGIN_DESCRIPTION: Supports transactions, row-level locking,
                        and foreign keys
    PLUGIN_LICENSE: GPL
    LOAD_OPTION: ON
...

```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```

mysql> SHOW PLUGINS\G
***** 1. row *****
    Name: binlog
    Status: ACTIVE
    Type: STORAGE ENGINE
    Library: NULL
    License: GPL
...
***** 10. row *****
    Name: InnoDB
    Status: ACTIVE
    Type: STORAGE ENGINE
    Library: ha_innodb_plugin.so
    License: GPL
...

```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

5.5.4 MySQL Enterprise Thread Pool

Note

MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <http://www.mysql.com/products/>.

As of MySQL 5.6.10, MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the one thread per connection model:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.

- With too many threads executing in parallel, context switching overhead is high. This also presents a challenging task to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.
- Too many transactions executing in parallel increases resource contention. In [InnoDB](#), this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

The thread pool plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions.

On Windows, the thread pool plugin requires Windows Vista or newer. On Linux, the plugin requires kernel 2.6.9 or higher.

5.5.4.1 Thread Pool Components

The thread pool feature comprises these components:

- A plugin library file contains a plugin for the thread pool code and plugins for several [INFORMATION_SCHEMA](#) tables.

For a detailed description of how the thread pool works, see [Section 5.5.4.3, “Thread Pool Operation”](#).

The [INFORMATION_SCHEMA](#) tables are named [TP_THREAD_STATE](#), [TP_THREAD_GROUP_STATE](#), and [TP_THREAD_GROUP_STATS](#). These tables provide information about thread pool operation. For more information, see [Section 21.31, “Thread Pool INFORMATION_SCHEMA Tables”](#).

- Several system variables are related to the thread pool. The [thread_handling](#) system variable has a value of [loaded-dynamically](#) when the server successfully loads the thread pool plugin.

The other related variables are implemented by the thread pool plugin; they are not available unless it is enabled:

- [thread_pool_algorithm](#): The concurrency algorithm to use for scheduling.
- [thread_pool_high_priority_connection](#): How to schedule statement execution for a session.
- [thread_pool_prio_kickup_timer](#): How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.
- [thread_pool_max_unused_threads](#): How many sleeping threads to permit.
- [thread_pool_size](#): The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.
- [thread_pool_stall_limit](#): The time before an executing statement is considered to be stalled.

If any variable implemented by the plugin is set to an illegal value at startup, plugin initialization fails and the plugin does not load.

For information about setting thread pool parameters, see [Section 5.5.4.4, “Thread Pool Tuning”](#).

- The Performance Schema exposes information about the thread pool and may be used to investigate operational performance. For more information, see [Chapter 22, MySQL Performance Schema](#).

5.5.4.2 Thread Pool Installation

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see [Section 5.5.2, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load` option. For example, if you name just the plugin library file, the server loads all plugins that it contains (that is, the thread pool plugin and all the `INFORMATION_SCHEMA` tables). To do this, put these lines in your `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load=thread_pool.so
```

That is equivalent to loading all thread pool plugins by naming them individually:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so;tp_thread_state=thread_pool.so;tp_thread_group_state=thread_pool.so
```

With `--plugin-load`, all plugins must be named on a single line. To make the option file easier to read, use `--plugin-load-add`, which enables naming plugins individually:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
plugin-load-add=tp_thread_group_state=thread_pool.so
plugin-load-add=tp_thread_group_stats=thread_pool.so
```

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the `INFORMATION_SCHEMA` tables, use an option like this:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use an option like this:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so;tp_thread_state=thread_pool.so
```

Note

If you do not load all the `INFORMATION_SCHEMA` tables, some or all MySQL Enterprise Monitor thread pool graphs will be empty.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE 'thread%' OR PLUGIN_NAME LIKE 'tp%';
```

| PLUGIN_NAME | PLUGIN_STATUS |
|-----------------------|---------------|
| thread_pool | ACTIVE |
| TP_THREAD_STATE | ACTIVE |
| TP_THREAD_GROUP_STATE | ACTIVE |
| TP_THREAD_GROUP_STATS | ACTIVE |

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `dynamically-loaded`. If the plugin fails to load, the server writes a message to the error log.

5.5.4.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

The number of thread groups is configurable using the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see [Section 5.5.4.4, “Thread Pool Tuning”](#).

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that the thread executes all statements from the connection.

The thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance. The algorithm works in the following manner:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
 - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.
 - Queuing occurs if the statement cannot begin executing immediately.
- If immediate execution occurs, execution is performed by the listener thread. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be

set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute. If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication master, a thread that is sending binary log events to a slave effectively runs forever.
- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.
- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for `InnoDB` and `MyISAM` tables, the thread pool prioritizes those for `InnoDB` over those for `MyISAM` unless `autocommit` is enabled. With `autocommit` enabled, all statements will be low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.
- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms or 100 per second will be moved from the low-priority queue to the high-priority queue.
- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.
- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even though the first thread is still executing.
- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.

- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.

The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.
- Binary log dump threads that read the binary log and send it to slaves. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.
- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` and `thread_pool_size`. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

5.5.4.4 Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

`thread_pool_size` is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

- If the primary storage engine is `InnoDB`, the optimal `thread_pool_size` setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.

For workloads such as DBT2 and Sysbench, the optimum for `InnoDB` seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is `MyISAM`, the `thread_pool_size` setting should be fairly low. We tend to get optimal performance for values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, `thread_pool_stall_limit`, is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout, the length of which can be tuned using the `thread_pool_stall_limit` system variable. This parameter

ensures that the server does not become completely blocked. The value of `thread_pool_stall_limit` has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

`thread_pool_stall_limit` also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of `thread_pool_stall_limit` should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the `thread_pool_stall_limit` parameter too high means that long-running statements will block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set `thread_pool_stall_limit` to 10 (meaning 100ms). The default value of 60ms is okay for servers that primarily execute very simple statements.

The `thread_pool_stall_limit` parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the `TP_THREAD_GROUP_STATS` table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM information_schema.TP_THREAD_GROUP_STATS;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of `thread_pool_stall_limit`.

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- `thread_pool_prio_kickup_timer` is set to 10000 (10 seconds).
- `thread_pool_stall_limit` is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements will be moved to the high-priority queue because it will always already contain statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those will become stalled and it will take 1 second for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it will take 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

5.6 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.5 and one from MySQL 5.6, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See [Section 4.2.3, “Specifying Program Options”](#). To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=dir_name` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see [Section 5.6.1, “Setting Up Multiple Data Directories”](#).

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num`

`--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause each server to listen to a different address.

- `--socket={file_name|pipe_name}`

`--socket` controls the Unix socket file path on Unix or the named pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name`

This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name`

This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name`
- `--log-bin[=file_name]`
- `--slow_query_log_file=file_name`
- `--log-error[=file_name]`

For further discussion of log file options, see [Section 5.4, “MySQL Server Logs”](#).

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=dir_name`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=dir_name` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

5.6.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=dir_name` option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with `MyISAM` and `MERGE` tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Create a New Data Directory

With this method, the data directory will be in the same state as when you first install MySQL. It will have the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See [Section 2.10, “Postinstallation Setup and Testing”](#).

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it `data` directory to where you are setting up the new instance.
- Windows MSI package installers create and set up the data directory that the installed server will use, but also create a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.
2. Copy the data directory to the location where the new data directory should be.
3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.
4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).
5. Start the new instance, telling it to use the new option file.

5.6.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in [Section 2.3, “Installing MySQL on Microsoft Windows”](#). The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in [Section 5.6, “Running Multiple MySQL Instances on One Machine”](#).

5.6.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in [Section 2.3.5.5, “Starting MySQL from the Windows Command Line”](#). To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run one instance of `mysqld` on port 3307 with a data directory of `C:\mydata1`, and another instance on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.
2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

3. Use the `--defaults-file` option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections with the `--shared-memory` option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` option.

5.6.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.5.9` and `C:\mysql-5.6.37`, respectively. (This might be the case if you are running 5.5.9 as your production server, but also want to conduct tests using 5.6.37.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see [Section 2.3.5.7, “Starting MySQL as a Windows Service”](#).

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.5.9 `mysqld` using the service name of `mysqld1` and the 5.6.37 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.5.9 and the `[mysqld2]` group for 5.6.37. For example, you can set up `C:\my.cnf` like this:

```
# options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.6.37
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
C:\> C:\mysql-5.6.37\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```
C:\> NET START mysqld1
C:\> NET START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.5.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.5.9
port = 3307
```

```
enable-named-pipe
socket = mypipe1
```

For the 5.6.37 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.6.37
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
      --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-5.6.37\bin\mysqld --install mysqld2
      --defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it.

5.6.3 Running Multiple MySQL Instances on Unix

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.5 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.6.37 server to have different operating parameters, use a `CMake` command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
            -DMYSQL_UNIX_ADDR=file_name \
            -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-5.6.37
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. To explicitly specify the connection protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=dir_name` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

[Section 4.9, “MySQL Program Environment Variables”](#), includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See [Section 4.3.4, “mysqld_multi — Manage Multiple MySQL Servers”](#).

5.6.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.
- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific

socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See [Section 4.9, “MySQL Program Environment Variables”](#).

- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See [Section 4.2.6, “Using Option Files”](#).
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See [Section 23.8.7, “C API Function Descriptions”](#).
- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
      . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See [Section 23.10, “MySQL Perl API”](#).

Other programming interfaces may provide similar capabilities for reading option files.

5.7 Tracing mysqld Using DTrace

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes (`query-start` and `query-done`) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

Figure 5.1 The MySQL Architecture Using Pluggable Storage Engines

Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels

([connection-start](#), [command-start](#), [query-start](#), and [query-exec-start](#)). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you will combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this will be given as the format and arguments of each probe are provided.

MySQL includes support for DTrace probes on these platforms:

- Solaris 10 Update 5 (Solaris 5/08) on SPARC, x86 and x86_64 platforms
- OS X 10.4 and higher
- Oracle Linux 6 and higher with UEK kernel (as of MySQL 5.6.20)

Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the `-DENABLE_DTRACE=1` or `-DENABLE_DTRACE=0` option to `CMake`.

If a non-Solaris platform includes DTrace support, building `mysqld` on that platform will include DTrace support.

Additional Resources

- For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).
- For an introduction to DTrace, see the MySQL Dev Zone article [Getting started with DTracing MySQL](#).

5.7.1 mysqld DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality.

Table 5.6 MySQL DTrace Probes

| Group | Probes |
|---------------------------------|--|
| Connection | connection-start , connection-done |
| Command | command-start , command-done |
| Query | query-start , query-done |
| Query Parsing | query-parse-start , query-parse-done |
| Query Cache | query-cache-hit , query-cache-miss |
| Query Execution | query-exec-start , query-exec-done |
| Row Level | insert-row-start , insert-row-done |
| | update-row-start , update-row-done |
| | delete-row-start , delete-row-done |
| Row Reads | read-row-start , read-row-done |
| Index Reads | index-read-row-start , index-read-row-done |
| Lock | handler-rdlock-start , handler-rdlock-done |
| | handler-wrlock-start , handler-wrlock-done |
| | handler-unlock-start , handler-unlock-done |
| Filesort | filesort-start , filesort-done |
| Statement | select-start , select-done |
| | insert-start , insert-done |

| Group | Probes |
|----------|---|
| | <code>insert-select-start</code> , <code>insert-select-done</code> |
| | <code>update-start</code> , <code>update-done</code> |
| | <code>multi-update-start</code> , <code>multi-update-done</code> |
| | <code>delete-start</code> , <code>delete-done</code> |
| | <code>multi-delete-start</code> , <code>multi-delete-done</code> |
| Network | <code>net-read-start</code> , <code>net-read-done</code> , <code>net-write-start</code> , <code>net-write-done</code> |
| Keycache | <code>keycache-read-start</code> , <code>keycache-read-block</code> , <code>keycache-read-done</code> , <code>keycache-read-hit</code> , <code>keycache-read-miss</code> , <code>keycache-write-start</code> , <code>keycache-write-block</code> , <code>keycache-write-done</code> |

Note

When extracting the argument data from the probes, each argument is available as `argN`, starting with `arg0`. To identify each argument within the definitions they are provided with a descriptive name, but you must access the information using the corresponding `argN` parameter.

5.7.1.1 Connection Probes

The `connection-start` and `connection-done` probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

```
connection-start(connectionid, user, host)
connection-done(status, connectionid)
```

- **connection-start**: Triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:
 - **connectionid**: An `unsigned long` containing the connection ID. This is the same as the process ID shown as the `Id` value in the output from `SHOW PROCESSLIST`.
 - **user**: The username used when authenticating. The value will be blank for the anonymous user.
 - **host**: The host of the client connection. For a connection made using Unix sockets, the value will be blank.
- **connection-done**: Triggered just as the connection to the client has been closed. The arguments are:
 - **status**: The status of the connection when it was closed. A logout operation will have a value of 0; any other termination of the connection has a nonzero value.
 - **connectionid**: The connection ID of the connection that was closed.

The following D script will quantify and summarize the average duration of individual connections, and provide a count, dumping the information every 60 seconds:

```
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
    self->start = timestamp;
}

mysql*:::connection-done
```

```

/self->start/
{
    @ = quantize(((timestamp - self->start)/1000000));
    self->start = 0;
}

tick-60s
{
    printa(@);
}

```

When executed on a server with a large number of clients you might see output similar to this:

```

1 57413                               :tick-60s

      value  ----- Distribution ----- count
      -1 |                                     0
       0 | @@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@ 30011
       1 |                                     59
       2 |                                     5
       4 |                                     20
       8 |                                     29
      16 |                                     18
      32 |                                     27
      64 |                                     30
     128 |                                     11
     256 |                                     10
     512 |                                     1
    1024 |                                     6
    2048 |                                     8
    4096 |                                     9
    8192 |                                     8
   16384 |                                     2
   32768 |                                     1
   65536 |                                     1
  131072 |                                     0
  262144 |                                     1
  524288 |                                     0

```

5.7.1.2 Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the [COM_CHANGE_USER](#) operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```

command-start(connectionid, command, user, host)
command-done(status)

```

- **command-start**: Triggered when a command is submitted to the server.
- **connectionid**: The connection ID of the client executing the command.
- **command**: An integer representing the command that was executed. Possible values are shown in the following table.

| Value | Name | Description |
|-------|-------------|---|
| 00 | COM_SLEEP | Internal thread state |
| 01 | COM_QUIT | Close connection |
| 02 | COM_INIT_DB | Select database (USE ...) |

| Value | Name | Description |
|-------|-------------------------|--|
| 03 | COM_QUERY | Execute a query |
| 04 | COM_FIELD_LIST | Get a list of fields |
| 05 | COM_CREATE_DB | Create a database (deprecated) |
| 06 | COM_DROP_DB | Drop a database (deprecated) |
| 07 | COM_REFRESH | Refresh connection |
| 08 | COM_SHUTDOWN | Shutdown server |
| 09 | COM_STATISTICS | Get statistics |
| 10 | COM_PROCESS_INFO | Get processes (SHOW PROCESSLIST) |
| 11 | COM_CONNECT | Initialize connection |
| 12 | COM_PROCESS_KILL | Kill process |
| 13 | COM_DEBUG | Get debug information |
| 14 | COM_PING | Ping |
| 15 | COM_TIME | Internal thread state |
| 16 | COM_DELAYED_INSERT | Delayed thread state |
| 17 | COM_CHANGE_USER | Change user |
| 18 | COM_BINLOG_DUMP | Used by a replication slave or mysqlbinlog to initiate a binary log read |
| 19 | COM_TABLE_DUMP | Used by a replication slave to get the master table information |
| 20 | COM_CONNECT_OUT | Used by a replication slave to log a connection to the server |
| 21 | COM_REGISTER_SLAVE | Used by a replication slave during registration |
| 22 | COM_STMT_PREPARE | Prepare a statement |
| 23 | COM_STMT_EXECUTE | Execute a statement |
| 24 | COM_STMT_SEND_LONG_DATA | Used by a slave when requesting extended data |
| 25 | COM_STMT_CLOSE | Close a prepared statement |
| 26 | COM_STMT_RESET | Reset a prepared statement |
| 27 | COM_SET_OPTIONS | Set a server option |
| 28 | COM_STMT_FETCH | Fetch a prepared statement |

- [user](#): The user executing the command.
- [host](#): The client host.
- [command-done](#): Triggered when the command execution completes. The [status](#) argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The [command-start](#) and [command-done](#) probes are best used when combined with the statement probes to get an idea of overall execution time.

5.7.1.3 Query Probes

The [query-start](#) and [query-done](#) probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```
query-start(query, connectionid, database, user, host)
```

```
query-done(status)
```

- **query-start**: Triggered after the query string has been received from the client. The arguments are:
 - **query**: The full text of the submitted query.
 - **connectionid**: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the **Id** value in the output from **SHOW PROCESSLIST**.
 - **database**: The database name on which the query is being executed.
 - **user**: The username used to connect to the server.
 - **host**: The hostname of the client.
- **query-done**: Triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, **status**, which returns 0 when the query is successfully executed and 1 if there was an error.

You can get a simple report of the execution time for each query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->querystart = timestamp;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-9d\n", self->who, self->db, self->query,
        (timestamp - self->querystart) / 1000000);
}
```

When executing the above script you should get a basic idea of the execution time of your queries:

```
shell> ./query.d
Who           Database      Query                                           Time(ms)
root@localhost test        select * from t1 order by i limit 10           0
root@localhost test        set global query_cache_size=0                 0
root@localhost test        select * from t1 order by i limit 10          776
root@localhost test        select * from t1 order by i limit 10          773
root@localhost test        select * from t1 order by i desc limit 10     795
```

5.7.1.4 Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

```
query-parse-start(query)
```

```
query-parse-done(status)
```

- **query-parse-start**: Triggered just before the statement is parsed by the MySQL query parser. The single argument, **query**, is a string containing the full text of the original query.
- **query-parse-done**: Triggered when the parsing of the original statement has been completed. The **status** is an integer describing the status of the operation. A **0** indicates that the query was successfully parsed. A **1** indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::query-parse-start
{
    self->parsestart = timestamp;
    self->parsequery = copyinstr(arg0);
}

mysql*:::query-parse-done
/arg0 == 0/
{
    printf("Parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}

mysql*:::query-parse-done
/arg0 != 0/
{
    printf("Error parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}
```

In the above script a predicate is used on **query-parse-done** so that different output is generated based on the status value of the probe.

When running the script and monitoring the execution:

```
shell> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms
```

5.7.1.5 Query Cache Probes

The query cache probes are fired when executing any query. The **query-cache-hit** query is triggered when a query exists in the query cache and can be used to return the query cache information. The arguments contain the original query text and the number of rows returned from the query cache for the query. If the query is not within the query cache, or the query cache is not enabled, then the **query-cache-miss** probe is triggered instead.

```
query-cache-hit(query, rows)
query-cache-miss(query)
```

- **query-cache-hit**: Triggered when the query has been found within the query cache. The first argument, **query**, contains the original text of the query. The second argument, **rows**, is an integer containing the number of rows in the cached query.
- **query-cache-miss**: Triggered when the query is not found within the query cache. The first argument, **query**, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine the differences in times between using or not using the query cache for specified queries. For example, in the

following D script, the query and query cache information are combined into the information output during monitoring:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %2s %-9s\n", "Who", "Database", "Query", "QC", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->querystart = timestamp;
    self->qc = 0;
}

mysql*:::query-cache-hit
{
    self->qc = 1;
}

mysql*:::query-cache-miss
{
    self->qc = 0;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %2s %-9d\n", self->who, self->db, self->query, (self->qc ? "Y" : "N"),
        (timestamp - self->querystart) / 1000000);
}
```

When executing the script you can see the effects of the query cache. Initially the query cache is disabled. If you set the query cache size and then execute the query multiple times you should see that the query cache is being used to return the query data:

```
shell> ./query-cache.d
root@localhost      test      select * from t1 order by i limit 10      N 1072
root@localhost      test      set global query_cache_size=262144      N 0
root@localhost      test      select * from t1 order by i limit 10      N 781
root@localhost      test      select * from t1 order by i limit 10      Y 0
```

5.7.1.6 Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and checking the query cache but before any privilege checks or optimization. By comparing the difference between the start and done probes you can monitor the time actually spent servicing the query (instead of just handling the parsing and other elements of the query).

```
query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)
```

Note

The information provided in the arguments for `query-start` and `query-exec-start` are almost identical and designed so that you can choose to monitor

either the entire query process (using `query-start`) or only the execution (using `query-exec-start`) while exposing the core information about the user, client, and query being executed.

- `query-exec-start`: Triggered when the execution of a individual query is started. The arguments are:
 - `query`: The full text of the submitted query.
 - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
 - `database`: The database name on which the query is being executed.
 - `user`: The username used to connect to the server.
 - `host`: The hostname of the client.
 - `exec_type`: The type of execution. Execution types are determined based on the contents of the query and where it was submitted. The values for each type are shown in the following table.

| Value | Description |
|-------|---|
| 0 | Executed query from <code>sql_parse</code> , top-level query. |
| 1 | Executed prepared statement |
| 2 | Executed cursor statement |
| 3 | Executed query in stored procedure |

- `query-exec-done`: Triggered when the execution of the query has completed. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

5.7.1.7 Row-Level Probes

The `*row-{start,done}` probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an `INSERT` statement with 100 rows of data, then the `insert-row-start` and `insert-row-done` probes will be triggered 100 times each, for each row insert.

```
insert-row-start(database, table)
insert-row-done(status)

update-row-start(database, table)
update-row-done(status)

delete-row-start(database, table)
delete-row-done(status)
```

- `insert-row-start`: Triggered before a row is inserted into a table.
- `insert-row-done`: Triggered after a row is inserted into a table.
- `update-row-start`: Triggered before a row is updated in a table.
- `update-row-done`: Triggered before a row is updated in a table.
- `delete-row-start`: Triggered before a row is deleted from a table.
- `delete-row-done`: Triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding `start` and `done` probes in each case:

- `database`: The database name.
- `table`: The table name.
- `status`: The status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a `query-done` or `query-exec-done` probes.

The following example script summarizes the duration of each row operation within a larger query:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %9s %-s \n",
        "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->rowdur = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) / 1000000;
    printf("%2d %-10s %-10s %9d %9d %s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
}

mysql*:::query-done
/ self->rowdur /
{
    printf("%34s %9d %s\n", "", (self->rowdur/1000000), "-> Row ops");
}

mysql*:::insert-row-start
{
    self->rowstart = timestamp;
}

mysql*:::delete-row-start
{
    self->rowstart = timestamp;
}

mysql*:::update-row-start
{
    self->rowstart = timestamp;
}
```

```

}

mysql*:::insert-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::delete-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::update-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

```

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

| St | Who | DB | ConnID | Dur ms | Query |
|----|------------|------|--------|--------|----------------------------------|
| 0 | @localhost | test | 13 | 20767 | insert into t1(select * from t2) |
| | | | | 4827 | -> Row ops |

5.7.1.8 Read Row Probes

The read row probes are triggered at a storage engine level each time a row read operation occurs. These probes are specified within each storage engine (as opposed to the `*row-start` probes which are in the storage engine interface). These probes can therefore be used to monitor individual storage engine row-level operations and performance. Because these probes are triggered around the storage engine row read interface, they may be hit a significant number of times during a basic query.

```

read-row-start(database, table, scan_flag)
read-row-done(status)

```

- **read-row-start**: Triggered when a row is read by the storage engine from the specified `database` and `table`. The `scan_flag` is set to 1 (true) when the read is part of a table scan (that is, a sequential read), or 0 (false) when the read is of a specific record.
- **read-row-done**: Triggered when a row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

5.7.1.9 Index Probes

The index probes are triggered each time a row is read using one of the indexes for the specified table. The probe is triggered within the corresponding storage engine for the table.

```

index-read-row-start(database, table)
index-read-row-done(status)

```

- **index-read-row-start**: Triggered when a row is read by the storage engine from the specified `database` and `table`.
- **index-read-row-done**: Triggered when an indexed row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

5.7.1.10 Lock Probes

The lock probes are called whenever an external lock is requested by MySQL for a table using the corresponding lock mechanism on the table as defined by the table's engine type. There are three different

types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

```
handler-rdlock-start(database, table)
handler-rdlock-done(status)

handler-wrlock-start(database, table)
handler-wrlock-done(status)

handler-unlock-start(database, table)
handler-unlock-done(status)
```

- **handler-rdlock-start**: Triggered when a read lock is requested on the specified `database` and `table`.
- **handler-wrlock-start**: Triggered when a write lock is requested on the specified `database` and `table`.
- **handler-unlock-start**: Triggered when an unlock request is made on the specified `database` and `table`.
- **handler-rdlock-done**: Triggered when a read lock request completes. The `status` is 0 if the lock operation succeeded, or >0 on failure.
- **handler-wrlock-done**: Triggered when a write lock request completes. The `status` is 0 if the lock operation succeeded, or >0 on failure.
- **handler-unlock-done**: Triggered when an unlock request completes. The `status` is 0 if the unlock operation succeeded, or >0 on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::handler-rdlock-start
{
    self->rdlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Read   %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-wrlock-start
{
    self->wrlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Write  %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-unlock-start
{
    self->unlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    printf("Start: Lock->Unlock %s.%s (%d ms lock duration)\n",
        copyinstr(arg0),copyinstr(arg1),
        (timestamp - self->lockmap[this->lockref])/1000000);
}
```

```
mysql*:::handler-rdlock-done
{
    printf("End:   Lock->Read   %d ms\n",
           (timestamp - self->rdlockstart)/1000000);
}

mysql*:::handler-wrlock-done
{
    printf("End:   Lock->Write  %d ms\n",
           (timestamp - self->wrlockstart)/1000000);
}

mysql*:::handler-unlock-done
{
    printf("End:   Lock->Unlock %d ms\n",
           (timestamp - self->unlockstart)/1000000);
}
```

When executed, you should get information both about the duration of the locking process itself, and of the locks on a specific table:

```
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (25743 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
```

5.7.1.11 Filesort Probes

The filesort probes are triggered whenever a filesort operation is applied to a table. For more information on filesort and the conditions under which it occurs, see [Section 8.2.1.13, “ORDER BY Optimization”](#).

```
filesort-start(database, table)
filesort-done(status, rows)
```

- **filesort-start**: Triggered when the filesort operation starts on a table. The two arguments to the probe, **database** and **table**, will identify the table being sorted.
- **filesort-done**: Triggered when the filesort operation completes. Two arguments are supplied, the **status** (0 for success, 1 for failure), and the number of rows sorted during the filesort process.

An example of this is in the following script, which tracks the duration of the filesort process in addition to the duration of the main query:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %18s %-s \n",
           "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}
```

```

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->filesort = 0;
    self->fsdb = "";
    self->fstable = "";
}

mysql*:::filesort-start
{
    self->filesort = timestamp;
    self->fsdb = copyinstr(arg0);
    self->fstable = copyinstr(arg1);
}

mysql*:::filesort-done
{
    this->elapsed = (timestamp - self->filesort) /1000;
    printf("%2d %-10s %-10s %9d %18d Filesort on %s\n",
        arg0, self->who, self->fsdb,
        self->connid, this->elapsed, self->fstable);
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000;
    printf("%2d %-10s %-10s %9d %18d %s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
}

```

Executing a query on a large table with an **ORDER BY** clause that triggers a filesort, and then creating an index on the table and then repeating the same query, you can see the difference in execution speed:

| St | Who | DB | ConnID | Dur microsec | Query |
|----|------------|------|--------|--------------|---------------------------------------|
| 0 | @localhost | test | 14 | 11335469 | Filesort on t1 |
| 0 | @localhost | test | 14 | 11335787 | select * from t1 order by i limit 100 |
| 0 | @localhost | test | 14 | 466734378 | create index t1a on t1 (i) |
| 0 | @localhost | test | 14 | 26472 | select * from t1 order by i limit 100 |

5.7.1.12 Statement Probes

The individual statement probes are provided to give specific information about different statement types. For the start probes the string of the query is provided as the only argument. Depending on the statement type, the information provided by the corresponding done probe will differ. For all done probes the status of the operation (0 for success, >0 for failure) is provided. For **SELECT**, **INSERT**, **INSERT ... (SELECT FROM ...)**, **DELETE**, and **DELETE FROM t1,t2** operations the number of rows affected is returned.

For **UPDATE** and **UPDATE t1,t2 ...** statements the number of rows matched and the number of rows actually changed is provided. This is because the number of rows actually matched by the corresponding **WHERE** clause, and the number of rows changed can differ. MySQL does not update the value of a row if the value already matches the new setting.

```

select-start(query)
select-done(status,rows)

insert-start(query)
insert-done(status,rows)

insert-select-start(query)

```

```

insert-select-done(status,rows)

update-start(query)
update-done(status,rowsmatched,rowschanged)

multi-update-start(query)
multi-update-done(status,rowsmatched,rowschanged)

delete-start(query)
delete-done(status,rows)

multi-delete-start(query)
multi-delete-done(status,rows)

```

- `select-start`: Triggered before a `SELECT` statement.
- `select-done`: Triggered at the end of a `SELECT` statement.
- `insert-start`: Triggered before a `INSERT` statement.
- `insert-done`: Triggered at the end of an `INSERT` statement.
- `insert-select-start`: Triggered before an `INSERT ... SELECT` statement.
- `insert-select-done`: Triggered at the end of an `INSERT ... SELECT` statement.
- `update-start`: Triggered before an `UPDATE` statement.
- `update-done`: Triggered at the end of an `UPDATE` statement.
- `multi-update-start`: Triggered before an `UPDATE` statement involving multiple tables.
- `multi-update-done`: Triggered at the end of an `UPDATE` statement involving multiple tables.
- `delete-start`: Triggered before a `DELETE` statement.
- `delete-done`: Triggered at the end of a `DELETE` statement.
- `multi-delete-start`: Triggered before a `DELETE` statement involving multiple tables.
- `multi-delete-done`: Triggered at the end of a `DELETE` statement involving multiple tables.

The arguments for the statement probes are:

- `query`: The query string.
- `status`: The status of the query. `0` for success, and `>0` for failure.
- `rows`: The number of rows affected by the statement. This returns the number rows found for `SELECT`, the number of rows deleted for `DELETE`, and the number of rows successfully inserted for `INSERT`.
- `rowsmatched`: The number of rows matched by the `WHERE` clause of an `UPDATE` operation.
- `rowschanged`: The number of rows actually changed during an `UPDATE` operation.

You use these probes to monitor the execution of these statement types without having to monitor the user or client executing the statements. A simple example of this is to track the execution times:

```

#!/usr/sbin/dtrace -s
#pragma D option quiet

```

```

dtrace:::BEGIN
{
    printf("%-60s %-8s %-8s %-8s\n", "Query", "RowsU", "RowsM", "Dur (ms)");
}

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->query = copyinstr(arg0);
    self->querystart = timestamp;
}

mysql*:::insert-done, mysql*:::select-done,
mysql*:::delete-done, mysql*:::multi-delete-done, mysql*:::insert-select-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
        self->query,
        0,
        arg1,
        this->elapsed);
    self->querystart = 0;
}

mysql*:::update-done, mysql*:::multi-update-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
        self->query,
        arg1,
        arg2,
        this->elapsed);
    self->querystart = 0;
}

```

When executed you can see the basic execution times and rows matches:

| Query | RowsU | RowsM | Dur (ms) |
|-----------------------------------|-------|-------|----------|
| select * from t2 | 0 | 275 | 0 |
| insert into t2 (select * from t2) | 0 | 275 | 9 |
| update t2 set i=5 where i > 75 | 110 | 110 | 8 |
| update t2 set i=5 where i < 25 | 254 | 134 | 12 |
| delete from t2 where i < 5 | 0 | 0 | 0 |

Another alternative is to use the aggregation functions in DTrace to aggregate the execution time of individual statements together:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->querystart = timestamp;
}

mysql*:::select-done
{

```

```

        @statements["select"] = sum(((timestamp - self->querystart)/1000000));
    }

mysql*:::insert-done, mysql*:::insert-select-done
{
    @statements["insert"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::update-done, mysql*:::multi-update-done
{
    @statements["update"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::delete-done, mysql*:::multi-delete-done
{
    @statements["delete"] = sum(((timestamp - self->querystart)/1000000));
}

tick-30s
{
    printa(@statements);
}

```

The script just shown aggregates the times spent doing each operation, which could be used to help benchmark a standard suite of tests.

| | |
|--------|-------|
| delete | 0 |
| update | 0 |
| insert | 23 |
| select | 2484 |
| | |
| delete | 0 |
| update | 0 |
| insert | 39 |
| select | 10744 |
| | |
| delete | 0 |
| update | 26 |
| insert | 56 |
| select | 10944 |
| | |
| delete | 0 |
| update | 26 |
| insert | 2287 |
| select | 15985 |

5.7.1.13 Network Probes

The network probes monitor the transfer of information from the MySQL server and clients of all types over the network. The probes are defined as follows:

```

net-read-start()
net-read-done(status, bytes)
net-write-start(bytes)
net-write-done(status)

```

- **net-read-start**: Triggered when a network read operation is started.
- **net-read-done**: Triggered when the network read operation completes. The `status` is an `integer` representing the return status for the operation, `0` for success and `1` for failure. The `bytes` argument is an integer specifying the number of bytes read during the process.
- **net-start-bytes**: Triggered when data is written to a network socket. The single argument, `bytes`, specifies the number of bytes written to the network socket.

- **net-write-done**: Triggered when the network write operation has completed. The single argument, **status**, is an integer representing the return status for the operation, **0** for success and **1** for failure.

You can use the network probes to monitor the time spent reading from and writing to network clients during execution. The following D script provides an example of this. Both the cumulative time for the read or write is calculated, and the number of bytes. Note that the dynamic variable size has been increased (using the **dynvarsize** option) to cope with the rapid firing of the individual probes for the network reads/writes.

```
#!/usr/sbin/dtrace -s

#pragma D option quiet
#pragma D option dynvarsize=4m

dtrace:::BEGIN
{
    printf("%-2s %-30s %-10s %9s %18s %-s \n",
        "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->db = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->netwrite = 0;
    self->netwritecum = 0;
    self->netwritebase = 0;
    self->netread = 0;
    self->netreadcum = 0;
    self->netreadbase = 0;
}

mysql*:::net-write-start
{
    self->netwrite += arg0;
    self->netwritebase = timestamp;
}

mysql*:::net-write-done
{
    self->netwritecum += (timestamp - self->netwritebase);
    self->netwritebase = 0;
}

mysql*:::net-read-start
{
    self->netreadbase = timestamp;
}

mysql*:::net-read-done
{
    self->netread += arg1;
    self->netreadcum += (timestamp - self->netreadbase);
    self->netreadbase = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) / 1000000;
    printf("%2d %-30s %-10s %9d %18d %-s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
    printf("Net read: %d bytes (%d ms) write: %d bytes (%d ms)\n",

```

```

        self->netread, (self->netreadcum/1000000),
        self->netwrite, (self->netwritecum/1000000));
}

```

When executing the above script on a machine with a remote client, you can see that approximately a third of the time spent executing the query is related to writing the query results back to the client.

| St | Who | DB | ConnID | Dur microsec | Query |
|--|---------------------------|------|--------|--------------|--------------------------------|
| 0 | root@::ffff:192.168.0.108 | test | 31 | 3495 | select * from t1 limit 1000000 |
| Net read: 0 bytes (0 ms) write: 10000075 bytes (1220 ms) | | | | | |

5.7.1.14 Keycache Probes

The keycache probes are triggered when using the index key cache used with the MyISAM storage engine. Probes exist to monitor when data is read into the keycache, cached key data is written from the cache into a cached file, or when accessing the keycache.

Keycache usage indicates when data is read or written from the index files into the cache, and can be used to monitor how efficient the memory allocated to the keycache is being used. A high number of keycache reads across a range of queries may indicate that the keycache is too small for size of data being accessed.

```

keycache-read-start(filepath, bytes, mem_used, mem_free)
keycache-read-block(bytes)
keycache-read-hit()
keycache-read-miss()
keycache-read-done(mem_used, mem_free)
keycache-write-start(filepath, bytes, mem_used, mem_free)
keycache-write-block(bytes)
keycache-write-done(mem_used, mem_free)

```

When reading data from the index files into the keycache, the process first initializes the read operation (indicated by `keycache-read-start`), then loads blocks of data (`keycache-read-block`), and then the read block is either matches the data being identified (`keycache-read-hit`) or more data needs to be read (`keycache-read-miss`). Once the read operation has completed, reading stops with the `keycache-read-done`.

Data will be read from the index file into the keycache only when the specified key is not already within the keycache.

- `keycache-read-start`: Triggered when the keycache read operation is started. Data is read from the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-read-block`: Triggered when the keycache reads a block of data, of the specified number of `bytes`, from the index file into the keycache.
- `keycache-read-hit`: Triggered when the block of data read from the index file matches the key data requested.
- `keycache-read-miss`: Triggered when the block of data read from the index file does not match the key data needed.
- `keycache-read-done`: Triggered when the keycache read operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

Keycache writes occur when the index information is updated during an `INSERT`, `UPDATE`, or `DELETE` operation, and the cached key information is flushed back to the index file.

- `keycache-write-start`: Triggered when the keycache write operation is started. Data is written to the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-write-block`: Triggered when the keycache writes a block of data, of the specified number of `bytes`, to the index file from the keycache.
- `keycache-write-done`: Triggered when the keycache write operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See [Section 6.1, “General Security Issues”](#).

- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see [Section 2.10, “Postinstallation Setup and Testing”](#).
- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.3, “MySQL User Account Management”](#).
- The features offered by security-related plugins. See [Section 6.5, “Security Plugins”](#).
- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.
- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See [Chapter 7, Backup and Recovery](#).

6.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see [Section 2.10, “Postinstallation Setup and Testing”](#).

For answers to some questions that are often asked about MySQL Server security issues, see [Section A.9, “MySQL 5.6 FAQ: Security”](#).

6.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical.
- Learn how the MySQL access privilege system works (see [Section 6.2, “The MySQL Access Privilege System”](#)). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.
- Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2()` or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.
- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where `server_host` is the host name or IP address of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See [Section 6.1.7, “Client Programming Security Guidelines”](#).
- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.
- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

Warning

If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

6.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. There is also a discussion of how MySQL uses password hashing internally and of a plugin that you can use to enforce stricter passwords.

6.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use the `mysql_config_editor` utility, which enables you to store authentication credentials in an encrypted login path file named `.mylogin.cnf`. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See [Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”](#).
- Use a `-p` or `--password=` option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

This is convenient *but insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `-p` or `--password` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
Enter password: *****
```

The `*` characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]  
password=your_pass
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

```
shell> mysql --defaults-file=/home/francis/mysql-opts
```

[Section 4.2.6, “Using Option Files”](#), discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. See [Section 4.9, “MySQL Program Environment Variables”](#).

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. On some systems, if you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see [Section 4.5.1.3, “mysql Logging”](#)). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

6.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See [Section 6.3.6, “Password Expiration and Sandbox Mode”](#).

The `validate_password` plugin can be used to enforce a policy on acceptable password. See [Section 6.5.3, “The Password Validation Plugin”](#).

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

6.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, `SET PASSWORD`, and statements that invoke the `PASSWORD()` function. If such statements are logged by the MySQL server as written, passwords in them become visible to anyone with access to the logs.

Beginning with MySQL 5.6.3, statement logging is modified to avoid writing passwords in cleartext for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
GRANT ... IDENTIFIED BY ...
SET PASSWORD ...
SLAVE START ... PASSWORD = ... (as of 5.6.4)
CREATE SERVER ... OPTIONS(... PASSWORD ...) (as of 5.6.9)
ALTER SERVER ... OPTIONS(... PASSWORD ...) (as of 5.6.9)
```

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, `INSERT` or `UPDATE` statements for the `mysql.user` table that refer to literal passwords are logged as is, so you should avoid such statements. (Direct manipulation of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

Contents of the audit log file produced by the audit log plugin are not encrypted. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. See [Section 6.5.4.2, “MySQL Enterprise Audit Security Considerations”](#).

To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the `mysql` database, grant access to those tables only to the database administrator.

Replication slaves store the password for the replication master in the master info repository, which can be either a file or a table (see [Section 17.2.2, “Replication Relay and Status Logs”](#)). Ensure that the repository can be accessed only by the database administrator. As of MySQL 5.6.4, an alternative to storing the password in a file is to use the `START SLAVE` statement to specify credentials for connecting to the master.

Use a restricted access mode to protect database backups that include log tables or log files containing passwords.

6.1.2.4 Password Hashing in MySQL

Note

The information in this section applies only for accounts that use the `mysql_native_password` or `mysql_old_password` authentication plugins.

MySQL lists user accounts in the `user` table of the `mysql` database. Each MySQL account can be assigned a password, although the `user` table does not store the cleartext version of the password, but a hash value computed from it.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account the client wants to use.

- After the client connects, it can (if it has sufficient privileges) set or change the password hash for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using a password-generating statement (`CREATE USER`, `GRANT`, or `SET PASSWORD`).

In other words, the server *checks* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD()` function or uses a password-generating statement to set or change a password.

Password hashing methods in MySQL have the history described following. These changes are illustrated by changes in the result from the `PASSWORD()` function that computes password hash values and in the structure of the `user` table where passwords are stored.

The Original (Pre-4.1) Hashing Method

The original hashing method produced a 16-byte string. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| 6f8c114b58f2ce9e   |
+-----+
```

To store account passwords, the `Password` column of the `user` table was at this point 16 bytes long.

The 4.1 Hashing Method

MySQL 4.1 introduced password hashing that provided better security and reduced the risk of passwords being intercepted. There were several aspects to this change:

- Different format of password values produced by the `PASSWORD()` function
- Widening of the `Password` column
- Control over the default hashing method
- Control over the permitted hashing methods for clients attempting to connect to the server

The changes in MySQL 4.1 took place in two stages:

- MySQL 4.1.0 used a preliminary version of the 4.1 hashing method. This method was short lived and the following discussion says nothing more about it.
- In MySQL 4.1.1, the hashing method was modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
```

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

To accommodate longer password hashes, the `Password` column in the `user` table was changed at this point to be 41 bytes, its current length.

A widened `Password` column can store password hashes in both the pre-4.1 and 4.1 formats. The format of any given hash value can be determined two ways:

- The length: 4.1 and pre-4.1 hashes are 41 and 16 bytes, respectively.
- Password hashes in the 4.1 format always begin with a `*` character, whereas passwords in the pre-4.1 format never do.

To permit explicit generation of pre-4.1 password hashes, two additional changes were made:

- The `OLD_PASSWORD()` function was added, which returns hash values in the 16-byte format.
- For compatibility purposes, the `old_passwords` system variable was added, to enable DBAs and applications control over the hashing method. The default `old_passwords` value of 0 causes hashing to use the 4.1 method (41-byte hash values), but setting `old_passwords=1` causes hashing to use the pre-4.1 method. In this case, `PASSWORD()` produces 16-byte values and is equivalent to `OLD_PASSWORD()`.

To permit DBAs control over how clients are permitted to connect, the `secure_auth` system variable was added. Starting the server with this variable disabled or enabled permits or prohibits clients to connect using the older pre-4.1 password hashing method. Before MySQL 5.6.5, `secure_auth` is disabled by default. As of 5.6.5, `secure_auth` is enabled by default to promote a more secure default configuration DBAs can disable it at their discretion, but this is not recommended, and pre-4.1 password hashes are deprecated and should be avoided. (For account upgrade instructions, see [Section 6.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”](#).)

In addition, the `mysql` client supports a `--secure-auth` option that is analogous to `secure_auth`, but from the client side. It can be used to prevent connections to less secure accounts that use pre-4.1 password hashing. This option is disabled by default before MySQL 5.6.7, enabled thereafter.

Compatibility Issues Related to Hashing Methods

The widening of the `Password` column in MySQL 4.1 from 16 bytes to 41 bytes affects installation or upgrade operations as follows:

- If you perform a new installation of MySQL, the `Password` column is made 41 bytes long automatically.
- Upgrades from MySQL 4.1 or later to current versions of MySQL should not give rise to any issues in regard to the `Password` column because both versions use the same column length and password hashing method.
- For upgrades from a pre-4.1 release to 4.1 or later, you must upgrade the system tables after upgrading. (See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).)

The 4.1 hashing method is understood only by MySQL 4.1 (and higher) servers and clients, which can result in some compatibility problems. A 4.1 or higher client can connect to a pre-4.1 server, because the client understands both the pre-4.1 and 4.1 password hashing methods. However, a pre-4.1 client that attempts to connect to a 4.1 or higher server may run into difficulties. For example, a 4.0 `mysql` client may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

This phenomenon also occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or higher. (See [Common Problems with MySQL and PHP](#).)

The following discussion describes the differences between the pre-4.1 and 4.1 hashing methods, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. (However, permitting connections by old clients is not recommended and should be avoided if possible.) Additional information can be found in [Section B.5.2.4, “Client does not support authentication protocol”](#). This information is of particular importance to PHP programmers migrating MySQL databases from versions older than 4.1 to 4.1 or higher.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
 - Pre-4.1 clients can connect, but because they know only about the pre-4.1 hashing method, they can authenticate only using accounts that have short hashes.
 - 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `old_passwords` system variable. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and `old_passwords` must not be set to 1.

Those conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using the `PASSWORD()` function or a password-generating statement. This is the behavior that occurs if you have upgraded from a version of MySQL older than 4.1 to 4.1 or later but have not yet run the `mysql_upgrade` program to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, the `PASSWORD()` function and password-generating statements generate long hashes unless the server was started with the `old_passwords` system variable set to 1 to force the server to generate short password hashes instead.

The purpose of the `old_passwords` system variable is to permit backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that permitted to occur, the account could no longer be used by pre-4.1 clients. With `old_passwords` disabled, the following undesirable scenario is possible:

- An old pre-4.1 client connects to an account that has a short password hash.
- The client changes its own password. With `old_passwords` disabled, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the 4.1 hashing method during authentication. (Once an account has a long password hash in the user table, only 4.1 and later clients can authenticate for it because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is problematic to run a 4.1 or higher server without `old_passwords` set to 1. By running the server with `old_passwords=1`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of `old_passwords=1` is that any passwords created or changed use short hashes, even for 4.1 or later clients. Thus, you lose the additional security provided by long password hashes. To create an account that has a long hash (for example, for use by 4.1 clients) or to change an existing account to use a long password hash, an administrator can set the session value of `old_passwords` set to 0 while leaving the global value set to 1:

```
mysql> SET @@session.old_passwords = 0;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@session.old_passwords, @@global.old_passwords;
+-----+-----+
| @@session.old_passwords | @@global.old_passwords |
+-----+-----+
| 0 | 1 |
+-----+-----+
1 row in set (0.00 sec)

mysql> CREATE USER 'newuser'@'localhost' IDENTIFIED BY 'newpass';
Query OK, 0 rows affected (0.03 sec)

mysql> SET PASSWORD FOR 'existinguser'@'localhost' = PASSWORD('existingpass');
Query OK, 0 rows affected (0.00 sec)
```

The following scenarios are possible in MySQL 4.1 or later. The factors are whether the `Password` column is short or long, and, if long, whether the server is started with `old_passwords` enabled or disabled.

Scenario 1: Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
- The value of `old_passwords` is irrelevant because with a short `Password` column, the server generates only short password hashes anyway.

This scenario occurs when a pre-4.1 MySQL installation has been upgraded to 4.1 or later but `mysql_upgrade` has not been run to upgrade the system tables in the `mysql` database. (This is not a recommended configuration because it does not permit use of more secure 4.1 password hashing.)

Scenario 2: Long `Password` column; server started with `old_passwords=1`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, newly created accounts have short password hashes because `old_passwords=1` prevents generation of long hashes. Also, if you create an account with a long hash before setting `old_passwords` to 1, changing the account's password while `old_passwords=1` results in the account being given a short password, causing it to lose the security benefits of a longer hash.

To create a new account that has a long password hash, or to change the password of any existing account to use a long hash, first set the session value of `old_passwords` set to 0 while leaving the global value set to 1, as described previously.

In this scenario, the server has an up to date `Password` column, but is running with the default password hashing method set to generate pre-4.1 hash values. This is not a recommended configuration but may be useful during a transitional period in which pre-4.1 clients and passwords are upgraded to 4.1 or later. When that has been done, it is preferable to run the server with `old_passwords=0` and `secure_auth=1`.

Scenario 3: Long `Password` column; server started with `old_passwords=0`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using the `PASSWORD()` function or a password-generating statement results in the account being given a long password hash. From that point on, no pre-4.1 client can connect to the server using that account. The client must upgrade to 4.1 or later.

If this is a problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

The disadvantages for each of the preceding scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.
