The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each [InnoDB](#) table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different [workloads](#), data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits [B-tree](#) nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization,

you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of [INSERT](#), [UPDATE](#) and [DELETE](#) operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations ([COMPRESS\\_OPS\\_OK](#)) is a high percentage of the total number of compression operations ([COMPRESS\\_OPS](#)), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase [KEY\\_BLOCK\\_SIZE](#) for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 15.9.1.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about [compression](#) for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

#### Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the [file-per-table](#) tablespace or [general tablespace](#) [.idb](#) files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the [innodb\\_compression\\_level](#) configuration option.

#### InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node

contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long [VARCHAR](#), [BLOB](#), or [TEXT](#) columns, as explained in the following sections.

## Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for [OLTP](#) applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the [innodb\\_compression\\_failure\\_threshold\\_pct](#), and [innodb\\_compression\\_pad\\_pct\\_max](#) configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If [innodb\\_strict\\_mode](#) is [ON](#), MySQL checks the maximum row size during [CREATE TABLE](#) or [CREATE INDEX](#). If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when [innodb\\_strict\\_mode](#) is [OFF](#), and a subsequent [INSERT](#) or [UPDATE](#) statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with [ALTER TABLE](#) and select a larger compressed page size ([KEY\\_BLOCK\\_SIZE](#)), shorten any column prefix indexes, or disable compression entirely with [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPACT](#).

[innodb\\_strict\\_mode](#) is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of [innodb\\_strict\\_mode](#). For more information, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).

## Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, [BLOB](#), [VARCHAR](#), and [TEXT](#) columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPRESSED](#), the values of [BLOB](#), [TEXT](#), or [VARCHAR](#) columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

### Note

For tables created in [ROW\\_FORMAT=DYNAMIC](#) or [ROW\\_FORMAT=COMPRESSED](#), [TEXT](#) and [BLOB](#) columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of MySQL use the [Antelope](#) file format, which supports only [ROW\\_FORMAT=REDUNDANT](#) and [ROW\\_FORMAT=COMPACT](#). In these formats, MySQL stores the first 768 bytes of [BLOB](#), [VARCHAR](#), and [TEXT](#) columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in [COMPRESSED](#) format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer [BLOB](#), [TEXT](#), or [VARCHAR](#) columns if the data is highly compressible, as is often the case with text data. Image data, such as [JPEG](#), is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For [file-per-table](#) tablespaces, using a 16K compressed page size can reduce storage and I/O costs for [BLOB](#), [VARCHAR](#), or [TEXT](#) columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size ([KEY\\_BLOCK\\_SIZE](#)). For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## Compression and the InnoDB Buffer Pool

In a compressed [InnoDB](#) table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if [innodb\\_page\\_size](#) is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the [buffer pool](#), then uncompresses the page to its original form. This section describes how [InnoDB](#) manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database

pages, MySQL can [evict](#) from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that [hot](#) (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an [I/O-bound](#) or [CPU-bound](#) manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

## Compression and the InnoDB Redo Log Files

Before a compressed page is written to a [data file](#), MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for [crash recovery](#), even in the unlikely case that the [zlib](#) library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of [log files](#), or a need for more frequent [checkpoints](#), can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Compressed tables require the [Barracuda](#) file format. To create a compressed table in a file-per-table tablespace, [innodb\\_file\\_per\\_table](#) must be enabled and [innodb\\_file\\_format](#) must be set to [Barracuda](#). There is no dependence on the [innodb\\_file\\_format](#) setting when creating a compressed table in a general tablespace. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#). The [MySQL Enterprise Backup](#) product supports the [Barracuda](#) file format.

### 15.9.1.6 Compression for OLTP Workloads

Traditionally, the [InnoDB compression](#) feature was recommended primarily for read-only or read-mostly [workloads](#), such as in a [data warehouse](#) configuration. The rise of [SSD](#) storage devices, which are fast but relatively small and expensive, makes compression attractive also for [OLTP](#) workloads: high-traffic, interactive web sites can reduce their storage requirements and their I/O operations per second ([IOPS](#)) by using compressed tables with applications that do frequent [INSERT](#), [UPDATE](#), and [DELETE](#) operations.

Configuration options introduced in MySQL 5.6 let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- [innodb\\_compression\\_level](#) lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.
- [innodb\\_compression\\_failure\\_threshold\\_pct](#) specifies a cutoff point for [compression failures](#) during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by [innodb\\_compression\\_pad\\_pct\\_max](#)
- [innodb\\_compression\\_pad\\_pct\\_max](#) lets you adjust the maximum amount of space reserved within each [page](#) to record changes to compressed rows, without needing to compress the entire page again.

The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.

- `innodb_log_compressed_pages` lets you disable writing of images of [re-compressed pages](#) to the [redo log](#). Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version will not change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

### 15.9.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with [file-per-table](#) tablespaces and [general tablespaces](#).

#### SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces

When `innodb_strict_mode` is enabled (the default as of MySQL 5.7.7), specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following error if `innodb_file_per_table` is disabled or if `innodb_file_format` is set to [Antelope](#) rather than [Barracuda](#).

```
ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option
```

#### Note

The table is not created if the current configuration does not permit using compressed tables.

When `innodb_strict_mode` is disabled, specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if `innodb_file_per_table` is disabled.

```
mysql> SHOW WARNINGS;
```

Level	Code	Message
Warning	1478	InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=4.
Warning	1478	InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table.
Warning	1478	InnoDB: assuming ROW_FORMAT=DYNAMIC.

Similar warnings are issued if `innodb_file_format` is set to [Antelope](#) rather than [Barracuda](#).

#### Note

These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.

Level	Code	Message
Error	1478	InnoDB: invalid KEY_BLOCK_SIZE=33333.
Error	1005	Can't create table 'test.x' (errno: 1478)

Table 15.8 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

Syntax	Warning or Error Condition	Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>
<code>ROW_FORMAT=REDUNDANT</code>	None	REDUNDANT
<code>ROW_FORMAT=COMPACT</code>	None	COMPACT
<code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified	Ignored for file-per-table tablespaces unless both <code>innodb_file_format=Barracuda</code> and <code>innodb_file_per_table</code> are enabled. General tablespaces support all row formats (with some restrictions) regardless of <code>innodb_file_format</code> and <code>innodb_file_per_table</code> settings. See <a href="#">Section 15.7.9, “InnoDB General Tablespaces”</a> .	the default row format for file-per-table tablespaces; the specified row format for general tablespaces
Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)	<code>KEY_BLOCK_SIZE</code> is ignored	the specified row format, or the default row format
<code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified	None; <code>KEY_BLOCK_SIZE</code> specified is used	COMPRESSED
<code>KEY_BLOCK_SIZE</code> is specified with REDUNDANT, COMPACT or DYNAMIC row format	<code>KEY_BLOCK_SIZE</code> is ignored	REDUNDANT, COMPACT or DYNAMIC
<code>ROW_FORMAT</code> is not one of REDUNDANT, COMPACT, DYNAMIC or COMPRESSED	Ignored if recognized by the MySQL parser. Otherwise, an error is issued.	the default row format or N/A

When `innodb_strict_mode` is ON, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters and issues errors. When `innodb_strict_mode` is OFF, MySQL issues warnings instead of errors for ignored invalid parameters. `innodb_strict_mode` is ON by default as of MySQL 5.7.7.

When `innodb_strict_mode` is ON, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

It is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

## SQL Compression Syntax Warnings and Errors for General Tablespaces

- If `FILE_BLOCK_SIZE` was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
ERROR 1478 (HY000): InnoDB: Tablespace `ts1` cannot contain a COMPRESSED table
```

- Attempting to add a table with an invalid [KEY\\_BLOCK\\_SIZE](#) to a general tablespace returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot
contain a table with physical page size 4096
```

For general tablespaces, the [KEY\\_BLOCK\\_SIZE](#) of the table must be equal to the [FILE\\_BLOCK\\_SIZE](#) of the tablespace divided by 1024. For example, if the [FILE\\_BLOCK\\_SIZE](#) of the tablespace is 8192, the [KEY\\_BLOCK\\_SIZE](#) of the table must be 8.

- Attempting to add a table with an uncompressed row format to a general tablespace configured to store compressed tables returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE 'ts3.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot
contain a table with physical page size 16384
```

[innodb\\_strict\\_mode](#) is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of [innodb\\_strict\\_mode](#). For more information, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).

For more information about using compressed tables with general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## 15.9.2 InnoDB Page Compression

As of MySQL 5.7.8, [InnoDB](#) supports page-level compression for tables that reside in [file-per-table](#) tablespaces. This feature is referred to as *Transparent Page Compression*. Page compression is enabled by specifying the [COMPRESSION](#) attribute with [CREATE TABLE](#) or [ALTER TABLE](#). Supported compression algorithms include [Zlib](#) and [LZ4](#).

### Supported Platforms

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher

- SLE11 kernel version 3.0-x
- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x
- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher
- Debian 7 kernel version 3.2 or higher

#### Note

All of the available file systems for a given Linux distribution may not support hole punching.

## How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

## Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the file system block size. For example, if `innodb_page_size=16K` and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.

## Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

**Table 15.9 Windows NTFS Cluster Size and Compression Units**

Cluster Size	Compression Unit
512 Bytes	8 KB
1 KB	16 KB
2 KB	32 KB
4 KB	64 KB

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the compression unit size.

The default NTFS cluster size is 4K, for which the compression unit size is 64K. This means that page compression has no benefit for an out-of-the box Windows NTFS configuration, as the maximum `innodb_page_size` is also 64K.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the `innodb_page_size` must be at least twice the size of the compression unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize [InnoDB](#) with an `innodb_page_size` value of 16K or greater.

## Enabling Page Compression

To enable page compression, specify the `COMPRESSION` attribute in the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an `ALTER TABLE` statement. However, `ALTER TABLE ... COMPRESSION` only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using `OPTIMIZE TABLE`.

```
ALTER TABLE t1 COMPRESSION="zlib";
OPTIMIZE TABLE t1;
```

## Disabling Page Compression

To disable page compression, set `COMPRESSION=None` using `ALTER TABLE`. Writes to the tablespace that occur after setting `COMPRESSION=None` no longer use page compression. To uncompress existing pages, you must rebuild the table using `OPTIMIZE TABLE` after setting `COMPRESSION=None`.

```
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

## Page Compression Metadata

Page compression metadata is found in the `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` table, in the following columns:

- `FS_BLOCK_SIZE`: The file system block size, which is the unit size used for hole punching.
- `FILE_SIZE`: The apparent size of the file, which represents the maximum size of the file, uncompressed.
- `ALLOCATED_SIZE`: The actual size of the file, which is the amount of space allocated on disk.

### Note

On Unix-like systems, `ls -l tablespace_name.ibd` shows the apparent file size (equivalent to `FILE_SIZE`) in bytes. To view the actual amount of space allocated on disk (equivalent to `ALLOCATED_SIZE`), use `du --block-size=1 tablespace_name.ibd`. The `--block-size=1` option prints the allocated space in bytes instead of blocks, so that it can be compared to `ls -l` output.

Use `SHOW CREATE TABLE` to view the current page compression setting (`zlib`, `Lz4`, or `None`). A table may contain a mix of pages with different compression settings.

In the following example, page compression metadata for the employees table is retrieved from the `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` table.

```
# Create the employees table with Zlib page compression

CREATE TABLE employees (
  emp_no      INT          NOT NULL,
  birth_date  DATE         NOT NULL,
  first_name  VARCHAR(14)  NOT NULL,
  last_name   VARCHAR(16)  NOT NULL,
```

```
gender      ENUM ('M','F') NOT NULL,  
hire_date   DATE           NOT NULL,  
PRIMARY KEY (emp_no)  
) COMPRESSION="zlib";  
  
# Insert data (not shown)  
  
# Query page compression metadata in INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES  
  
mysql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE FROM  
INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='employees/employees'\G  
***** 1. row *****  
SPACE: 45  
NAME: employees/employees  
FS_BLOCK_SIZE: 4096  
FILE_SIZE: 23068672  
ALLOCATED_SIZE: 19415040
```

Page compression metadata for the employees table shows that the apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

### Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) \* 2 > [innodb\\_page\\_size](#).
- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, the temporary tablespace, and general tablespaces.
- Page compression is not supported for undo log tablespaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables ([ROW\\_FORMAT=COMPRESSED](#)) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed tablespace on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run [ALTER TABLE ... COMPRESSION=None](#) and [OPTIMIZE TABLE](#).
- Page-compressed tablespaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.
- Preserving page compression when moving a page-compressed tablespace file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMFS than on other platforms, as NVMFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large [InnoDB](#) page size and relatively small file system block size could result in write amplification. For example, a maximum [InnoDB](#) page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.

## 15.10 InnoDB File-Format Management

As [InnoDB](#) evolves, data file formats that are not compatible with prior versions of [InnoDB](#) are sometimes required to support new features. To help manage compatibility in upgrade and downgrade situations, and systems that run different versions of MySQL, [InnoDB](#) uses named file formats. [InnoDB](#) currently supports two named file formats, [Antelope](#) and [Barracuda](#).

- [Antelope](#) is the original [InnoDB](#) file format, which previously did not have a name. It supports the [COMPACT](#) and [REDUNDANT](#) row formats for [InnoDB](#) tables.
- [Barracuda](#) is the newest file format. It supports all [InnoDB](#) row formats including the newer [COMPRESSED](#) and [DYNAMIC](#) row formats. The features associated with [COMPRESSED](#) and [DYNAMIC](#) row formats include compressed tables, efficient storage of off-page columns, and index key prefixes up to 3072 bytes ([innodb\\_large\\_prefix](#)). See [Section 15.11, “InnoDB Row Storage and Row Formats”](#).

This section discusses enabling [InnoDB](#) file formats for new [InnoDB](#) tables, verifying compatibility of different file formats between MySQL releases, and identifying the file format in use.

InnoDB file format settings do not apply to tables stored in [general tablespaces](#) (introduced in MySQL 5.7.6). General tablespaces provide support for all row formats and associated features. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

### Note

The following file format configuration parameters have new default values as of MySQL 5.7.7:

- The [innodb\\_file\\_format](#) default value was changed to [Barracuda](#). The previous default value was [Antelope](#).
- The [innodb\\_large\\_prefix](#) default value was changed to [ON](#). The previous default was [OFF](#).

The following file format configuration parameters are deprecated in MySQL 5.7.7 and may be removed in a future release:

- [innodb\\_file\\_format](#)
- [innodb\\_file\\_format\\_check](#)
- [innodb\\_file\\_format\\_max](#)
- [innodb\\_large\\_prefix](#)

The file format configuration parameters were provided for creating tables compatible with earlier versions of [InnoDB](#) in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, the parameters are no longer required. Future removal of the [innodb\\_file\\_format](#) parameter will require a new mechanism for managing compatibility of [InnoDB](#) tables and tablespaces among different versions of MySQL.

### 15.10.1 Enabling File Formats

The [innodb\\_file\\_format](#) configuration option enables an [InnoDB](#) file format for [file-per-table](#) tablespaces.

[Barracuda](#) is the default `innodb_file_format` setting as of MySQL 5.7.7. Prior to MySQL 5.7.7, the default file format is [Antelope](#).

**Note**

The `innodb_file_format` configuration option is deprecated and may be removed in a future release. For more information, see [Section 15.10, “InnoDB File-Format Management”](#).

You can set the value of `innodb_file_format` on the command line when you start `mysqld`, or in the option file (`my.cnf` on Unix, `my.ini` on Windows). You can also change it dynamically with a `SET GLOBAL` statement.

```
SET GLOBAL innodb_file_format=Barracuda;
```

## Usage notes

- [InnoDB](#) file format settings do not apply to tables stored in [general tablespaces](#). General tablespaces provide support for all row formats and associated features. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).
- As of MySQL 5.7.6, the `innodb_file_format` setting is not applicable when using the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE` to store a `DYNAMIC` table in the system tablespace.
- As of MySQL 5.7.9, the `innodb_file_format` setting is ignored when creating tables that use the `DYNAMIC` row format. For more information, see [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#).

## 15.10.2 Verifying File Format Compatibility

InnoDB incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an old release of the MySQL server on InnoDB data files that use a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

### Backward Compatibility

You only need to consider backward file format compatibility when using a recent version of InnoDB (MySQL 5.5 and higher with InnoDB) alongside an older version (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with an older version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with an old version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to the earlier Antelope file format is to copy the data to a new table, in a tablespace that uses the earlier format.

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as `'Compressed'` or `'Dynamic'`, the tablespace containing the table supports the Barracuda format.

## Internal Details

Every InnoDB file-per-table tablespace (represented by a `*.ibd` file) is labeled with a file format identifier. The system tablespace (represented by the `ibdata` files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with `ROW_FORMAT=DYNAMIC`, updates the file header of the corresponding file-per-table `.ibd` file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support the Barracuda file format. To protect against anomalous behavior, InnoDB performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in [Section 15.13.1, “Overview of Online DDL”](#).)

General tablespaces, which are also represented by a `*.ibd` file, support both Antelope and Barracuda file formats. For more information about general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more `ibdata` files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
- Zero or more single-table tablespaces (also called “file per table” files, named `*.ibd` files).
- InnoDB log files; usually two, `ib_logfile0` and `ib_logfile1`. Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding `.frm` files that contain metadata about InnoDB tables. The `.frm` files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

### 15.10.2.1 Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., `innodb_fast_shutdown` is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check`, which is `ON` by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is `ON`, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a
file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` will be useful (with future releases of InnoDB) if you manually “downgrade” all of the tables in an ib-file set (as described in [Downgrading the InnoDB Storage Engine](#)). You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a new file format that is not supported by the software you are using. If you set the configuration parameter `innodb_file_format_check` to `OFF`, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a
file format that this version doesn't support
```

#### Note

This is a dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was a crash or “fast shutdown”. You should only set `innodb_file_format_check` to `OFF` if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs.

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in [Section 15.10.2.2, “Compatibility Check When a Table Is Opened”](#). Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the latest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

### 15.10.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses a specific file format, even if the file format is supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses a supported format.

Versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in [Section 15.10.3, “Identifying the File Format in Use”](#).

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a newer file format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to `OFF`), the table-level checking described in this section still applies.

Users are *strongly* urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It may be possible to rebuild such tables to use the Antelope format.

### 15.10.3 Identifying the File Format in Use

If you enable a different [file format](#) using the `innodb_file_format` configuration option, the change only applies to newly created tables. Also, when you create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required to support the table's features. For example, if you enable the [Barracuda](#) file format, and create a new table that does not use the Dynamic or Compressed row format, the new tablespace that contains the table is tagged as using the [Antelope](#) file format.

It is easy to identify the file format used by a given table. The table uses the [Antelope](#) file format if the row format reported by `SHOW TABLE STATUS` is either `Compact` or `Redundant`. The table uses the [Barracuda](#) file format if the row format reported by `SHOW TABLE STATUS` is either `Compressed` or `Dynamic`.

```
mysql> SHOW TABLE STATUS\G
***** 1. row *****
      Name: t1
```

```

Engine: InnoDB
Version: 10
Row_format: Compact
  Rows: 0
Avg_row_length: 0
Data_length: 16384
Max_data_length: 0
Index_length: 16384
  Data_free: 0
Auto_increment: 1
Create_time: 2014-11-03 13:32:10
Update_time: NULL
Check_time: NULL
Collation: latin1_swedish_ci
Checksum: NULL
Create_options:
Comment:

```

You can also identify the file format used by a given table or tablespace using [InnoDB INFORMATION\\_SCHEMA](#) tables. For example:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1'\G
***** 1. row *****
TABLE_ID: 44
NAME: test/t1
FLAG: 1
N_COLS: 6
SPACE: 30
FILE_FORMAT: Antelope
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='test/t1'\G
***** 1. row *****
SPACE: 30
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0

```

### 15.10.4 Modifying the File Format

Each InnoDB tablespace file (with a name matching `*.ibd`) is tagged with the file format used to create its table and indexes. The way to modify the file format is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the following command on each table that you want to modify:

```
ALTER TABLE t ROW_FORMAT=format_name;
```

If you are modifying the file format to downgrade to an older MySQL version, there may be incompatibilities in table storage formats that require additional steps. For information about downgrading to a previous MySQL version, see [Section 2.11.2, “Downgrading MySQL”](#).

## 15.11 InnoDB Row Storage and Row Formats

This section discusses how InnoDB features such as table [compression](#), off-page storage of long variable-length column values, and large index key prefixes ([innodb\\_large\\_prefix](#)) are controlled by the row format of an [InnoDB](#) table. It also discusses considerations for choosing the right row format, and compatibility of row formats between MySQL releases.

## 15.11.1 Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk [page](#), queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into [pages](#). The pages that make up each table are arranged in a tree data structure called a [B-tree index](#). Table data and [secondary indexes](#) both use this type of structure. The B-tree index that represents an entire table is known as the [clustered index](#), which is organized according to the [primary key](#) columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as [BLOB](#) and [VARCHAR](#) that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#). We call such columns [off-page columns](#). The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The following sections describe how to configure the row format of [InnoDB](#) tables to control how variable-length columns values are stored. Row format configuration also determines the availability of the [table compression](#) feature and the large index key prefix feature ([innodb\\_large\\_prefix](#)).

## 15.11.2 Specifying the Row Format for a Table

In MySQL 5.7.8 and earlier, rows are stored in [COMPACT](#) format by default. As of MySQL 5.7.9, the default row format is defined by [innodb\\_default\\_row\\_format](#), which has a default value of [DYNAMIC](#). The default row format is used when the [ROW\\_FORMAT](#) table option is not defined explicitly or when [ROW\\_FORMAT=DEFAULT](#) is specified.

The row format of a table can be defined explicitly using the [ROW\\_FORMAT](#) table option in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined [ROW\\_FORMAT](#) setting overrides the implicit default. Specifying [ROW\\_FORMAT=DEFAULT](#) is equivalent to using the implicit default.

The [innodb\\_default\\_row\\_format](#) option, introduced in MySQL 5.7.9, can be set dynamically:

```
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid [innodb\\_default\\_row\\_format](#) options include [DYNAMIC](#), [COMPACT](#), and [REDUNDANT](#). The [COMPRESSED](#) row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. Attempting to set [innodb\\_default\\_row\\_format](#) to [COMPRESSED](#) returns an error:

```
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format'
can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by [innodb\\_default\\_row\\_format](#) when a [ROW\\_FORMAT](#) option is not specified explicitly or when [ROW\\_FORMAT=DEFAULT](#) is used. For example, the following [CREATE TABLE](#) statements use the row format defined by [innodb\\_default\\_row\\_format](#).

```
CREATE TABLE t1 (c1 INT);
```

```
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`.

Table-rebuilding operations include `ALTER TABLE` operations that use `ALGORITHM=COPY` or `ALTER TABLE` operations that use `ALGORITHM=INPLACE` where table rebuilding is required. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) for an overview of the online status of DDL operations. `OPTIMIZE TABLE` is also a table-rebuilding operation.

The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```
mysql> SELECT @@innodb_default_row_format;
+-----+
| @@innodb_default_row_format |
+-----+
| dynamic                     |
+-----+

mysql> CREATE TABLE t1 (c1 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 54
        NAME: test/t1
        FLAG: 33
      N_COLS: 4
      SPACE: 35
  FILE_FORMAT: Barracuda
    ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
  SPACE_TYPE: Single

mysql> SET GLOBAL innodb_default_row_format=COMPACT;

mysql> ALTER TABLE t1 ADD COLUMN (c2 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 55
        NAME: test/t1
        FLAG: 1
      N_COLS: 5
      SPACE: 36
  FILE_FORMAT: Antelope
    ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
  SPACE_TYPE: Single
```

Consider the following potential issues before changing the row format of existing tables from `REDUNDANT` or `COMPACT` to `DYNAMIC`.

- The `REDUNDANT` and `COMPACT` row format supports a maximum index key prefix length of 767 bytes whereas `DYNAMIC` and `COMPRESSED` row formats support an index key prefix length of 3072 bytes if the `innodb_large_prefix` configuration option is enabled. In a replication environment, if `innodb_default_row_format` is set to `DYNAMIC` on the master and set to `COMPACT` on the slave, the following DDL statement, which does not explicitly define a row format, succeeds on the master but fails on the slave:

```
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see [Section 15.8.8, “Limits on InnoDB Tables”](#).

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, refer to the limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

To view the row format of a table, issue a `SHOW TABLE STATUS` statement or query `INFORMATION_SCHEMA.TABLES`.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
```

The row format of an InnoDB table determines its physical row structure. See [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#) for more information.

### 15.11.3 DYNAMIC and COMPRESSED Row Formats

When a table is created with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, InnoDB can store long variable-length column values (for `VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. InnoDB also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, InnoDB chooses the longest columns for off-page storage until the clustered index record fits on the B-tree page. `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `REDUNDANT` formats), but the `DYNAMIC` row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The `DYNAMIC` format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The `COMPRESSED` row format uses similar internal details for off-page storage as the `DYNAMIC` row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the `COMPRESSED` row format, the `KEY_BLOCK_SIZE` option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the `COMPRESSED` row format, see [Section 15.9, “InnoDB Table and Page Compression”](#).

Both `DYNAMIC` and `COMPRESSED` row formats support index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` configuration option, which is enabled by default as of MySQL 5.7.7. See the `innodb_large_prefix` option description for more information.

Tables that use the `COMPRESSED` row format can be created in `file-per-table` tablespaces or `general tablespaces` (introduced in MySQL 5.7.6). The system tablespace does not support the `COMPRESSED` row format. To store a `COMPRESSED` table in a file-per-table tablespace, `innodb_file_per_table` must be enabled and `innodb_file_format` must be set to `Barracuda`. The `innodb_file_per_table` and `innodb_file_format` configuration options are not applicable to general tablespaces. General tablespaces support all row formats with the caveat that compressed and uncompressed tables cannot

coexist in the same general tablespace due to different physical page sizes. For more information about general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

In MySQL 5.7.5 and earlier, tables that use the `DYNAMIC` row format can only be stored in `file-per-table` tablespaces, requiring that `innodb_file_per_table` be enabled and `innodb_file_format` be set to `Barracuda`.

As of MySQL 5.7.6, `DYNAMIC` tables can be stored in `file-per-table` tablespaces, general tablespaces, and the system tablespace. To store `DYNAMIC` tables in the system tablespace, you must use the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE`. The `innodb_file_per_table` and `innodb_file_format` configuration options are not applicable to general tablespaces, nor are they applicable when using the `TABLESPACE [=] innodb_system` table option to store `DYNAMIC` tables in the system tablespace.

As of MySQL 5.7.9, you can add a `DYNAMIC` table to the system tablespace by disabling `innodb_file_per_table` and using a regular `CREATE TABLE` or `ALTER TABLE` statement. The `innodb_file_format` setting is ignored. A `DYNAMIC` table always uses the `Barracuda` file format.

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format and therefore handle `CHAR` storage in the same way as the `COMPACT` row format. For more information, see [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#).

## 15.11.4 COMPACT and REDUNDANT Row Formats

Early versions of `InnoDB` used an unnamed file format (now called `Antelope`) for database files. With that file format, tables are defined with `ROW_FORMAT=COMPACT` or `ROW_FORMAT=REDUNDANT`. With these row formats, `InnoDB` stores up to the first 768 bytes of variable-length columns (`VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) in the index record within the `B-tree` node, with the remainder stored on the overflow pages. `InnoDB` also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

With the `Antelope` file format, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the `B-tree` node. This works well for relatively short `BLOBS`, but may cause `B-tree` nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause `B-tree` nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

To preserve compatibility with earlier versions of `InnoDB`, `COMPACT` remained the default row format up to MySQL 5.7.8. As of MySQL 5.7.9, the default row format is `DYNAMIC`, as defined by the `innodb_default_row_format` configuration option. See [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#) for more information.

For information about the physical row structure of tables that use the `REDUNDANT` or `COMPACT` row format, see [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#).

## 15.12 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The `ACID` design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, `InnoDB` tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a `fast shutdown`.

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as [InnoDB](#) tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

### 15.12.1 InnoDB Disk I/O

[InnoDB](#) uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, [InnoDB](#) uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, [InnoDB](#) still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

#### Read-Ahead

If [InnoDB](#) can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in [InnoDB](#):

- In sequential read-ahead, if [InnoDB](#) notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if [InnoDB](#) notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

#### Doublewrite Buffer

[InnoDB](#) uses a novel file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default in most cases (`innodb_doublewrite=ON`). It adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, [InnoDB](#) first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does [InnoDB](#) write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write (causing a [torn page](#) condition), [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during recovery.

As of MySQL 5.7.4, if system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

## 15.12.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the **InnoDB system tablespace**. The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, **InnoDB** allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option (the default), which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by **InnoDB** within the system tablespace. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

As of MySQL 5.7.6, you can also store tables in **general tablespaces**. General tablespaces are shared tablespaces created using `CREATE TABLESPACE` syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

### Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database **pages**. Every tablespace in a MySQL instance has the same **page size**. By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the `innodb_page_size` option when you create the MySQL instance. As of MySQL 5.7.6, you can also increase the page size to 32KB or 64KB. For more information, refer to the `innodb_page_size` documentation.

The pages are grouped into **extents** of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For page size of 64KB, extent size is 4MB. The “files” inside a tablespace are called **segments** in **InnoDB**. (These segments are different from the **rollback segment**, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, **InnoDB** allocates the first 32 pages to it one at a time. After that, **InnoDB** starts to allocate whole extents to the segment. **InnoDB** can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in **InnoDB**. One is for nonleaf nodes of the **B-tree**, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an **InnoDB** tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, **InnoDB** reports the extents that are definitely free in the tablespace. **InnoDB** always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, **InnoDB** contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the **purge** operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 15.3, “InnoDB Multi-Versioning”](#).)

## How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings. For example, the maximum row length is slightly less than 8KB for the default 16KB InnoDB page size. For 64KB pages, the maximum row length is slightly less than 16KB.

If a row does not exceed the maximum row length, all of it is stored locally within the page. If a row exceeds the maximum row length, [variable-length columns](#) are chosen for external off-page storage until the row fits within the maximum row length limit. External off-page storage for variable-length columns differs by row format:

- *COMPACT and REDUNDANT Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See [Section 15.11.4, “COMPACT and REDUNDANT Row Formats”](#).

- *DYNAMIC and COMPRESSED Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#).

`LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

## 15.12.3 InnoDB Checkpoints

Making your [log files](#) very large may reduce disk I/O during [checkpointing](#). It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

## How Checkpoint Processing Works

InnoDB implements a [checkpoint](#) mechanism known as [fuzzy checkpointing](#). InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During [crash recovery](#), InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

## 15.12.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in [B-trees](#), and their [fill factor](#) may

vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

You can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table.

As of MySQL 5.7.4, both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL](#) (`ALGORITHM=COPY`). For more information, see [Section 15.13.1, “Overview of Online DDL”](#).

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the `InnoDB` filespace management algorithm guarantees that fragmentation in the index does not occur.

### 15.12.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when [truncating](#) an `InnoDB` table, the table must be stored in its own `.ibd` file. For a table to be stored in its own `.ibd` file, `innodb_file_per_table` must be enabled when the table is created. Additionally, there cannot be a [foreign key](#) constraint between the table being truncated and other tables, otherwise the `TRUNCATE TABLE` operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new `.ibd` file, and the freed space is returned to the operating system. This is in contrast to truncating `InnoDB` tables that are stored within the `InnoDB system tablespace` (tables created when `innodb_file_per_table=OFF`) and tables stored in shared `general tablespaces`, where only `InnoDB` can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that [physical backups](#) can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) or in a general tablespace leaves blocks of unused space in the tablespace.

## 15.13 InnoDB and Online DDL

The [online DDL](#) feature enhances many types of `ALTER TABLE` operations to avoid table copying or blocking of `DML` operations while `DDL` is in progress, or both.

The [online DDL](#) feature has the following benefits:

- It improves responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
- It lets you adjust the balance between performance and concurrency during the DDL operation, by choosing whether to block access to the table entirely (`LOCK=EXCLUSIVE` clause), allow queries but

not DML (`LOCK=SHARED` clause), or allow full query and DML access to the table (`LOCK=NONE` clause). When you omit the `LOCK` clause or specify `LOCK=DEFAULT`, MySQL allows as much concurrency as possible depending on the type of operation.

- Performing changes in-place where possible, rather than creating a new copy of the table, avoids temporary increases in disk space usage and I/O overhead associated with copying the table and reconstructing secondary indexes.

## 15.13.1 Overview of Online DDL

Historically, many DDL operations on InnoDB tables were expensive. Many `ALTER TABLE` operations worked by creating a new, empty table defined with the requested table options and indexes, then copying the existing rows to the new table one-by-one, updating the indexes as the rows were inserted. After all rows from the original table were copied, the old table was dropped and the copy was renamed with the name of the original table.

MySQL 5.5, and MySQL 5.1 with the InnoDB Plugin, optimized `CREATE INDEX` and `DROP INDEX` to avoid the table-copying behavior. That feature was known as **Fast Index Creation**. MySQL 5.6 enhanced many other types of `ALTER TABLE` operations to avoid copying the table. Another enhancement allowed `SELECT` queries and `INSERT`, `UPDATE`, and `DELETE` (DML) statements to proceed while the table is being altered. In MySQL 5.7, `ALTER TABLE RENAME INDEX` was also enhanced to avoid table copying. This combination of features is now known as **online DDL**.

This mechanism also means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without any secondary indexes, then adding the secondary indexes after the data is loaded.

Although no syntax changes are required in the `CREATE INDEX` or `DROP INDEX` commands, some factors affect the performance, space usage, and semantics of this operation (see [Section 15.13.9, “Limitations of Online DDL”](#)).

The online DDL enhancements in MySQL 5.6 improved many DDL operations that formerly required a table copy or blocked DML operations on the table, or both. [Table 15.10, “Summary of Online Status for DDL Operations”](#) shows the variations of the `ALTER TABLE` statement and shows how the online DDL feature applies to each.

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables. For more information, see [Section 15.13.8, “Online DDL for Partitioned InnoDB Tables”](#).

- The “In-Place?” column shows which operations allow the `ALGORITHM=INPLACE` clause; the preferred value is “Yes”.
- The “Copies Table?” column shows which operations are able to avoid the expensive table-copying operation; the preferred value is “No”. This column is mostly the reverse of the “In-Place?” column, except that a few operations allow `ALGORITHM=INPLACE` but still involve some amount of table copying.
- The “Allows Concurrent DML?” column shows which operations can be performed fully online; the preferred value is “Yes”. You can specify `LOCK=NONE` to assert that full concurrency is allowed during the DDL, but MySQL automatically allows this level of concurrency when possible. When concurrent DML is allowed, concurrent queries are also always allowed.
- The “Allows Concurrent Queries?” column shows which DDL operations allow queries on the table while the operation is in progress; the preferred value is “Yes”. Concurrent query is allowed during all online DDL operations. It is shown with “Yes” listed for all cells, for reference purposes. You can specify `LOCK=SHARED` to assert that concurrent queries are allowed during the DDL, but MySQL automatically allows this level of concurrency when possible.

- The “Notes” column explains any exceptions to the “Yes/No” values of the other columns, such as when the answer depends on the setting of a configuration option or some other clause in the DDL statement. The values “Yes\*” and “No\*” indicate that an answer depends on these additional notes.

**Table 15.10 Summary of Online Status for DDL Operations**

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
CREATE INDEX, ADD INDEX	Yes*	No*	Yes	Yes	Some restrictions for FULLTEXT index; see next row.
ADD FULLTEXT INDEX	Yes	No*	No	Yes	Creating the first FULLTEXT index for a table involves a table copy, unless there is a user-supplied FTS_DOC_ID column. Subsequent FULLTEXT indexes on the same table can be created in-place.
ADD SPATIAL INDEX	Yes	No	No	Yes	In-place support was added in MySQL 5.7.5. Bulk load is not supported.
RENAME INDEX	Yes	No	Yes	Yes	Only modifies table metadata.
DROP INDEX	Yes	No	Yes	Yes	Only modifies table metadata.
OPTIMIZE TABLE	Yes	Yes	Yes	Yes	Uses ALGORITHM=INPLACE as of MySQL 5.7.4. ALGORITHM=COPY is used if old_alter_table=1 or mysqld --skip-new option is enabled. OPTIMIZE TABLE using online DDL (ALGORITHM=INPLACE) is not supported for tables with FULLTEXT indexes.
Set default value for a column	Yes	No	Yes	Yes	Only modifies table metadata.
Change auto-increment value for a column	Yes	No	Yes	Yes	Modifies a value stored in memory, not the data file.
Add a foreign key constraint	Yes*	No*	Yes	Yes	To avoid copying the table, disable foreign_key_checks during constraint creation.
Drop a foreign key constraint	Yes	No	Yes	Yes	The foreign_key_checks option can be enabled or disabled.
Rename a column	Yes*	No*	Yes*	Yes	To allow concurrent DML, keep the same data type and only change the column name. Prior to MySQL 5.7.8, ALGORITHM=INPLACE is supported for renaming a generated virtual column but not for renaming a generated stored column. As of MySQL 5.7.8, ALGORITHM=INPLACE is not supported for renaming a generated column.

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
Add a column	Yes*	Yes*	Yes*	Yes	Concurrent DML is not allowed when adding an <a href="#">auto-increment</a> column. Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is supported for adding a <a href="#">generated virtual column</a> but not for adding a <a href="#">generated stored column</a> . Adding a generated virtual column does not require a table copy.
Drop a column	Yes	Yes*	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is supported for dropping a generated column. Dropping a <a href="#">generated virtual column</a> does not require a table copy.
Reorder columns	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change <a href="#">ROW_FORMAT</a> property	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change <a href="#">KEY_BLOCK_SIZE</a> property	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Make column <a href="#">NULL</a>	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Make column <a href="#">NOT NULL</a>	Yes*	Yes	Yes	Yes	<a href="#">STRICT_ALL_TABLES</a> or <a href="#">STRICT_TRANS_TABLES SQL_MODE</a> is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. For more

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
					information, see <a href="#">Section 14.1.8, “ALTER TABLE Syntax”</a> . Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change data type of column	No*	Yes*	No	Yes	Exception: <code>VARCHAR</code> size may be increased using online <code>ALTER TABLE</code> . See <a href="#">InnoDB Online DDL Column Properties</a> for more information.
Add <a href="#">primary key</a>	Yes*	Yes	Yes	Yes	Although <code>ALGORITHM=INPLACE</code> is allowed, the data is reorganized substantially, so it is still an expensive operation. <code>ALGORITHM=INPLACE</code> is not allowed under certain conditions if columns have to be converted to <code>NOT NULL</code> . See <a href="#">Example 15.9, “Creating and Dropping the Primary Key”</a> .
Drop <a href="#">primary key</a> and add another	Yes	Yes	Yes	Yes	<code>ALGORITHM=INPLACE</code> is only allowed when you add a new primary key in the same <code>ALTER TABLE</code> ; the data is reorganized substantially, so it is still an expensive operation.
Drop <a href="#">primary key</a>	No	Yes	No	Yes	Restrictions apply when you drop a primary key without adding a new one in the same <code>ALTER TABLE</code> statement.
Convert character set	No	Yes	No	Yes	Rebuilds the table if the new character encoding is different.
Specify character set	No	Yes	No	Yes	Rebuilds the table if the new character encoding is different.
Rebuild with <code>FORCE</code> option	Yes	Yes	Yes	Yes	Uses <code>ALGORITHM=INPLACE</code> as of MySQL 5.7.4. <code>ALGORITHM=COPY</code> is used if <code>old_alter_table=1</code> or <code>mysqld --skip-new</code> option is enabled. Table rebuild using online DDL ( <code>ALGORITHM=INPLACE</code> ) is not supported for tables with FULLTEXT indexes.
Rebuild with “null” <code>ALTER TABLE ... ENGINE=INNODB</code>	Yes	Yes	Yes	Yes	Uses <code>ALGORITHM=INPLACE</code> as of MySQL 5.7.4. <code>ALGORITHM=COPY</code> is used if <code>old_alter_table=1</code> or <code>mysqld --skip-new</code> option is

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
					enabled. Table rebuild using online DDL ( <code>ALGORITHM=INPLACE</code> ) is not supported for tables with FULLTEXT indexes.
Set table-level <a href="#">persistent statistics</a> options ( <code>STATS_PERSISTENT</code> , <code>STATS_AUTO_RECALC</code> , <code>STATS_SAMPLE_PAGES</code> )	Yes	No	Yes	Yes	Only modifies table metadata.

The following sections shows the basic syntax, and usage notes related to online DDL, for each of the major operations that can be performed with concurrent DML, in-place, or both:

## Secondary Indexes

- Create [secondary indexes](#): `CREATE INDEX name ON table (col_list)` or `ALTER TABLE table ADD INDEX name (col_list)`. (Creating a FULLTEXT index still requires locking the table.)
- Drop [secondary indexes](#): `DROP INDEX name ON table;` or `ALTER TABLE table DROP INDEX name`

Creating and dropping secondary indexes on [InnoDB](#) tables skips the table-copying behavior.

In MySQL 5.6 and higher, the table remains available for read and write operations while the index is being created or dropped. The `CREATE INDEX` or `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table. Previously, modifying the table while an index is being created or dropped typically resulted in a [deadlock](#) that cancelled the `INSERT`, `UPDATE`, or `DELETE` statement on the table.

## Column Properties

- Set a default value for a column: `ALTER TABLE tbl ALTER COLUMN col SET DEFAULT literal` or `ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT`

The default values for columns are stored in the `.frm` file for the table, not the [InnoDB data dictionary](#).

- Changing the [auto-increment](#) value for a column: `ALTER TABLE table AUTO_INCREMENT=next_value;`

Especially in a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and you can restart the auto-increment sequence from 1.

- Renaming a column: `ALTER TABLE tbl CHANGE old_col_name new_col_name datatype`

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, this operation can always be performed online.

You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key

only works with the in-place mode of `ALTER TABLE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the command to use `ALGORITHM=COPY` behind the scenes, the `ALTER TABLE` statement will fail.

- Extending `VARCHAR` size using an in-place `ALTER TABLE` statement, as in this example:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(255);
```

The number of length bytes required by a `VARCHAR` column must remain the same. For `VARCHAR` values of 0 to 255, one length byte is required to encode the value. For `VARCHAR` values of 256 bytes or more, two length bytes are required. As a result, in-place `ALTER TABLE` only supports increasing `VARCHAR` size from 0 to 255 bytes or increasing `VARCHAR` size from a value equal to or greater than 256 bytes. In-place `ALTER TABLE` does not support increasing `VARCHAR` size from less than 256 bytes to a value equal to or greater than 256 bytes. In this case, the number of required length bytes would change from 1 to 2, which is only supported by a table copy (`ALGORITHM=COPY`). For example, attempting to change `VARCHAR` column size from 255 to 256 using in-place `ALTER TABLE` would return an error:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
ERROR 0A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change
column type INPLACE. Try ALGORITHM=COPY.
```

Decreasing `VARCHAR` size using in-place `ALTER TABLE` is not supported. Decreasing `VARCHAR` size requires a table copy (`ALGORITHM=COPY`).

## Foreign Keys

- Adding or dropping a [foreign key constraint](#):

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1) REFERENCES tbl2(col2) referential_actions;
ALTER TABLE tbl1 DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled. Creating a foreign key online requires `foreign_key_checks` to be disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
show create table table\G
```

Or, query the `information_schema.table_constraints` table and use the `constraint_name` and `constraint_type` columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

If [foreign keys](#) are already present in the table being altered (that is, it is a [child table](#) containing any `FOREIGN KEY ... REFERENCE` clauses), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table caused associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.

- In the same way, if a table is the [parent table](#) in a foreign key relationship, even though it does not contain any [FOREIGN KEY](#) clauses, it could wait for the [ALTER TABLE](#) to complete if an [INSERT](#), [UPDATE](#), or [DELETE](#) statement caused an [ON UPDATE](#) or [ON DELETE](#) action in the child table.

## Notes on [ALGORITHM=COPY](#)

Any [ALTER TABLE](#) operation run with the [ALGORITHM=COPY](#) clause prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of [LOCK=SHARED](#) (allow queries but not DML). You can further restrict concurrency for such operations by specifying [LOCK=EXCLUSIVE](#), which prevents DML and queries.

## Concurrent DML but Table Copy Still Required

Some other [ALTER TABLE](#) operations allow concurrent DML but still require a table copy. However, the table copy for these operations is faster than it was in MySQL 5.5 and prior.

- Adding, dropping, or reordering columns.
- Adding or dropping a [primary key](#).
- Changing the [ROW\\_FORMAT](#) or [KEY\\_BLOCK\\_SIZE](#) properties for a table.
- Changing the nullable status for a column.
- [OPTIMIZE TABLE](#)
- Rebuilding a table with the [FORCE](#) option
- Rebuilding a table using a “null” [ALTER TABLE ... ENGINE=INNODB](#) statement

## Maintaining [CREATE TABLE](#) Statements

As your database schema evolves with new columns, data types, constraints, indexes, and so on, keep your [CREATE TABLE](#) statements up to date with the latest table definitions. Even with the performance improvements of online DDL, it is more efficient to create stable database structures at the beginning, rather than creating part of the schema and then issuing [ALTER TABLE](#) statements afterward.

The main exception to this guideline is for [secondary indexes](#) on tables with large numbers of rows. It is typically most efficient to create the table with all details specified except the secondary indexes, load the data, then create the secondary indexes. You can use the same technique with [foreign keys](#) (load the data first, then set up the foreign keys) if you know the initial data is clean and do not need consistency checks during the loading process.

Whatever sequence of [CREATE TABLE](#), [CREATE INDEX](#), [ALTER TABLE](#), and similar statements went into putting a table together, you can capture the SQL needed to reconstruct the current form of the table by issuing the statement [SHOW CREATE TABLE table\G](#) (uppercase [\G](#) required for tidy formatting). This output shows clauses such as numeric precision, [NOT NULL](#), and [CHARACTER SET](#) that are sometimes added behind the scenes, which you may want to leave out when cloning the table on a new system or setting up foreign key columns with identical type.

## 15.13.2 Performance and Concurrency Considerations for Online DDL

[Online DDL](#) improves several aspects of MySQL operation, such as performance, concurrency, availability, and scalability:

- Because queries and [DML](#) operations on the table can proceed while the DDL is in progress, applications that access the table are more responsive. Reduced [locking](#) and waiting for other resources throughout the MySQL server leads to greater scalability, even for operations not involving the table being altered.

- For in-place operations, by avoiding the disk I/O and CPU cycles to rebuild the table, you minimize the overall load on the database and maintain good performance and high throughput during the DDL operation.
- For in-place operations, because less data is read into the [buffer pool](#) than if all the data was copied, you avoid purging frequently accessed data from memory, which formerly could cause a temporary performance dip after a DDL operation.

If an online operation requires temporary sort files, [InnoDB](#) creates them in the temporary file directory by default, not the directory containing the original table. If this directory is not large enough to hold such files, you may need to set the `tmpdir` system variable to a different directory. Alternatively, you can define a separate temporary directory for [InnoDB](#) online `ALTER TABLE` operations using the `innodb_tmpdir` configuration option. This option was introduced in MySQL 5.7.11 to help avoid temporary directory overflows that could occur as a result of large temporary sort files created during online `ALTER TABLE` operations. For more information, see [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).

## Locking Options for Online DDL

While an [InnoDB](#) table is being changed by a DDL operation, the table may or may not be [locked](#), depending on the internal workings of that operation and the `LOCK` clause of the `ALTER TABLE` statement. By default, MySQL uses as little locking as possible during a DDL operation; you specify the clause either to make the locking more restrictive than it normally would be (thus limiting concurrent DML, or DML and queries), or to ensure that some expected degree of locking is allowed for an operation. If the `LOCK` clause specifies a level of locking that is not available for that specific kind of DDL operation, such as `LOCK=SHARED` or `LOCK=NONE` while creating or dropping a primary key, the clause works like an assertion, causing the statement to fail with an error. The following list shows the different possibilities for the `LOCK` clause, from the most permissive to the most restrictive:

- For DDL operations with `LOCK=NONE`, both queries and concurrent DML are allowed. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=NONE` if keeping the table fully available is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables involving customer signups or purchases, to avoid making those tables unavailable by mistakenly issuing an expensive `ALTER TABLE` statement.
- For DDL operations with `LOCK=SHARED`, any writes to the table (that is, DML operations) are blocked, but the data in the table can be read. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=SHARED` if keeping the table available for queries is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables in a data warehouse, where it is OK to delay data load operations until the DDL is finished, but queries cannot be delayed for long periods.
- For DDL operations with `LOCK=DEFAULT`, or with the `LOCK` clause omitted, MySQL uses the lowest level of locking that is available for that kind of operation, allowing concurrent queries, DML, or both wherever possible. This is the setting to use when making pre-planned, pre-tested changes that you know will not cause any availability problems based on the workload for that table.
- For DDL operations with `LOCK=EXCLUSIVE`, both queries and DML operations are blocked. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=EXCLUSIVE` if the primary concern is finishing the DDL in the shortest time possible, and it is OK to make applications wait when they try to access the table. You might also use `LOCK=EXCLUSIVE` if the server is supposed to be idle, to avoid unexpected accesses to the table.

Depending on the internal workings of the online DDL operation and the `LOCK` clause of the `ALTER TABLE` statement, an online DDL operation may wait for currently executing transactions that are accessing the table to [commit](#) or [roll back](#) before completing because exclusive access to the table is required for

a brief time during the initial and final phases of the DDL operation. These online DDL statements also wait for table-accessing transactions started while the DDL is in progress to commit or roll back before completing. Consequently, in the case of long running transactions performing inserts, updates, deletes, or `SELECT ... FOR UPDATE` on the table, an online `ALTER TABLE` operation can time out as it waits for exclusive access to the table. DML operations that are run on the table while the online `ALTER TABLE` operation waits for an exclusive table lock may also be blocked.

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the old-style mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the ideal techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

A newly created InnoDB secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

## Performance of In-Place versus Table-Copying DDL Operations

The raw performance of an online DDL operation is largely determined by whether the operation is performed in-place, or requires copying and rebuilding the entire table. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) to see what kinds of operations can be performed in-place, and any requirements for avoiding table-copy operations.

The performance speedup from in-place DDL applies to operations on secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a [clustered index](#) organized based on the [primary key](#), forming what some database systems call an “index-organized table”. Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

To judge the relative performance of online DDL operations, you can run such operations on a big [InnoDB](#) table using current and earlier versions of MySQL. You can also run all the performance tests under the latest MySQL version, simulating the previous DDL behavior for the “before” results, by setting the `old_alter_table` system variable. Issue the statement `set old_alter_table=1` in the session, and measure DDL performance to record the “before” figures. Then `set old_alter_table=0` to re-enable the newer, faster behavior, and run the DDL operations again to record the “after” figures.

For a basic idea of whether a DDL operation does its changes in-place or performs a table copy, look at the “rows affected” value displayed after the command finishes. For example, here are lines you might see after doing different types of DDL operations:

- Changing the default value of a column (super-fast, does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and does require rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

#### Note

Changing the data type of a column requires rebuilding all the rows of the table with the exception of changing `VARCHAR` size, which may be performed using online `ALTER TABLE`. See [InnoDB Online DDL Column Properties](#) for more information.

For example, before running a DDL operation on a big table, you might check whether the operation will be fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a tiny amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A non-zero value means the operation will require rebuilding the entire table, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replication slave server one at a time.

For a deeper understanding of the reduction in MySQL processing, examine the `performance_schema` and `INFORMATION_SCHEMA` tables related to `InnoDB` before and after DDL operations, to see the number of physical reads, writes, memory allocations, and so on.

### 15.13.3 SQL Syntax for Online DDL

Typically, you do not need to do anything special to enable [online DDL](#) when using the `ALTER TABLE` statement for `InnoDB` tables. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) for the kinds of DDL operations that can be performed in-place, allowing concurrent DML, or both. Some variations require particular combinations of configuration settings or `ALTER TABLE` clauses.

You can control the various aspects of a particular online DDL operation by using the `LOCK` and `ALGORITHM` clauses of the `ALTER TABLE` statement. These clauses come at the end of the statement, separated from the table and column specifications by commas. The `LOCK` clause is useful for fine-tuning the degree of concurrent access to the table. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues with existing DDL code. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, specify a clause on the `ALTER TABLE` statement such as `LOCK=NONE` (allow both reads and writes) or `LOCK=SHARED` (allow reads). The operation halts immediately if the requested level of concurrency is not available.
- To compare performance, run one statement with `ALGORITHM=INPLACE` and another with `ALGORITHM=COPY`, as an alternative to setting the `old_alter_table` configuration option.
- To avoid tying up the server with an `ALTER TABLE` operation that copies the table, include `ALGORITHM=INPLACE`. The statement halts immediately if it cannot use the in-place mechanism. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) for a list of the DDL operations that can or cannot be performed in-place.

See [Section 15.13.2, “Performance and Concurrency Considerations for Online DDL”](#) for more details about the `LOCK` clause. For full examples of using online DDL, see [Section 15.13.5, “Examples of Online DDL”](#).

## 15.13.4 Combining or Separating DDL Statements

Before the introduction of [online DDL](#), it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done in-place, as shown in [Table 15.10, “Summary of Online Status for DDL Operations”](#), now you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),  
CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
ALTER TABLE t1 ADD INDEX i1(c1);  
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);  
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed in-place, that is, that still copy and rebuild the table.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

## 15.13.5 Examples of Online DDL

Here are code examples showing some operations whose performance, concurrency, and scalability are improved by the latest [online DDL](#) enhancements.

- [Example 15.1, “Schema Setup Code for Online DDL Experiments”](#) sets up tables named `BIG_TABLE` and `SMALL_TABLE` used in the subsequent examples.
- [Example 15.2, “Speed and Efficiency of CREATE INDEX and DROP INDEX”](#) illustrates the performance aspects of creating and dropping indexes.
- [Example 15.3, “Concurrent DML During CREATE INDEX and DROP INDEX”](#) shows queries and DML statements running during a `DROP INDEX` operation.
- [Example 15.4, “Renaming a Column”](#) demonstrates the speed improvement for renaming a column, and shows the care needed to keep the data type precisely the same when doing the rename operation.

- [Example 15.5, “Dropping Foreign Keys”](#) demonstrates how foreign keys work with online DDL. Because two tables are involved in foreign key operations, there are extra locking considerations. Thus, tables with foreign keys sometimes have restrictions for online DDL operations.
- [Example 15.6, “Changing Auto-Increment Value”](#) demonstrates how auto-increment columns work with online DDL. Tables with auto-increment columns sometimes have restrictions for online DDL operations.
- [Example 15.7, “Controlling Concurrency with the LOCK Clause”](#) demonstrates the options to permit or restrict concurrent queries and DML operations while an online DDL operation is in progress. It shows the situations when the DDL statement might wait, or the concurrent transaction might wait, or the concurrent transaction might cancel a DML statement due to a deadlock error.
- [Example 15.8, “Schema Setup Code for Online DDL Experiments”](#) demonstrates creating and dropping multiple indexes in a single statement, which can be more efficient than using a separate statement for each index operation.
- [Example 15.9, “Creating and Dropping the Primary Key”](#) demonstrates how it is more efficient to define a [primary key](#) when creating the table, and relatively expensive to add one later.

### Example 15.1 Schema Setup Code for Online DDL Experiments

Here is the code that sets up the initial tables used in these demonstrations:

```
/*
Setup code for the online DDL demonstration:
- Set up some config variables.
- Create 2 tables that are clones of one of the INFORMATION_SCHEMA tables
  that always has some data. The "small" table has a couple of thousand rows.
  For the "big" table, keep doubling the data until it reaches over a million rows.
- Set up a primary key for the sample tables, since we are demonstrating InnoDB aspects.
*/

set autocommit = 0;
set foreign_key_checks = 1;
set global innodb_file_per_table = 1;
set old_alter_table=0;
prompt mysql;

use test;

\! echo "Setting up 'small' table:"
drop table if exists small_table;
create table small_table as select * from information_schema.columns;
alter table small_table add id int unsigned not null primary key auto_increment;
select count(id) from small_table;

\! echo "Setting up 'big' table:"
drop table if exists big_table;
create table big_table as select * from information_schema.columns;
show create table big_table\G

insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;
```

```
alter table big_table add id int unsigned not null primary key auto_increment;
select count(id) from big_table;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
Setting up 'small' table:
Query OK, 0 rows affected (0.01 sec)

Query OK, 1678 rows affected (0.13 sec)
Records: 1678 Duplicates: 0 Warnings: 0

Query OK, 1678 rows affected (0.07 sec)

### Example 15.2 Speed and Efficiency of CREATE INDEX and DROP INDEX

Here is a sequence of statements demonstrating the relative speed of [CREATE INDEX](#) and [DROP INDEX](#) statements. For a small table, the elapsed time is less than a second whether we use the fast or slow technique, so we look at the “rows affected” output to verify which operations can avoid the table rebuild. For a large table, the difference in efficiency is obvious because skipping the table rebuild saves substantial time.

```

\! clear

\! echo "=== Create and drop index (small table, new/fast technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=inplace;

-- Compare against the older slower DDL.

\! echo "=== Create and drop index (small table, old/slow technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=copy;

-- In the above example, we examined the "rows affected" number,
-- ideally looking for a zero figure. Let's try again with a larger
-- sample size, where we'll see that the actual time taken can
-- vary significantly.

\! echo "=== Create and drop index (big table, new/fast technique) ==="

```

```

\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd
drop index i_dtyp_big on big_table, algorithm=inplace;

\! echo "=== Create and drop index (big table, old/slow technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd
drop index i_dtyp_big on big_table, algorithm=copy;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

Query OK, 0 rows affected (0.00 sec)

=== Create and drop index (small table, new/fast technique) ===

Data size (kilobytes) before index created:
384 data/test/small_table.ibd
Query OK, 0 rows affected (0.04 sec)

=== Create and drop index (big table, old/slow technique) ===

Data size (kilobytes) before index created:

```

```
335872 data/test/big_table.ibd
Query OK, 1718272 rows affected (1 min 5.01 sec)
Records: 1718272 Duplicates: 0 Warnings: 0

Data size after index created:
348160 data/test/big_table.ibd
Query OK, 1718272 rows affected (46.59 sec)
Records: 1718272 Duplicates: 0 Warnings: 0
```

### Example 15.3 Concurrent DML During CREATE INDEX and DROP INDEX

Here are some snippets of code that are run in separate [mysql](#) sessions connected to the same database, to illustrate DML statements (insert, update, or delete) running at the same time as [CREATE INDEX](#) and [DROP INDEX](#).

```
/*
CREATE INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
create index i_concurrent on big_table(table_name);
```

```
/*
DROP INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
drop index i_concurrent on big_table;
```

```
/*
Some queries and insert/update/delete statements to run against a table
while an index is being created or dropped. Previously, these operations
would have stalled during the index create/drop period and possibly
timed out or deadlocked.
*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

-- In the test instance, that column has about 1.7M rows, with 136 different values.
-- Sample values: COLUMNS (20480), ENGINES (6144), EVENTS (24576), FILES (38912),
-- TABLES (21504), VIEWS (10240).

set autocommit = 0;
use test;

select distinct character_set_name from big_table where table_name = 'FILES';
delete from big_table where table_name = 'FILES';
select distinct character_set_name from big_table where table_name = 'FILES';

-- I'll issue the final rollback interactively, not via script,
-- the better to control the timing.
-- rollback;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
mysql: source concurrent_ddl_create.sql
Database changed
Query OK, 0 rows affected (1 min 25.15 sec)

```

### Example 15.4 Renaming a Column

Here is a demonstration of using `ALTER TABLE` to rename a column. We use the new, fast DDL mechanism to change the name, then the old, slow DDL mechanism (with `old_alter_table=1`) to restore the original column name.

Notes:

- Because the syntax for renaming a column also involves re-specifying the data type, be careful to specify exactly the same data type to avoid a costly table rebuild. In this case, we checked the output of `show create table table\G` and copied any clauses such as `CHARACTER SET` and `NOT NULL` from the original column definition.
- Again, renaming a column for a small table is fast enough that we need to examine the “rows affected” number to verify that the new DDL mechanism is more efficient than the old one. With a big table, the difference in elapsed time makes the improvement obvious.

```
/*
Run through a sequence of 'rename column' statements.
Because this operation involves only metadata, not table data,
it is fast for big and small tables, with new or old DDL mechanisms.
*/

\! clear

\! echo "Rename column (fast technique, small table):"
alter table small_table change `IS_NULLABLE` `NULLABLE` varchar(3) character
set utf8 not null, algorithm=inplace;
\! echo "Rename back to original name (slow technique):"
alter table small_table change `NULLABLE` `IS_NULLABLE` varchar(3) character
set utf8 not null, algorithm=copy;
```

```
\! echo "Rename column (fast technique, big table):"
alter table big_table change `IS_NULLABLE` `NULLABLE` varchar(3) character
  set utf8 not null, algorithm=inplace;
\! echo "Rename back to original name (slow technique):"
alter table big_table change `NULLABLE` `IS_NULLABLE` varchar(3) character
  set utf8 not null, algorithm=copy;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
Rename column (fast technique, small table):
Query OK, 0 rows affected (0.05 sec)

Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
Query OK, 0 rows affected (0.00 sec)

Query OK, 1678 rows affected (0.35 sec)
Records: 1678 Duplicates: 0 Warnings: 0

Rename column (fast technique, big table):
Query OK, 0 rows affected (0.00 sec)

Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
Query OK, 0 rows affected (0.00 sec)

Query OK, 1718272 rows affected (1 min 0.00 sec)
Records: 1718272 Duplicates: 0 Warnings: 0

Query OK, 0 rows affected (0.00 sec)
```

### Example 15.5 Dropping Foreign Keys

Here is a demonstration of foreign keys, including improvement to the speed of dropping a foreign key constraint.

```
/*
Demonstrate aspects of foreign keys that are or aren't affected by the DDL improvements.
- Create a new table with only a few values to serve as the parent table.
- Set up the 'small' and 'big' tables as child tables using a foreign key.
- Verify that the ON DELETE CASCADE clause makes changes ripple from parent to child tables.
- Drop the foreign key constraints, and optionally associated indexes. (This is the operation that is sped up.
*/

\! clear

-- Make sure foreign keys are being enforced, and allow
-- rollback after doing some DELETES that affect both
-- parent and child tables.
set foreign_key_checks = 1;
set autocommit = 0;

-- Create a parent table, containing values that we know are already present
-- in the child tables.
drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment, schema_name
  varchar(64) character set utf8 not null, index i_schema (schema_name)) as select distinct
  table_schema schema_name from small_table;
```

```

show create table schema_names\G
show create table small_table\G
show create table big_table\G

-- Creating the foreign key constraint still involves a table rebuild when foreign_key_checks=1,
-- as illustrated by the "rows affected" figure.
alter table small_table add constraint small_fk foreign key i_table_schema (table_schema)
    references schema_names(schema_name) on delete cascade;
alter table big_table add constraint big_fk foreign key i_table_schema (table_schema)
    references schema_names(schema_name) on delete cascade;

show create table small_table\G
show create table big_table\G

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- big_table is the parent table.
-- schema_names is the parent table.
-- big_table is the child table.
-- (One row in the parent table can have many "children" in the child table.)
-- Changes to the parent table can ripple through to the child table.
-- For example, removing the value 'test' from schema_names.schema_name will
-- result in the removal of 20K or so rows from big_table.

delete from schema_names where schema_name = 'test';

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- Because we've turned off autocommit, we can still get back those deleted rows
-- if the DELETE was issued by mistake.
rollback;

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- All of the cross-checking between parent and child tables would be
-- deadly slow if there wasn't the requirement for the corresponding
-- columns to be indexed!

-- But we can get rid of the foreign key using a fast operation
-- that doesn't rebuild the table.
-- If we didn't specify a constraint name when setting up the foreign key, we would
-- have to find the auto-generated name such as 'big_table_ibfk_1' in the
-- output from 'show create table'.

-- For the small table, drop the foreign key and the associated index.
-- Having an index on a small table is less critical.

\! echo "DROP FOREIGN KEY and INDEX from small_table:"
alter table small_table drop foreign key small_fk, drop index small_fk;

-- For the big table, drop the foreign key and leave the associated index.
-- If we are still doing queries that reference the indexed column, the index is
-- very important to avoid a full table scan of the big table.
\! echo "DROP FOREIGN KEY from big_table:"
alter table big_table drop foreign key big_fk;

show create table small_table\G
show create table big_table\G

```

### Example 15.6 Changing Auto-Increment Value

Here is an illustration of increasing the [auto-increment](#) lower limit for a table column, demonstrating how this operation now avoids a table rebuild, plus other facts about [InnoDB](#) auto-increment columns.

```

/*
If this script is run after foreign_key.sql, the schema_names table is
already set up. But to allow this script to run multiple times without
running into duplicate ID errors, we set up the schema_names table
all over again.
*/

\! clear

\! echo "=== Adjusting the Auto-Increment Limit for a Table ==="
\! echo

drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment,
  schema_name varchar(64) character set utf8 not null, index i_schema (schema_name))
as select distinct table_schema schema_name from small_table;

\! echo "Initial state of schema_names table."
\! echo "AUTO_INCREMENT is included in SHOW CREATE TABLE output."
\! echo "Note how MySQL reserved a block of IDs."
\! echo "Only 4 IDs are needed in this transaction. The next inserted values get IDs 8 and 9."
show create table schema_names\G
select * from schema_names order by id;

\! echo "Inserting even a tiny amount of data can produce gaps in the ID sequence."
insert into schema_names (schema_name) values ('eight'), ('nine');

\! echo "Bumping auto-increment lower limit to 20 (fast mechanism):"

```

```

alter table schema_names auto_increment=20, algorithm=inplace;

\! echo "Inserting 2 rows that should get IDs 20 and 21:"
insert into schema_names (schema_name) values ('foo'), ('bar');
commit;

\! echo "Bumping auto-increment lower limit to 30 (slow mechanism):"
alter table schema_names auto_increment=30, algorithm=copy;

\! echo "Inserting 2 rows that should get IDs 30 and 31:"
insert into schema_names (schema_name) values ('bletch'),('baz');
commit;

select * from schema_names order by id;

\! echo "Final state of schema_names table."
\! echo "AUTO_INCREMENT value shows the next inserted row would get ID=32."
show create table schema_names\G

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

=== Adjusting the Auto-Increment Limit for a Table ===

### Example 15.7 Controlling Concurrency with the LOCK Clause

This example shows how to use the `LOCK` clause of the `ALTER TABLE` statement to allow or deny concurrent access to the table while an online DDL operation is in progress. The clause has settings that allow queries and DML statements (`LOCK=NONE`), just queries (`LOCK=SHARED`), or no concurrent access at all (`LOCK=EXCLUSIVE`).

In one session, we run a succession of `ALTER TABLE` statements to create and drop an index, using different values for the `LOCK` clause to see what happens with waiting or deadlocking in either session. We are using the same `BIG_TABLE` table as in previous examples, starting with approximately 1.7 million rows. For illustration purposes, we will index and query the `IS_NULLABLE` column. (Although in real life it would be silly to make an index for a tiny column with only 2 distinct values.)

```

mysql: desc big_table;
+----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+----+-----+-----+-----+-----+-----+
| TABLE_CATALOG | varchar(512) | NO | | | |
| TABLE_SCHEMA | varchar(64) | NO | | | |
| TABLE_NAME | varchar(64) | NO | | | |

```

COLUMN_NAME	varchar(64)	NO			
ORDINAL_POSITION	bigint(21) unsigned	NO		0	
COLUMN_DEFAULT	longtext	YES		NULL	

IS_NULLABLE	varchar(3)	NO			
-------------	------------	----	--	--	--

...

```

+-----+-----+-----+-----+-----+-----+
21 rows in set (0.14 sec)

mysql: alter table big_table add index i1(is_nullable);
Query OK, 0 rows affected (20.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.02 sec)

mysql: alter table big_table add index i1(is_nullable), lock=exclusive;
Query OK, 0 rows affected (19.44 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.03 sec)

mysql: alter table big_table add index i1(is_nullable), lock=shared;
Query OK, 0 rows affected (16.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.05 sec)

mysql: alter table big_table add index i1(is_nullable), lock=none;
Query OK, 0 rows affected (12.26 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.01 sec)

... repeat statements like the above while running queries ...
... and DML statements at the same time in another session ...

```

Nothing dramatic happens in the session running the DDL statements. Sometimes, an `ALTER TABLE` takes unusually long because it is waiting for another transaction to finish, when that transaction modified the table during the DDL or queried the table before the DDL:

```

mysql: alter table big_table add index i1(is_nullable), lock=none;

Query OK, 0 rows affected (59.27 sec)

mysql: -- The previous ALTER took so long because it was waiting for all the concurrent
mysql: -- transactions to commit or roll back.

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (41.05 sec)

mysql: -- Even doing a SELECT on the table in the other session first causes
mysql: -- the ALTER TABLE above to stall until the transaction
mysql: -- surrounding the SELECT is committed or rolled back.

```

Here is the log from another session running concurrently, where we issue queries and DML statements against the table before, during, and after the DDL operations shown in the previous listings. This first listing shows queries only. We expect the queries to be allowed during DDL operations using `LOCK=NONE` or `LOCK=SHARED`, and for the query to wait until the DDL is finished if the `ALTER TABLE` statement includes `LOCK=EXCLUSIVE`.

```

mysql: show variables like 'autocommit';
+-----+-----+
| Variable_name | Value |

```

```

+-----+-----+
| autocommit | ON |
+-----+-----+
1 row in set (0.01 sec)

mysql: -- A trial query before any ADD INDEX in the other session:
mysql: -- Note: because autocommit is enabled, each
mysql: -- transaction finishes immediately after the query.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES         |
+-----+
2 rows in set (4.49 sec)

mysql: -- Index is being created with LOCK=EXCLUSIVE on the ALTER statement.
mysql: -- The query waits until the DDL is finished before proceeding.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES         |
+-----+

2 rows in set (17.26 sec)

mysql: -- Index is being created with LOCK=SHARED on the ALTER statement.
mysql: -- The query returns its results while the DDL is in progress.
mysql: -- The same thing happens with LOCK=NONE on the ALTER statement.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES         |
+-----+

2 rows in set (3.11 sec)

mysql: -- Once the index is created, and with no DDL in progress,
mysql: -- queries referencing the indexed column are very fast:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.20 sec)

mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES         |
+-----+

2 rows in set (0.00 sec)

```

Now in this concurrent session, we run some transactions including DML statements, or a combination of DML statements and queries. We use [DELETE](#) statements to illustrate predictable, verifiable changes to the table. Because the transactions in this part can span multiple statements, we run these tests with [autocommit](#) turned off.

```

mysql: set global autocommit = off;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Count the rows that will be involved in our DELETE statements:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|    411648 |
+-----+
1 row in set (0.95 sec)

mysql: -- After this point, any DDL statements back in the other session
mysql: -- stall until we commit or roll back.

mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.14 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|    400000 |
+-----+
1 row in set (1.04 sec)

mysql: rollback;
Query OK, 0 rows affected (0.09 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|    411648 |
+-----+
1 row in set (0.93 sec)

mysql: -- OK, now we're going to try that during index creation with LOCK=NONE.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.21 sec)

mysql: -- We expect that now there will be 400000 'YES' rows left:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|    400000 |
+-----+
1 row in set (1.25 sec)

mysql: -- In the other session, the ALTER TABLE is waiting before finishing,
mysql: -- because _this_ transaction hasn't committed or rolled back yet.
mysql: rollback;
Query OK, 0 rows affected (0.11 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|    411648 |
+-----+
1 row in set (0.19 sec)

mysql: -- The ROLLBACK left the table in the same state we originally found it.
mysql: -- Now let's make a permanent change while the index is being created,
mysql: -- again with ALTER TABLE ... , LOCK=NONE.
mysql: -- First, commit so the DROP INDEX in the other shell can finish;

```

```
mysql: -- the previous SELECT started a transaction that accessed the table.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now we add the index back in the other shell, then issue DML in this one
mysql: -- while the DDL is running.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.23 sec)

mysql: commit;
Query OK, 0 rows affected (0.01 sec)

mysql: -- In the other shell, the ADD INDEX has finished.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|    400000 |
+-----+
1 row in set (0.19 sec)

mysql: -- At the point the new index is finished being created, it contains entries
mysql: -- only for the 400000 'YES' rows left when all concurrent transactions are finished.
mysql:
mysql: -- Now we will run a similar test, while ALTER TABLE ... , LOCK=SHARED is running.
mysql: -- We expect a query to complete during the ALTER TABLE, but for the DELETE
mysql: -- to run into some kind of issue.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- As expected, the query returns results while the LOCK=SHARED DDL is running:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|    400000 |
+-----+
1 row in set (2.07 sec)

mysql: -- The DDL in the other session is not going to finish until this transaction
mysql: -- is committed or rolled back. If we tried a DELETE now and it waited because
mysql: -- of LOCK=SHARED on the DDL, both transactions would wait forever (deadlock).
mysql: -- MySQL detects this condition and cancels the attempted DML statement.
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
mysql: -- The transaction here is still going, so in the other shell, the ADD INDEX operation
mysql: -- is waiting for this transaction to commit or roll back.
mysql: rollback;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now let's try issuing a query and some DML, on one line, while running
mysql: -- ALTER TABLE ... , LOCK=EXCLUSIVE in the other shell.
mysql: -- Notice how even the query is held up until the DDL is finished.
mysql: -- By the time the DELETE is issued, there is no conflicting access
mysql: -- to the table and we avoid the deadlock error.
mysql: select count(*) from big_table where is_nullable = 'YES'; delete from big_table
      where is_nullable = 'YES' limit 100000;
+-----+
| count(*) |
+-----+
|    400000 |
+-----+

1 row in set (15.98 sec)

Query OK, 100000 rows affected (2.81 sec)
```

```

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|   300000 |
+-----+
1 row in set (0.17 sec)

mysql: rollback;
Query OK, 0 rows affected (1.36 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|   400000 |
+-----+
1 row in set (0.19 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Next, we try ALTER TABLE ... , LOCK=EXCLUSIVE in the other session
mysql: -- and only issue DML, not any query, in the concurrent transaction here.
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
Query OK, 100000 rows affected (16.37 sec)

mysql: -- That was OK because the ALTER TABLE did not have to wait for the transaction
mysql: -- here to complete. The DELETE in this session waited until the index was ready.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|   300000 |
+-----+
1 row in set (0.16 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)

```

In the preceding example listings, we learned that:

- The **LOCK** clause for **ALTER TABLE** is set off from the rest of the statement by a comma.
- Online DDL operations might wait before starting, until any prior transactions that access the table are committed or rolled back.
- Online DDL operations might wait before completing, until any concurrent transactions that access the table are committed or rolled back.
- While an online DDL operation is running, concurrent queries are relatively straightforward, as long as the **ALTER TABLE** statement uses **LOCK=NONE** or **LOCK=SHARED**.
- Pay attention to whether **autocommit** is turned on or off. If it is turned off, be careful to end transactions in other sessions (even just queries) before performing DDL operations on the table.
- With **LOCK=SHARED**, concurrent transactions that mix queries and DML could encounter deadlock errors and have to be restarted after the DDL is finished.
- With **LOCK=NONE**, concurrent transactions can freely mix queries and DML. The DDL operation waits until the concurrent transactions are committed or rolled back.
- With **LOCK=EXCLUSIVE**, concurrent transactions can freely mix queries and DML, but those transactions wait until the DDL operation is finished before they can access the table.

### Example 15.8 Schema Setup Code for Online DDL Experiments

You can create multiple indexes on a table with one `ALTER TABLE` statement. This is relatively efficient, because the clustered index of the table needs to be scanned only once (although the data is sorted separately for each new index). For example:

```
CREATE TABLE T1(A INT PRIMARY KEY, B INT, C CHAR(1)) ENGINE=InnoDB;  
INSERT INTO T1 VALUES (1,2,'a'), (2,3,'b'), (3,2,'c'), (4,3,'d'), (5,2,'e');  
COMMIT;  
ALTER TABLE T1 ADD INDEX (B), ADD UNIQUE INDEX (C);
```

The above statements create table `T1` with the primary key on column `A`, insert several rows, then build two new indexes on columns `B` and `C`. If there were many rows inserted into `T1` before the `ALTER TABLE` statement, this approach is much more efficient than creating all the secondary indexes before loading the data.

Because dropping InnoDB secondary indexes also does not require any copying of table data, it is equally efficient to drop multiple indexes with a single `ALTER TABLE` statement or multiple `DROP INDEX` statements:

```
ALTER TABLE T1 DROP INDEX B, DROP INDEX C;
```

or:

```
DROP INDEX B ON T1;  
DROP INDEX C ON T1;
```

### Example 15.9 Creating and Dropping the Primary Key

Restructuring the `clustered index` for an `InnoDB` table always requires copying the table data. Thus, it is best to define the `primary key` when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later, to avoid rebuilding the table.

Defining a `PRIMARY KEY` later causes the data to be copied, as in the following example:

```
CREATE TABLE T2 (A INT, B INT);  
INSERT INTO T2 VALUES (NULL, 1);  
ALTER TABLE T2 ADD PRIMARY KEY (B);
```

When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

When you add a primary key using the `ALGORITHM=COPY` clause, MySQL actually converts `NULL` values in the associated columns to default values: 0 for numbers, the empty string for character-based columns and BLOBs, and 0000-00-00 00:00:00 for `DATETIME`. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only allowed when the `SQL_MODE` setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ADD PRIMARY KEY ... , ALGORITHM=INPLACE` is allowed, but the statement can still fail if the requested primary key columns contain any `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

The following examples show the different possibilities for the `ADD PRIMARY KEY` clause. With the `ALGORITHM=COPY` clause, the operation succeeds despite the presence of `NULL` values in the primary key columns; the data is silently changed, which could cause problems.

```
mysql> CREATE TABLE add_pk_via_copy (c1 INT, c2 VARCHAR(10), c3 DATETIME);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO add_pk_via_copy VALUES (1,'a','2014-11-03 11:01:37'),(NULL,NULL,NULL);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE add_pk_via_copy ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=COPY;
Query OK, 2 rows affected, 3 warnings (0.07 sec)
Records: 2 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'c1' at row 2 |
| Warning | 1265 | Data truncated for column 'c2' at row 2 |
| Warning | 1265 | Data truncated for column 'c3' at row 2 |
+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT * FROM add_pk_via_copy;
+----+----+-----+
| c1 | c2 | c3 |
+----+----+-----+
| 0 | | 0000-00-00 00:00:00 |
| 1 | a | 2014-11-03 11:01:37 |
+----+----+-----+
2 rows in set (0.00 sec)
```

With the `ALGORITHM=INPLACE` clause, the operation could fail for different reasons, because this setting considers data integrity a high priority: the statement gives an error if the `SQL_MODE` setting is not “strict” enough, or if the primary key columns contain any `NULL` values. Once we address both of those requirements, the `ALTER TABLE` operation succeeds.

```
mysql> CREATE TABLE add_pk_via_inplace (c1 INT, c2 VARCHAR(10), c3 DATETIME);
Query OK, 0 rows affected (0.02 sec)

mysql> INSERT INTO add_pk_via_inplace VALUES (1,'a','2014-11-03 11:01:37'),(NULL,NULL,NULL);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM add_pk_via_inplace;
+----+----+-----+
| c1 | c2 | c3 |
+----+----+-----+
| 1 | a | 2014-11-03 11:01:37 |
| NULL | NULL | NULL |
+----+----+-----+
2 rows in set (0.00 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: cannot silently convert NULL values, as required in this SQL_MODE. Try ALGORITHM=COPY.

mysql> SET sql_mode='strict_trans_tables';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=INPLACE;
ERROR 1138 (22004): Invalid use of NULL value
mysql> DELETE FROM add_pk_via_inplace WHERE c1 IS NULL OR c2 IS NULL OR c3 IS NULL;
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM add_pk_via_inplace;
+-----+-----+-----+
| c1    | c2    | c3                |
+-----+-----+-----+
| 1     | a     | 2014-11-03 11:01:37 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=INPLACE;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

If you create a table without a primary key, InnoDB chooses one for you, which can be the first [UNIQUE](#) key defined on [NOT NULL](#) columns, or a system-generated key. To avoid any uncertainty and the potential space requirement for an extra hidden column, specify the [PRIMARY KEY](#) clause as part of the [CREATE TABLE](#) statement.

### 15.13.6 Implementation Details of Online DDL

Each [ALTER TABLE](#) operation for an [InnoDB](#) table is governed by several aspects:

- Whether there is any change to the physical representation of the table, or whether it purely a change to metadata that can be done without touching the table itself.
- Whether the volume of data in the table stays the same, increases, or decreases.
- Whether a change in table data involves the clustered index, secondary indexes, or both.
- Whether there are any [foreign key](#) relationships between the table being altered and some other table. The mechanics differ depending on whether the [foreign\\_key\\_checks](#) configuration option is enabled or disabled.
- Whether the table is partitioned. Partitioning clauses of [ALTER TABLE](#) are turned into low-level operations involving one or more tables, and those operations follow the regular rules for online DDL.
- Whether the table data must be copied, whether the table can be reorganized “in-place”, or a combination of both.
- Whether the table contains any [auto-increment](#) columns.
- What degree of [locking](#) is required, either by the nature of the underlying database operations, or a [LOCK](#) clause that you specify in the [ALTER TABLE](#) statement.

This section explains how these factors affect the different kinds of [ALTER TABLE](#) operations on [InnoDB](#) tables.

### Error Conditions for Online DDL

Here are the primary reasons why an online DDL operation could fail:

- If a [LOCK](#) clause specifies a low degree of locking ([SHARED](#) or [NONE](#)) that is not compatible with the particular type of DDL operation.
- If a timeout occurs while waiting to get an [exclusive lock](#) on the table, which may be needed briefly during the initial and final phases of the DDL operation.

- If the `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).
- If the `ALTER TABLE` takes so long, and concurrent DML modifies the table so much, that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.
- If concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a [primary key](#) index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively [rolled back](#).

Although the configuration option `innodb_file_per_table` has a dramatic effect on the representation for an `InnoDB` table, all online DDL operations work equally well whether that option is enabled or disabled, and whether the table is physically located in its own `.ibd` file or inside the [system tablespace](#).

`InnoDB` has two types of indexes: the [clustered index](#) representing all the data in the table, and optional [secondary indexes](#) to speed up queries. Since the clustered index contains the data values in its B-tree nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal `InnoDB` system tables and the MySQL data dictionary tables are updated to reflect the fact that the index no longer exists. `InnoDB` returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, `InnoDB` scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

## Primary Key and Secondary Key Indexes

Historically, the MySQL server and `InnoDB` have each kept their own metadata about table and index structures. The MySQL server stores this information in `.frm` files that are not protected by a transactional mechanism, while `InnoDB` has its own [data dictionary](#) as part of the [system tablespace](#). If a DDL operation was interrupted by a crash or other unexpected event partway through, the metadata could be left inconsistent between these two locations, causing problems such as startup errors or inability to access the table that was being altered. Now that `InnoDB` is the default storage engine, addressing such issues is a high priority. These enhancements to DDL operations reduce the window of opportunity for such issues to occur.

### 15.13.7 How Crash Recovery Works with Online DDL

Although no data is lost if the server crashes while an `ALTER TABLE` statement is executing, the [crash recovery](#) process is different for [clustered indexes](#) and [secondary indexes](#).

If the server crashes while creating an `InnoDB` secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

### 15.13.8 Online DDL for Partitioned InnoDB Tables

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables. Online DDL rules are outlined in [Table 15.10, “Summary of Online Status for DDL Operations”](#).

`ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned InnoDB tables, and are only allowed in conjunction with `ALGORITHM=DEFAULT` and `LOCK=DEFAULT`.

If you use an `ALTER TABLE` partitioning clause in an `ALTER TABLE` statement, the partitioned table will be “re-partitioned” using the `ALTER TABLE COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table will include any changes applied by the `ALTER TABLE` statement and the table data will be copied into the new table structure.

If you do not change the table's partitioning using `ALTER TABLE` partitioning clauses or perform any other partition management in your `ALTER TABLE` statement, `ALTER TABLE` will use the `INPLACE` algorithm on each table partition. Be aware, however, that when `INPLACE ALTER TABLE` operations are performed on each partition, there will be increased demand on system resources due to operations being performed on multiple partitions.

Even though partitioning clauses of the `ALTER TABLE` statement do not go through the same internal online DDL API as regular non-partitioned InnoDB tables, MySQL still attempts to minimize data copying and locking where possible:

- `ADD PARTITION` and `DROP PARTITION` for tables partitioned by `RANGE` or `LIST` do not copy any existing data.
- `TRUNCATE PARTITION` does not copy any existing data, for all types of partitioned tables.
- Concurrent queries are allowed during `ADD PARTITION` and `COALESCE PARTITION` for tables partitioned by `HASH` or `LIST`. MySQL copies the data while holding a shared lock.
- For `REORGANIZE PARTITION`, `REBUILD PARTITION`, or `ADD PARTITION` or `COALESCE PARTITION` for a table partitioned by `LINEAR HASH` or `LIST`, concurrent queries are allowed. Data from the affected partitions is copied while holding a shared metadata (read) lock at the table level.

#### Note

Full-text search (FTS) and foreign keys are not supported by InnoDB partitioned tables. For more information, see [Section 13.9.5, “Full-Text Restrictions”](#) and [Section 21.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

### 15.13.9 Limitations of Online DDL

Take the following limitations into account when running online DDL operations:

- An online DDL operation that copies the table can cause an error if the operation uses all of the available disk space on the file system where the data directory (`datadir`) resides. To avoid this problem, ensure that there is enough disk space to accommodate online `ALTER TABLE` operations that copy the table. During these operations, MySQL writes temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration variable). Each temporary file is large enough to hold one column in the new table or index, and each one is removed as soon as it is merged into the final table or index. Such operations may require temporary space equal to the amount of data in the table plus indexes.

As of MySQL 5.7.11, you can use the `innodb_tmpdir` configuration option to define a separate temporary directory for online DDL operations. The `innodb_tmpdir` option was introduced to help avoid temporary directory overflows that could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

- The table is copied, rather than using Fast Index Creation when you create an index on a `TEMPORARY TABLE`. This has been reported as MySQL Bug #39833.
- InnoDB handles error cases when users attempt to drop indexes needed for foreign keys. See [Section B.3, “Server Error Codes and Messages”](#) for information related to error 1553.
- The `ALTER TABLE` clause `LOCK=NONE` is not allowed if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- Depending on the internal workings of the online DDL operation and the `LOCK` clause of the `ALTER TABLE` statement, an online DDL operation may require exclusive access to the table for a brief time during the initial and final phases of the DDL operation. Thus, an online DDL operation might wait before finishing if there is a long-running transaction performing inserts, updates, deletes, or `SELECT ... FOR UPDATE` on the table; and an online DDL operation might wait before finishing if a similar long-running transaction is started while the `ALTER TABLE` is in progress.
- When running an online DDL operation, the thread that runs the `ALTER TABLE` statement will apply an “online log” of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (`ERROR 1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the “online log”. This is similar to the idea of a foreign key constraint check in InnoDB in which constraints must hold during a transaction.
- `OPTIMIZE TABLE` for an InnoDB table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Prior to 5.7.4, there is no online DDL support for this operation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. As of 5.7.4, `OPTIMIZE TABLE` is supported with the addition of online DDL support for rebuilding regular and partitioned InnoDB tables. For additional information, see [Section 15.13.1, “Overview of Online DDL”](#).
- InnoDB tables created before MySQL 5.6 do not support `ALTER TABLE ... ALGORITHM=INPLACE` for tables that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALTER TABLE ... ALGORITHM=COPY`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

- These limitations are generally applicable to online DDL operations on large tables where table copying is involved:
  - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
  - Progress monitoring capability for online DDL operations is limited until MySQL 5.7.6, which introduces Performance Schema stage events for monitoring `ALTER TABLE` progress. See [Section 15.16.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#).
  - Rollback of an online DDL operation can be expensive should the operation fail.
  - Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the master before it is run on the slave. Also, DML that was processed concurrently on the master is only processed on the slave after the DDL operation on the slave is completed (Bug #73196).

For additional information related to running online DDL operations on large tables, see [Section 15.13.2, “Performance and Concurrency Considerations for Online DDL”](#).

## 15.14 InnoDB Startup Options and System Variables

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the InnoDB adaptive hash index, you can use `--innodb_adaptive_hash_index` or `--skip-innodb_adaptive_hash_index` on the command line, or `innodb_adaptive_hash_index` or `skip-innodb_adaptive_hash_index` in an option file.
- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
- Many system variables can be changed at runtime (see [Section 6.1.6.2, “Dynamic System Variables”](#)).
- For information about `GLOBAL` and `SESSION` variable scope modifiers, refer to the `SET` statement documentation.
- Certain options control the locations and layout of the InnoDB data files. [Section 15.6.1, “InnoDB Startup Configuration”](#) explains how to use these options.
- Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and your database workload.
- For more information on specifying options and system variables, see [Section 5.2.3, “Specifying Program Options”](#).

**Table 15.11** InnoDB Option/Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<code>daemon_memcached_enable_binlog</code>	Yes	Yes	Yes		Global	No

## InnoDB Command Options

- `--ignore-builtin-innodb`

<b>Deprecated</b>	5.5.22	
<b>Command-Line Format</b>	<code>--ignore-builtin-innodb</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">ignore_builtin_innodb</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean

In MySQL 5.1, this option caused the server to behave as if the built-in [InnoDB](#) were not present, which enabled the [InnoDB Plugin](#) to be used instead. In MySQL 5.7, [InnoDB](#) is the default storage engine and [InnoDB Plugin](#) is not used, so this option is ignored.

- `--innodb[=value]`

<b>Deprecated</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb[=value]</code>	
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	ON
	<b>Valid Values</b>	OFF
		ON
		FORCE

Controls loading of the [InnoDB](#) storage engine, if the server was compiled with [InnoDB](#) support. This option has a tristate format, with possible values of [OFF](#), [ON](#), or [FORCE](#). See [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To disable [InnoDB](#), use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is [InnoDB](#), the server does not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and [TEMPORARY](#) tables.

As of MySQL 5.7.5, the [InnoDB](#) storage engine can no longer be disabled, and the `--innodb=OFF` and `--skip-innodb` options are deprecated and have no effect. Their use results in a warning. These options will be removed in a future MySQL release.

- `--innodb-status-file`

<b>Command-Line Format</b>	<code>--innodb-status-file</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Controls whether [InnoDB](#) creates a file named `innodb_status.pid` in the MySQL data directory. If enabled, [InnoDB](#) periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

By default, the file is not created. To create it, start `mysqld` with the `--innodb-status-file=1` option. The file is deleted during normal shutdown.

- `--skip-innodb`

Disable the [InnoDB](#) storage engine. See the description of `--innodb`.

## InnoDB System Variables

- `daemon_memcached_enable_binlog`

<b>Command-Line Format</b>	<code>--daemon_memcached_enable_binlog=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_enable_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	false

Enable this option on the [master server](#) to use the [InnoDB memcached](#) plugin ([daemon\\_memcached](#)) with the MySQL [binary log](#). This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the [--log-bin](#) option.

For more information, see [Section 15.20.6, “The InnoDB memcached Plugin and Replication”](#).

- [daemon\\_memcached\\_engine\\_lib\\_name](#)

<b>Command-Line Format</b>	<a href="#">--daemon_memcached_engine_lib_name=library</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">daemon_memcached_engine_lib_name</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<a href="#">innodb_engine.so</a>

Specifies the shared library that implements the [InnoDB memcached](#) plugin.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- [daemon\\_memcached\\_engine\\_lib\\_path](#)

<b>Command-Line Format</b>	<a href="#">--daemon_memcached_engine_lib_path=directory</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">daemon_memcached_engine_lib_path</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	directory name
	<b>Default</b>	<a href="#">NULL</a>

The path of the directory containing the shared library that implements the [InnoDB memcached](#) plugin. The default value is [NULL](#), representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a [memcached](#) plugin for a different storage engine that is located outside of the MySQL plugin directory.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- [daemon\\_memcached\\_option](#)

<b>Command-Line Format</b>	<a href="#">--daemon_memcached_option=options</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">daemon_memcached_option</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string

	<b>Default</b>	
--	----------------	--

Used to pass space-separated memcached options to the underlying `memcached` memory object caching daemon on startup. For example, you might change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.

See [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#) for usage details. For information about `memcached` options, refer to the `memcached` man page.

- `daemon_memcached_r_batch_size`

<b>Command-Line Format</b>	<code>--daemon_memcached_r_batch_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_r_batch_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1

Specifies how many `memcached` read operations (`get` operations) to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_w_batch_size`.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to `memcached` operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the `memcached` interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- `daemon_memcached_w_batch_size`

<b>Command-Line Format</b>	<code>--daemon_memcached_w_batch_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_w_batch_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1

Specifies how many `memcached` write operations, such as `add`, `set`, and `incr`, to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_r_batch_size`.

This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last *N*-1 uncommitted write operations could be lost if a crash occurs.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- `ignore_built_in_innodb`

<b>Deprecated</b>	5.5.22	
<b>Command-Line Format</b>	<code>--ignore-builtin-innodb</code>	
<b>System Variable</b>	<b>Name</b>	<code>ignore_built_in_innodb</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean

See the description of `--ignore-builtin-innodb` under “InnoDB Command Options” earlier in this section.

- `innodb_adaptive_flushing`

<b>Command-Line Format</b>	<code>--innodb_adaptive_flushing=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_flushing</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the [InnoDB buffer pool](#) based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_adaptive_flushing_lwm`

<b>Command-Line Format</b>	<code>--innodb_adaptive_flushing_lwm=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_flushing_lwm</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	10
	<b>Min Value</b>	0
	<b>Max Value</b>	70
		2494

Defines the low water mark representing percentage of redo log capacity at which [adaptive flushing](#) is enabled. For more information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- [innodb\\_adaptive\\_hash\\_index](#)

<b>Command-Line Format</b>	<code>--innodb_adaptive_hash_index=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_adaptive_hash_index</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">ON</a>

Whether the [InnoDB adaptive hash index](#) is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable [adaptive hash indexing](#) to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See [Section 15.4.3, “Adaptive Hash Index”](#) for details.

This variable is enabled by default. You can modify this parameter using the `SET GLOBAL` statement, without restarting the server. Changing the setting requires the [SUPER](#) privilege. You can also use `--skip-innodb_adaptive_hash_index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- [innodb\\_adaptive\\_hash\\_index\\_parts](#)

<b>Introduced</b>	5.7.8	
<b>Command-Line Format</b>	<code>--innodb_adaptive_hash_index_parts=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_adaptive_hash_index_parts</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	numeric
	<b>Default</b>	<a href="#">8</a>
	<b>Min Value</b>	<a href="#">1</a>
	<b>Max Value</b>	<a href="#">512</a>

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

Prior to MySQL 5.7.8, the adaptive hash index search system was protected by a single latch ([btr\\_search\\_latch](#)) which could become a point of contention. With the introduction of the

`innodb_adaptive_hash_index_parts` option, the search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see [Section 15.4.3, “Adaptive Hash Index”](#).

- `innodb_adaptive_max_sleep_delay`

<b>Command-Line Format</b>	<code>--innodb_adaptive_max_sleep_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_max_sleep_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	150000
	<b>Min Value</b>	0
	<b>Max Value</b>	1000000

Permits InnoDB to automatically adjust the value of `innodb_thread_sleep_delay` up or down according to the current workload. Any non-zero value enables automated, dynamic adjustment of the `innodb_thread_sleep_delay` value, up to the maximum value specified in the `innodb_adaptive_max_sleep_delay` option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_additional_mem_pool_size`

<b>Deprecated</b>	5.6.3	
<b>Removed</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_additional_mem_pool_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_additional_mem_pool_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	8388608
	<b>Min Value</b>	2097152
	<b>Max Value</b>	4294967295

The size in bytes of a memory pool InnoDB uses to store [data dictionary](#) information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If

[InnoDB](#) runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

This variable relates to the [InnoDB](#) internal memory allocator, which is unused if [innodb\\_use\\_sys\\_malloc](#) is enabled. For more information, see [Section 15.6.4, “Configuring the Memory Allocator for InnoDB”](#).

[innodb\\_additional\\_mem\\_pool\\_size](#) was deprecated in MySQL 5.6.3 and removed in MySQL 5.7.4.

- [innodb\\_api\\_bk\\_commit\\_interval](#)

<b>Command-Line Format</b>	<code>--innodb_api_bk_commit_interval=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_api_bk_commit_interval</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	5
	<b>Min Value</b>	1
	<b>Max Value</b>	1073741824

How often to auto-commit idle connections that use the [InnoDB memcached](#) interface, in seconds. For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- [innodb\\_api\\_disable\\_rowlock](#)

<b>Command-Line Format</b>	<code>--innodb_api_disable_rowlock=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_api_disable_rowlock</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Use this option to disable row locks when [InnoDB memcached](#) performs DML operations. By default, [innodb\\_api\\_disable\\_rowlock](#) is disabled, which means that [memcached](#) requests row locks for [get](#) and [set](#) operations. When [innodb\\_api\\_disable\\_rowlock](#) is enabled, [memcached](#) requests a table lock instead of row locks.

[innodb\\_api\\_disable\\_rowlock](#) is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_enable_binlog`

<b>Command-Line Format</b>	<code>--innodb_api_enable_binlog=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_enable_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Lets you use the `InnoDB memcached` plugin with the MySQL [binary log](#). For more information, see [Enabling the InnoDB memcached Binary Log](#).

- `innodb_api_enable_md1`

<b>Command-Line Format</b>	<code>--innodb_api_enable_md1=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_enable_md1</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Locks the table used by the `InnoDB memcached` plugin, so that it cannot be dropped or altered by [DDL](#) through the SQL interface. For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_trx_level`

<b>Command-Line Format</b>	<code>--innodb_api_trx_level=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_trx_level</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>0</code>

Controls the transaction [isolation level](#) on queries processed by the `memcached` interface. The constants corresponding to the familiar names are:

- `0 = READ UNCOMMITTED`

- 1 = `READ COMMITTED`
- 2 = `REPEATABLE READ`
- 3 = `SERIALIZABLE`

For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_autoextend_increment`

<b>Command-Line Format</b>	<code>--innodb_autoextend_increment=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_autoextend_increment</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	64
	<b>Min Value</b>	1
	<b>Max Value</b>	1000

The increment size (in megabytes) for extending the size of an auto-extending [InnoDB system tablespace](#) file when it becomes full. The default value is 64. For related information, see [System Tablespace Data File Configuration](#), and [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

The `innodb_autoextend_increment` setting does not affect [file-per-table](#) tablespace files or [general tablespace](#) files. These files are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- `innodb_autoinc_lock_mode`

<b>Command-Line Format</b>	<code>--innodb_autoinc_lock_mode=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_autoinc_lock_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Valid Values</b>	0
		1
		2

The [lock mode](#) to use for generating [auto-increment](#) values. Permissible values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved”, respectively. The default setting is 1 (“consecutive”). For the characteristics of each lock mode, see [InnoDB AUTO\\_INCREMENT Lock Modes](#).

- [innodb\\_background\\_drop\\_list\\_empty](#)

<b>Introduced</b>	5.7.10	
<b>Command-Line Format</b>	<code>--innodb_background_drop_list_empty=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_background_drop_list_empty</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Enabling the [innodb\\_background\\_drop\\_list\\_empty](#) debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table [t1](#) on the background drop list, test case B waits until the background drop list is empty before creating table [t1](#).

- [innodb\\_buffer\\_pool\\_chunk\\_size](#)

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_buffer_pool_chunk_size</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_buffer_pool_chunk_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>134217728</code>
	<b>Min Value</b>	<code>1048576</code>
	<b>Max Value</b>	<code>innodb_buffer_pool_size / innodb_buffer_pool_instances</code>

[innodb\\_buffer\\_pool\\_chunk\\_size](#) defines the chunk size for InnoDB buffer pool resizing operations. The [innodb\\_buffer\\_pool\\_size](#) parameter is dynamic, which allows you to resize the buffer pool without restarting the server.

To avoid copying all buffer pool pages during resizing operations, the operation is performed in “chunks”. By default, [innodb\\_buffer\\_pool\\_chunk\\_size](#) is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of [innodb\\_page\\_size](#). [innodb\\_buffer\\_pool\\_chunk\\_size](#) can be increased or decreased in units of 1MB (1048576 bytes).

The following conditions apply when altering the [innodb\\_buffer\\_pool\\_chunk\\_size](#) value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.
- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than the current buffer pool size. The adjustment occurs when the buffer pool is initialized.

### Important

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before changing `innodb_buffer_pool_chunk_size`, calculate the effect it will have on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_dump_at_shutdown`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_dump_at_shutdown=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_dump_at_shutdown</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies whether to record the pages cached in the [InnoDB buffer pool](#) when the MySQL server is shut down, to shorten the [warmup](#) process at the next restart. Typically used in combination with `innodb_buffer_pool_load_at_startup`. The `innodb_buffer_pool_dump_pct` option defines the percentage of most recently used buffer pool pages to dump.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default as of MySQL 5.7.7.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_dump_now`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_dump_now=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_dump_now</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Immediately records the pages cached in the [InnoDB buffer pool](#). Typically used in combination with [innodb\\_buffer\\_pool\\_load\\_now](#).

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_dump\\_pct](#)

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--innodb_buffer_pool_dump_pct=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_buffer_pool_dump_pct</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	integer
	<b>Default</b>	100
	<b>Min Value</b>	1
	<b>Max Value</b>	100
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	integer
	<b>Default</b>	25
	<b>Min Value</b>	1
	<b>Max Value</b>	100

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. Prior to MySQL 5.7.7, the default value is 100 (dump all pages). As of MySQL 5.7.7, the default value is 25. For example, if there are 4 buffer pools with 100 pages each, and [innodb\\_buffer\\_pool\\_dump\\_pct](#) is set to 25, the 25 most recently used pages from each buffer pool are dumped.

The change to the [innodb\\_buffer\\_pool\\_dump\\_pct](#) default value in MySQL 5.7.7 coincides with default value changes for [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#), which are both enabled by default as of MySQL 5.7.7.

- [innodb\\_buffer\\_pool\\_filename](#)

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_filename=file</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_buffer_pool_filename</a>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<code>ib_buffer_pool</code>

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named `ib_buffer_pool` and is located in the `InnoDB` data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a `SET` statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or `InnoDB` will return a startup error indicating that there is no such file or directory.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_instances`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_instances=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_instances</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b> (Windows, 32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<code>(autosized)</code>
	<b>Min Value</b>	1
	<b>Max Value</b>	64
<b>Permitted Values (Other)</b>	<b>Type</b>	integer
	<b>Default</b>	8 (or 1 if <code>innodb_buffer_pool_size &lt; 1GB</code> )
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of regions that the `InnoDB buffer pool` is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing

function. Each buffer pool manages its own free lists, [flush lists](#), [LRUs](#), and all other data structures connected to a buffer pool, and is protected by its own buffer pool [mutex](#).

This option only takes effect when setting [innodb\\_buffer\\_pool\\_size](#) to 1GB or more. The total buffer pool size is divided among all the buffer pools. For best efficiency, specify a combination of [innodb\\_buffer\\_pool\\_instances](#) and [innodb\\_buffer\\_pool\\_size](#) so that each buffer pool instance is at least 1GB.

The default value on 32-bit Windows systems depends on the value of [innodb\\_buffer\\_pool\\_size](#), as described below:

- If [innodb\\_buffer\\_pool\\_size](#) is greater than 1.3GB, the default for [innodb\\_buffer\\_pool\\_instances](#) is  $\text{innodb\_buffer\_pool\_size}/128\text{MB}$ , with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
- Otherwise, the default is 1.

On all other platforms, the default value is 8 when [innodb\\_buffer\\_pool\\_size](#) is greater than or equal to 1GB. Otherwise, the default is 1.

For related information, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).

- [innodb\\_buffer\\_pool\\_load\\_abort](#)

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_load_abort=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_buffer_pool_load_abort</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Interrupts the process of restoring [InnoDB buffer pool](#) contents triggered by [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) or [innodb\\_buffer\\_pool\\_load\\_now](#).

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#)

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_load_at_startup=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_buffer_pool_load_at_startup</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

<b>Permitted Values</b> (>= 5.7.7)	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies that, on MySQL server startup, the [InnoDB buffer pool](#) is automatically [warmed up](#) by loading the same pages it held at an earlier time. Typically used in combination with [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#).

Both [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) are enabled by default as of MySQL 5.7.7.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_load\\_now](#)

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_load_now=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_buffer_pool_load_now</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Immediately [warms up](#) the [InnoDB buffer pool](#) by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_size](#)

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_size=#</code>	
<b>System Variable</b> (<= 5.7.4)	<b>Name</b>	<a href="#">innodb_buffer_pool_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>System Variable</b> (>= 5.7.5)	<b>Name</b>	<a href="#">innodb_buffer_pool_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	134217728
	<b>Min Value</b>	5242880
	<b>Max Value</b>	$2^{32}-1$

<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	134217728
	<b>Min Value</b>	5242880
	<b>Max Value</b>	$2^{64}-1$

The size in bytes of the [buffer pool](#), the memory area where [InnoDB](#) caches table and index data. The default value is 128MB. The maximum value depends on the CPU architecture; the maximum is 4294967295 ( $2^{32}-1$ ) on 32-bit systems and 18446744073709551615 ( $2^{64}-1$ ) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting [innodb\\_buffer\\_pool\\_instances](#) to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- [InnoDB](#) reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant. To reduce the initialization period, you can save the buffer pool state at server shutdown and restore it at server startup. See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

When you increase or decrease buffer pool size, the operation is performed in chunks. Chunk size is defined by the [innodb\\_buffer\\_pool\\_chunk\\_size](#) configuration option, which has a default of 128 MB.

Buffer pool size must always be equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#). If you alter the buffer pool size to a value that is not equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#), buffer pool size is automatically adjusted to a value that is equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#) that is not less than the specified buffer pool size.

[innodb\\_buffer\\_pool\\_size](#) can be set dynamically, which allows you to resize the buffer pool without restarting the server. The [Innodb\\_buffer\\_pool\\_resize\\_status](#) status variable reports the status of online buffer pool resizing operations. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- [innodb\\_change\\_buffer\\_max\\_size](#)

<b>Command-Line Format</b>	<a href="#">--innodb_change_buffer_max_size=#</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_change_buffer_max_size</a>

<b>Permitted Values</b>	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
	<b>Type</b>	integer
	<b>Default</b>	25
	<b>Min Value</b>	0
	<b>Max Value</b>	50

Maximum size for the [InnoDB change buffer](#), as a percentage of the total size of the [buffer pool](#). You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.5, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_change\\_buffering](#)

<b>Command-Line Format</b>	<code>--innodb_change_buffering=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_change_buffering</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<a href="#">all</a>
	<b>Valid Values</b>	<a href="#">none</a>
		<a href="#">inserts</a>
		<a href="#">deletes</a>
		<a href="#">changes</a>
		<a href="#">purges</a>
		<a href="#">all</a>

Whether [InnoDB](#) performs [change buffering](#), an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table.

**Table 15.12 Permitted Values for [innodb\\_change\\_buffering](#)**

Value	Description
<a href="#">none</a>	Do not buffer any operations.
<a href="#">inserts</a>	Buffer insert operations.
<a href="#">deletes</a>	Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation.
<a href="#">changes</a>	Buffer inserts and delete-marking operations.

Value	Description
<a href="#">purges</a>	Buffer the physical deletion operations that happen in the background.
<a href="#">all</a>	The default. Buffer inserts, delete-marking operations, and purges.

For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.5, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_change\\_buffering\\_debug](#)

<b>Command-Line Format</b>	<code>--innodb_change_buffering_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_change_buffering_debug</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Max Value</b>	2

Sets a debug flag for [InnoDB](#) change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes a crash at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the [WITH\\_DEBUG CMake](#) option.

- [innodb\\_checksum\\_algorithm](#)

<b>Command-Line Format</b>	<code>--innodb_checksum_algorithm=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_checksum_algorithm</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	enumeration
	<b>Default</b>	<a href="#">innodb</a>
	<b>Valid Values</b>	<a href="#">innodb</a>
		<a href="#">crc32</a>
		<a href="#">none</a>
		<a href="#">strict_innodb</a>
		<a href="#">strict_crc32</a>
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	enumeration
	<b>Default</b>	<a href="#">crc32</a>
	<b>Valid Values</b>	<a href="#">innodb</a>
		<a href="#">crc32</a>

	<code>none</code>
	<code>strict_innodb</code>
	<code>strict_crc32</code>
	<code>strict_none</code>

Specifies how to generate and verify the [checksum](#) stored in the disk blocks of [InnoDB tablespaces](#).

The default value for `innodb_checksum_algorithm` changed from `innodb` to `crc32` in MySQL 5.6.6 but switched back to `innodb` in 5.6.7 for improved compatibility of [InnoDB](#) data files during a downgrade to an earlier MySQL version, and for use with [MySQL Enterprise Backup](#). The limitations encountered included:

- `.ibd` files containing CRC32 checksums could cause problems downgrading to MySQL versions prior to 5.6.3. MySQL 5.6.3 and up recognizes either the new or old checksum values for the block as correct when reading the block from disk, ensuring that data blocks are compatible during upgrade and downgrade regardless of the algorithm setting. If data written with new checksum values is processed by a level of MySQL earlier than 5.6.3, it could be reported as corrupted.
- Versions of [MySQL Enterprise Backup](#) up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. [MySQL Enterprise Backup](#) adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the [MySQL Enterprise Backup 3.8.1 Change History](#) for more information.

As of MySQL 5.7.7, `crc32` is once again the default value for `innodb_checksum_algorithm`.

`innodb_checksum_algorithm` replaced the `innodb_checksums` option in MySQL 5.6.3. The following values were provided for compatibility, up to and including MySQL 5.7.6:

- `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=innodb`.
- `innodb_checksums=OFF` is the same as `innodb_checksum_algorithm=none`.

As of MySQL 5.7.7, with a default `innodb_checksum_algorithm` value of `crc32`, `innodb_checksums=ON` is now the same as `innodb_checksum_algorithm=crc32`. `innodb_checksums=OFF` is still the same as `innodb_checksum_algorithm=none`.

To avoid conflicts, remove references to `innodb_checksums` from MySQL configuration files and startup scripts.

The value `innodb` is backward-compatible with earlier versions of MySQL. The value `crc32` uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 32 bits at a time, which is faster than the `innodb` checksum algorithm, which scans blocks 8 bits at a time. The value `none` writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the `crc32` algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

**Note**

Prior to MySQL 5.7.8, a strict mode setting for `innodb_checksum_algorithm` caused InnoDB to halt when encountering a *valid* but non-matching checksum. In MySQL 5.7.8 and later, only an error message is printed, and the page is accepted as valid if it has a valid `innodb`, `crc32` or `none` checksum.

The following table shows the difference between the `none`, `innodb`, and `crc32` option values, and their strict counterparts. `none`, `innodb`, and `crc32` write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all InnoDB data files in an instance are created under an identical `innodb_checksum_algorithm` value.

**Table 15.13 innodb\_checksum\_algorithm Settings**

Value	Generated checksum (when writing)	Permitted checksums (when reading)
none	A constant number.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
crc32	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
strict_none	A constant number	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.
strict_innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.
strict_crc32	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.

- `innodb_checksums`

<b>Deprecated</b>	5.6.3	
<b>Command-Line Format</b>	<code>--innodb_checksums</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_checksums</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

InnoDB can use [checksum](#) validation on all tablespace pages read from disk to ensure extra fault tolerance against hardware faults or corrupted data files. This validation is enabled by default. Under specialized circumstances (such as when running benchmarks) this safety feature can be disabled with `--skip-innodb-checksums`. You can specify the method of calculating the checksum using the `innodb_checksum_algorithm` option.

In MySQL 5.6.3 and higher, `innodb_checksums` is deprecated, replaced by `innodb_checksum_algorithm`.

Prior to MySQL 5.7.7, `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=innodb`. As of MySQL 5.7.7, the `innodb_checksum_algorithm` default value is `crc32`, and `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=crc32`. `innodb_checksums=OFF` is the same as `innodb_checksum_algorithm=none`.

Remove any `innodb_checksums` options from your configuration files and startup scripts to avoid conflicts with `innodb_checksum_algorithm`. `innodb_checksums=OFF` automatically sets `innodb_checksum_algorithm=none`. `innodb_checksums=ON` is ignored and overridden by any other setting for `innodb_checksum_algorithm`.

- `innodb_cmp_per_index_enabled`

<b>Command-Line Format</b>	<code>--innodb_cmp_per_index_enabled=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_cmp_per_index_enabled</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>
	<b>Valid Values</b>	<code>OFF</code>
		<code>ON</code>

Enables per-index compression-related statistics in the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or slave instances during performance tuning related to [InnoDB compressed](#) tables.

For more information, see [Section 23.31.6, “The INFORMATION\\_SCHEMA INNODB\\_CMP\\_PER\\_INDEX and INNODB\\_CMP\\_PER\\_INDEX\\_RESET Tables”](#), and [Section 15.9.1.4, “Monitoring Compression at Runtime”](#).

- `innodb_commit_concurrency`

<b>Command-Line Format</b>	<code>--innodb_commit_concurrency=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_commit_concurrency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes

## InnoDB System Variables

Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	1000

The number of [threads](#) that can [commit](#) at the same time. A value of 0 (the default) permits any number of [transactions](#) to commit simultaneously.

The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- `innodb_compress_debug`

Introduced	5.7.8	
Command-Line Format	<code>--innodb_compress_debug=#</code>	
System Variable	Name	<code>innodb_compress_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>none</code>
	Valid Values	<code>none</code>
		<code>zlib</code>
		<code>lz4</code>
		<code>lz4hc</code>

Compresses all tables using a specified compression algorithm without having to define a [COMPRESSION](#) attribute for each table. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

For related information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- `innodb_compression_failure_threshold_pct`

Command-Line Format	<code>--innodb_compression_failure_threshold_pct=#</code>	
System Variable	Name	<code>innodb_compression_failure_threshold_pct</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	5
	Min Value	0

	<b>Max Value</b>	100
--	------------------	-----

Sets the cutoff point at which MySQL begins adding padding within [compressed](#) pages to avoid expensive [compression failures](#). A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_compression\\_level](#)

<b>Command-Line Format</b>	<code>--innodb_compression_level=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_compression_level</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	6
	<b>Min Value</b>	0
	<b>Max Value</b>	9

Specifies the level of zlib compression to use for [InnoDB compressed](#) tables and indexes.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_compression\\_pad\\_pct\\_max](#)

<b>Command-Line Format</b>	<code>--innodb_compression_pad_pct_max=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_compression_pad_pct_max</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	50
	<b>Min Value</b>	0
	<b>Max Value</b>	75

Specifies the maximum percentage that can be reserved as free space within each compressed [page](#), allowing room to reorganize the data and modification log within the page when a [compressed](#) table or index is updated and the data might be recompressed. Only applies when [innodb\\_compression\\_failure\\_threshold\\_pct](#) is set to a non-zero value, and the rate of [compression failures](#) passes the cutoff point.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- `innodb_concurrency_tickets`

<b>Command-Line Format</b>	<code>--innodb_concurrency_tickets=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_concurrency_tickets</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	5000
	<b>Min Value</b>	1
	<b>Max Value</b>	4294967295

Determines the number of [threads](#) that can enter [InnoDB](#) concurrently. A thread is placed in a queue when it tries to enter [InnoDB](#) if the number of threads has already reached the concurrency limit. When a thread is permitted to enter [InnoDB](#), it is given a number of “tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave [InnoDB](#) freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter [InnoDB](#). The default value is 5000.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a non-zero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the `INFORMATION_SCHEMA.INNODB_TRX` table.

For more information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_create_intrinsic`

<b>Introduced</b>	5.7.5
<b>Removed</b>	5.7.6
<b>Command-Line Format</b>	<code>--innodb_create_intrinsic=#</code>

<b>System Variable</b>	<b>Name</b>	<code>innodb_create_intrinsic</code>
	<b>Variable Scope</b>	Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

When `innodb_create_intrinsic` is enabled, `CREATE TEMPORARY TABLE` creates “optimized temporary tables” instead of normal temporary tables.

An optimized temporary table is a lightweight subclass of temporary table that excludes certain functionality and benefits from optimizations that make it faster than a normal temporary table. Like normal temporary tables, optimized temporary tables are only visible to the current connection and are dropped when the connection is terminated. Unlike normal temporary tables, optimized temporary tables are operational when InnoDB is in read-only mode.

Row format `COMPRESSED` is not supported. If you attempt to create a compressed optimized temporary table, the `innodb_create_intrinsic=ON` setting is ignored and InnoDB creates a normal temporary table.

Metadata for optimized temporary tables is not available in the `INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO` table.

Undo logging is disabled for optimized temporary tables, which means that rollback is not supported.

Atomicity for optimized temporary tables is supported at the row-level, not at the statement level.

Statistics generated by the same workload may differ for optimized temporary tables compared to normal temporary tables, as optimized temporary tables may use a different algorithm to complete certain types of operations.

The `innodb_create_intrinsic` option was removed in MySQL 5.7.6.

- `innodb_data_file_path`

<b>Command-Line Format</b>	<code>--innodb_data_file_path=name</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_data_file_path</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<code>ibdata1:12M:autoextend</code>

Defines the path and file size for individual InnoDB system tablespace data files. The full directory path for system tablespace data files is formed by concatenating path defined by `innodb_data_home_dir` and `innodb_data_file_path`. File sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 10MB. If you do not specify `innodb_data_file_path`, the default behavior

is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also [use raw disk partitions as data files](#). For more information about configuring system tablespace data files, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

As of MySQL 5.7.8, the following minimum file sizes are enforced for the *first* system tablespace data file (`ibdata1`) to ensure that there is enough space for doublewrite buffer pages:

- For an `innodb_page_size` value of 16KB or less, the minimum data file size is 3MB.
- For an `innodb_page_size` value of 32KB, the minimum data file size is 6MB.
- For an `innodb_page_size` value of 64KB, the minimum data file size is 12MB.
- `innodb_data_home_dir`

<b>Command-Line Format</b>	<code>--innodb_data_home_dir=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_data_home_dir</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	directory name

The common part of the directory path for [InnoDB system tablespace](#) data files. This setting does not affect the location of [file-per-table](#) tablespaces when `innodb_file_per_table` is enabled. The default value is the MySQL `data` directory. If you specify the value as an empty string, you can specify an absolute file paths for `innodb_data_file_path`.

For related information, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

- `innodb_deadlock_detect`

<b>Introduced</b>	5.7.15	
<b>Command-Line Format</b>	<code>--innodb_deadlock_detect</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_deadlock_detect</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>ON</code>

This option is used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.

For related information, see [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

- `innodb_default_row_format`

<b>Introduced</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_default_row_format=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_default_row_format</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>DYNAMIC</code>
	<b>Valid Values</b>	<code>DYNAMIC</code>
		<code>COMPACT</code>
		<code>REDUNDANT</code>

The `innodb_default_row_format` option, introduced in MySQL 5.7.9, defines the default row format for InnoDB tables and user-created temporary tables. The default setting is `DYNAMIC`. Other permitted values are `COMPACT` and `REDUNDANT`. The `COMPRESSED` row format, which is not supported for use in the `system tablespace`, cannot be defined as the default.

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used.

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. For more information, see [Section 15.11.2, “Specifying the Row Format for a Table”](#).

Internal InnoDB temporary tables created by the server to process queries use the `DYNAMIC` row format, regardless of the `innodb_default_row_format` setting.

In MySQL 5.7.8 and earlier, the default row format is `COMPACT`.

- `innodb_disable_sort_file_cache`

<b>Command-Line Format</b>	<code>--innodb_disable_sort_file_cache=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_disable_sort_file_cache</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- `innodb_disable_resize_buffer_pool_debug`

<b>Introduced</b>	5.7.6
-------------------	-------

<b>Command-Line Format</b>	<code>--innodb_disable_resize_buffer_pool_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_disable_resize_buffer_pool_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Disables resizing of the [InnoDB](#) buffer pool. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_doublewrite`

<b>Command-Line Format</b>	<code>--innodb-doublewrite</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_doublewrite</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

When enabled (the default), [InnoDB](#) stores all data twice, first to the [doublewrite buffer](#), then to the actual [data files](#). This variable can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

As of MySQL 5.7.4, if system tablespace data files (`ibdata*` files) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

For related information, see [Section 15.4.7, “Doublewrite Buffer”](#).

- `innodb_fast_shutdown`

<b>Command-Line Format</b>	<code>--innodb_fast_shutdown[=#]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_fast_shutdown</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Valid Values</b>	0 1

2

The `InnoDB shutdown` mode. If the value is 0, `InnoDB` does a [slow shutdown](#), a full [purge](#) and a change buffer merge before shutting down. If the value is 1 (the default), `InnoDB` skips these operations at shutdown, a process known as a [fast shutdown](#). If the value is 2, `InnoDB` flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the [crash recovery](#) operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- `innodb_fil_make_page_dirty_debug`

<b>Command-Line Format</b>	<code>--innodb_fil_make_page_dirty_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_fil_make_page_dirty_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Max Value</b>	$2^{32}-1$

By default, setting `innodb_fil_make_page_dirty_debug` to the ID of a tablespace immediately dirties the first page of the tablespace. If `innodb_saved_page_number_debug` is set to a non-default value, setting `innodb_fil_make_page_dirty_debug` dirties the specified page. The `innodb_fil_make_page_dirty_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_file_format`

<b>Deprecated</b>	5.7.7	
<b>Command-Line Format</b>	<code>--innodb_file_format=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_file_format</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	string
	<b>Default</b>	<code>Antelope</code>
	<b>Valid Values</b>	<code>Antelope</code> <code>Barracuda</code>

<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	string
	<b>Default</b>	<a href="#">Barracuda</a>
	<b>Valid Values</b>	<a href="#">Antelope</a> <a href="#">Barracuda</a>

Enables an [InnoDB](#) file format for [file-per-table](#) tablespaces. Supported file formats are [Antelope](#) and [Barracuda](#). [Antelope](#) is the original [InnoDB](#) file format, which supports [REDUNDANT](#) and [COMPACT](#) row formats. [Barracuda](#) is the newer file format, which supports [COMPRESSED](#) and [DYNAMIC](#) row formats.

[COMPRESSED](#) and [DYNAMIC](#) row formats enable important storage features for [InnoDB](#) tables. See [Section 15.11, “InnoDB Row Storage and Row Formats”](#).

Changing the `innodb_file_format` setting does not affect the file format of existing [InnoDB](#) tablespace files.

The `innodb_file_format` setting does not apply to general tablespaces, which support tables of all row formats. See [Section 15.7.9, “InnoDB General Tablespaces”](#).

The `innodb_file_format` default value was changed to [Barracuda](#) in MySQL 5.7.7.

As of MySQL 5.7.9, the `innodb_file_format` setting is ignored when creating tables that use the [DYNAMIC](#) row format. A table created using the [DYNAMIC](#) row format always uses the [Barracuda](#) file format, regardless of the `innodb_file_format` setting. To use the [COMPRESSED](#) row format, `innodb_file_format` must be set to [Barracuda](#).

The `innodb_file_format` option is deprecated in MySQL 5.7.7 and will be removed in a future release. The purpose of the `innodb_file_format` option was to allow users to downgrade to the built-in version of [InnoDB](#) in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, downgrade support provided by this option is no longer necessary.

For more information, see [Section 15.10, “InnoDB File-Format Management”](#).

- `innodb_file_format_check`

<b>Deprecated</b>	5.7.7	
<b>Command-Line Format</b>	<code>--innodb_file_format_check=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_file_format_check</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">ON</a>

This variable can be set to 1 or 0 at server startup to enable or disable whether [InnoDB](#) checks the [file format](#) tag in the [system tablespace](#) (for example, [Antelope](#) or [Barracuda](#)). If the tag is checked and is higher than that supported by the current version of [InnoDB](#), an error occurs and [InnoDB](#) does not start. If the tag is not higher, [InnoDB](#) sets the value of `innodb_file_format_max` to the file format tag.

**Note**

Despite the default value sometimes being displayed as `ON` or `OFF`, always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line string.

The `innodb_file_format_check` option is deprecated in MySQL 5.7.7 together with the `innodb_file_format` option. Both options will be removed in a future release.

- `innodb_file_format_max`

<b>Deprecated</b>	5.7.7	
<b>Command-Line Format</b>	<code>--innodb_file_format_max=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_file_format_max</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.8)</b>	<b>Type</b>	string
	<b>Default</b>	<code>Antelope</code>
	<b>Valid Values</b>	<code>Antelope</code> <code>Barracuda</code>
<b>Permitted Values (&gt;= 5.7.9)</b>	<b>Type</b>	string
	<b>Default</b>	<code>Barracuda</code>
	<b>Valid Values</b>	<code>Antelope</code> <code>Barracuda</code>

At server startup, InnoDB sets the value of this variable to the `file format` tag in the `system tablespace` (for example, `Antelope` or `Barracuda`). If the server creates or opens a table with a “higher” file format, it sets the value of `innodb_file_format_max` to that format.

The `innodb_file_format_max` option is deprecated in MySQL 5.7.7 together with the `innodb_file_format` option. Both options will be removed in a future release.

- `innodb_file_per_table`

<b>Command-Line Format</b>	<code>--innodb_file_per_table</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_file_per_table</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>ON</code>

When `innodb_file_per_table` is enabled (the default in 5.6.6 and higher), InnoDB stores the data and indexes for each newly created table in a separate `.ibd file`, rather than in the system tablespace.

The storage for these InnoDB tables is reclaimed when the tables are dropped or truncated. This setting enables several other InnoDB features, such as table [compression](#). See [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#) for details about such features as well as advantages and disadvantages of using per-table tablespaces.

Be aware that enabling `innodb_file_per_table` also means that an `ALTER TABLE` operation will move InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (`ALGORITHM=COPY`). An exception to this rule is for tables that were placed in the system tablespace using the `TABLESPACE=innodb_system` option with `CREATE TABLE` or `ALTER TABLE`. These tables are unaffected by the `innodb_file_per_table` setting and can only be moved to file-per-table tablespaces using `ALTER TABLE ... TABLESPACE=innodb_file_per_table`.

When `innodb_file_per_table` is disabled, InnoDB stores the data for all tables and indexes in the `ibdata files` that make up the [system tablespace](#). This setting reduces the performance overhead of filesystem operations for operations such as `DROP TABLE` or `TRUNCATE TABLE`. It is most appropriate for a server environment where entire storage devices are devoted to MySQL data. Because the system tablespace never shrinks, and is shared across all databases in an [instance](#), avoid loading huge amounts of temporary data on a space-constrained system when `innodb_file_per_table=OFF`. Set up a separate instance in such cases, so that you can drop the entire instance to reclaim the space.

By default, `innodb_file_per_table` is enabled as of MySQL 5.6.6, disabled before that. Consider disabling it if backward compatibility with MySQL 5.5 or 5.1 is a concern. This will prevent `ALTER TABLE` from moving InnoDB tables from the system tablespace to individual `.ibd` files.

`innodb_file_per_table` is dynamic and can be set `ON` or `OFF` using `SET GLOBAL`. You can also set this parameter in the MySQL [configuration file](#) (`my.cnf` or `my.ini`) but this requires shutting down and restarting the server.

Dynamically changing the value of this parameter requires the [SUPER](#) privilege and immediately affects the operation of all connections.

- `innodb_fill_factor`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_fill_factor=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_fill_factor</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	100
	<b>Min Value</b>	10
	<b>Max Value</b>	100

As of MySQL 5.7.5, InnoDB performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. For example, setting

`innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather than a hard limit.

As of MySQL 5.7.8, an `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth (MySQL Bug #74325).

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries.

For more information, see [Section 15.8.12, “Sorted Index Builds”](#).

- `innodb_flush_log_at_timeout`

<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_log_at_timeout</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	2700

Write and flush the logs every *N* seconds. `innodb_flush_log_at_timeout` was introduced in MySQL 5.6.6. It allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. Prior to MySQL 5.6.6, flushing frequency was once per second. The default setting for `innodb_flush_log_at_timeout` is also once per second.

- `innodb_flush_log_at_trx_commit`

<b>Command-Line Format</b>	<code>--innodb_flush_log_at_trx_commit[=#]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_log_at_trx_commit</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	1
	<b>Valid Values</b>	0
		1
		2

Controls the balance between strict [ACID](#) compliance for [commit](#) operations, and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can

achieve better performance by changing the default value, but then you can lose up to a second of transactions in a crash.

- The default value of 1 is required for full ACID compliance. With this value, the contents of the [InnoDB log buffer](#) are written out to the [log file](#) at each transaction commit and the log file is [flushed](#) to disk.
- With a value of 0, the contents of the [InnoDB log buffer](#) are written to the log file approximately once per second and the log file is flushed to disk. No writes from the log buffer to the log file are performed at transaction commit. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions with any `mysqld` process crash.
- With a value of 2, the contents of the [InnoDB log buffer](#) are written to the log file after each transaction commit and the log file is flushed to disk approximately once per second. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions in an operating system crash or a power outage.
- As of MySQL 5.6.6, [InnoDB log flushing frequency](#) is controlled by [innodb\\_flush\\_log\\_at\\_timeout](#), which allows you to set log flushing frequency to *N* seconds (where *N* is 1 ... 2700, with a default value of 1). However, any `mysqld` process crash can erase up to *N* seconds of transactions.
- DDL changes and other internal [InnoDB](#) activities flush the [InnoDB log](#) independent of the [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) setting.
- [InnoDB's crash recovery](#) works regardless of the [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses [InnoDB](#) with transactions:

- If binary logging is enabled, set [sync\\_binlog=1](#).
- Always set [innodb\\_flush\\_log\\_at\\_trx\\_commit=1](#).

### Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt [InnoDB](#) data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command [hdparm](#) to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

- [innodb\\_flush\\_method](#)

<b>Command-Line Format</b>	<code>--innodb_flush_method=name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_flush_method</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No

<b>Permitted Values (Unix)</b>	<b>Type</b>	string
	<b>Default</b>	NULL
	<b>Valid Values</b>	fsync
		O_DSYNC
		littlesync
		nosync
		O_DIRECT
		O_DIRECT_NO_FSYNC
<b>Permitted Values (Windows)</b>	<b>Type</b>	string
	<b>Default</b>	NULL
	<b>Valid Values</b>	async_unbuffered
		normal
		unbuffered

Defines the method used to [flush](#) data to the [InnoDB data files](#) and [log files](#), which can affect I/O throughput.

If `innodb_flush_method=NULL` on a Unix-like system, the `fsync` option is used by default. If `innodb_flush_method=NULL` on Windows, the `async_unbuffered` option is used by default.

The `innodb_flush_method` options for Unix-like systems include:

- **fsync**: InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.
- **O\_DSYNC**: InnoDB uses `O_DSYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- **littlesync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **nosync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **O\_DIRECT**: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
- **O\_DIRECT\_NO\_FSYNC**: InnoDB uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call afterward. This setting is suitable for some types of file systems but not others. For example, it is not suitable for XFS. If you are not sure whether the file system you use requires an `fsync()`, for example to preserve all file metadata, use `O_DIRECT` instead. This option was introduced in MySQL 5.6.7 (Bug #11754304, Bug #45892).

The `innodb_flush_method` options for Windows systems include:

- **async\_unbuffered**: InnoDB uses Windows asynchronous I/O and non-buffered I/O. `async_unbuffered` is the default setting on Windows systems.
- **normal**: InnoDB uses a simulated asynchronous I/O and buffered I/O.

- `unbuffered`: InnoDB uses a simulated asynchronous I/O and non-buffered I/O.

How each settings affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `InnoDB_data_fsyncks` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system's file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_flush_neighbors`

<b>Command-Line Format</b>	<code>--innodb_flush_neighbors</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_neighbors</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	1
	<b>Valid Values</b>	0
		1
		2

Specifies whether **flushing** a page from the InnoDB **buffer pool** also flushes other **dirty pages** in the same **extent**.

- The default value of 1 flushes contiguous dirty pages in the same extent from the buffer pool.
- A setting of 0 turns `innodb_flush_neighbors` off and no other dirty pages are flushed from the buffer pool.
- A setting of 2 flushes dirty pages in the same extent from the buffer pool.

When the table data is stored on a traditional **HDD** storage device, flushing such **neighbor pages** in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on **SSD**, seek time is not a significant factor and you can turn this setting off to spread out the write operations. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_flush_sync`

<b>Introduced</b>	5.7.8	
<b>Command-Line Format</b>	<code>--innodb_flush_sync=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_sync</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

The `innodb_flush_sync` parameter, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored for bursts of I/O activity that occur at [checkpoints](#). To adhere to the limit on InnoDB background I/O activity defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

- `innodb_flushing_avg_loops`

<b>Command-Line Format</b>	<code>--innodb_flushing_avg_loops=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flushing_avg_loops</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	30
	<b>Min Value</b>	1
	<b>Max Value</b>	1000

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#). Increasing the value makes the rate of [flush](#) operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

- `innodb_force_load_corrupted`

<b>Command-Line Format</b>	<code>--innodb_force_load_corrupted</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_force_load_corrupted</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Lets InnoDB load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, turn this setting back off and restart the server.

- `innodb_force_recovery`

<b>Command-Line Format</b>	<code>--innodb_force_recovery=#</code>
----------------------------	--

<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_force_recovery</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	6

The [crash recovery](#) mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about [innodb\\_force\\_recovery](#), see [Section 15.21.2, “Forcing InnoDB Recovery”](#).

### Warning

Only set this variable to a value greater than 0 in an emergency situation, so that you can start [InnoDB](#) and dump your tables. As a safety measure, [InnoDB](#) prevents [INSERT](#), [UPDATE](#), or [DELETE](#) operations when [innodb\\_force\\_recovery](#) is greater than 0. Also, as of 5.7.3, an [innodb\\_force\\_recovery](#) setting of 4 or greater places [InnoDB](#) into read-only mode.

These restrictions may cause replication administration commands to fail with an error, as replication options such as [--relay-log-info-repository=TABLE](#) and [--master-info-repository=TABLE](#) store information in tables in [InnoDB](#).

- [innodb\\_ft\\_aux\\_table](#)

<b>Command-Line Format</b>	<a href="#">--innodb_ft_aux_table=#</a> ( <a href="#">&gt;= 5.7.2</a> )	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_aux_table</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

Specifies the qualified name of an [InnoDB](#) table containing a [FULLTEXT](#) index. This variable is intended for diagnostic purposes.

After you set this variable to a name in the format [db\\_name/table\\_name](#), the [INFORMATION\\_SCHEMA](#) tables [INNODB\\_FT\\_INDEX\\_TABLE](#), [INNODB\\_FT\\_INDEX\\_CACHE](#), [INNODB\\_FT\\_CONFIG](#), [INNODB\\_FT\\_DELETED](#), and [INNODB\\_FT\\_BEING\\_DELETED](#) will show information about the search index for the specified table.

- [innodb\\_ft\\_cache\\_size](#)

<b>Command-Line Format</b>	<a href="#">--innodb_ft_cache_size=#</a>
----------------------------	--

<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_cache_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	8000000
	<b>Min Value</b>	1600000
	<b>Max Value</b>	80000000

The memory allocated, in bytes, for the [InnoDB FULLTEXT](#) search index cache, which holds a parsed document in memory while creating an [InnoDB FULLTEXT](#) index. Index inserts and updates are only committed to disk when the [innodb\\_ft\\_cache\\_size](#) size limit is reached. [innodb\\_ft\\_cache\\_size](#) defines the cache size on a per table basis. To set a global limit for all tables, see [innodb\\_ft\\_total\\_cache\\_size](#).

- [innodb\\_ft\\_enable\\_diag\\_print](#)

<b>Command-Line Format</b>	<a href="#">--innodb_ft_enable_diag_print=#</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_enable_diag_print</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and will not be of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

```
FTS SYNC for table test, deleted count: 100 size: 10000 bytes
SYNC words: 100
```

- FTS optimize progress. For example:

```
FTS start optimize test
FTS_OPTIMIZE: optimize "mysql"
FTS_OPTIMIZE: processed "mysql"
```

- FTS index build progress. For example:

```
Number of doc processed: 1000
```

- For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

```
FTS Search Processing time: 1 secs: 100 millisc: row(s) 10000
Full Search Memory: 245666 (bytes), Row: 10000
```

- `innodb_ft_enable_stopword`

<b>Command-Line Format</b>	<code>--innodb_ft_enable_stopword=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_enable_stopword</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies that a set of [stopwords](#) is associated with an InnoDB FULLTEXT index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

- `innodb_ft_max_token_size`

<b>Command-Line Format</b>	<code>--innodb_ft_max_token_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_max_token_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	84
	<b>Min Value</b>	10
	<b>Max Value</b>	84
<b>Permitted Values (&lt;= 5.7.2)</b>	<b>Type</b>	integer
	<b>Default</b>	84
	<b>Min Value</b>	10
	<b>Max Value</b>	252
<b>Permitted Values (&gt;= 5.7.3)</b>	<b>Type</b>	integer
	<b>Default</b>	84
	<b>Min Value</b>	10

	<b>Max Value</b>	84
--	------------------	----

Maximum character length of words that are stored in an InnoDB `FULLTEXT` index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

- `innodb_ft_min_token_size`

<b>Command-Line Format</b>	<code>--innodb_ft_min_token_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_min_token_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	3
	<b>Min Value</b>	0
	<b>Max Value</b>	16

Minimum length of words that are stored in an InnoDB `FULLTEXT` index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common word that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

- `innodb_ft_num_word_optimize`

<b>Command-Line Format</b>	<code>--innodb_ft_num_word_optimize=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_num_word_optimize</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	2000

Number of words to process during each `OPTIMIZE TABLE` operation on an InnoDB `FULLTEXT` index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of `OPTIMIZE TABLE` statements, each picking up where the last left off.

- `innodb_ft_result_cache_limit`

<b>Introduced</b>	5.7.2
<b>Command-Line Format</b>	<code>--innodb_ft_result_cache_limit=#</code>
<b>System Variable</b>	<b>Name</b> <code>innodb_ft_result_cache_limit</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (>= 5.7.4)	<b>Type</b>	integer
	<b>Default</b>	2000000000
	<b>Min Value</b>	1000000
	<b>Max Value</b>	$2^{32}-1$
<b>Permitted Values</b> (Unix, 32-bit platforms, >= 5.7.2, <= 5.7.3)	<b>Type</b>	integer
	<b>Default</b>	2000000000
	<b>Min Value</b>	1000000
	<b>Max Value</b>	$2^{32}-1$
<b>Permitted Values</b> (Unix, 64-bit platforms, >= 5.7.2, <= 5.7.3)	<b>Type</b>	integer
	<b>Default</b>	2000000000
	<b>Min Value</b>	1000000
	<b>Max Value</b>	$2^{64}-1$
<b>Permitted Values</b> (Windows, >= 5.7.2, <= 5.7.3)	<b>Type</b>	integer
	<b>Default</b>	2000000000
	<b>Min Value</b>	1000000
	<b>Max Value</b>	$2^{32}-1$

The [InnoDB](#) FULLTEXT search (FTS) query result cache limit (defined in bytes) per FTS query or per thread. Intermediate and final [InnoDB](#) FTS query results are handled in memory. Use [innodb\\_ft\\_result\\_cache\\_limit](#) to place a size limit on the [InnoDB](#) FTS query result cache to avoid excessive memory consumption in case of very large [InnoDB](#) FTS query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when an FTS query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

As of MySQL 5.7.4, the maximum value of [innodb\\_ft\\_result\\_cache\\_limit](#) for all platform types and platform bit sizes is  $2^{32}-1$ . Bug #71554.

- [innodb\\_ft\\_server\\_stopword\\_table](#)

<b>Command-Line Format</b>	<code>--innodb_ft_server_stopword_table=db_name/table_name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_server_stopword_table</a>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	NULL

This option is used to specify your own [InnoDB FULLTEXT](#) index stopwords list for all [InnoDB](#) tables. To configure your own stopwords list for a specific [InnoDB](#) table, use [innodb\\_ft\\_user\\_stopword\\_table](#).

Set [innodb\\_ft\\_server\\_stopword\\_table](#) to the name of the table containing a list of stopwords, in the format *db\_name/table\_name*.

The stopwords table must exist before you configure [innodb\\_ft\\_server\\_stopword\\_table](#). [innodb\\_ft\\_enable\\_stopword](#) must be enabled and [innodb\\_ft\\_server\\_stopword\\_table](#) option must be configured before you create the [FULLTEXT](#) index.

The stopwords table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named *value*.

For more information, see [Section 13.9.4, “Full-Text Stopwords”](#).

- [innodb\\_ft\\_sort\\_pll\\_degree](#)

<b>Command-Line Format</b>	<code>--innodb_ft_sort_pll_degree=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_sort_pll_degree</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	2
	<b>Min Value</b>	1
	<b>Max Value</b>	32

Number of threads used in parallel to index and tokenize text in an [InnoDB FULLTEXT](#) index, when building a [search index](#). See [innodb\\_sort\\_buffer\\_size](#) for additional usage information.

- [innodb\\_ft\\_total\\_cache\\_size](#)

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--innodb_ft_total_cache_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_total_cache_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	640000000

	<b>Min Value</b>	32000000
	<b>Max Value</b>	1600000000

The total memory allocated, in bytes, for the [InnoDB FULLTEXT](#) search index cache for all tables. Creating numerous tables, each with a full-text search index, could consume a significant portion of available memory. [innodb\\_ft\\_total\\_cache\\_size](#), defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a force sync is triggered.

- [innodb\\_ft\\_user\\_stopword\\_table](#)

<b>Command-Line Format</b>	<code>--innodb_ft_user_stopword_table=db_name/table_name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_user_stopword_table</a>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<a href="#">NULL</a>

This option is used to specify your own [InnoDB FULLTEXT](#) index stopwords list on a specific table. To configure your own stopwords list for all [InnoDB](#) tables, use [innodb\\_ft\\_server\\_stopword\\_table](#).

Set [innodb\\_ft\\_user\\_stopword\\_table](#) to the name of the table containing a list of stopwords, in the format *db\_name/table\_name*.

The stopwords table must exist before you configure [innodb\\_ft\\_user\\_stopword\\_table](#). [innodb\\_ft\\_enable\\_stopword](#) must be enabled and [innodb\\_ft\\_user\\_stopword\\_table](#) must be configured before you create the [FULLTEXT](#) index.

The stopwords table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named *value*.

For more information, see [Section 13.9.4, “Full-Text Stopwords”](#).

- [innodb\\_io\\_capacity](#)

<b>Command-Line Format</b>	<code>--innodb_io_capacity=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_io_capacity</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (32-bit platforms)</b>	<b>Type</b>	integer
	<b>Default</b>	200
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{32}-1$

<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	200
	<b>Min Value</b>	100
	<b>Max Value</b>	2**64-1

The `innodb_io_capacity` parameter sets an upper limit on I/O activity performed by InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the change buffer.

The `innodb_io_capacity` limit is a total limit for all buffer pool instances. When dirty pages are flushed, the limit is divided equally among buffer pool instances.

`innodb_io_capacity` should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly for caching to provide a significant benefit.

The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes.

In general, you can increase the value as a function of the number of drives used for InnoDB I/O. For example, you can increase the value on systems that use multiple disks or solid-state disks (SSD).

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that could perform about 100 IOPS.

Although you can specify a very high value such as one million, in practice such large values have little if any benefit. Generally, a value of 20000 or higher is not recommended unless you have proven that lower values are insufficient for your workload.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

You can set `innodb_io_capacity` to any number 100 or greater to a maximum defined by `innodb_io_capacity_max`. `innodb_io_capacity` can be set in the MySQL option file (`my.cnf` or `my.ini`) or changed dynamically using a `SET GLOBAL` statement, which requires the `SUPER` privilege.

The `innodb_flush_sync` configuration option, introduced in MySQL 5.7.8, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. `innodb_flush_sync` is enabled by default.

See [Section 15.6.8, “Configuring the InnoDB Master Thread I/O Rate”](#) for more guidelines about this option. For general information about InnoDB I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_io_capacity_max`

<b>Command-Line Format</b>	<code>--innodb_io_capacity_max=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_io_capacity_max</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<a href="#">see description</a>
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{32}-1$
<b>Permitted Values</b> (Unix, 64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<a href="#">see description</a>
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{64}-1$
<b>Permitted Values</b> (Windows, 64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<a href="#">see description</a>
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{32}-1$

If flushing activity falls behind, InnoDB can flush more aggressively than the limit imposed by `innodb_io_capacity`. `innodb_io_capacity_max` defines an upper limit for I/O capacity in such situations.

The `innodb_io_capacity_max` setting is a total limit for all buffer pool instances.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity`, with a minimum value of 2000.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use a solid-state disk (SSD) or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSD or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend beyond the `innodb_io_capacity` limit if necessary.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to `DEFAULT` using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the maximum value.

For a brief period during MySQL 5.6 development, this variable was known as `innodb_max_io_capacity`.

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_large_prefix`

<b>Deprecated</b>	5.7.7	
<b>Command-Line Format</b>	<code>--innodb_large_prefix</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_large_prefix</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>ON</code>

When this option is enabled, index key prefixes longer than 767 bytes (up to 3072 bytes) are allowed for InnoDB tables that use the `DYNAMIC` and `COMPRESSED` row formats. See [Section 15.8.8, “Limits on InnoDB Tables”](#) for the relevant maximums associated with index key prefixes under various settings.

For tables that use the `REDUNDANT` and `COMPACT` row formats, this option does not affect the permitted index key prefix length.

`innodb_large_prefix` is enabled by default in MySQL 5.7.7. This change coincides with the default value change for `innodb_file_format`, which is set to `Barracuda` by default in MySQL 5.7.7. Together, these default value changes allow larger index key prefixes to be created when using `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`. If either option is set to a non-default value, index key prefixes larger than 767 bytes are silently truncated.

`innodb_large_prefix` is deprecated in MySQL 5.7.7 and will be removed in a future release. `innodb_large_prefix` was introduced in MySQL 5.5 to disable large index key prefixes for compatibility with earlier versions of InnoDB that do not support large index key prefixes.

- `innodb_limit_optimistic_insert_debug`

<b>Command-Line Format</b>	<code>--innodb_limit_optimistic_insert_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_limit_optimistic_insert_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>0</code>
	<b>Min Value</b>	<code>0</code>

	<b>Max Value</b>	2**32-1
--	------------------	---------

Limits the number of records per [B-tree](#) page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_lock_wait_timeout`

<b>Command-Line Format</b>	<code>--innodb_lock_wait_timeout=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_lock_wait_timeout</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	50
	<b>Min Value</b>	1
	<b>Max Value</b>	1073741824

The length of time in seconds an [InnoDB transaction](#) waits for a [row lock](#) before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another [InnoDB](#) transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is [rolled back](#) (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 15.21.4, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or [OLTP](#) systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to [InnoDB](#) row locks only. A MySQL [table lock](#) does not happen inside [InnoDB](#) and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to [deadlocks](#) when `innodb_deadlock_detect` is enabled (the default) because [InnoDB](#) detects deadlocks immediately and rolls back one of the deadlocked transactions. When `innodb_deadlock_detect` is disabled, [InnoDB](#) relies on `innodb_lock_wait_timeout` for transaction rollback when a deadlock occurs.

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires the [SUPER](#) privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_locks_unsafe_for_binlog`

<b>Deprecated</b>	5.6.3	
<b>Command-Line Format</b>	<code>--innodb_locks_unsafe_for_binlog</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_locks_unsafe_for_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

This variable affects how InnoDB uses [gap locking](#) for searches and index scans. As of MySQL 5.6.3, `innodb_locks_unsafe_for_binlog` is deprecated and will be removed in a future MySQL release.

Normally, InnoDB uses an algorithm called next-key locking that combines index-row locking with [gap locking](#). InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order. See [Section 15.5.1, “InnoDB Locking”](#).

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effects of enabling `innodb_locks_unsafe_for_binlog` are the same as setting the transaction isolation level to `READ COMMITTED`, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For additional details about the effect of isolation level on gap locking, see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if `innodb_locks_unsafe_for_binlog` is enabled, InnoDB guarantees at most an isolation level of `READ COMMITTED`. (Conflict serializability is still guaranteed.) For additional information about phantoms, see [Section 15.5.4, “Phantom Rows”](#).

Enabling `innodb_locks_unsafe_for_binlog` has additional effects:

- For `UPDATE` or `DELETE` statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For `UPDATE` statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 15.8.9, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an `UPDATE` using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an `UPDATE` by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As InnoDB executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If InnoDB does not modify the row and `innodb_locks_unsafe_for_binlog` is enabled, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

If `innodb_locks_unsafe_for_binlog` is disabled, the first `UPDATE` acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `innodb_locks_unsafe_for_binlog` is enabled, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, InnoDB does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

- `innodb_log_buffer_size`

Command-Line Format	<code>--innodb_log_buffer_size=#</code>	
System Variable	Name	<code>innodb_log_buffer_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values (<= 5.7.5)	Type	integer
	Default	8388608
	Min Value	262144
	Max Value	4294967295
Permitted Values (>= 5.7.6)	Type	integer
	Default	16777216
	Min Value	1048576
	Max Value	4294967295

The size in bytes of the buffer that InnoDB uses to write to the `log files` on disk. The default value changed from 8MB to 16MB in 5.7.6 with the introduction of 32k and 64k `innodb_page_size` values. A large `log buffer` enables large `transactions` to run without a need to write the log to disk before the transactions `commit`. Thus, if you have transactions that update, insert, or delete many rows, making the

log buffer larger saves disk I/O. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_log_checksum_algorithm`

<b>Introduced</b>	5.7.8	
<b>Removed</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_log_checksum_algorithm=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_log_checksum_algorithm</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>innodb</code>
	<b>Valid Values</b>	<code>innodb</code>
		<code>crc32</code>
		<code>none</code>
		<code>strict_innodb</code>
		<code>strict_crc32</code>
		<code>strict_none</code>

This configuration option was removed in MySQL 5.7.9 and replaced by `innodb_log_checksums`.

Specifies how to generate and verify the [checksum](#) stored in each redo log disk block. `innodb_log_checksum_algorithm` supports same algorithms as `innodb_checksum_algorithm`. Previously, only the `innodb` algorithm was supported for redo log disk blocks. `innodb_log_checksum_algorithm=innodb` is the default setting.

The `strict_*` forms work the same as `innodb`, `crc32`, and `none`, except that InnoDB halts if it encounters a mix of checksum values in the same redo log. You can only use these options in a completely new instance. The `strict_*` settings are somewhat faster, because they do not need to compute both new and old checksum values to accept both during disk reads.

The following table illustrates the difference between the `none`, `innodb`, and `crc32` option values, and their `strict_*` counterparts. `none`, `innodb`, and `crc32` write the specified type checksum value into each data block, but for compatibility accept any of the other checksum values when verifying a block during a read operation. The `strict_*` form of each parameter only recognizes one kind of checksum, which makes verification faster but requires that all InnoDB redo logs in an instance be created under the identical `innodb_log_checksum_algorithm` value.

**Table 15.14 Allowed Settings for `innodb_log_checksum_algorithm`**

Value	Generated checksum (when writing)	Allowed checksums (when reading)
none	A constant number.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .

Value	Generated checksum (when writing)	Allowed checksums (when reading)
crc32	A checksum calculated using the <a href="#">crc32</a> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <a href="#">none</a> , <a href="#">innodb</a> , or <a href="#">crc32</a> .
strict_none	A constant number	Only the checksum generated by <a href="#">none</a> .
strict_innodb	A checksum calculated in software, using the original algorithm from <a href="#">InnoDB</a> .	Only the checksum generated by <a href="#">innodb</a> .
strict_crc32	A checksum calculated using the <a href="#">crc32</a> algorithm, possibly done with a hardware assist.	Only the checksum generated by <a href="#">crc32</a> .

- [innodb\\_log\\_checksums](#)

<b>Introduced</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_log_checksums=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_checksums</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">ON</a>

Enables or disables checksums for redo log pages. [innodb\\_log\\_checksums](#) replaces [innodb\\_log\\_checksum\\_algorithm](#), which was removed in MySQL 5.7.9.

[innodb\\_log\\_checksums=ON](#) enables the [CRC-32C](#) checksum algorithm for redo log pages. When [innodb\\_log\\_checksums](#) is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

- [innodb\\_log\\_compressed\\_pages](#)

<b>Command-Line Format</b>	<code>--innodb_log_compressed_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_compressed_pages</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">ON</a>

Specifies whether images of [re-compressed pages](#) are written to the [redo log](#). Re-compression may occur when changes are made to compressed data.

[innodb\\_log\\_compressed\\_pages](#) is enabled by default to prevent corruption that could occur if a different version of the [zlib](#) compression algorithm is used during recovery. If you are certain that the

`zlib` version will not change, you can disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling `innodb_log_compressed_pages`, compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the `Log sequence number` (LSN) in the `LOG` section of `SHOW ENGINE INNODB STATUS` output, or monitoring `Innodb_os_log_written` status for the number of bytes written to the redo log files.

- `innodb_log_file_size`

<b>Command-Line Format</b>	<code>--innodb_log_file_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_log_file_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.10)</b>	<b>Type</b>	integer
	<b>Default</b>	50331648
	<b>Min Value</b>	1048576
	<b>Max Value</b>	512GB / <code>innodb_log_files_in_group</code>
<b>Permitted Values (&gt;= 5.7.11)</b>	<b>Type</b>	integer
	<b>Default</b>	50331648
	<b>Min Value</b>	4194304
	<b>Max Value</b>	512GB / <code>innodb_log_files_in_group</code>

The size in bytes of each `log file` in a `log group`. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, would allow you to approach the limit but not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. Larger log files also make `crash recovery` slower, although improvements to recovery performance in MySQL 5.5 and higher make the log file size less of a consideration. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

The minimum `innodb_log_file_size` value was increased from 1MB to 4MB in MySQL 5.7.11.

- `innodb_log_files_in_group`

<b>Command-Line Format</b>	<code>--innodb_log_files_in_group=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_log_files_in_group</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	2
	<b>Min Value</b>	2
	<b>Max Value</b>	100

The number of [log files](#) in the [log group](#). InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of these files is specified by [innodb\\_log\\_group\\_home\\_dir](#). The combined size of log files ([innodb\\_log\\_file\\_size](#) \* [innodb\\_log\\_files\\_in\\_group](#)) can be up to 512GB.

- [innodb\\_log\\_group\\_home\\_dir](#)

<b>Command-Line Format</b>	<code>--innodb_log_group_home_dir=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_group_home_dir</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	directory name

The directory path to the InnoDB [redo log](#) files, whose number is specified by [innodb\\_log\\_files\\_in\\_group](#). If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Their size is given by the size of the [innodb\\_log\\_file\\_size](#) system variable.

- [innodb\\_log\\_write\\_ahead\\_size](#)

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_log_write_ahead_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_write_ahead_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	8192
	<b>Min Value</b>	512 (log file block size)
	<b>Max Value</b>	Equal to <a href="#">innodb_page_size</a>

The write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set [innodb\\_log\\_write\\_ahead\\_size](#) to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file

system due to a mismatch between write-ahead block size for redo logs and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size ( $2^n$ ). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to `innodb_page_size`. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` value is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size will result in “read-on-write”. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

- `innodb_lru_scan_depth`

<b>Command-Line Format</b>	<code>--innodb_lru_scan_depth=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_lru_scan_depth</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	1024
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{32}-1$
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	1024
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{64}-1$

A parameter that influences the algorithms and heuristics for the `flush` operation for the InnoDB buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed once a second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth` \* `innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct`

<b>Command-Line Format</b>	<code>--innodb_max_dirty_pages_pct=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_dirty_pages_pct</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.4)</b>	<b>Type</b>	numeric
	<b>Default</b>	75
	<b>Min Value</b>	0
	<b>Max Value</b>	99
<b>Permitted Values (&gt;= 5.7.5)</b>	<b>Type</b>	numeric
	<b>Default</b>	75
	<b>Min Value</b>	0
	<b>Max Value</b>	99.99

InnoDB tries to [flush](#) data from the [buffer pool](#) so that the percentage of [dirty pages](#) does not exceed this value. The default value is 75.

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).

For additional information about this variable, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct_lwm`

<b>Command-Line Format</b>	<code>--innodb_max_dirty_pages_pct_lwm=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_dirty_pages_pct_lwm</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.4)</b>	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	99
<b>Permitted Values (&gt;= 5.7.5)</b>	<b>Type</b>	numeric

## InnoDB System Variables

	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	99.99

Low water mark representing percentage of [dirty pages](#) where preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely. For additional information about this variable, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_max_purge_lag`

<b>Command-Line Format</b>	<code>--innodb_max_purge_lag=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_purge_lag</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

This variable controls how to delay `INSERT`, `UPDATE`, and `DELETE` operations when `purge` operations are lagging (see [Section 15.3, “InnoDB Multi-Versioning”](#)). The default value is 0 (no delays).

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by `UPDATE` or `DELETE` operations. The length of this list represents the `purge_lag` value. When `purge_lag` exceeds `innodb_max_purge_lag`, each `INSERT`, `UPDATE`, and `DELETE` operation is delayed.

To prevent excessive delays in extreme situations where `purge_lag` becomes huge, you can put a cap on the amount of delay by setting the `innodb_max_purge_lag_delay` configuration option. The delay is computed at the beginning of a purge batch.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged InnoDB table rows.

The lag value is displayed as the history list length in the `TRANSACTIONS` section of InnoDB Monitor output. For example, if the output includes the following lines, the lag value is 20:

```
-----
TRANSACTIONS
-----
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_purge_lag_delay`

<b>Command-Line Format</b>	<code>--innodb_max_purge_lag_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_purge_lag_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0

Specifies the maximum delay in milliseconds for the delay imposed by the `innodb_max_purge_lag` configuration option. Any non-zero value represents an upper limit on the delay period computed from the formula based on the value of `innodb_max_purge_lag`. The default of zero means that there is no upper limit imposed on the delay interval.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_undo_log_size`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_max_undo_log_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_undo_log_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1073741824
	<b>Min Value</b>	10485760
	<b>Max Value</b>	$2^{64}-1$

`innodb_max_undo_log_size` defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1024 MiB (1073741824 bytes).

For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_merge_threshold_set_all_debug`

<b>Introduced</b>	5.7.6	
<b>Command-Line Format</b>	<code>--innodb_merge_threshold_set_all_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_merge_threshold_set_all_debug</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	50
	<b>Min Value</b>	1
	<b>Max Value</b>	50

Overrides the current `MERGE_THRESHOLD` setting with the specified value for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option. For related information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `innodb_monitor_disable`

<b>Command-Line Format</b>	<code>--innodb_monitor_disable=[counter module pattern all]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_disable</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

Turns off one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

As of MySQL 5.7.8, `innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 14.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_enable`

<b>Command-Line Format</b>	<code>--innodb_monitor_enable=[counter module pattern all]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_enable</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

Turns on one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

As of MySQL 5.7.8, `innodb_monitor_enable='latch'` enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 14.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset`

<b>Command-Line Format</b>	<code>--innodb_monitor_reset=[counter module pattern all]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_reset</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

Resets to zero the count value for one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

As of MySQL 5.7.8, `innodb_monitor_reset='latch'` resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 14.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset_all`

<b>Command-Line Format</b>	<code>--innodb_monitor_reset_all=[counter module pattern all]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_reset_all</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

Resets all values (minimum, maximum, and so on) for one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

- `innodb_numa_interleave`

<b>Introduced</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_numa_interleave=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_numa_interleave</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Enables the NUMA interleave memory policy for allocation of the [InnoDB](#) buffer pool. When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the [InnoDB](#) buffer pool is allocated, the NUMA memory policy is set back to `MPOL_DEFAULT`. For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

- `innodb_old_blocks_pct`

<b>Command-Line Format</b>	<code>--innodb_old_blocks_pct=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_old_blocks_pct</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	37
	<b>Min Value</b>	5
	<b>Max Value</b>	95

Specifies the approximate percentage of the [InnoDB buffer pool](#) used for the old block [sublist](#). The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with `innodb_old_blocks_time`. See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information. See [Section 15.6.3.1, “The InnoDB Buffer Pool”](#) for information about buffer pool management, such as the [LRU](#) algorithm and [eviction](#) policies.

- `innodb_old_blocks_time`

<b>Command-Line Format</b>	<code>--innodb_old_blocks_time=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_old_blocks_time</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1000
	<b>Min Value</b>	0
	<b>Max Value</b>	$2^{32}-1$

Non-zero values protect against the [buffer pool](#) being filled up by data that is referenced only for a brief period, such as during a [full table scan](#). Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds (ms) a block inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many ms after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This variable is often used in combination with `innodb_old_blocks_pct`. See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information. See [Section 15.6.3.1, “The InnoDB Buffer Pool”](#) for information about buffer pool management, such as the [LRU](#) algorithm and [eviction](#) policies.

- `innodb_online_alter_log_max_size`

<b>Command-Line Format</b>	<code>--innodb_online_alter_log_max_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_online_alter_log_max_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	134217728
	<b>Min Value</b>	65536
	<b>Max Value</b>	$2^{64}-1$

Specifies an upper limit on the size of the temporary log files used during [online DDL](#) operations for [InnoDB](#) tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If any temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also causes a longer period at the end of the DDL operation when the table is locked to apply the data from the log.

- `innodb_open_files`

<b>Command-Line Format</b>	<code>--innodb_open_files=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_open_files</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	-1 (autosized)
	<b>Min Value</b>	10
	<b>Max Value</b>	4294967295

This variable is relevant only if you use multiple [InnoDB tablespaces](#). It specifies the maximum number of `.ibd` files that MySQL can keep open at one time. The minimum value is 10. The default value is 300 if `innodb_file_per_table` is not enabled, and the higher of 300 and `table_open_cache` otherwise.

The file descriptors used for `.ibd` files are for InnoDB tables only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_optimize_fulltext_only`

<b>Command-Line Format</b>	<code>--innodb_optimize_fulltext_only=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_optimize_fulltext_only</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Changes the way the `OPTIMIZE TABLE` statement operates on InnoDB tables. Intended to be enabled temporarily, during maintenance operations for InnoDB tables with `FULLTEXT` indexes.

By default, `OPTIMIZE TABLE` reorganizes the data in the [clustered index](#) of the table. When this option is enabled, `OPTIMIZE TABLE` skips this reorganization of the table data, and instead processes the newly added, deleted, and updated token data for a `FULLTEXT` index. See [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#) for more information about `FULLTEXT` indexes for InnoDB tables.

- `innodb_optimize_point_storage`

<b>Introduced</b>	5.7.5	
<b>Removed</b>	5.7.6	
<b>Command-Line Format</b>	<code>--innodb_optimize_point_storage=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_optimize_point_storage</code>
	<b>Variable Scope</b>	Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Enable this variable before creating a column of type `POINT` to store the `POINT` data type internally as variable-length `BLOB` data.

This variable was removed in MySQL 5.7.6.

- `innodb_page_cleaners`

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_page_cleaners=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_page_cleaners</code>
	<b>Variable Scope</b>	Global

	Dynamic Variable	No
<b>Permitted Values (&lt;= 5.7.7)</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	64
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	integer
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of page cleaner threads that flush dirty pages from buffer pool instances. The page cleaner threads perform flush list and LRU flushing. A single page cleaner thread was introduced in MySQL 5.6.2 to offload buffer pool flushing work from the [InnoDB](#) master thread. As of MySQL 5.7.4, [InnoDB](#) provides support for multiple page cleaner threads. A value of 1 maintains the pre-MySQL 5.7.4 configuration in which there is a single page cleaner thread. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The [innodb\\_page\\_cleaners](#) default value was changed from 1 to 4 in MySQL 5.7.8. If the number of page cleaner threads exceeds the number of buffer pool instances, [innodb\\_page\\_cleaners](#) is automatically set to the same value as [innodb\\_buffer\\_pool\\_instances](#).

If your workload is write-IO bound (when flushing dirty pages from buffer pool instances to data files) and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multi-threaded page cleaner support is extended to shutdown and recovery phases in MySQL 5.7.5.

As of MySQL 5.7.6, the [setpriority\(\)](#) system call is used on Linux platforms (where it is supported and where the [mysqld](#) execution user is authorized) to give [page\\_cleaner](#) threads priority over other MySQL/InnoDB threads to help page flushing keep pace with the current workload. [mysqld](#) execution user authorization can be configured in [/etc/security/limits.conf](#). For example, if [mysqld](#) is run under the [mysql](#) user, you might authorize the [mysql](#) user by adding lines similar to the following to [/etc/security/limits.conf](#):

```
mysql      hard    nice    -20
mysql      soft    nice    -20
```

Refer to your Linux operating system documentation for more information.

- [innodb\\_page\\_size](#)

<b>Command-Line Format</b>	<a href="#">--innodb_page_size=#k</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_page_size</a>
	<b>Variable Scope</b>	Global

	Dynamic Variable	No
Permitted Values (<= 5.7.5)	Type	enumeration
	Default	16384
	Valid Values	4k
		8k
		16k
		4096
		8192
		16384
Permitted Values (>= 5.7.6)	Type	enumeration
	Default	16384
	Valid Values	4k
		8k
		16k
		32k
		64k
		4096
		8192
		16384
		32768
		65536

Specifies the [page size](#) for all [InnoDB tablespaces](#) in a MySQL [instance](#). You can specify page size using the values 64k, 32k, [16k](#) (the default), [8k](#), or [4k](#). Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

#### Important

[innodb\\_page\\_size](#) can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size.

Support for 32k and 64k page sizes was added in MySQL 5.7.6. For both 32k and 64k page sizes, the maximum row length is approximately 16000 bytes. [ROW\\_FORMAT=COMPRESSED](#) is not supported when [innodb\\_page\\_size](#) is set to 32KB or 64KB. For [innodb\\_page\\_size=32k](#), extent size is 2MB. For [innodb\\_page\\_size=64k](#), extent size is 4MB. [innodb\\_log\\_buffer\\_size](#) should be set to at least 16M (which is the default as of MySQL 5.7.6) when using 32k or 64k page sizes.

The default page size of 16KB and larger is appropriate for a wide range of [workloads](#), particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for [OLTP](#) workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with [SSD](#) storage devices, which typically use small block sizes. Keeping the [InnoDB](#) page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file (`ibdata1`) differs depending on the `innodb_page_size` value. See the `innodb_data_file_path` option description for more information.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_print_all_deadlocks`

<b>Command-Line Format</b>	<code>--innodb_print_all_deadlocks=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_print_all_deadlocks</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

When this option is enabled, information about all [deadlocks](#) in InnoDB user transactions is recorded in the `mysqld error log`. Otherwise, you see information about only the last deadlock, using the `SHOW ENGINE INNODB STATUS` command. An occasional InnoDB deadlock is not necessarily an issue, because InnoDB detects the condition immediately, and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are happening if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue [DML](#) or `SELECT ... FOR UPDATE` statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

- `innodb_purge_batch_size`

<b>Command-Line Format</b>	<code>--innodb_purge_batch_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_purge_batch_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>300</code>
	<b>Min Value</b>	<code>1</code>
	<b>Max Value</b>	<code>5000</code>

Defines the number of undo log pages that purge parses and processes in one batch from the [history list](#). In a multi-threaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread. The `innodb_purge_batch_size` option also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The `innodb_purge_batch_size` option is intended for advanced performance tuning in combination with the `innodb_purge_threads` setting. Most MySQL users need not change `innodb_purge_batch_size` from its default value.

- `innodb_purge_threads`

<b>Command-Line Format</b>	<code>--innodb_purge_threads=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_purge_threads</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.7)</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	32
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	integer
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	32

The number of background threads devoted to the `InnoDB purge` operation. A minimum value of 1 signifies that the purge operation is always performed by a background thread, never as part of the `master thread`. Running the purge operation in one or more background threads helps reduce internal contention within `InnoDB`, improving scalability. Increasing the value to greater than 1 creates that many separate purge threads, which can improve efficiency on systems where `DML` operations are performed on multiple tables. The maximum is 32.

The `innodb_purge_threads` default value was changed from 1 to 4 in MySQL 5.7.8.

- `innodb_purge_rseg_truncate_frequency`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_purge_rseg_truncate_frequency=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_purge_rseg_truncate_frequency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	128
	<b>Min Value</b>	1

	<b>Max Value</b>	128
--	------------------	-----

`innodb_purge_rseg_truncate_frequency` defines the frequency with which the purge system frees rollback segments. An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. Reducing the `innodb_purge_rseg_truncate_frequency` value increases the frequency with which the purge thread frees rollback segments. The default value is 128.

`innodb_purge_rseg_truncate_frequency` is intended for use with `innodb_undo_log_truncate`. For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_random_read_ahead`

<b>Command-Line Format</b>	<code>--innodb_random_read_ahead=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_random_read_ahead</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Enables the random [read-ahead](#) technique for optimizing InnoDB I/O.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for details about the performance considerations for the different types of read-ahead requests. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_ahead_threshold`

<b>Command-Line Format</b>	<code>--innodb_read_ahead_threshold=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_read_ahead_threshold</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	56
	<b>Min Value</b>	0
	<b>Max Value</b>	64

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#). If InnoDB reads at least `innodb_read_ahead_threshold` pages sequentially from an [extent](#) (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through this read-ahead mechanism, and how many of them are evicted from the buffer pool without ever being accessed, can be useful to help fine-tune the `innodb_read_ahead_threshold` parameter. As of MySQL 5.5, `SHOW ENGINE INNODB STATUS` output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables. These variables indicate the number of pages brought into the [buffer pool](#) by read-ahead requests, and the number of such pages [evicted](#) from the buffer pool without ever being accessed respectively. These counters provide global values since the last server restart.

`SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the [BUFFER POOL AND MEMORY](#) section of the output.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_io_threads`

<b>Command-Line Format</b>	<code>--innodb_read_io_threads=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_read_io_threads</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of I/O threads for read operations in InnoDB. The default value is 4. Its counterpart for write threads is `innodb_write_io_threads`. See [Section 15.6.7, “Configuring the Number of Background InnoDB I/O Threads”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

- `innodb_read_only`

<b>Command-Line Format</b>	<code>--innodb_read_only=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_read_only</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Starts [InnoDB](#) in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. See [Section 15.6.2, “Configuring InnoDB for Read-Only Operation”](#) for usage instructions.

- [innodb\\_replication\\_delay](#)

<b>Command-Line Format</b>	--innodb_replication_delay=#	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_replication_delay</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

The replication thread delay (in ms) on a slave server if [innodb\\_thread\\_concurrency](#) is reached.

- [innodb\\_rollback\\_on\\_timeout](#)

<b>Command-Line Format</b>	--innodb_rollback_on_timeout	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_rollback_on_timeout</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

In MySQL 5.7, [InnoDB rolls back](#) only the last statement on a transaction timeout by default. If [--innodb\\_rollback\\_on\\_timeout](#) is specified, a transaction timeout causes [InnoDB](#) to abort and roll back the entire transaction.

- [innodb\\_rollback\\_segments](#)

<b>Command-Line Format</b>	--innodb_rollback_segments=#	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_rollback_segments</a>

## InnoDB System Variables

<b>Permitted Values</b>	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
	<b>Type</b>	integer
	<b>Default</b>	128
	<b>Min Value</b>	1
	<b>Max Value</b>	128

Defines how many of the [rollback segments](#) in the [system tablespace](#) are used for InnoDB [transactions](#). This setting, while still valid, is replaced by [innodb\\_undo\\_logs](#).

- [innodb\\_saved\\_page\\_number\\_debug](#)

<b>Command-Line Format</b>	<code>--innodb_saved_page_number_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_saved_page_number_debug</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Max Value</b>	$2^{23}-1$

Saves a page number. Setting the [innodb\\_fil\\_make\\_page\\_dirty\\_debug](#) option dirties the page defined by [innodb\\_saved\\_page\\_number\\_debug](#). The [innodb\\_saved\\_page\\_number\\_debug](#) option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- [innodb\\_sort\\_buffer\\_size](#)

<b>Command-Line Format</b>	<code>--innodb_sort_buffer_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_sort_buffer_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1048576
	<b>Min Value</b>	65536
	<b>Max Value</b>	67108864

Specifies the size of sort buffers used for sorting data during creation of an [InnoDB](#) index. The size specified defines the amount of data filled in memory for an internal sort and written out to disk, which can be referred to as a “run”. During the merge phase, pairs of buffers of the specified size are “read in” and merged. The larger the setting, the fewer “runs” and merges there are, which is important to understand from a tuning perspective.

This sort area is only used for merge sorts during index creation, not during later index maintenance operations. Buffers are deallocated when index creation completes.

The value of this option also controls the amount by which the temporary log file is extended, to record concurrent DML during [online DDL](#) operations.

Before this setting was made configurable, the size was hardcoded to 1048576 bytes (1MB), and that value remains the default.

During an [ALTER TABLE](#) or [CREATE TABLE](#) statement that creates an index, 3 buffers are allocated, each with a size defined by this option. Additionally, auxiliary pointers are allocated to rows in the sort buffer so that the sort can run on pointers (as opposed to moving rows during the sort operation).

For a typical sort operation, a formula such as this can be used to estimate memory consumption:

```
(6 /*FTS_NUM_AUX_INDEX*/ * (3*@@global.innodb_sort_buffer_size)
+ 2 * number_of_partitions * number_of_secondary_indexes_created
* (@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*/)
* 8 /*64-bit sizeof *buf->tuples*/)
```

`@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)` indicates the maximum tuples held. `2 * (@@global.innodb_sort_buffer_size/*dict_index_get_min_size(index)*/) * 8 /*64-bit size of *buf->tuples*/` indicates auxiliary pointers allocated.

#### Note

For 32-bit, multiply by 4 instead of 8.

For parallel sorts on a full-text index, multiply by the `innodb_ft_sort_pll_degree` setting:

```
(6 /*FTS_NUM_AUX_INDEX*/ * @@global.innodb_ft_sort_pll_degree)
```

- [innodb\\_spin\\_wait\\_delay](#)

<b>Command-Line Format</b>	<code>--innodb_spin_wait_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_spin_wait_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	6
	<b>Min Value</b>	0

## InnoDB System Variables

	<b>Max Value</b>	2**32-1
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	6
	<b>Min Value</b>	0
	<b>Max Value</b>	2**64-1

The maximum delay between polls for a [spin](#) lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. The default value is 6. See [Section 15.6.9, “Configuring Spin Lock Polling”](#) for more information.

- [innodb\\_stats\\_auto\\_recalc](#)

<b>Command-Line Format</b>	<code>--innodb_stats_auto_recalc=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_stats_auto_recalc</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">ON</a>

Causes [InnoDB](#) to automatically recalculate [persistent statistics](#) after the data in a table is changed substantially. The threshold value is currently 10% of the rows in the table. This setting applies to tables created when the [innodb\\_stats\\_persistent](#) option is enabled, or where the clause [STATS\\_PERSISTENT=1](#) is enabled by a [CREATE TABLE](#) or [ALTER TABLE](#) statement. The amount of data sampled to produce the statistics is controlled by the [innodb\\_stats\\_persistent\\_sample\\_pages](#) configuration option.

For additional information about [innodb\\_stats\\_auto\\_recalc](#), see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- [innodb\\_stats\\_include\\_delete\\_marked](#)

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--innodb_stats_include_delete_marked=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_stats_include_delete_marked</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">OFF</a>

By default, [InnoDB](#) reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, [InnoDB](#) excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than [READ UNCOMMITTED](#). To avoid this scenario, [innodb\\_stats\\_include\\_delete\\_marked](#) can be enabled to ensure that [InnoDB](#) includes delete-marked records when calculating persistent optimizer statistics.

When [innodb\\_stats\\_include\\_delete\\_marked](#) is enabled, [ANALYZE TABLE](#) considers delete-marked records when recalculating statistics.

[innodb\\_stats\\_include\\_delete\\_marked](#) is a global setting that affects all [InnoDB](#) tables, and it is only applicable to persistent optimizer statistics.

For related information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- [innodb\\_stats\\_method](#)

<b>Command-Line Format</b>	<code>--innodb_stats_method=name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_stats_method</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<a href="#">nulls_equal</a>
	<b>Valid Values</b>	<a href="#">nulls_equal</a>
		<a href="#">nulls_unequal</a>
		<a href="#">nulls_ignored</a>

How the server treats [NULL](#) values when collecting [statistics](#) about the distribution of index values for [InnoDB](#) tables. This variable has three possible values, [nulls\\_equal](#), [nulls\\_unequal](#), and [nulls\\_ignored](#). For [nulls\\_equal](#), all [NULL](#) index values are considered equal and form a single value group that has a size equal to the number of [NULL](#) values. For [nulls\\_unequal](#), [NULL](#) values are considered unequal, and each [NULL](#) forms a distinct value group of size 1. For [nulls\\_ignored](#), [NULL](#) values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 9.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- [innodb\\_stats\\_on\\_metadata](#)

<b>Command-Line Format</b>	<code>--innodb_stats_on_metadata</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_stats_on_metadata</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean

	<b>Default</b>	OFF
--	----------------	-----

When this variable is enabled, InnoDB updates [statistics](#) when metadata statements such as `SHOW TABLE STATUS` or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Leaving this setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of [execution plans](#) for queries that involve InnoDB tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing this setting requires the `SUPER` privilege and immediately affects the operation of all connections.

This variable is disabled by default.

- `innodb_stats_persistent`

<b>Command-Line Format</b>	<code>--innodb_stats_persistent=setting</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_persistent</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON
	<b>Valid Values</b>	OFF
		ON
		0
		1

Specifies whether InnoDB index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in [query execution plans](#). This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information about this option, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_persistent_sample_pages`

<b>Command-Line Format</b>	<code>--innodb_stats_persistent_sample_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_persistent_sample_pages</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer

	<b>Default</b>	20
--	----------------	----

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by [ANALYZE TABLE](#). Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O during the execution of [ANALYZE TABLE](#) for an InnoDB table. For additional information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

#### Note

Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy [ANALYZE TABLE](#) execution time. To estimate the number of database pages that will be accessed, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

This option only applies when the `innodb_stats_persistent` setting is turned on for a table; when that option is turned off for a table, the `innodb_stats_transient_sample_pages` setting applies instead.

- `innodb_stats_sample_pages`

<b>Deprecated</b>	5.6.3	
<b>Command-Line Format</b>	<code>--innodb_stats_sample_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_sample_pages</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	8
	<b>Min Value</b>	1
	<b>Max Value</b>	$2^{64}-1$

Deprecated, use `innodb_stats_transient_sample_pages` instead.

- `innodb_stats_transient_sample_pages`

<b>Command-Line Format</b>	<code>--innodb_stats_transient_sample_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_transient_sample_pages</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	8

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by [ANALYZE TABLE](#). The default value is 8. Increasing the value

improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O when opening an [InnoDB](#) table or recalculating statistics. For additional information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

#### Note

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages that will be accessed, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

This option only applies when the `innodb_stats_persistent` setting is turned off for a table; when this option is turned on for a table, the `innodb_stats_persistent_sample_pages` setting applies instead. Takes the place of the `innodb_stats_sample_pages` option. See [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#) for more information.

- `innodb_status_output`

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_status_output</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_status_output</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Enables or disables periodic output for the standard [InnoDB](#) Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the [InnoDB](#) Lock Monitor. See [Section 15.17, “InnoDB Monitors”](#) for additional information.

- `innodb_status_output_locks`

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_status_output_locks</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_status_output_locks</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Enables or disables the [InnoDB](#) Lock Monitor. When enabled, the [InnoDB](#) Lock Monitor prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the [InnoDB](#) Lock Monitor is printed as part of the standard [InnoDB](#) Monitor output. The standard [InnoDB](#) Monitor must therefore be enabled for the [InnoDB](#) Lock Monitor to print data to the MySQL error log periodically. See [Section 15.17, “InnoDB Monitors”](#) for more information.

- `innodb_strict_mode`

<b>Command-Line Format</b>	<code>--innodb_strict_mode=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_strict_mode</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>ON</code>

When `innodb_strict_mode` is `ON`, InnoDB returns errors rather than warnings for certain conditions. As of MySQL 5.7.7, the default value is `ON`.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is `ON`, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE`, `CREATE INDEX`, and `OPTIMIZE TABLE` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses on `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is `OFF`, InnoDB ignores conflicting clauses and creates the table or index, with only a warning in the message log. The resulting table might have different behavior than you intended, such as having no compression when you tried to create a compressed table. When `innodb_strict_mode` is `ON`, such problems generate an immediate error and the table or index is not created, avoiding a troubleshooting session later.

You can turn `innodb_strict_mode` `ON` or `OFF` on the command line when you start `mysqld`, or in the configuration file `my.cnf` or `my.ini`. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).

- `innodb_support_xa`

<b>Deprecated</b>	5.7.10
<b>Command-Line Format</b>	<code>--innodb_support_xa</code>

<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_support_xa</a>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">TRUE</a>

Enables [InnoDB](#) support for two-phase commit in [XA](#) transactions, causing an extra disk flush for transaction preparation. This setting is the default. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you turn it off, transactions can be written to the binary log in a different order from the one in which the live database is committing them. This can produce different data when the binary log is replayed in disaster recovery or on a replication slave. Do not turn it off on a replication master server unless you have an unusual setup where only one thread is able to change data.

[innodb\\_support\\_xa](#) is deprecated and will be removed in a future MySQL release. [InnoDB](#) support for two-phase commit in XA transactions is always enabled as of MySQL 5.7.10. Disabling [innodb\\_support\\_xa](#) is no longer permitted as it makes replication unsafe and prevents performance gains associated with binary log group commit.

- [innodb\\_sync\\_array\\_size](#)

<b>Command-Line Format</b>	<a href="#">--innodb_sync_array_size=#</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_sync_array_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<a href="#">1</a>
	<b>Min Value</b>	<a href="#">1</a>
	<b>Max Value</b>	<a href="#">1024</a>

Splits an internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing this option value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- [innodb\\_sync\\_spin\\_loops](#)

<b>Command-Line Format</b>	<a href="#">--innodb_sync_spin_loops=#</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_sync_spin_loops</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	30
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended. The default value is 30.

- `innodb_sync_debug`

<b>Introduced</b>	5.7.8	
<b>Command-Line Format</b>	<code>--innodb_sync_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_sync_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enables sync debug checking for the InnoDB storage engine. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

Prior to MySQL 5.7.8, enabling InnoDB sync debug checking required that the Debug Sync facility be enabled using the `ENABLE_DEBUG_SYNC CMake` option. This requirement was removed in MySQL 5.7.8 with the introduction of the `innodb_sync_debug` configuration option.

- `innodb_table_locks`

<b>Command-Line Format</b>	<code>--innodb_table_locks</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_table_locks</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	TRUE

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

In MySQL 5.7, `innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- `innodb_temp_data_file_path`

<b>Introduced</b>	5.7.1	
<b>Command-Line Format</b>	<code>--innodb_temp_data_file_path=file</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_temp_data_file_path</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<code>ibtmp1:12M:autoextend</code>

Specifies the path, file name, and file size for InnoDB temporary tablespace data files. The full directory path for a file is formed by concatenating `innodb_data_home_dir` to the path specified by `innodb_temp_data_file_path`. File size is specified in KB, MB, or GB (1024MB) by appending `K`, `M`, or `G` to the size value. The sum of the sizes of the files must be slightly larger than 12MB. If you do not specify `innodb_temp_data_file_path`, the default behavior is to create a single auto-extending temporary tablespace data file, slightly larger than 12MB, named `ibtmp1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support big files. Use of raw disk partitions for temporary tablespace data files is not supported.

The name of a InnoDB temporary table tablespace data file cannot be the same as the name of a InnoDB data file. Any inability or error creating a temporary tablespace data file is treated as fatal and server startup will be refused. The temporary table tablespace has a dynamically generated space ID, which can change on each server restart.

The InnoDB temporary tablespace is shared by all non-compressed InnoDB temporary tables. Compressed InnoDB temporary tables reside in per-table tablespace files, which are located in the temporary file directory defined by `tmpdir`.

Metadata about active InnoDB temporary tables is found in `INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO`.

- `innodb_tmpdir`

<b>Introduced</b>	5.7.11	
<b>Command-Line Format</b>	<code>--innodb_tmpdir=path</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_tmpdir</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	directory name
	<b>Default</b>	<code>NULL</code>

The `innodb_tmpdir` option is used to define an alternate directory for temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

Online `ALTER TABLE` operations that rebuild a table also create an *intermediate* table file in the same directory as the original table. The `innodb_tmpdir` option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is NULL (the default), temporary files are created MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration option). If an `innodb_tmpdir` directory is specified, existence of the directory and permissions are only checked when `innodb_tmpdir` is configured using a `SET` statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online `ALTER TABLE` operation reports an error if `innodb_tmpdir` is set to an invalid directory. `innodb_tmpdir` overrides the MySQL `tmpdir` setting but only for online `ALTER TABLE` operations.

The `FILE` privilege is required to configure `innodb_tmpdir`.

The `innodb_tmpdir` option was introduced to help avoid overflowing a temporary file directory located on a `tmpfs` file system. Such overflows could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

In replication environments, only consider replicating an `innodb_tmpdir` setting if all servers have the same operating system environment. Otherwise, replicating an `innodb_tmpdir` setting could result in a replication failure when running online `ALTER TABLE` operations that rebuild the table. If server operating environments differ, it is recommended that you configure `innodb_tmpdir` on each server individually.

For related information, see [Where InnoDB Stores Temporary Files](#).

- `innodb_thread_concurrency`

<b>Command-Line Format</b>	<code>--innodb_thread_concurrency=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_thread_concurrency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	1000

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable (InnoDB uses operating system threads to process user transactions). Once the number of threads reaches this limit, additional threads are placed into a wait state within a “First In, First Out” (FIFO) queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The range of this variable is 0 to 1000. A value of 0 (the default) is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking enables InnoDB to create as many threads as it needs. A value of 0 also disables the `queries inside InnoDB` and `queries in queue counters` in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

Consider setting this variable if your MySQL instance shares CPU resources with other applications, or if your workload or number of concurrent users is growing. The correct setting depends on workload, computing environment, and the version of MySQL that you are running. You will need to test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which allows you to experiment with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is less than 64, set `innodb_thread_concurrency=0`.
- If your workload is consistently heavy or occasionally spikes, start by setting `innodb_thread_concurrency=128`, and lowering the value to 96, 80, 64, and so on, until you find the number of threads that provides the best performance. For example, suppose your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or even 200. You find that performance is stable at 80 concurrent users but starts to show a regression above this number. In this case, you would set `innodb_thread_concurrency=80` to avoid impacting performance.
- If you do not want InnoDB to use more than a certain number of vCPUs for user threads (20 vCPUs for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance results). If your goal is to isolate MySQL from other applications, you may consider binding the `mysqld` process exclusively to the vCPUs. Be aware, however, that exclusive binding could result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you might bind the `mysqld` process to the vCPUs but also allow other applications to use some or all of the vCPUs.

#### Note

From an operating system perspective, using a resource management solution (if available) to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of vCPU time to a given application while other critical processes *are not* running, and scale that value back to 40% when other critical processes *are* running.

- `innodb_thread_concurrency` values that are too high can cause performance regression due to increased contention on system internals and resources.
- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of vCPUs.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

For related information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_trx_purge_view_update_only_debug`

<b>Command-Line Format</b>	<code>--innodb_trx_purge_view_update_only_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_trx_purge_view_update_only_debug</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_trx_rseg_n_slots_debug`

<b>Command-Line Format</b>	<code>--innodb_trx_rseg_n_slots_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_trx_rseg_n_slots_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Max Value</b>	1024

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsexf_undo_find_free` function which looks for a free slot for an undo log segment. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_thread_sleep_delay`

<b>Command-Line Format</b>	<code>--innodb_thread_sleep_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_thread_sleep_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> ( $\geq 5.7.4$ )	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	1000000
<b>Permitted Values</b> (32-bit platforms, $\leq 5.7.3$ )	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

<b>Permitted Values</b> (64-bit platforms, <= 5.7.3)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615

How long [InnoDB](#) threads sleep before joining the [InnoDB](#) queue, in microseconds. The default value is 10000. A value of 0 disables sleep. In MySQL 5.6.3 and higher, you can set the configuration option [innodb\\_adaptive\\_max\\_sleep\\_delay](#) to the highest value you would allow for [innodb\\_thread\\_sleep\\_delay](#), and InnoDB automatically adjusts [innodb\\_thread\\_sleep\\_delay](#) up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

For more information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- [innodb\\_undo\\_directory](#)

<b>Command-Line Format</b>	<code>--innodb_undo_directory=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_undo_directory</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b> (<= 5.7.7)	<b>Type</b>	directory name
	<b>Default</b>	.
<b>Permitted Values</b> (>= 5.7.8)	<b>Type</b>	directory name

The path where [InnoDB](#) creates separate tablespaces for the undo logs. Typically used to place undo logs on a different storage device. Used in conjunction with [innodb\\_undo\\_logs](#) and [innodb\\_undo\\_tablespaces](#), which determine the disk layout of the undo logs outside the [system tablespace](#).

Prior to MySQL 5.7.8, the [innodb\\_undo\\_directory](#) default value is “.”, which represents the same directory where [InnoDB](#) creates its other log files by default. As of MySQL 5.7.8, there is no default value (it is NULL). If a path is not specified, undo tablespaces are created in the MySQL data directory, as defined by [datadir](#).

For more information about configuring separate tablespaces for undo logs, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- [innodb\\_undo\\_log\\_truncate](#)

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_undo_log_truncate=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_undo_log_truncate</a>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

When you enable `innodb_undo_log_truncate`, undo tablespaces that exceed the threshold value defined by `innodb_max_undo_log_size` are marked for truncation. Only undo logs that reside in undo tablespaces can be truncated. Truncation of undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces and two redo-enabled undo logs configured to use the undo tablespaces. This means that `innodb_undo_tablespaces` must be set to a value equal to or greater than 2, and `innodb_undo_logs` must set to a value equal to or greater than 35.

The `innodb_purge_rseg_truncate_frequency` configuration option can be used to expedite truncation of undo tablespaces.

For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_undo_logs`

<b>Command-Line Format</b>	<code>--innodb_undo_logs=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_undo_logs</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	128
	<b>Min Value</b>	0
	<b>Max Value</b>	128

Defines the number of [rollback segments](#) used by InnoDB. The `innodb_undo_logs` option replaces `innodb_rollback_segments`.

One rollback segment is always assigned to the system tablespace, and as of MySQL 5.7.2, 32 rollback segments are reserved for use by temporary tables and are hosted in the temporary tablespace (`ibtmp1`). To allocate additional rollback segments for data-modifying transactions that generate undo records, `innodb_undo_logs` must be set to a value greater than 33. If you configure separate undo tablespaces, the rollback segment in the system tablespace is rendered inactive. Each rollback segment can support a maximum of 1024 data-modifying transactions.

When `innodb_undo_logs` is set to 32 or less, InnoDB assigns one rollback segment to the system tablespace and 32 to the temporary tablespace (`ibtmp1`).

When `innodb_undo_logs` is set to a value greater than 32, InnoDB assigns one rollback segment to the system tablespace, 32 to the temporary tablespace (`ibtmp1`), and additional rollback segments to undo tablespaces, if present. If undo tablespaces are not present, additional rollback segments are assigned to the system tablespace.

Although you can increase or decrease the number of rollback segments used by [InnoDB](#), the number of rollback segments physically present in the system never decreases. Thus you might start with a low value for this parameter and gradually increase it, to avoid allocating rollback segments that are not required. If [innodb\\_undo\\_logs](#) is not set, it defaults to the maximum value of 128. For the total number of available rollback segments, rather than the number of active ones, see the [Innodb\\_available\\_undo\\_logs](#) status variable.

For information about rollback segments, see [Section 15.3, “InnoDB Multi-Versioning”](#). For information about configuring separate undo tablespaces, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- [innodb\\_undo\\_tablespaces](#)

<b>Command-Line Format</b>	<code>--innodb_undo_tablespaces=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_undo_tablespaces</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.7)</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	126
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	95

The number of [tablespace](#) files that [rollback segments](#) are divided between. By default, rollback segments are assigned to the [system tablespace](#), and the system tablespace is always assigned at least one rollback segment.

Because undo logs can become large during long-running transactions, having undo logs in multiple tablespaces reduces the maximum size of any one tablespace. The undo tablespace files are created in the location defined by [innodb\\_undo\\_directory](#), with names in the form of [undoN](#), where *N* is a sequential series of integers (including leading zeros). The default size of an undo tablespace file is 10M.

#### Important

[innodb\\_undo\\_tablespaces](#) can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default setting (0). Attempting to restart [InnoDB](#) with a greater number of undo tablespaces than specified when the MySQL instance was initialized results in a startup failure and an error stating that [InnoDB](#) did not find the expected number of undo tablespaces.

As MySQL 5.7.2, 32 of 128 rollback segments are reserved for temporary tables, as described in [Section 15.4.12.1, “InnoDB Temporary Table Undo Logs”](#). One rollback segment is always assigned to the system tablespace, which leaves 95 rollback segments available for undo tablespaces. This change effectively reduces the `innodb_undo_tablespaces` maximum limit from 126 to 95, and in MySQL 5.7.8, the `innodb_undo_tablespaces` maximum value is reduced to 95.

For information about configuring separate undo tablespaces, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_use_native_aio`

<b>Command-Line Format</b>	<code>--innodb_use_native_aio=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_use_native_aio</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to touch this option, because it is enabled by default.

As of MySQL 5.5, the [asynchronous I/O](#) capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in the output of the command `SHOW ENGINE INNODB STATUS\G`.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0` disabled (use `innodb_use_native_aio=0` in the option file). This option may also be turned off automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` filesystem, and Linux kernel that does not support AIO on `tmpfs`.

- `innodb_use_sys_malloc`

<b>Deprecated</b>	5.6.3	
<b>Removed</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_use_sys_malloc=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_use_sys_malloc</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Whether InnoDB uses the operating system memory allocator (ON) or its own (OFF). The default value is ON. See [Section 15.6.4, “Configuring the Memory Allocator for InnoDB”](#) for more information.

`innodb_use_sys_malloc` was deprecated in MySQL 5.6.3 and removed in MySQL 5.7.4.

- `innodb_version`

The InnoDB version number. In 5.7, the separate numbering for InnoDB does not apply and this value is the same as for the `version` variable.

- `innodb_write_io_threads`

<b>Command-Line Format</b>	<code>--innodb_write_io_threads=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_write_io_threads</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. See [Section 15.6.7, “Configuring the Number of Background InnoDB I/O Threads”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

You should also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

## 15.15 InnoDB INFORMATION\_SCHEMA Tables

This section provides information and usage examples for [InnoDB INFORMATION\\_SCHEMA](#) tables.

[InnoDB INFORMATION\\_SCHEMA](#) tables provide metadata, status information, and statistics about various aspects of the [InnoDB](#) storage engine. You can view a list of [InnoDB INFORMATION\\_SCHEMA](#) tables by issuing a `SHOW TABLES` statement on the [INFORMATION\\_SCHEMA](#) database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see [Section 23.31](#), “[InnoDB INFORMATION\\_SCHEMA Tables](#)”. For general information regarding the [MySQL INFORMATION\\_SCHEMA](#) database, see [Chapter 23](#), [INFORMATION\\_SCHEMA Tables](#).

## 15.15.1 InnoDB INFORMATION\_SCHEMA Tables about Compression

There are two pairs of [InnoDB INFORMATION\\_SCHEMA](#) tables about compression that can provide insight into how well compression is working overall:

- [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) contain information about the number of compression operations and the amount of time spent performing compression.
- [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) contain information about the way memory is allocated for compression.

### 15.15.1.1 INNODB\_CMP and INNODB\_CMP\_RESET

The [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) tables contain status information about operations related to compressed tables, which are described in [Section 15.9](#), “[InnoDB Table and Page Compression](#)”. The [PAGE\\_SIZE](#) column reports the compressed [page size](#).

These two tables have identical contents, but reading from [INNODB\\_CMP\\_RESET](#) resets the statistics on compression and uncompression operations. For example, if you archive the output of [INNODB\\_CMP\\_RESET](#) every 60 minutes, you see the statistics for each hourly period. If you monitor the output of [INNODB\\_CMP](#) (making sure never to read [INNODB\\_CMP\\_RESET](#)), you see the cumulated statistics since InnoDB was started.

For the table definition, see [Section 23.31.4](#), “[The INFORMATION\\_SCHEMA INNODB\\_CMP and INNODB\\_CMP\\_RESET Tables](#)”.

### 15.15.1.2 INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET

The [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) tables contain status information about compressed pages that reside in the buffer pool. Please consult [Section 15.9](#), “[InnoDB Table and Page Compression](#)” for further information on compressed tables and the use of the buffer pool. The [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) tables should provide more useful statistics on compression.

## Internal Details

[InnoDB](#) uses a [buddy allocator](#) system to manage memory allocated to [pages of various sizes](#), from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) tables have identical contents, but reading from [INNODB\\_CMPMEM\\_RESET](#) resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of [INNODB\\_CMPMEM\\_RESET](#), it would show the hourly statistics. If you never read [INNODB\\_CMPMEM\\_RESET](#) and monitored the output of [INNODB\\_CMPMEM](#) instead, it would show the cumulated statistics since [InnoDB](#) was started.

For the table definition, see [Section 23.31.5](#), “[The INFORMATION\\_SCHEMA INNODB\\_CMPMEM and INNODB\\_CMPMEM\\_RESET Tables](#)”.

### 15.15.1.3 Using the Compression Information Schema Tables

#### Example 15.10 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 15.9, “InnoDB Table and Page Compression”](#), `INNODB_CMP`, `INNODB_CMP_PER_INDEX`, and `INNODB_CMPMEM`).

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMP` under a light [workload](#). The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

page size	compress ops	compress ops ok	compress time	uncompress ops	uncompress time
1024	0	0	0	0	0
2048	0	0	0	0	0
4096	0	0	0	0	0
8192	1048	921	0	61	0
16384	0	0	0	0	0

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the [buffer pool](#). The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light [workload](#). Some memory is unusable due to fragmentation of the memory allocator for compressed pages:  $\text{SUM}(\text{PAGE\_SIZE} * \text{PAGES\_FREE}) = 6784$ . This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of  $\text{SUM}(\text{PAGE\_SIZE} * \text{RELOCATION\_OPS})$  bytes has consumed less than a second ( $\text{SUM}(\text{RELOCATION\_TIME}) = 0$ ).

page size	pages used	pages free	relocation ops	relocation time
64	5910	0	2436	0
128	0	1	0	0
256	0	0	0	0
512	0	1	0	0
1024	0	0	0	0
2048	0	1	0	0
4096	0	1	0	0
8192	6169	0	5	0
16384	0	0	0	0

### 15.15.2 InnoDB INFORMATION\_SCHEMA Transaction and Locking Information

Three `InnoDB INFORMATION_SCHEMA` tables enable you to monitor transactions and diagnose potential locking problems:

- [INNODB\\_TRX](#): Contains information about every transaction currently executing inside [InnoDB](#), including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.
- [INNODB\\_LOCKS](#): Each transaction in InnoDB that is waiting for another transaction to release a lock ([INNODB\\_TRX.TRX\\_STATE](#) is [LOCK\\_WAIT](#)) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock that blocks a transaction is always held in a mode incompatible with the mode of requested lock (read vs. write, shared vs. exclusive). The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, [INNODB\\_LOCKS](#) contains one row that describes each lock the transaction has requested, and for which it is waiting. [INNODB\\_LOCKS](#) also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock ([INNODB\\_TRX.TRX\\_STATE](#) is [RUNNING](#), [LOCK\\_WAIT](#), [ROLLING\\_BACK](#) or [COMMITTING](#)).
- [INNODB\\_LOCK\\_WAITS](#): This table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The [REQUESTED\\_LOCK\\_ID](#) value refers to the lock requested by a transaction, and the [BLOCKING\\_LOCK\\_ID](#) value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in [INNODB\\_LOCK\\_WAITS](#) have the same value for [REQUESTED\\_LOCK\\_ID](#) and different values for [BLOCKING\\_LOCK\\_ID](#).

For more information about the preceding tables, see [Section 23.31.27](#), “The [INFORMATION\\_SCHEMA INNODB\\_TRX](#) Table”, [Section 23.31.13](#), “The [INFORMATION\\_SCHEMA INNODB\\_LOCKS](#) Table”, and [Section 23.31.14](#), “The [INFORMATION\\_SCHEMA INNODB\\_LOCK\\_WAITS](#) Table”.

### 15.15.2.1 Using InnoDB Transaction and Locking Information

#### Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about [InnoDB](#) transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see [Section 15.15.2](#), “[InnoDB INFORMATION\\_SCHEMA Transaction and Locking Information](#)”.)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- Session A:

```
BEGIN;  
SELECT a FROM t FOR UPDATE;  
SELECT SLEEP(100);
```

- Session B:

```
SELECT b FROM t FOR UPDATE;
```

- Session C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```

SELECT
  r.trx_id waiting_trx_id,
  r.trx_mysql_thread_id waiting_thread,
  r.trx_query waiting_query,
  b.trx_id blocking_trx_id,
  b.trx_mysql_thread_id blocking_thread,
  b.trx_query blocking_query
FROM
  information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b
  ON b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r
  ON r.trx_id = w.requesting_trx_id;

```

Or, more simply, use the `sys` schema `innodb_lock_waits` view:

```

SELECT
  waiting_trx_id,
  waiting_pid,
  waiting_query,
  blocking_trx_id,
  blocking_pid,
  blocking_query
FROM sys.innodb_lock_waits;

```

waiting trx id	waiting thread	waiting query	blocking trx id	blocking thread	blocking query
A4	6	SELECT b FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A4	6	SELECT b FROM t FOR UPDATE

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id [A4](#), thread [6](#)) and Session C (trx id [A5](#), thread [7](#)) are both waiting for Session A (trx id [A3](#), thread [5](#)).
- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the tables `INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`.

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_TRX`.

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
A3	RUN- NING	2008-01-15 16:44:54	NULL	NULL	2	5	SELECT SLEEP(100)
A4	LOCK WAIT	2008-01-15 16:45:09	A4:1:3:2	2008-01-15 16:45:09	2	6	SELECT b FROM t FOR UPDATE
A5	LOCK WAIT	2008-01-15 16:45:14	A5:1:3:2	2008-01-15 16:45:14	2	7	SELECT c FROM t FOR UPDATE

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCKS`.

lock id	lock trx id	lock mode	lock type	lock table	lock index	lock data
A3:1:3:2	A3	X	RECORD	test.t	PRIMARY	0x0200
A4:1:3:2	A4	X	RECORD	test.t	PRIMARY	0x0200
A5:1:3:2	A5	X	RECORD	test.t	PRIMARY	0x0200

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCK_WAITS`.

requesting trx id	requested lock id	blocking trx id	blocking lock id
A4	A4:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A4	A4:1:3:2

## Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal InnoDB locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the `INFORMATION_SCHEMA` tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables show that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D`, and `77B` to commit.
- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.
- Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.
- Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.
- Transaction `77A` is running, currently executing `SELECT`.
- Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.
- Transaction `E55` (executing an `INSERT`) is waiting for transaction `19C` to commit.
- Transaction `19C` is running, currently executing an `INSERT`.

### Note

There may be inconsistencies between queries shown in the `INFORMATION_SCHEMA.PROCESSLIST` and `INNODB_TRX` tables. For an explanation, see [Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

The following table shows the contents of `INFORMATION_SCHEMA.PROCESSLIST` for a system running a heavy workload.

ID	USER	HOST	DB	COMMAND	TIME	STATE	INFO
384	root	localhost	test	Query	10	update	INSERT INTO t2 VALUES ...

ID	USER	HOST	DB	COMMAND	TIME	STATE	INFO
257	root	localhost	test	Query	3	update	INSERT INTO t2 VALUES ...
130	root	localhost	test	Query	0	update	INSERT INTO t2 VALUES ...
61	root	localhost	test	Query	1	update	INSERT INTO t2 VALUES ...
8	root	localhost	test	Query	1	update	INSERT INTO t2 VALUES ...
4	root	localhost	test	Query	0	preparing	SELECT * FROM PROCESSLIST
2	root	localhost	test	Sleep	566		NULL

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_TRX` for a system running a heavy [workload](#).

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
77F	LOCK WAIT	2008-01-15 13:10:16	77F	2008-01-15 13:10:16	1	876	INSERT INTO t09 (D, B, C) VALUES ...
77E	LOCK WAIT	2008-01-15 13:10:16	77E	2008-01-15 13:10:16	1	875	INSERT INTO t09 (D, B, C) VALUES ...
77D	LOCK WAIT	2008-01-15 13:10:16	77D	2008-01-15 13:10:16	1	874	INSERT INTO t09 (D, B, C) VALUES ...
77B	LOCK WAIT	2008-01-15 13:10:16	77B:733:12:1	2008-01-15 13:10:16	4	873	INSERT INTO t09 (D, B, C) VALUES ...
77A	RUN-NING	2008-01-15 13:10:16	NULL	NULL	4	872	SELECT b, c FROM t09 WHERE ...
E56	LOCK WAIT	2008-01-15 13:10:06	E56:743:6:2	2008-01-15 13:10:06	5	384	INSERT INTO t2 VALUES ...
E55	LOCK WAIT	2008-01-15 13:10:06	E55:743:38:2	2008-01-15 13:10:13	965	257	INSERT INTO t2 VALUES ...
19C	RUN-NING	2008-01-15 13:09:10	NULL	NULL	2900	130	INSERT INTO t2 VALUES ...
E15	RUN-NING	2008-01-15 13:08:59	NULL	NULL	5395	61	INSERT INTO t2 VALUES ...
51D	RUN-NING	2008-01-15 13:08:47	NULL	NULL	9807	8	INSERT INTO t2 VALUES ...

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_LOCK_WAITS` for a system running a heavy [workload](#).

requesting trx id	requested lock id	blocking trx id	blocking lock id
77F	77F:806	77E	77E:806

requesting trx id	requested lock id	blocking trx id	blocking lock id
77F	77F:806	77D	77D:806
77F	77F:806	77B	77B:806
77E	77E:806	77D	77D:806
77E	77E:806	77B	77B:806
77D	77D:806	77B	77B:806
77B	77B:733:12:1	77A	77A:733:12:1
E56	E56:743:6:2	E55	E55:743:6:2
E55	E55:743:38:2	19C	19C:743:38:2

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_LOCKS` for a system running a heavy [workload](#).

lock id	lock trx id	lock mode	lock type	lock table	lock index	lock data
77F:806	77F	AUTO_INC	TABLE	test.t09	NULL	NULL
77E:806	77E	AUTO_INC	TABLE	test.t09	NULL	NULL
77D:806	77D	AUTO_INC	TABLE	test.t09	NULL	NULL
77B:806	77B	AUTO_INC	TABLE	test.t09	NULL	NULL
77B:733:12:1	77B	X	RECORD	test.t09	PRIMARY	supremum pseudo- record
77A:733:12:1	77A	X	RECORD	test.t09	PRIMARY	supremum pseudo- record
E56:743:6:2	E56	S	RECORD	test.t2	PRIMARY	0, 0
E55:743:6:2	E55	X	RECORD	test.t2	PRIMARY	0, 0
E55:743:38:2	E55	S	RECORD	test.t2	PRIMARY	1922, 1922
19C:743:38:2	19C	X	RECORD	test.t2	PRIMARY	1922, 1922

### 15.15.2.2 InnoDB Lock and Lock-Wait Information

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA.INNODB_TRX` table indicates transaction state values.)

The `INNODB_LOCKS` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The `INNODB_LOCK_WAITS` table shows which locks already held by a transaction are blocking locks requested by other transactions.

### 15.15.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

The data exposed by the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading joins between the transaction and locking tables, InnoDB collects the required transaction and locking information into an intermediate buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time “snapshot”. If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you join any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the `PROCESS` privilege are allowed to `SELECT` from them.

As described previously, the data that fills the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`) is fetched automatically and saved to an intermediate buffer that provides a “point-in-time” snapshot. The data across all three tables is consistent when queried from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. The data from the `PROCESSLIST` table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. `INNODB_TRX` may reference rows that are not present in `PROCESSLIST` or the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` may differ from the one in `PROCESSLIST.INFO`.

## 15.15.3 InnoDB INFORMATION\_SCHEMA System Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB `INFORMATION_SCHEMA` system tables. This information comes from the InnoDB internal system tables (also referred to as the InnoDB data dictionary), which cannot be queried directly like regular InnoDB tables. Traditionally, you would get this type of information using the techniques from [Section 15.17, “InnoDB Monitors”](#), setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The InnoDB `INFORMATION_SCHEMA` table interface allows you to query this data using SQL.

With the exception of `INNODB_SYS_TABLESTATS`, for which there is no corresponding internal system table, `InnoDB INFORMATION_SCHEMA` system tables are populated with data read directly from internal `InnoDB` system tables rather than from metadata that is cached in memory.

`InnoDB INFORMATION_SCHEMA` system tables include the tables listed below. `INNODB_SYS_DATAFILES` and `INNODB_SYS_TABLESPACES` were added in MySQL 5.6.6 with the introduction of support for the `DATA DIRECTORY='directory'` clause of the `CREATE TABLE` statement, which allows `InnoDB file-per-table` tablespaces (`.ibd` files) to be created in a location outside the MySQL data directory.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_SYS%';
+-----+
| Tables_in_information_schema (INNODB_SYS%) |
+-----+
| INNODB_SYS_DATAFILES                       |
| INNODB_SYS_TABLESTATS                     |
| INNODB_SYS_FOREIGN                         |
| INNODB_SYS_COLUMNS                         |
| INNODB_SYS_INDEXES                        |
| INNODB_SYS_FIELDS                         |
| INNODB_SYS_TABLESPACES                     |
| INNODB_SYS_FOREIGN_COLS                    |
| INNODB_SYS_TABLES                         |
+-----+
```

The table names are indicative of the type of data provided:

- `INNODB_SYS_TABLES` provides metadata about `InnoDB` tables, equivalent to the information in the `SYS_TABLES` table in the `InnoDB` data dictionary.
- `INNODB_SYS_COLUMNS` provides metadata about `InnoDB` table columns, equivalent to the information in the `SYS_COLUMNS` table in the `InnoDB` data dictionary.
- `INNODB_SYS_INDEXES` provides metadata about `InnoDB` indexes, equivalent to the information in the `SYS_INDEXES` table in the `InnoDB` data dictionary.
- `INNODB_SYS_FIELDS` provides metadata about the key columns (fields) of `InnoDB` indexes, equivalent to the information in the `SYS_FIELDS` table in the `InnoDB` data dictionary.
- `INNODB_SYS_TABLESTATS` provides a view of low-level status information about `InnoDB` tables that is derived from in-memory data structures. There is no corresponding internal `InnoDB` system table.
- `INNODB_SYS_DATAFILES` provides data file path information for `InnoDB` file-per-table and general tablespaces, equivalent to information in the `SYS_DATAFILES` table in the `InnoDB` data dictionary.
- `INNODB_SYS_TABLESPACES` provides metadata about `InnoDB` file-per-table and general tablespaces, equivalent to the information in the `SYS_TABLESPACES` table in the `InnoDB` data dictionary.
- `INNODB_SYS_FOREIGN` provides metadata about foreign keys defined on `InnoDB` tables, equivalent to the information in the `SYS_FOREIGN` table in the `InnoDB` data dictionary.
- `INNODB_SYS_FOREIGN_COLS` provides metadata about the columns of foreign keys that are defined on `InnoDB` tables, equivalent to the information in the `SYS_FOREIGN_COLS` table in the `InnoDB` data dictionary.

`InnoDB INFORMATION_SCHEMA` system tables can be joined together through fields such as `TABLE_ID`, `INDEX_ID`, and `SPACE`, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the `InnoDB INFORMATION_SCHEMA` documentation for information about the columns of each table.

**Example 15.11 InnoDB INFORMATION\_SCHEMA System Tables**

This example uses a simple table (`t1`) with a single index (`i1`) to demonstrate the type of metadata found in the `InnoDB INFORMATION_SCHEMA` system tables.

1. Create a test database and table `t1`:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE t1 (
  col1 INT,
  col2 CHAR(10),
  col3 VARCHAR(10))
ENGINE = InnoDB;

mysql> CREATE INDEX i1 ON t1(col1);
```

2. After creating the table `t1`, query `INNODB_SYS_TABLES` to locate the metadata for `test/t1`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G

***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
        FLAG: 1
      N_COLS: 6
      SPACE: 57
  FILE_FORMAT: Antelope
  ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
  ...
```

Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by `InnoDB` (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The ID of the table's `SPACE` is 57 (a value of 0 would indicate that the table resides in the system tablespace). The `FILE_FORMAT` is Antelope, and the `ROW_FORMAT` is Compact. `ZIP_PAGE_SIZE` only applies to tables with a `Compressed` row format.

3. Using the `TABLE_ID` information from `INNODB_SYS_TABLES`, query the `INNODB_SYS_COLUMNS` table for information about the table's columns.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G

***** 1. row *****
TABLE_ID: 71
  NAME: col1
  POS: 0
  MTYPE: 6
  PRTYPE: 1027
  LEN: 4

***** 2. row *****
TABLE_ID: 71
  NAME: col2
  POS: 1
  MTYPE: 2
  PRTYPE: 524542
  LEN: 10

***** 3. row *****
TABLE_ID: 71
  NAME: col3
  POS: 2
  MTYPE: 1
  PRTYPE: 524303
  LEN: 10
```

In addition to the `TABLE_ID` and column `NAME`, `INNODB_SYS_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or “main type” (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRTYPE` or “precise type” (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`).

- Using the `TABLE_ID` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_INDEXES` for information about the indexes associated with table `t1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 71 \G
***** 1. row *****
      INDEX_ID: 111
        NAME: GEN_CLUST_INDEX
      TABLE_ID: 71
        TYPE: 1
      N_FIELDS: 0
        PAGE_NO: 3
          SPACE: 57
MERGE_THRESHOLD: 50
***** 2. row *****
      INDEX_ID: 112
        NAME: i1
      TABLE_ID: 71
        TYPE: 0
      N_FIELDS: 1
        PAGE_NO: 4
          SPACE: 57
MERGE_THRESHOLD: 50
```

`INNODB_SYS_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by `InnoDB` if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FIELDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A non-zero value indicates that the index does not reside in the system tablespace. `MERGE_THRESHOLD` defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, `InnoDB` attempts to merge the index page with a neighboring index page.

- Using the `INDEX_ID` information from `INNODB_SYS_INDEXES`, query `INNODB_SYS_FIELDS` for information about the fields of index `i1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 112 \G
***** 1. row *****
INDEX_ID: 112
      NAME: coll
      POS: 0
```

`INNODB_SYS_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (`i1`) had been defined on multiple fields, `INNODB_SYS_FIELDS` would provide metadata for each of the indexed fields.

- Using the `SPACE` information from `INNODB_SYS_TABLES`, query `INNODB_SYS_TABLESPACES` table for information about the table's tablespace.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57 \G
***** 1. row *****
```

```

SPACE: 57
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0

```

In addition to the [SPACE](#) ID of the tablespace and the [NAME](#) of the associated table, [INNODB\\_SYS\\_TABLESPACES](#) provides tablespace [FLAG](#) data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace [FILE\\_FORMAT](#), [ROW\\_FORMAT](#), [PAGE\\_SIZE](#), and [ZIP\\_PAGE\\_SIZE](#) data ([ZIP\\_PAGE\\_SIZE](#) is applicable to tablespaces with a [Compressed](#) row format).

7. Using the [SPACE](#) information from [INNODB\\_SYS\\_TABLES](#) once again, query [INNODB\\_SYS\\_DATAFILES](#) for the location of the tablespace data file.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
PATH: ./test/t1.ibd

```

The datafile is located in the `test` directory under MySQL's `data` directory. If a [file-per-table](#) tablespace were created in a location outside the MySQL data directory using the [DATA DIRECTORY](#) clause of the [CREATE TABLE](#) statement, the tablespace [PATH](#) would be a fully qualified directory path.

8. As a final step, insert a row into table `t1` ([TABLE\\_ID](#) = 71) and view the data in the [INNODB\\_SYS\\_TABLESTATS](#) table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an [InnoDB](#) table. This information is derived from in-memory data structures. There is no corresponding internal [InnoDB](#) system table.

```

mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71 \G
***** 1. row *****
TABLE_ID: 71
NAME: test/t1
STATS_INITIALIZED: Initialized
NUM_ROWS: 1
CLUST_INDEX_SIZE: 1
OTHER_INDEX_SIZE: 0
MODIFIED_COUNTER: 1
AUTOINC: 0
REF_COUNT: 1

```

The [STATS\\_INITIALIZED](#) field indicates whether or not statistics have been collected for the table. [NUM\\_ROWS](#) is the current estimated number of rows in the table. The [CLUST\\_INDEX\\_SIZE](#) and [OTHER\\_INDEX\\_SIZE](#) fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The [MODIFIED\\_COUNTER](#) value shows the number of rows modified by DML operations and cascade operations from foreign keys. The [AUTOINC](#) value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The [REF\\_COUNT](#) value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

### Example 15.12 Foreign Key INFORMATION\_SCHEMA System Tables

The [INNODB\\_SYS\\_FOREIGN](#) and [INNODB\\_SYS\\_FOREIGN\\_COLS](#) tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the [INNODB\\_SYS\\_FOREIGN](#) and [INNODB\\_SYS\\_FOREIGN\\_COLS](#) tables.

1. Create the test database with parent and child tables:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE parent (id INT NOT NULL,
    -> PRIMARY KEY (id)) ENGINE=INNODB;

mysql> CREATE TABLE child (id INT, parent_id INT,
    -> INDEX par_ind (parent_id),
    -> CONSTRAINT fk1
    -> FOREIGN KEY (parent_id) REFERENCES parent(id)
    -> ON DELETE CASCADE) ENGINE=INNODB;
```

2. After the parent and child tables are created, query `INNODB_SYS_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
***** 1. row *****
      ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
  N_COLS: 1
    TYPE: 1
```

Metadata includes the foreign key `ID` (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the “referenced” table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1, which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_SYS_FOREIGN` table definition for more information about `TYPE` values.

3. Using the foreign key `ID`, query `INNODB_SYS_FOREIGN_COLS` to view data about the columns of the foreign key.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
```

`FOR_COL_NAME` is the name of the foreign key column in the child table, and `REF_COL_NAME` is the name of the referenced column in the parent table. The `POS` value is the ordinal position of the key field within the foreign key index, starting at zero.

### Example 15.13 Joining InnoDB INFORMATION\_SCHEMA System Tables

This example demonstrates joining three `InnoDB INFORMATION_SCHEMA` system tables (`INNODB_SYS_TABLES`, `INNODB_SYS_TABLESPACES`, and `INNODB_SYS_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNODB_SYS_TABLES: a`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES: b`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS: c`

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```
mysql> SELECT a.NAME, a.FILE_FORMAT, a.ROW_FORMAT,
  @page_size :=
    IF(a.ROW_FORMAT='Compressed',
      b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
    AS page_size,
  ROUND((@page_size * c.CLUST_INDEX_SIZE)
    /(1024*1024)) AS pk_mb,
  ROUND((@page_size * c.OTHER_INDEX_SIZE)
    /(1024*1024)) AS secidx_mb
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES a
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES b on a.NAME = b.NAME
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS c on b.NAME = c.NAME
WHERE a.NAME LIKE 'employees/%'
ORDER BY a.NAME DESC;
```

NAME	FILE_FORMAT	ROW_FORMAT	page_size	pk_mb	secidx_mb
employees/titles	Antelope	Compact	16384	20	11
employees/salaries	Antelope	Compact	16384	91	33
employees/employees	Antelope	Compact	16384	15	0
employees/dept_manager	Antelope	Compact	16384	0	0
employees/dept_emp	Antelope	Compact	16384	12	10
employees/departments	Antelope	Compact	16384	0	0

### 15.15.4 InnoDB INFORMATION\_SCHEMA FULLTEXT Index Tables

With the introduction of `FULLTEXT` index support for `InnoDB` tables in MySQL 5.6.4, the following tables were added to the `INFORMATION_SCHEMA` database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_FT%) |
+-----+
| INNODB_FT_CONFIG                           |
| INNODB_FT_BEING_DELETED                   |
| INNODB_FT_DELETED                         |
| INNODB_FT_DEFAULT_STOPWORD               |
| INNODB_FT_INDEX_TABLE                     |
| INNODB_FT_INDEX_CACHE                     |
+-----+
```

#### Table Overview

- `INNODB_FT_CONFIG`: Displays metadata about the `FULLTEXT` index and associated processing for an `InnoDB` table.
- `INNODB_FT_BEING_DELETED`: Provides a snapshot of the `INNODB_FT_DELETED` table that is only used during an `OPTIMIZE TABLE` maintenance operation. When `OPTIMIZE TABLE` is run, the `INNODB_FT_BEING_DELETED` table is emptied, and `DOC_IDS` are removed from the `INNODB_FT_DELETED` table. Because the contents of `INNODB_FT_BEING_DELETED` typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running `OPTIMIZE TABLE` on tables with `FULLTEXT` indexes, see [Section 13.9.6, “Fine-Tuning MySQL Full-Text Search”](#).
- `INNODB_FT_DELETED`: Records rows that are deleted from the `FULLTEXT` index for an `InnoDB` table. To avoid expensive index reorganization during DML operations for an `InnoDB FULLTEXT` index, the

information about newly deleted words is stored separately, filtered out of search results when you perform a text search, and removed from the main search index only when you run `OPTIMIZE TABLE`.

- `INNODB_FT_DEFAULT_STOPWORD`: Holds a list of [stopwords](#) that are used by default when creating a `FULLTEXT` index.

For information about the `INNODB_FT_DEFAULT_STOPWORD` table, see [Section 13.9.4, “Full-Text Stopwords”](#).

- `INNODB_FT_INDEX_TABLE`: Contains data about the inverted index used to process text searches against the `FULLTEXT` index.
- `INNODB_FT_INDEX_CACHE`: Contains token information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by `innodb_ft_cache_size` or `innodb_ft_total_cache_size`.

#### Note

With the exception of the `INNODB_FT_DEFAULT_STOPWORD` table, you must set the `innodb_ft_aux_table` configuration variable to the name of the table (*database\_name/table\_name*) that contains the `FULLTEXT` index. Otherwise, the InnoDB `FULLTEXT` index `INFORMATION_SCHEMA` tables appear empty.

### Example 15.14 InnoDB FULLTEXT Index INFORMATION\_SCHEMA Tables

This example uses a table with a `FULLTEXT` index to demonstrate the data contained in the `FULLTEXT` index `INFORMATION_SCHEMA` tables.

1. Create a table with a `FULLTEXT` index and insert some data:

```
mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');
```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the `FULLTEXT` index. If this variable is not set, the InnoDB `FULLTEXT` `INFORMATION_SCHEMA` tables appear empty, with the exception of the `INNODB_FT_DEFAULT_STOPWORD` table.

```
SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shutdown or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
+-----+-----+-----+-----+-----+-----+
| WORD | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+-----+
|      |              |              |           |        |         |
|      |              |              |           |        |         |
|      |              |              |           |        |         |
|      |              |              |           |        |         |
|      |              |              |           |        |         |
```

1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

4. Enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on InnoDB tables, and is intended to be enabled temporarily, during maintenance operations on InnoDB tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> OPTIMIZE TABLE articles;
```

Table	Op	Msg_type	Msg_text
test.articles	optimize	status	OK

5. Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
Query OK, 3 rows affected (0.11 sec)
```

7. Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
```

DOC_ID
2
3
4

8. Run `OPTIMIZE TABLE` to remove the deleted records.

```
mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.articles | optimize | status   | OK       |
+-----+-----+-----+-----+
```

The `INNODB_FT_DELETED` table should now appear empty.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

- Query the `INNODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:

- `optimize_checkpoint_limit` is the number of seconds after which an `OPTIMIZE TABLE` run will stop.
- `synced_doc_id` is the next `DOC_ID` to be issued.
- `stopword_table_name` is the *database/table* name for a user-defined stopword table. This field appears empty if there is no user-defined stopword table.
- `use_stopword` indicates whether or not a stopword table is used, which is defined when the `FULLTEXT` index is created.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY              | VALUE |
+-----+-----+
| optimize_checkpoint_limit | 180   |
| synced_doc_id      | 8     |
| stopword_table_name |       |
| use_stopword       | 1     |
+-----+-----+
```

## 15.15.5 InnoDB INFORMATION\_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the `InnoDB` buffer pool. The tables were introduced in MySQL 5.6.2 and later backported to MySQL 5.5 (in MySQL 5.5.28) and MySQL 5.1 (in MySQL 5.1.66).

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
+-----+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%) |
+-----+-----+
| INNODB_BUFFER_PAGE_LRU                        |
| INNODB_BUFFER_PAGE                            |
| INNODB_BUFFER_POOL_STATS                      |
+-----+-----+
```

### Table Overview

- `INNODB_BUFFER_PAGE`: Holds information about each page in the `InnoDB` buffer pool.
- `INNODB_BUFFER_PAGE_LRU`: Holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The `INNODB_BUFFER_PAGE_LRU` table has the same columns

as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

- `INNODB_BUFFER_POOL_STATS`: Provides buffer pool status information. Much of the same information is provided by `SHOW ENGINE INNODB STATUS` output, or may be obtained using InnoDB buffer pool server status variables.

### Warning

Querying the `INNODB_BUFFER_PAGE` table or `INNODB_BUFFER_PAGE_LRU` table can introduce significant performance overhead. Do not query these tables on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

### Example 15.15 Querying System Data in the `INNODB_BUFFER_PAGE` Table

This query provides an approximate count of pages that contain system data by excluding pages where the `TABLE_NAME` value is either `NULL` or includes a slash `/` or period `.` in the table name, which indicates a user-defined table.

```
SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

COUNT(*)
1516

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
  ) AS system_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ROUND((system_pages/total_pages) * 100)
  ) AS system_page_percentage;
```

system_pages	total_pages	system_page_percentage
295	8192	4

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

PAGE_TYPE
SYSTEM
IBUF_BITMAP
UNKNOWN

FILE_SPACE_HEADER	
INODE	
UNDO_LOG	
ALLOCATED	
+-----+	

**Example 15.16 Querying User Data in the INNODB\_BUFFER\_PAGE Table**

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is `NOT NULL` and `NOT LIKE '%INNODB_SYS_TABLES%'`.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE '%INNODB_SYS_TABLES%';
```

+-----+	
COUNT(*)	
+-----+	
7897	
+-----+	

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```
mysql> SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
) AS user_pages,
(
SELECT COUNT(*)
FROM information_schema.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((user_pages/total_pages) * 100)
) AS user_page_percentage;
```

+-----+		
user_pages	total_pages	user_page_percentage
+-----+		
7897	8192	96
+-----+		

This query identifies user-defined tables with pages in the buffer pool:

```
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
AND TABLE_NAME NOT LIKE 'mysql`.`innodb_%';
```

+-----+	
TABLE_NAME	
+-----+	
`employees`.`salaries`	
`employees`.`employees`	
+-----+	

**Example 15.17 Querying Index Data in the INNODB\_BUFFER\_PAGE Table**

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = 'employees`.`salaries`';
```

+-----+		
INDEX_NAME	Pages	Total Data (MB)
+-----+		
emp_no	1609	25

This query returns the number of pages and total data size of pages for all indexes defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = 'employees`.`salaries`'
GROUP BY INDEX_NAME;
```

INDEX_NAME	Pages	Total Data (MB)
emp_no	1608	25
PRIMARY	6086	95

### Example 15.18 Querying LRU\_POSITION Data in the INNODB\_BUFFER\_PAGE\_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the `employees.employees` table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME='employees`.`employees`' AND LRU_POSITION < 3072;
```

COUNT(LRU_POSITION)
548

### Example 15.19 Querying the INNODB\_BUFFER\_POOL\_STATS Table

The `INNODB_BUFFER_POOL_STATS` table provides information similar to `SHOW ENGINE INNODB STATUS` and `InnoDB` buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
***** 1. row *****
                POOL_ID: 0
                POOL_SIZE: 8192
                FREE_BUFFERS: 1
                DATABASE_PAGES: 8173
                OLD_DATABASE_PAGES: 3014
                MODIFIED_DATABASE_PAGES: 0
                PENDING_DECOMPRESS: 0
                PENDING_READS: 0
                PENDING_FLUSH_LRU: 0
                PENDING_FLUSH_LIST: 0
                PAGES_MADE_YOUNG: 15907
                PAGES_NOT_MADE_YOUNG: 3803101
                PAGES_MADE_YOUNG_RATE: 0
                PAGES_MADE_NOT_YOUNG_RATE: 0
                NUMBER_PAGES_READ: 3270
                NUMBER_PAGES_CREATED: 13176
                NUMBER_PAGES_WRITTEN: 15109
                PAGES_READ_RATE: 0
                PAGES_CREATE_RATE: 0
                PAGES_WRITTEN_RATE: 0
                NUMBER_PAGES_GET: 33069332
                HIT_RATE: 0
```

```

YOUNG_MAKE_PER_THOUSAND_GETS: 0
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
  NUMBER_PAGES_READ_AHEAD: 2713
    NUMBER_READ_AHEAD_EVICTED: 0
      READ_AHEAD_RATE: 0
        READ_AHEAD_EVICTED_RATE: 0
          LRU_IO_TOTAL: 0
            LRU_IO_CURRENT: 0
              UNCOMPRESS_TOTAL: 0
                UNCOMPRESS_CURRENT: 0

```

For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see [Section 15.17.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

```

mysql> SHOW ENGINE INNODB STATUS \G
...
-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 137428992
Dictionary memory allocated 579084
Buffer pool size      8192
Free buffers          1
Database pages        8173
Old database pages    3014
Modified db pages     0
Pending reads         0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 15907, not young 3803101
0.00 youngs/s, 0.00 non-youngs/s
Pages read 3270, created 13176, written 15109
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 8173, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...

```

For status variable descriptions, see [Section 6.1.7, “Server Status Variables”](#).

```

mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_dump_status | not started |
| Innodb_buffer_pool_load_status | not started |
| Innodb_buffer_pool_resize_status | not started |
| Innodb_buffer_pool_pages_data | 8173 |
| Innodb_buffer_pool_bytes_data | 133906432 |
| Innodb_buffer_pool_pages_dirty | 0 |
| Innodb_buffer_pool_bytes_dirty | 0 |
| Innodb_buffer_pool_pages_flushed | 15109 |
| Innodb_buffer_pool_pages_free | 1 |
| Innodb_buffer_pool_pages_misc | 18 |
| Innodb_buffer_pool_pages_total | 8192 |
| Innodb_buffer_pool_read_ahead_rnd | 0 |
| Innodb_buffer_pool_read_ahead | 2713 |
| Innodb_buffer_pool_read_ahead_evicted | 0 |
| Innodb_buffer_pool_read_requests | 33069332 |
| Innodb_buffer_pool_reads | 558 |
| Innodb_buffer_pool_wait_free | 0 |
| Innodb_buffer_pool_write_requests | 11985961 |
+-----+-----+

```

## 15.15.6 InnoDB INFORMATION\_SCHEMA Metrics Table

The `INNODB_METRICS` table, introduced in MySQL 5.6.2, consolidates all InnoDB performance and resource-related counters into a single `INFORMATION_SCHEMA` table.

The columns of the `INNODB_METRICS` table are shown in the following example. For a description of each column, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 46273
    MAX_COUNT: 46273
    MIN_COUNT: NULL
    AVG_COUNT: 492.2659574468085
COUNT_RESET: 46273
MAX_COUNT_RESET: 46273
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
   TIME_ENABLED: 2014-11-28 16:07:53
  TIME_DISABLED: NULL
  TIME_ELAPSED: 94
    TIME_RESET: NULL
      STATUS: enabled
        TYPE: status_counter
    COMMENT: Number of rows inserted
```

### Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following configuration options:

- `innodb_monitor_enable`: Enables one or more counters.

```
SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_disable`: Disables one or more counters.

```
SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset`: Resets the count value for one or more counters to zero.

```
SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset_all`: Resets all values for one or more counters. A counter must be disabled before using `innodb_monitor_reset_all`.

```
SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];
```

You can also enable counters and counter modules at startup using the MySQL server configuration file. For example, to enable the `log` module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of your `my.cnf` configuration file.

```
[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in your configuration file, you must specify the `innodb_monitor_enable` configuration option followed by counter and module names separated by a comma, as shown in the example above. Only the `innodb_monitor_enable` option can be used in your configuration file. The disable and reset configuration options are only supported on the command line.

**Note**

Because each counter imposes some degree of runtime overhead on the server, typically you enable more counters on test and development servers during experimentation and benchmarking, and only enable counters on production servers to diagnose known issues or monitor aspects that are likely to be bottlenecks for a particular server and workload.

**Counters**

The counters represented in the [INNODB\\_METRICS](#) table are subject to change, so for the most up-to-date list, query a running MySQL server. The list below shows counters that are available as of MySQL 5.7.6.

Counters that are enabled by default correspond to those used by [SHOW ENGINE INNODB STATUS](#). Counters used by [SHOW ENGINE INNODB STATUS](#) are always “on” at a system level but you can disable these counters for the [INNODB\\_METRICS](#) table, as required. Also, counter status is not persistent. Unless specified otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by additions or changes to the [INNODB\\_METRICS](#) table, it is recommended that you review releases notes and query the [INNODB\\_METRICS](#) table for the new release prior to upgrading.

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

name	subsystem	status

## Counter Modules

The module names correspond to, but are not identical to, the values from the `SUBSYSTEM` column of the `INNODB_METRICS` table. Rather enabling, disabling, or resetting counters individually, you can use module names to quickly enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE subsystem = 'dml';
+-----+-----+-----+
| name          | subsystem | status |
+-----+-----+-----+
| dml_reads     | dml       | enabled |
| dml_inserts   | dml       | enabled |
| dml_deletes   | dml       | enabled |
| dml_updates   | dml       | enabled |
+-----+-----+-----+
```

Here are the values you can use for `module_name` with the `innodb_monitor_enable` and related configuration options, along with the corresponding `SUBSYSTEM` names:

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_buffer` (subsystem = `buffer`)
- `module_buffer_page` (subsystem = `buffer_page_io`)
- `module_compress` (subsystem = `compression`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)
- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `recovery`)
- `module_metadata` (subsystem = `metadata`)
- `module_os` (subsystem = `os`)
- `module_purge` (subsystem = `purge`)
- `module_trx` (subsystem = `transaction`)

### Example 15.20 Working with INNODB\_METRICS Table Counters

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the `INNODB_METRICS` table.

1. Create a simple `InnoDB` table:

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the `dml_inserts` counter.

```
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the `dml_inserts` counter can be found in the `COMMENT` column of the `INNODB_METRICS` table:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-----+-----+
| NAME          | COMMENT                                |
+-----+-----+
| dml_inserts   | Number of rows inserted              |
+-----+-----+
```

3. Query the `INNODB_METRICS` table for the `dml_inserts` counter data. Because no DML operations have been performed, the counter values are zero or NULL. The `TIME_ENABLED` and `TIME_ELAPSED` values indicate when the counter was last enabled and how many seconds have elapsed since this time.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 0
    MAX_COUNT: 0
    MIN_COUNT: NULL
    AVG_COUNT: 0
    COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 28
    TIME_RESET: NULL
      STATUS: enabled
        TYPE: status_counter
    COMMENT: Number of rows inserted
```

4. Insert three rows of data into the table.

```
mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)
```

5. Query the `INNODB_METRICS` table again for the `dml_inserts` counter data. A number of counter values have now incremented including `COUNT`, `MAX_COUNT`, `AVG_COUNT`, and `COUNT_RESET`. Refer to the `INNODB_METRICS` table definition for descriptions of these values.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
```

```

SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.046153846153846156
COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 65
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted

```

6. Reset the `dml_inserts` counter, and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The `%_RESET` values that were reported previously, such as `COUNT_RESET` and `MAX_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```

mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.03529411764705882
  COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
    TIME_ENABLED: 2014-12-04 14:18:28
  TIME_DISABLED: NULL
    TIME_ELAPSED: 85
    TIME_RESET: 2014-12-04 14:19:44
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted

```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disbaled`.

```

mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.030612244897959183
  COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
    TIME_ENABLED: 2014-12-04 14:18:28
  TIME_DISABLED: 2014-12-04 14:20:06
    TIME_ELAPSED: 98

```

```

TIME_RESET: NULL
STATUS: disabled
TYPE: status_counter
COMMENT: Number of rows inserted

```

**Note**

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify `dml_%` to enable, disable, or reset all counters that begin with `dml_%`.

- After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```

mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 0
    MAX_COUNT: NULL
    MIN_COUNT: NULL
    AVG_COUNT: NULL
    COUNT_RESET: 0
MAX_COUNT_RESET: NULL
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
    TIME_ENABLED: NULL
    TIME_DISABLED: NULL
    TIME_ELAPSED: NULL
    TIME_RESET: NULL
      STATUS: disabled
      TYPE: status_counter
    COMMENT: Number of rows inserted

```

## 15.15.7 InnoDB INFORMATION\_SCHEMA Temporary Table Information Table

The `INNODB_TEMP_TABLE_INFO` table, introduced in MySQL 5.7.1, provides users with a snapshot of active InnoDB temporary tables. The table contains metadata about all user and system-created temporary tables that are active within a given InnoDB instance with the exception of optimized temporary tables that are used internally by InnoDB.

```

mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_TEMP%) |
+-----+
| INNODB_TEMP_TABLE_INFO                       |
+-----+

```

For the table definition, see [Section 23.31.26, “The INFORMATION\\_SCHEMA INNODB\\_TEMP\\_TABLE\\_INFO Table”](#).

### Example 15.21 INNODB\_TEMP\_TABLE\_INFO

This example demonstrates characteristics of the `INNODB_TEMP_TABLE_INFO` table.

- Create a simple InnoDB temporary table with a single column:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

2. Query the `INNODB_TEMP_TABLE_INFO` table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 194
        NAME: #sql7a79_1_0
        N_COLS: 4
        SPACE: 182
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
```

The `TABLE_ID` is a unique identifier for the temporary table. The `NAME` column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of columns (`N_COLS`) is 4 rather than 1 because InnoDB always creates three hidden table columns (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). `PER_TABLE_TABLESPACE` and `IS_COMPRESSED` only report `TRUE` for compressed temporary tables.

3. Create a compressed temporary table. Before you do so, ensure that `innodb_file_format` is set to `Barracuda`, which is required to create tables with a compressed row format.

```
mysql> SET GLOBAL innodb_file_format="Barracuda";
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TEMPORARY TABLE t2 (c1 INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)
```

4. Query the `INNODB_TEMP_TABLE_INFO` table again.

```
mysql> CREATE TEMPORARY TABLE t2 (c1 INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 195
        NAME: #sql7a79_1_1
        N_COLS: 4
        SPACE: 183
PER_TABLE_TABLESPACE: TRUE
      IS_COMPRESSED: TRUE
***** 2. row *****
      TABLE_ID: 194
        NAME: #sql7a79_1_0
        N_COLS: 4
        SPACE: 182
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
```

`PER_TABLE_TABLESPACE` and `IS_COMPRESSED` report `TRUE` for the compressed temporary table. The `SPACE` ID for the compressed temporary table is different because compressed temporary tables are created in separate per-table tablespaces. Non-compressed temporary tables share a single tablespace (`ibtmp1`, by default) and report the same `SPACE` ID.

5. Restart MySQL and query the `INNODB_TEMP_TABLE_INFO` table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
Empty set (0.00 sec)
```

An empty set is returned because the `INNODB_TEMP_TABLE_INFO` table and the data within it are not persisted to disk on server shutdown.

## 6. Create a new temporary table.

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

7. Query the `INNODB_TEMP_TABLE_INFO` table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 196
        NAME: #sql7b0e_1_0
       N_COLS: 4
        SPACE: 184
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
```

The `SPACE` ID is new because it is dynamically generated on server restart.

## 15.15.8 Retrieving InnoDB Tablespace Metadata from INFORMATION\_SCHEMA.FILES

As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including [file-per-table tablespaces](#), [general tablespaces](#), the [system tablespace](#), [temporary table tablespaces](#), and [undo tablespaces](#) (if present).

This section provides InnoDB-specific usage examples. For more information about data provided by the `INFORMATION_SCHEMA.FILES` table, see [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

### Note

The `INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES` tables also provide metadata about InnoDB tablespaces, but data is limited to file-per-table and general tablespaces.

This query retrieves metadata about the InnoDB system tablespace from fields of the `INFORMATION_SCHEMA.FILES` table that are pertinent to InnoDB tablespaces. `INFORMATION_SCHEMA.FILES` fields that are not relevant to InnoDB always return NULL, and are excluded from the query.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system' \G
***** 1. row *****
      FILE_ID: 0
      FILE_NAME: ./ibdata1
      FILE_TYPE: TABLESPACE
TABLESPACE_NAME: innodb_system
    FREE_EXTENTS: 0
    TOTAL_EXTENTS: 12
    EXTENT_SIZE: 1048576
    INITIAL_SIZE: 12582912
    MAXIMUM_SIZE: NULL
AUTOEXTEND_SIZE: 67108864
      DATA_FREE: 4194304
          ENGINE: NORMAL
```

This query retrieves the `FILE_ID` (equivalent to the space ID) and the `FILE_NAME` (which includes path information) for InnoDB file-per-table and general tablespaces. File-per-table and general tablespaces have a `.ibd` file extension.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
```

```
WHERE FILE_NAME LIKE '%.ibd%' ORDER BY FILE_ID;
```

FILE_ID	FILE_NAME
2	./mysql/plugin.ibd
3	./mysql/servers.ibd
4	./mysql/help_topic.ibd
5	./mysql/help_category.ibd
6	./mysql/help_relation.ibd
7	./mysql/help_keyword.ibd
8	./mysql/time_zone_name.ibd
9	./mysql/time_zone.ibd
10	./mysql/time_zone_transition.ibd
11	./mysql/time_zone_transition_type.ibd
12	./mysql/time_zone_leap_second.ibd
13	./mysql/innodb_table_stats.ibd
14	./mysql/innodb_index_stats.ibd
15	./mysql/slave_relay_log_info.ibd
16	./mysql/slave_master_info.ibd
17	./mysql/slave_worker_info.ibd
18	./mysql/gtid_executed.ibd
19	./mysql/server_cost.ibd
20	./mysql/engine_cost.ibd
21	./sys/sys_config.ibd
23	./test/t1.ibd
26	/home/user/test/test/t2.ibd

This query retrieves the `FILE_ID` and `FILE_NAME` for InnoDB temporary tablespaces. Temporary tablespace file names are prefixed by `ibtmp`.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%ibtmp%';
```

FILE_ID	FILE_NAME
22	./ibtmp1

Similarly, InnoDB undo tablespace file names are prefixed by `undo`. The following query returns the `FILE_ID` and `FILE_NAME` for InnoDB undo tablespaces, if separate undo tablespaces are configured.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%undo%';
```

## 15.16 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see [Chapter 24, MySQL Performance Schema](#).

You can profile certain internal InnoDB operations using the MySQL [Performance Schema feature](#). This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the [Performance Schema feature](#). For example, you should know how enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see [Section 24.1, “Performance Schema Quick Start”](#).

- You should be familiar with Performance Schema instruments that are available for [InnoDB](#). To view [InnoDB](#)-related instruments, you can query the `setup_instruments` table for instrument names that contain 'innodb'.

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE '%innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	NO	NO
wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
wait/synch/mutex/innodb/file_format_max_mutex	NO	NO
...		
wait/io/file/innodb/innodb_data_file	YES	YES
wait/io/file/innodb/innodb_log_file	YES	YES
wait/io/file/innodb/innodb_temp_file	YES	YES
stage/innodb/alter table (end)	YES	YES
stage/innodb/alter table (flush)	YES	YES
stage/innodb/alter table (insert)	YES	YES
stage/innodb/alter table (log apply index)	YES	YES
stage/innodb/alter table (log apply table)	YES	YES
stage/innodb/alter table (merge sort)	YES	YES
stage/innodb/alter table (read PK and internal sort)	YES	YES
stage/innodb/buffer pool load	YES	YES
memory/innodb/buf_buf_pool	NO	NO
memory/innodb/dict_stats_bg_recalc_pool_t	NO	NO
memory/innodb/dict_stats_index_map_t	NO	NO
memory/innodb/dict_stats_n_diff_on_level	NO	NO
memory/innodb/other	NO	NO
memory/innodb/row_log_buf	NO	NO
memory/innodb/row_merge_sort	NO	NO
memory/innodb/std	NO	NO
memory/innodb/sync_debug_latches	NO	NO
memory/innodb/trx_sys_t::rw_trx_ids	NO	NO
...		

```
155 rows in set (0.00 sec)
```

For additional information about the instrumented [InnoDB](#) objects, you can query Performance Schema [instances tables](#), which provide additional information about instrumented objects. Instance tables relevant to [InnoDB](#) include:

- The `mutex_instances` table
- The `rwlock_instances` table
- The `cond_instances` table
- The `file_instances` table

#### Note

Mutexes and RW-locks related to the [InnoDB](#) buffer pool are not included in this coverage; the same applies to the output of the `SHOW ENGINE INNODB MUTEX` command.

For example, to view information about instrumented [InnoDB](#) file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```
mysql> SELECT * FROM file_instances WHERE EVENT_NAME LIKE '%innodb%'\G
***** 1. row *****
FILE_NAME: /path/to/mysql-5.7/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
***** 2. row *****
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 3. row *****
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 4. row *****
FILE_NAME: /path/to/mysql-5.7/data/mysql/engine_cost.ibd
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
...
```

- You should be familiar with [performance\\_schema](#) tables that store [InnoDB](#) event data. Tables relevant to [InnoDB](#)-related events include:
  - The [Wait Event](#) tables, which store wait events.
  - The [Summary](#) tables, which provide aggregated information for terminated events over time. Summary tables include [file I/O summary tables](#), which aggregate information about I/O operations.
  - [Stage Event](#) tables, which store event data for [InnoDB ALTER TABLE](#) and buffer pool load operations. For more information, see [Section 15.16.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#), and [Monitoring Buffer Pool Load Progress Using Performance Schema](#).

If you are only interested in [InnoDB](#)-related objects, use the clause `WHERE EVENT_NAME LIKE '%innodb%'` or `WHERE NAME LIKE '%innodb%'` (as required) when querying these tables.

## 15.16.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

As of MySQL 5.7.6, you can monitor [ALTER TABLE](#) progress for [InnoDB](#) tables using [Performance Schema](#).

There are seven stage events that represent different phases of [ALTER TABLE](#). Each stage event reports a running total of [WORK\\_COMPLETED](#) and [WORK\\_ESTIMATED](#) for the overall [ALTER TABLE](#) operation as it progresses through its different phases. [WORK\\_ESTIMATED](#) is calculated using a formula that takes into account all of the work that [ALTER TABLE](#) performs, and may be revised during [ALTER TABLE](#) processing. [WORK\\_COMPLETED](#) and [WORK\\_ESTIMATED](#) values are an abstract representation of all of the work performed by [ALTER TABLE](#).

In order of occurrence, [ALTER TABLE](#) stage events include:

- [stage/innodb/alter table \(read PK and internal sort\)](#): This stage is active when [ALTER TABLE](#) is in the reading-primary-key phase. It starts with [WORK\\_COMPLETED=0](#) and [WORK\\_ESTIMATED](#) set to the estimated number of pages in the primary key. When the stage is completed, [WORK\\_ESTIMATED](#) is updated to the actual number of pages in the primary key.

- `stage/innodb/alter table (merge sort)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (insert)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (log apply index)`: This stage includes the application of DML log generated while `ALTER TABLE` was running.
- `stage/innodb/alter table (flush)`: Before this stage begins, `WORK_ESTIMATED` is updated with a more accurate estimate, based on the length of the flush list.
- `stage/innodb/alter table (log apply table)`: This stage includes the application of concurrent DML log generated while `ALTER TABLE` was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.
- `stage/innodb/alter table (end)`: Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while `ALTER TABLE` was running.

#### Note

InnoDB `ALTER TABLE` stage events do not currently account for the addition of spatial indexes.

## ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the `stage/innodb/alter table%` stage event instruments and related consumer tables to monitor `ALTER TABLE` progress. For information about Performance Schema stage event instruments and related consumers, see [Section 24.10.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/alter%` instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES' WHERE NAME LIKE 'stage/innodb/alter%';
Query OK, 7 rows affected (0.00 sec)
Rows matched: 7 Changed: 7 Warnings: 0
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

3. Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the `employees` table of the `employees` sample database.

```
mysql> ALTER TABLE employees.employees ADD COLUMN middle_name varchar(14) AFTER first_name;
Query OK, 0 rows affected (9.27 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

4. Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_current;
+-----+-----+-----+
| EVENT_NAME                                | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) | 280           | 1245           |
+-----+-----+-----+
```

```
+-----+-----+-----+
1 row in set (0.01 sec)
```

The `events_stages_current` table returns an empty set if the `ALTER TABLE` operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/alter table (read PK and internal sort)	886	1213
stage/innodb/alter table (flush)	1213	1213
stage/innodb/alter table (log apply table)	1597	1597
stage/innodb/alter table (end)	1597	1597
stage/innodb/alter table (log apply table)	1981	1981

```
5 rows in set (0.00 sec)
```

As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 1981.

## 15.16.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using Performance Schema. Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable InnoDB mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available InnoDB mutex wait instruments, query the Performance Schema `setup_instruments` table, as shown below. All InnoDB mutex wait instruments are disabled by default.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	NO	NO
wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
wait/synch/mutex/innodb/file_format_max_mutex	NO	NO
wait/synch/mutex/innodb/fil_system_mutex	NO	NO
wait/synch/mutex/innodb/flush_list_mutex	NO	NO
wait/synch/mutex/innodb/fts_bg_threads_mutex	NO	NO
wait/synch/mutex/innodb/fts_delete_mutex	NO	NO
wait/synch/mutex/innodb/fts_optimize_mutex	NO	NO

wait/synch/mutex/innodb/fts_doc_id_mutex	NO	NO
wait/synch/mutex/innodb/log_flush_order_mutex	NO	NO
wait/synch/mutex/innodb/hash_table_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_bitmap_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_mutex	NO	NO
wait/synch/mutex/innodb/page_zip_stat_per_index_mutex	NO	NO
wait/synch/mutex/innodb/purge_sys_pq_mutex	NO	NO
wait/synch/mutex/innodb/recv_sys_mutex	NO	NO
wait/synch/mutex/innodb/recv_writer_mutex	NO	NO
wait/synch/mutex/innodb/redo_rseg_mutex	NO	NO
wait/synch/mutex/innodb/noredolog_rseg_mutex	NO	NO

-----+-----+-----+  
49 rows in set (0.02 sec)

- Some [InnoDB](#) mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all [InnoDB](#) mutex instances are instrumented and enabled, add the following [performance-schema-instrument](#) rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all [InnoDB](#) mutexes, you can disable specific instruments by adding additional [performance-schema-instrument](#) rules to your MySQL configuration file. For example, to disable [InnoDB](#) mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

#### Note

Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the [performance-schema-instrument](#) rules to your configuration file, restart the server. All the [InnoDB](#) mutexes except for those related to full text search are enabled. To verify, query the [setup\\_instruments](#) table. The [ENABLED](#) and [TIMED](#) columns should be set to [YES](#) for the instruments that you enabled.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	YES	YES
wait/synch/mutex/innodb/innobase_share_mutex	YES	YES
wait/synch/mutex/innodb/autoinc_mutex	YES	YES
...		
wait/synch/mutex/innodb/zip_pad_mutex	YES	YES

49 rows in set (0.00 sec)

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers SET enabled = 'YES'
-> WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	YES
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

15 rows in set (0.00 sec)

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
-> --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

The number of summarized wait events.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed wait events.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed wait events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed wait events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
-> FROM performance_schema.events_waits_summary_global_by_event_name
-> WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
-> ORDER BY COUNT_STAR DESC;
```

EVENT_NAME	COUNT_STAR	SUM_TIMER_WAIT_MS
wait/synch/mutex/innodb/os_mutex	78831	10.3283
wait/synch/mutex/innodb/log_sys_mutex	41488	6510.3233
wait/synch/mutex/innodb/trx_sys_mutex	29770	1107.9687
wait/synch/mutex/innodb/lock_mutex	24212	104.0724
wait/synch/mutex/innodb/trx_mutex	22756	1.9421
wait/synch/mutex/innodb/rseg_mutex	20333	3.6220
wait/synch/mutex/innodb/dict_sys_mutex	13422	2.2284
wait/synch/mutex/innodb/mutex_list_mutex	12694	344.1164
wait/synch/mutex/innodb/fil_system_mutex	9208	0.9542
wait/synch/mutex/innodb/rw_lock_list_mutex	8304	0.1794
wait/synch/mutex/innodb/trx_undo_mutex	6190	0.6801
wait/synch/mutex/innodb/buf_pool_mutex	2869	29.4623
wait/synch/mutex/innodb/innobase_share_mutex	2005	0.1349
wait/synch/mutex/innodb/flush_list_mutex	1274	0.1300
wait/synch/mutex/innodb/file_format_max_mutex	1016	0.0469
wait/synch/mutex/innodb/purge_sys_bh_mutex	1004	0.0326
wait/synch/mutex/innodb/buf_dblwr_mutex	640	0.0437
wait/synch/mutex/innodb/log_flush_order_mutex	437	0.0510
wait/synch/mutex/innodb/recv_sys_mutex	394	0.0202
wait/synch/mutex/innodb/srv_sys_mutex	169	0.5259
wait/synch/mutex/innodb/lock_wait_mutex	154	0.1172
wait/synch/mutex/innodb/ibuf_mutex	9	0.0027
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	2	0.0009
wait/synch/mutex/innodb/ut_list_mutex	1	0.0001
wait/synch/mutex/innodb/recv_writer_mutex	1	0.0005

25 rows in set (0.01 sec)

**Note**

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the `events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

## 15.17 InnoDB Monitors

[InnoDB](#) monitors provide information about the [InnoDB](#) internal state. This information is useful for performance tuning.

### 15.17.1 InnoDB Monitor Types

There are four types of [InnoDB](#) monitors:

- The standard [InnoDB](#) Monitor displays the following types of information:
  - Table and record locks held by each active transaction.
  - Lock waits of a transaction.
  - Semaphore waits of threads.
  - Pending file I/O requests.
  - Buffer pool statistics.
  - Purge and change buffer merge activity of the main [InnoDB](#) thread.
- The [InnoDB](#) Lock Monitor prints additional lock information as part of the standard [InnoDB](#) Monitor output.
- The [InnoDB](#) Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures.
- The [InnoDB](#) Table Monitor prints the contents of the [InnoDB](#) internal data dictionary.

**Note**

The Tablespace Monitor and Table Monitor were deprecated in MySQL 5.6.3 and have been removed in MySQL 5.7.4. For the Tablespace Monitor, equivalent functionality will be introduced before the GA release of MySQL 5.7. For the Table Monitor, equivalent information can be obtained from [InnoDB INFORMATION\\_SCHEMA](#) tables.

For additional information about [InnoDB](#) monitors, see:

- Mark Leith: [InnoDB Table and Tablespace Monitors](#)

### 15.17.2 Enabling InnoDB Monitors

When you enable [InnoDB](#) monitors for periodic output, [InnoDB](#) writes their output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, [InnoDB](#)

monitors print data about every 15 seconds. Server output usually is directed to the error log (see [Section 6.4.2, “The Error Log”](#)). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

InnoDB sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. InnoDB removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb-status-file=1` is set.

InnoDB monitors should be enabled only when you actually want to see monitor information because output generation does result in some performance decrement. Also, if you enable monitor output, your error log may become quite large if you forget to disable it later.

#### Note

To assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see [Section 15.21, “InnoDB Troubleshooting”](#).

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT
=====
```

The header for the standard InnoDB Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

Enabling an InnoDB monitor for periodic output involves using a `CREATE TABLE` statement to create a specially named InnoDB table that is associated with the monitor. For example, to enable the standard InnoDB Monitor, you would create an InnoDB table named `innodb_monitor`.

Using `CREATE TABLE` syntax is just a way to pass a command to the InnoDB engine through MySQL's SQL parser. The only things that matter are the table name and that it be an InnoDB table. The structure of the table is not relevant. If you shut down the server, the monitor does not restart automatically when you restart the server. Drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor.

#### Note

The `CREATE TABLE` method of enabling InnoDB monitors was removed in MySQL 5.7.4. Use the `innodb_status_output` and `innodb_status_output_locks` system variables to enable the standard InnoDB Monitor and InnoDB Lock Monitor.

The `PROCESS` privilege is required to enable and disable InnoDB Monitors.

## Enabling the Standard InnoDB Monitor

Prior to MySQL 5.7.4, enable the standard InnoDB Monitor for periodic output by creating the `innodb_monitor` table:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To disable the standard [InnoDB](#) Monitor, drop the table:

```
DROP TABLE innodb_monitor;
```

As of MySQL 5.7.4, enable the standard [InnoDB](#) Monitor by setting the `innodb_status_output` system variable to [ON](#).

```
set GLOBAL innodb_status_output=ON;
```

To disable the standard [InnoDB](#) Monitor, set `innodb_status_output` to [OFF](#).

When you shut down the server, the `innodb_status_output` variable is set to the default [OFF](#) value.

## Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard [InnoDB](#) Monitor for periodic output, you can obtain standard [InnoDB](#) Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes [InnoDB](#) Lock Monitor data if the [InnoDB](#) Lock Monitor is enabled.

## Enabling the InnoDB Lock Monitor

Prior to MySQL 5.7.4, enable the [InnoDB](#) Lock Monitor for periodic output by creating the `innodb_lock_monitor` table:

```
CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;
```

To disable the [InnoDB](#) Lock Monitor, drop the table:

```
DROP TABLE innodb_lock_monitor;
```

[InnoDB](#) Lock Monitor data is printed with the standard [InnoDB](#) Monitor output. Both the [InnoDB](#) standard Monitor and [InnoDB](#) Lock Monitor must be enabled to have [InnoDB](#) Lock Monitor data printed periodically.

As of MySQL 5.7.4, you can also enable the [InnoDB](#) Lock Monitor by setting the `innodb_status_output_locks` system variable to [ON](#). As with the `CREATE TABLE` method for enabling [InnoDB](#) Monitors, both the [InnoDB](#) standard Monitor and [InnoDB](#) Lock Monitor must be enabled to have [InnoDB](#) Lock Monitor data printed periodically:

```
set GLOBAL innodb_status_output=ON;  
set GLOBAL innodb_status_output_locks=ON;
```

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default [OFF](#) value.

To disable the [InnoDB](#) Lock Monitor, set `innodb_status_output_locks` to [OFF](#). Set `innodb_status_output` to [OFF](#) to also disable the standard [InnoDB](#) Monitor.

**Note**

To enable the [InnoDB](#) Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

**Enabling the InnoDB Tablespace Monitor**

To enable the [InnoDB](#) Tablespace Monitor for periodic output, create the `innodb_tablespace_monitor` table:

```
CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;
```

To disable the standard [InnoDB](#) Tablespace Monitor, drop the table:

```
DROP TABLE innodb_tablespace_monitor;
```

**Note**

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

**Enabling the InnoDB Table Monitor**

To enable the [InnoDB](#) Table Monitor for periodic output, create the `innodb_table_monitor` table:

```
CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;
```

To disable the [InnoDB](#) Table Monitor, drop the table:

```
DROP TABLE innodb_table_monitor;
```

**Note**

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

**15.17.3 InnoDB Standard Monitor and Lock Monitor Output**

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to the server's error output.

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
  Type: InnoDB
  Name:
Status:
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT
=====
```

```

## Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the [Metrics](#) chapter in the [Oracle Enterprise Manager for MySQL Database User's Guide](#).

### Status

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time [InnoDB](#) Monitor output was printed.

### BACKGROUND THREAD

The [srv\\_master\\_thread](#) lines shows work done by the main background thread.

### SEMAPHORES

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside [InnoDB](#). Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the [innodb\\_thread\\_concurrency](#) system variable smaller than the default value might help in such situations. The [Spin rounds per wait](#) line shows the number of spinlock rounds per OS wait for a mutex.

The line that reports mutex spin waits, rounds, and OS waits information was removed from [SHOW ENGINE INNODB STATUS](#) output in MySQL 5.7.8. Mutex metrics are reported by [SHOW ENGINE INNODB MUTEX](#).

### LATEST FOREIGN KEY ERROR

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

#### LATEST DETECTED DEADLOCK

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 15.5.1, “InnoDB Locking”](#).

#### TRANSACTIONS

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

#### FILE I/O

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 15.14, “InnoDB Startup Options and System Variables”](#).

#### INSERT BUFFER AND ADAPTIVE HASH INDEX

This section shows the status of the InnoDB insert buffer (also referred to as the [change buffer](#)) and the adaptive hash index.

For related information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.4.3, “Adaptive Hash Index”](#).

#### LOG

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See [Section 15.12.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

#### BUFFER POOL AND MEMORY

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#). For additional information about the operation of the buffer pool, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

#### ROW OPERATIONS

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

## 15.17.4 InnoDB Tablespace Monitor Output

### Note

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from `INFORMATION_SCHEMA` tables.

The [InnoDB](#) Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. The Tablespace Monitor does not describe file-per-table tablespaces created with the [innodb\\_file\\_per\\_table](#) option.

Example [InnoDB](#) Tablespace Monitor output:

```
=====
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT
=====
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28

...
SEGMENT id 0 601 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
NUMBER of file segments: 73
Validating tablespace
Validation ok
-----
END OF INNODB TABLESPACE MONITOR OUTPUT
=====
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

In this example using the default [page size](#), the tablespace consists of database pages that are 16KB each. The pages are grouped into [extents](#) of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- [id](#): The tablespace ID. A value of 0 refers to the shared tablespace.
- [size](#): The current tablespace size in pages.

- **free limit**: The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.
- **free extents**: The number of free extents.
- **not full frag extents, used pages**: The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.
- **full frag extents**: The number of completely full fragment extents.
- **first seg id not used**: The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2  
fragm pages 32; free extents 0; not full extents 0: pages 0
```

Segment information includes these values:

**id**: The segment ID.

**space, page**: The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. InnoDB uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (**id**, **res**, and so forth) are derived from information in the inode.

**res**: The number of pages allocated (reserved) for the segment.

**used**: The number of allocated pages in use by the segment.

**full ext**: The number of extents allocated for the segment that are completely used.

**fragm pages**: The number of initial pages that have been allocated to the segment.

**free extents**: The number of extents allocated for the segment that are completely unused.

**not full extents**: The number of extents allocated for the segment that are partially used.

**pages**: The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and InnoDB allocates the first pages for it one at a time, up to 32 pages (this is the **fragm pages** value). After that, InnoDB allocates complete extents. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0  
fragm pages 32; free extents 0; not full extents 1: pages 14
```

It is possible for a segment that has extents allocated to it to have a **fragm pages** value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

## 15.17.5 InnoDB Table Monitor Output

### Note

The [InnoDB](#) Table Monitor was removed in MySQL 5.7.4. Equivalent information can be obtained from [InnoDB INFORMATION\\_SCHEMA](#) tables. See [Section 23.31](#), “[InnoDB INFORMATION\\_SCHEMA Tables](#)”.

The [InnoDB](#) Table Monitor prints the contents of the [InnoDB](#) internal data dictionary.

The output contains one section per table. The [SYS\\_FOREIGN](#) and [SYS\\_FOREIGN\\_COLS](#) sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created [InnoDB](#) table. Suppose that the following two tables have been created in the [test](#) database:

```
CREATE TABLE parent
(
  par_id      INT NOT NULL,
  fname       CHAR(20),
  lname       CHAR(20),
  PRIMARY KEY (par_id),
  UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id      INT NOT NULL,
  child_id    INT NOT NULL,
  name        VARCHAR(40),
  birth       DATE,
  weight       DECIMAL(10,2),
  misc_info   VARCHAR(255),
  last_update TIMESTAMP,
  PRIMARY KEY (par_id, child_id),
  INDEX (name),
  FOREIGN KEY (par_id) REFERENCES parent (par_id)
    ON DELETE CASCADE
    ON UPDATE CASCADE
) ENGINE = INNODB;
```

Then the Table Monitor output will look something like this (reformatted slightly):

```
=====
090420 12:09:32 INNODB TABLE MONITOR OUTPUT
=====
-----
TABLE: name SYS_FOREIGN, id 0 11, columns 7, indexes 3, appr.rows 1

-----
END OF INNODB TABLE MONITOR OUTPUT
=====

```

For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in *db\_name/tbl\_name* format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The **COLUMNS** part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as **DB\_ROW\_ID** (row ID), **DB\_TRX\_ID** (transaction ID), and **DB\_ROLL\_PTR** (a pointer to the rollback/undo data).

- `DATA_xxx`: These symbols indicate the data type. There may be multiple `DATA_xxx` symbols for a given column.
- `prtype`: The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.
- `len`: The column length in bytes.

Each `INDEX` part of the table section provides the name and characteristics of one table index:

- `name`: The index name. If the name is `PRIMARY`, the index is a primary key. If the name is `GEN_CLUST_INDEX`, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-`NULL` unique index. See [Section 15.8.9, "Clustered and Secondary Indexes"](#).
- `id`: The index ID.
- `fields`: The number of fields in the index, as a value in `m/n` format:
  - `m` is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.
  - `n` is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.
- `uniq`: The number of leading fields that are enough to determine index values uniquely.
- `type`: The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a `type` value of 3. An index with a `type` value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.
- `root page`: The index root page number.
- `appr. key vals`: The approximate index cardinality.
- `leaf pages`: The approximate number of leaf pages in the index.
- `size pages`: The approximate total number of pages in the index.
- `FIELDS`: The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal `DB_ROW_ID` (row ID) field. `DB_TRX_ID` and `DB_ROLL_PTR` are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the `FOREIGN KEY` definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

## 15.18 InnoDB Backup and Recovery

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these techniques, alone or in combination: [hot backup](#) with MySQL Enterprise Backup; [cold backup](#) by copying files while the MySQL

server is shut down; [physical backup](#) for fast operation (especially for restore); [logical backup](#) with `mysqldump` for smaller data volumes or to record the structure of schema objects.

## Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including [InnoDB](#) and [MyISAM](#) tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying [InnoDB](#) tables, reads and writes to both [InnoDB](#) and [MyISAM](#) tables can continue. During the copying of [MyISAM](#) tables, reads (but not writes) to those tables are permitted. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with MySQL's binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see [Section 28.2, “MySQL Enterprise Backup Overview”](#).

## Cold Backups

If you can shut down your MySQL server, you can make a binary backup that consists of all files used by [InnoDB](#) to manage its tables. Use the following procedure:

1. Do a [slow shutdown](#) of the MySQL server and make sure that it stops without errors.
2. Copy all [InnoDB](#) data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all the `.frm` files for [InnoDB](#) tables to a safe place.
4. Copy all [InnoDB](#) log files (`ib_logfile` files) to a safe place.
5. Copy your `my.cnf` configuration file or files to a safe place.

## Alternative Backup Types

In addition to making binary backups as just described, regularly make dumps of your tables with `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See [Section 8.3.1, “Establishing a Backup Policy”](#).

Replication works with [InnoDB](#) tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

## Performing Recovery

To recover your [InnoDB](#) database to the present from the time at which the binary backup was made, you must run your MySQL server with binary logging turned on, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 8.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

To recover from a crash of your MySQL server, the only requirement is to restart it. [InnoDB](#) automatically checks the logs and performs a roll-forward of the database to the present. [InnoDB](#) automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
```

```
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264

```

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of InnoDB consistency problems, see [Section 15.21.2, “Forcing InnoDB Recovery”](#) for steps to start the instance in a diagnostic mode where you can dump the data.

### 15.18.1 The InnoDB Recovery Process

InnoDB crash recovery consists of several steps:

- Applying the [redo log](#): Redo log application is the first step and is performed during initialization, before accepting any connections. If all changes were flushed from the [buffer pool](#) to the [tablespaces](#) (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, the redo log application can be skipped. If the redo log files are missing at startup, InnoDB skips the redo log application.

Removing redo logs to speed up the recovery process is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered an option after a clean shutdown is performed, with `innodb_fast_shutdown` set to 0 or 1.

- [Rolling back incomplete transactions](#): Any transactions that were active at the time of crash or [fast shutdown](#). The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are in the process of being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an `innodb_force_recovery` setting of 3 or greater. See [Section 15.21.2, “Forcing InnoDB Recovery”](#) for more information.

- [Change buffer merge](#): Applying changes from the change buffer (part of the [system tablespace](#)) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- **Purge**: Deleting delete-marked records that are no longer visible for any active transaction.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, InnoDB attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, InnoDB rolls back any transactions that were not committed or in **XA PREPARE** state when the server crashed. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is needed from the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In that case, see [Section 15.21.2, “Forcing InnoDB Recovery”](#) for the steps to troubleshoot such an issue.

For information about the binary log and InnoDB crash recovery, see [Section 6.4.4, “The Binary Log”](#).

## 15.18.2 Tablespace Discovery During Crash Recovery

If, during crash recovery, InnoDB encounters redo logs written since the last checkpoint, the redo logs must be applied to the affected tablespaces. The process that identifies affected tablespaces is referred to as *tablespace discovery*.

Prior to MySQL 5.7.5, tablespace files were referenced in redo logs by a `space_id`, which is a numeric identifier. In the file system, however, **file-per-table** tablespaces are known by a `*.ibd` file name, which required that InnoDB construct a “space\_id-file name” map in order to apply redo logs. To construct the map, InnoDB traversed the data directory, reading the first page of each `*.ibd` file. This process could result in unnecessary downtime for MySQL instances with numerous `*.ibd` files.

In MySQL 5.6.6, the introduction of support for the **CREATE TABLE DATA DIRECTORY** clause for **file-per-table** tablespaces further complicated tablespace discovery. The **DATA DIRECTORY** enhancement introduced `.isl` files as placeholders that point to the location of `*.ibd` files stored outside of the MySQL data directory.

In MySQL 5.7.5, instead of reading the first page of all `$datadir/*/*.ibd` files and checking the contents of `$datadir/*/*.isl` files before applying redo logs, InnoDB uses a new redo log record type to identify the file-per-table tablespaces that have been modified since the last checkpoint. An **MLOG\_FILE\_NAME** record, which contains the tablespace `space_id` and file name, is written to the redo log when a tablespace page is modified. The benefits of **MLOG\_FILE\_NAME** redo log records include:

- Elimination of file system scans prior to redo log application. The **MLOG\_FILE\_NAME** redo log record provides the information necessary to identify and locate tablespaces that have changed since the last checkpoint.
- Only `*.ibd` files modified since the last checkpoint are accessed.
- `*.ibd` files that are not attached to the InnoDB instance are ignored when redo logs are applied.
- InnoDB no longer silently discards redo log records for missing `*.ibd` files unless there is an **MLOG\_FILE\_DELETE** record in the redo log. For example, if a file rename fails, resulting in a “missing” `*.ibd` file, you can manually rename the file and restart crash recovery. Missing `*.ibd` files are ignored in `innodb_force_recovery` mode.
- During recovery, the redo log is read from the last checkpoint to the detected logical end of the log. If tablespace files that are referenced in the scanned portion of the redo log are missing, startup is refused.

- Failure scenarios related to inconsistent \*.isl files are eliminated. \*.isl files are now only used after redo log apply, when opening tables.

In MySQL 5.7.6, two tablespace discovery searches were added with the introduction of InnoDB general tablespaces.

- The first search traverses SYS\_TABLESPACES and related entries in SYS\_DATAFILES, in the internal data dictionary. All previously created general tablespaces are opened, including general tablespaces that are empty.
- The second search traverses SYS\_TABLES, in the internal data dictionary. For tables with a SPACE ID greater than 0, the SPACE ID is looked up in SYS\_DATAFILES to ensure that the tablespace is opened.

## 15.19 InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, make a copy of the InnoDB tablespace and the log files, as well as the .frm files of the InnoDB tables, and move the copies to the slave. If the innodb\_file\_per\_table option is enabled, copy the .ibd files as well. For the proper procedure to do this, see [Section 15.18, “InnoDB Backup and Recovery”](#).

To make a new slave without taking down the master or an existing slave, use the [MySQL Enterprise Backup](#) product. If you can shut down the master or an existing slave, take a [cold backup](#) of the InnoDB tablespaces and log files and use that to set up a slave.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 14.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

**Replication and CASCADE.** Cascading actions for InnoDB tables on the master are replicated on the slave *only* if the tables sharing the foreign key relation use InnoDB on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the master using the following CREATE TABLE statements:

```
CREATE TABLE fc1 (
  i INT PRIMARY KEY,
  j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
  m INT PRIMARY KEY,
  n INT,
  FOREIGN KEY ni (n) REFERENCES fc1 (i)
    ON DELETE CASCADE
) ENGINE = InnoDB;
```

Suppose that the slave does not have InnoDB support enabled. If this is the case, then the tables on the slave are created, but they use the MyISAM storage engine, and the FOREIGN KEY option is ignored. Now we insert some rows into the tables on the master:

```

master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2  Duplicates: 0  Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3  Duplicates: 0  Warnings: 0

```

At this point, on both the master and the slave, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```

master> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+-----+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+-----+
3 rows in set (0.00 sec)

```

Now suppose that you perform the following `DELETE` statement on the master:

```

master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```

master> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 2 | 2 |
+-----+
1 row in set (0.00 sec)

```

However, the cascade does not propagate on the slave because on the slave the `DELETE` for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```
slave> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+-----+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the [InnoDB](#) storage engine, which means that none of the changes are logged.

## 15.20 InnoDB memcached Plugin

The [InnoDB memcached](#) plugin (`daemon_memcached`) provides an integrated [memcached](#) daemon that automatically stores and retrieves data from [InnoDB](#) tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can use simple `get`, `set`, and `incr` operations that avoid the performance overhead associated with SQL parsing and constructing a query optimization plan. You can also access the same [InnoDB](#) tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This “NoSQL-style” interface uses the [memcached](#) API to speed up database operations, letting [InnoDB](#) handle memory caching using its [buffer pool](#) mechanism. Data modified through [memcached](#) operations such as `add`, `set`, and `incr` are stored to disk, in [InnoDB](#) tables. The combination of [memcached](#) simplicity and [InnoDB](#) reliability and consistency provides users with the best of both worlds, as explained in [Section 15.20.1, “Benefits of the InnoDB memcached Plugin”](#). For an architectural overview, see [Section 15.20.2, “InnoDB memcached Architecture”](#).

### 15.20.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the `daemon_memcached` plugin. The combination of [InnoDB](#) tables and [memcached](#) offers advantages over using either by themselves.

- Direct access to the [InnoDB](#) storage engine avoids the parsing and planning overhead of SQL.
- Running [memcached](#) in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data written using the [memcached](#) protocol is transparently written to an [InnoDB](#) table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.
- Data requested through the [memcached](#) protocol is transparently queried from an [InnoDB](#) table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the [InnoDB](#) buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using [InnoDB](#) configuration options.
- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.
- [InnoDB](#) can handle composing and decomposing multiple column values into a single [memcached](#) item value, reducing the amount of string parsing and concatenation required in your application. For

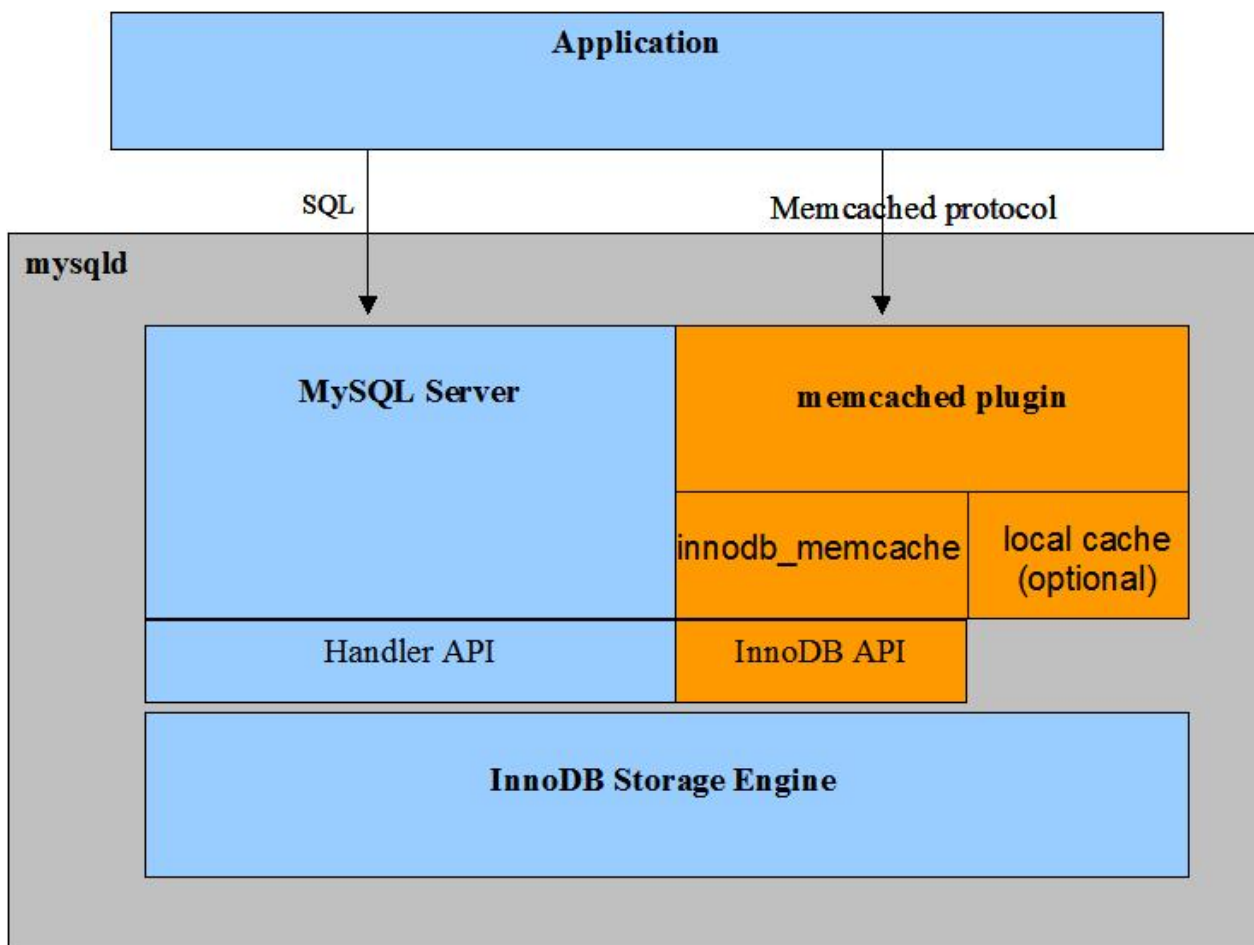

example, you can store the string value `2 | 4 | 6 | 8` in the `memcached` cache, and have `InnoDB` split the value based on a separator character, then store the result in four numeric columns.

- The transfer between memory and disk is handled automatically, simplifying application logic.
- Data is stored in a MySQL database to protect against crashes, outages, and corruption.
- You can access the underlying `InnoDB` table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.
- You can ensure high availability by using the `daemon_memcached` plugin on a `master server` in combination with MySQL replication.
- The integration of `memcached` with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more `add`, `incr`, and similar write operations in your application without concern that data could be lost. You can stop and start the `memcached` server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of `InnoDB` crash recovery, replication, and backup capabilities.
- The way `InnoDB` does fast `primary key` lookups is a natural fit for `memcached` single-item queries. The direct, low-level database access path used by the `daemon_memcached` plugin is much more efficient for key-value lookups than equivalent SQL queries.
- The serialization features of `memcached`, which can turn complex data structures, binary files, or even code blocks into storeable strings, offer a simple way to get such objects into a database.
- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as `AVG( )` and `MAX( )` on `memcached` data. All of these operations are expensive or complicated using `memcached` by itself.
- You do not need to manually load data into `memcached` at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the `InnoDB buffer pool`.
- Because `memcached` consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.
- Because data consistency is enforced by mechanisms used for regular `InnoDB` tables, you do not have to worry about stale `memcached` data or fallback logic to query the database in the case of a missing key.

## 15.20.2 InnoDB memcached Architecture

The `InnoDB memcached` plugin implements `memcached` as a MySQL plugin daemon that accesses the `InnoDB` storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the `daemon_memcached` plugin, compared with SQL.

Features of the `daemon_memcached` plugin:

- `memcached` as a daemon plugin of `mysqld`. Both `mysqld` and `memcached` run in the same process space, with very low latency access to data.
- Direct access to `InnoDB` tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.
- Standard `memcached` protocols, including the text-based protocol and the binary protocol. The `daemon_memcached` plugin passes all 55 compatibility tests of the `memcapable` command.
- Multi-column support. You can map multiple columns into the “value” part of the key/value store, with column values delimited by a user-specified separator character.
- By default, the `memcached` protocol is used to read and write data directly to `InnoDB`, letting MySQL manage in-memory caching using the `InnoDB buffer pool`. The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for `memcached get` requests.
- Advanced users can configure the system as a traditional `memcached` server, with all data cached only in the `memcached` engine (memory caching), or use a combination of the “`memcached` engine” (memory caching) and the `InnoDB memcached` engine (`InnoDB` as backend persistent storage).
- Control over how often data is passed back and forth between `InnoDB` and `memcached` operations through the `innodb_api_bk_commit_interval`, `daemon_memcached_r_batch_size`, and

`daemon_memcached_w_batch_size` configuration options. Batch size options default to a value of 1 for maximum reliability.

- The ability to specify `memcached` options through the `daemon_memcached_option` configuration parameter. For example, you can change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.
- The `innodb_api_trx_level` configuration option controls the transaction `isolation level` on queries processed by `memcached`. Although `memcached` has no concept of `transactions`, you can use this option to control how soon `memcached` sees changes caused by SQL statements issued on the table used by the `daemon_memcached` plugin. By default, `innodb_api_trx_level` is set to `READ UNCOMMITTED`.
- The `innodb_api_enable_md1` option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by `DDL` through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in `InnoDB` storage until `memcached` or some other user stops using it. “MDL” stands for “metadata locking”.

## Differences Between InnoDB memcached and Traditional memcached

You may already be familiar with using `memcached` with MySQL, as described in [Section 17.2, “Using MySQL with memcached”](#). This section describes how features of the integrated `InnoDB memcached` plugin differ from traditional `memcached`.

- **Installation:** The `memcached` library comes with the MySQL server, making installation and setup relatively easy. Installation involves running the `innodb_memcached_config.sql` script to create a `demo_test` table for `memcached` to use, issuing an `INSTALL PLUGIN` statement to enable the `daemon_memcached` plugin, and adding desired `memcached` options to a MySQL configuration file or startup script. You might still install the traditional `memcached` distribution for additional utilities such as `memcp`, `memcat`, and `memcapable`.

For comparison with traditional `memcached`, see [Section 17.2.1, “Installing memcached”](#).

- **Deployment:** With traditional `memcached`, it is typical to run large numbers of low-capacity `memcached` servers. A typical deployment of the `daemon_memcached` plugin, however, involves a smaller number of moderate or high-powered servers that are already running MySQL. The benefit of this configuration is in improving efficiency of individual database servers rather than exploiting unused memory or distributing lookups across large numbers of servers. In the default configuration, very little memory is used for `memcached`, and in-memory lookups are served from the `InnoDB buffer pool`, which automatically caches the most recently and frequently used data. As with a traditional MySQL server instance, keep the value of the `innodb_buffer_pool_size` configuration option as high as practical (without causing paging at the OS level), so that as much work as possible is performed in memory.

For comparison with traditional `memcached`, see [Section 17.2.2.2, “memcached Deployment”](#).

- **Expiry:** By default (that is, using the `innodb_only` caching policy), the latest data from the `InnoDB` table is always returned, so the expiry options have no practical effect. If you change the caching policy to `caching` or `cache-only`, the expiry options work as usual, but requested data might be stale if it is updated in the underlying table before it expires from the memory cache.

For comparison with traditional `memcached`, see [Section 17.2.2.4, “Data Expiry”](#).

- **Namespaces:** `memcached` is like a large directory where you give files elaborate names with prefixes and suffixes to keep the files from conflicting. The `daemon_memcached` plugin lets you use similar naming conventions for keys, with one addition. Key names in the format

`@@table_id.key.table_id` are decoded to reference a specific a table, using mapping data from the `innodb_memcache.containers` table. The `key` is looked up in or written to the specified table.

The `@@` notation only works for individual calls to `get`, `add`, and `set` functions, but not others such as `incr` or `delete`. To designate a default table for subsequent `memcached` operations within a session, perform a `get` request using the `@@` notation with a `table_id`, but without the key portion. For example:

```
get @@table_id
```

Subsequent `get`, `set`, `incr`, `delete`, and other operations use the table designated by `table_id` in the `innodb_memcache.containers.name` column.

For comparison with traditional `memcached`, see [Section 17.2.2.3, “Using Namespaces”](#).

- Hashing and distribution: The default configuration, which uses the `innodb_only` caching policy, is suitable for a traditional deployment configuration where all data is available on all servers, such as a set of replication slave servers.

If you physically divide data, as in a sharded configuration, you can split data across several machines running the `daemon_memcached` plugin, and use the traditional `memcached` hashing mechanism to route requests to a particular machine. On the MySQL side, you would typically let all data be inserted by `add` requests to `memcached` so that appropriate values are stored in the database on the appropriate server.

For comparison with traditional `memcached`, see [Section 17.2.2.5, “memcached Hashing/Distribution Types”](#).

- Memory usage: By default (with the `innodb_only` caching policy), the `memcached` protocol passes information back and forth with `InnoDB` tables, and the `InnoDB` buffer pool handles in-memory lookups instead of `memcached` memory usage growing and shrinking. Relatively little memory is used on the `memcached` side.

If you switch the caching policy to `caching` or `cache-only`, the normal rules of `memcached` memory usage apply. Memory for `memcached` data values is allocated in terms of “slabs”. You can control slab size and maximum memory used for `memcached`.

Either way, you can monitor and troubleshoot the `daemon_memcached` plugin using the familiar `statistics` system, accessed through the standard protocol, over a `telnet` session, for example. Extra utilities are not included with the `daemon_memcached` plugin. You can use the `memcached-tool` script to install a full `memcached` distribution.

For comparison with traditional `memcached`, see [Section 17.2.2.7, “Memory Allocation within memcached”](#).

- Thread usage: MySQL threads and `memcached` threads co-exist on the same server. Limits imposed on threads by the operating system apply to the total number of threads.

For comparison with traditional `memcached`, see [Section 17.2.2.8, “memcached Thread Support”](#).

- Log usage: Because the `memcached` daemon is run alongside the MySQL server and writes to `stderr`, the `-v`, `-vv`, and `-vvv` options for logging write output to the MySQL `error log`.

For comparison with traditional `memcached`, see [Section 17.2.2.9, “memcached Logs”](#).

- `memcached` operations: Familiar `memcached` operations such as `get`, `set`, `add`, and `delete` are available. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional `memcached`, see [Section 17.2.3.1, “Basic memcached Operations”](#).

- Using `memcached` as a MySQL front end: This is the primary purpose of the `InnoDB memcached` plugin. An integrated `memcached` daemon improves application performance, and having `InnoDB` handle data transfers between memory and disk simplifies application logic.

For comparison with traditional `memcached`, see [Section 17.2.3.2, “Using memcached as a MySQL Caching Layer”](#).

- Utilities: The MySQL server includes the `libmemcached` library but not additional command-line utilities. To use commands such as `memcp`, `memcat`, and `memcapable` commands, install a full `memcached` distribution. When `memrm` and `memflush` remove items from the cache, the items are also removed from the underlying `InnoDB` table.

For comparison with traditional `memcached`, see [libmemcached Command-Line Utilities](#).

- Programming interfaces: You can access the MySQL server through the `daemon_memcached` plugin using all supported languages: `C` and `C++`, `Java`, `Perl`, `Python`, `PHP`, and `Ruby`. Specify the server hostname and port as with a traditional `memcached` server. By default, the `daemon_memcached` plugin listens on port `11211`. You can use both the [text and binary protocols](#). You can customize the [behavior](#) of `memcached` functions at runtime. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional `memcached`, see [Section 17.2.3, “Developing a memcached Application”](#).

- Frequently asked questions: MySQL has an extensive FAQ for traditional `memcached`. The FAQ is mostly applicable, except that using `InnoDB` tables as a storage medium for `memcached` data means that you can use `memcached` for more write-intensive applications than before, rather than as a read-only cache.

See [Section 17.2.5, “memcached FAQ”](#).

## 15.20.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the `daemon_memcached` plugin on a MySQL server. Because the `memcached` daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

### Note

Before setting up the `daemon_memcached` plugin, consult [Section 15.20.4, “Security Considerations for the InnoDB memcached Plugin”](#) to understand the security procedures required to prevent unauthorized access.

### Prerequisites

- The `daemon_memcached` plugin is only supported on Linux, Solaris, and OS X platforms. Other operating systems are not supported.
- When building MySQL from source, you must build with `-DWITH_INNODB_MEMCACHED=ON`. This build option generates two shared libraries in the MySQL plugin directory (`plugin_dir`) that are required to run the `daemon_memcached` plugin:
  - `libmemcached.so`: the `memcached` daemon plugin to MySQL.
  - `innodb_engine.so`: an `InnoDB` API plugin to `memcached`.

- `libevent` must be installed.
- If you did not build MySQL from source, the `libevent` library is not included in your installation. Use the installation method for your operating system to install `libevent` 1.4.12 or later. For example, depending on the operating system, you might use `apt-get`, `yum`, or `port install`. For example, on Ubuntu Linux, use:

```
sudo apt-get install libevent-dev
```

- If you installed MySQL from a source code release, `libevent` 1.4.12 is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of `libevent`, no action is required. If you want to use a local system version of `libevent`, you must build MySQL with the `-DWITH_LIBEVENT` build option set to `system` or `yes`.

## Installing and Configuring the InnoDB memcached Plugin

1. Configure the `daemon_memcached` plugin so it can interact with InnoDB tables by running the `innodb_memcached_config.sql` configuration script, which is located in `MYSQL_HOME/share`. This script installs the `innodb_memcache` database with three required tables (`cache_policies`, `config_options`, and `containers`). It also installs the `demo_test` sample table in the `test` database.

```
mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
```

Running the `innodb_memcached_config.sql` script is a one-time operation. The tables remain in place if you later uninstall and re-install the `daemon_memcached` plugin.

```
mysql> USE innodb_memcache;
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies            |
| config_options            |
| containers                 |
+-----+

mysql> USE test;
mysql> SHOW TABLES;
+-----+
| Tables_in_test            |
+-----+
| demo_test                 |
+-----+
```

Of these tables, the `innodb_memcache.containers` table is the most important. Entries in the `containers` table provide a mapping to InnoDB table columns. Each InnoDB table used with the `daemon_memcached` plugin requires an entry in the `containers` table.

The `innodb_memcached_config.sql` script inserts a single entry in the `containers` table that provides a mapping for the `demo_test` table. It also inserts a single row of data into the `demo_test` table. This data allows you to immediately verify the installation after the setup is completed.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
    db_table: demo_test
  key_columns: c1
value_columns: c2
```

```

        flags: c3
        cas_column: c4
        expire_time_column: c5
        unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+-----+

```

For more information about `innodb_memcache` tables and the `demo_test` sample table, see [Section 15.20.7, “InnoDB memcached Plugin Internals”](#).

2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.

## Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a `telnet` session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```

telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
get AA
VALUE AA 8 12
HELLO, HELLO
END

```

2. Insert data using a `set` command.

```

set BB 10 0 16
GOODBYE, GOODBYE
STORED

```

where:

- `set` is the command to store a value
- `BB` is the key
- `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused
- `0` is the expiration time (TTL); specify `0` if unused
- `16` is the length of the supplied value block in bytes
- `GOODBYE, GOODBYE` is the value that is stored

3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
| BB | GOODBYE, GOODBYE | 10 | 1 | 0 |
+-----+-----+-----+-----+-----+
```

4. Return to the telnet session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
END
quit
```

If you shut down the MySQL server, which also shuts off the integrated `memcached` server, further attempts to access the `memcached` data will fail with a connection error. Normally, the `memcached` data also disappears at this point, and you would require application logic to load the data back into memory when `memcached` is restarted. However, the `InnoDB memcached` plugin automates this process for you.

When you restart MySQL, `get` operations once again return the key/value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL `test.demo_test` table.

## Creating a New Table and Column Mapping

This example shows how to setup your own `InnoDB` table with the `daemon_memcached` plugin.

1. Create an `InnoDB` table. The table must have a key column with a unique index. The key column of the city table is `city_id`, which is defined as the primary key. The table must also include columns for `flags`, `cas`, and `expiry` values. There may be one or more value columns. The `city` table has three value columns (`name`, `state`, `country`).

### Note

There is no special requirement with respect to column names as long as a valid mapping is added to the `innodb_memcache.containers` table.

```
mysql> CREATE TABLE city (
-> city_id VARCHAR(32),
-> name VARCHAR(1024),
-> state VARCHAR(1024),
-> country VARCHAR(1024),
-> flags INT,
-> cas BIGINT UNSIGNED,
-> expiry INT,
-> primary key(city_id)
-> ) ENGINE=InnoDB;
```

2. Add an entry to the `innodb_memcache.containers` table so that the `daemon_memcached` plugin knows how to access the `InnoDB` table. The entry must satisfy the `innodb_memcache.containers` table definition. For a description of each field, see [Section 15.20.7, “InnoDB memcached Plugin Internals”](#).

```
mysql> DESCRIBE innodb_memcache.containers;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|
```

Field	Type	Null	Key	Default	Extra
name	varchar(50)	NO	PRI	NULL	
db_schema	varchar(250)	NO		NULL	
db_table	varchar(250)	NO		NULL	
key_columns	varchar(250)	NO		NULL	
value_columns	varchar(250)	YES		NULL	
flags	varchar(250)	NO		0	
cas_column	varchar(250)	YES		NULL	
expire_time_column	varchar(250)	YES		NULL	
unique_idx_name_on_key	varchar(250)	NO		NULL	

The `innodb_memcache.containers` table entry for the `city` table is defined as:

```
mysql> INSERT INTO `innodb_memcache`.`containers` (
  -> `name`, `db_schema`, `db_table`, `key_columns`, `value_columns`,
  -> `flags`, `cas_column`, `expire_time_column`, `unique_idx_name_on_key`)
  -> VALUES ('default', 'test', 'city', 'city_id', 'name|state|country',
  -> 'flags','cas','expiry','PRIMARY');
```

- `default` is specified for the `containers.name` column to configure the `city` table as the default InnoDB table to be used with the `daemon_memcached` plugin.
  - Multiple InnoDB table columns (`name`, `state`, `country`) are mapped to `containers.value_columns` using a "|" delimiter.
  - The `flags`, `cas_column`, and `expire_time_column` fields of the `innodb_memcache.containers` table are typically not significant in applications using the `daemon_memcached` plugin. However, a designated InnoDB table column is required for each. When inserting data, specify 0 for these columns if they are unused.
3. After updating the `innodb_memcache.containers` table, restart the `daemon_memcache` plugin to apply the changes.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

4. Using telnet, insert data into the `city` table using a `memcached set` command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the `test.city` table to verify that the data you inserted was stored.

```
mysql> SELECT * FROM test.city;
+-----+-----+-----+-----+-----+-----+
| city_id | name      | state      | country | flags | cas | expiry |
+-----+-----+-----+-----+-----+-----+
| B       | BANGALORE | BANGALORE  | IN      | 0     | 3   | 0       |
+-----+-----+-----+-----+-----+-----+
```

6. Using MySQL, insert additional data into the `test.city` table.

```
mysql> INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0 ,0);
```

```
mysql> INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

### Note

It is recommended that you specify a value of 0 for the `flags`, `cas_column`, and `expire_time_column` fields if they are unused.

- Using telnet, issue a `memcached get` command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

## Configuring the InnoDB memcached Plugin

Traditional `memcached` configuration options may be specified in a MySQL configuration file or a `mysqld` startup string, encoded in the argument of the `daemon_memcached_option` configuration parameter. `memcached` configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make `memcached` listen on port 11222 instead of the default port 11211, specify `-p11222` as an argument of the `daemon_memcached_option` configuration option:

```
mysqld .... --daemon_memcached_option="-p11222"
```

Other `memcached` options can be encoded in the `daemon_memcached_option` string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the `daemon_memcached` plugin. These include:

- `daemon_memcached_engine_lib_name`: Specifies the shared library that implements the InnoDB `memcached` plugin. The default setting is `innodb_engine.so`.
- `daemon_memcached_engine_lib_path`: The path of the directory containing the shared library that implements the InnoDB `memcached` plugin. The default is NULL, representing the plugin directory.
- `daemon_memcached_r_batch_size`: Defines the batch commit size for read operations (`get`). It specifies the number of `memcached` read operations after which a `commit` occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every `get` request accesses the most recently committed data in the InnoDB table, whether the data was updated through `memcached` or by SQL. When the value is greater than 1, the counter for read operations is incremented with each `get` call. A `flush_all` call resets both read and write counters.
- `daemon_memcached_w_batch_size`: Defines the batch commit size for write operations (`set`, `replace`, `append`, `prepend`, `incr`, `decr`, and so on). `daemon_memcached_w_batch_size` is set to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each `add`, `set`, `incr`, `decr`, and `delete` call. A `flush_all` call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for `memcached` (such as the NDB `memcached` engine).

`daemon_memcached` plugin configuration parameters may be specified in the MySQL configuration file or in a `mysqld` startup string. They take effect when you load the `daemon_memcached` plugin.

When making changes to `daemon_memcached` plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```
mysql> UNINSTALL PLUGIN daemon_memcached;  
  
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

## 15.20.4 Security Considerations for the InnoDB memcached Plugin

### Caution

Consult this section before deploying the `daemon_memcached` plugin on a production server, or even on a test server if the MySQL instance contains sensitive data.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, only keep non-sensitive data in the MySQL instance that uses the `daemon_memcached` plugin, and wall off any servers that use this configuration from potential intruders. Do not allow `memcached` access to these servers from the Internet; only allow access from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

## Password-Protecting memcached Using SASL

SASL support provides the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains how to enable SASL with the `daemon_memcached` plugin. The steps are almost identical to those performed to enable SASL for a traditional `memcached` server.

SASL stands for “Simple Authentication and Security Layer”, a standard for adding authentication support to connection-based protocols. `memcached` added SASL support in version 1.4.3.

SASL authentication is only supported with the binary protocol.

`memcached` clients are only able to access InnoDB tables that are registered in the `innodb_memcache.containers` table. Even though a DBA can place access restrictions on such tables, access through `memcached` applications cannot be controlled. For this reason, SASL support is provided to control access to InnoDB tables associated with the `daemon_memcached` plugin.

The following section shows how to build, enable, and test an SASL-enabled `daemon_memcached` plugin.

## Building and Enabling SASL with the InnoDB memcached Plugin

By default, an SASL-enabled `daemon_memcached` plugin is not included in MySQL release packages, since an SASL-enabled `daemon_memcached` plugin requires building `memcached` with SASL libraries. To enable SASL support, download the MySQL source and rebuild the `daemon_memcached` plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:

```
sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
```

2. Build the `daemon_memcached` plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your `cmake` options. `memcached` also provides *simple cleartext password support*, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1` `cmake` option.

In summary, add following three `cmake` options:

```
cmake ... -DWITH_INNOODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
```

3. Install the `daemon_memcached` plugin, as described in [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).
4. Configure a user name and password file. (This example uses `memcached` simple cleartext password support.)

- a. In a file, create a user named `testname` and define the password as `testpasswd`:

```
echo "testname:testpasswd:::::::::" >/home/jy/memcached-sasl-db
```

- b. Configure the `MEMCACHED_SASL_PWDB` environment variable to inform `memcached` of the user name and password file:

```
export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
```

- c. Inform `memcached` that a cleartext password is used:

```
echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
export SASL_CONF_PATH=/home/jy/work2/msasl/clients
```

5. Enable SASL by restarting the MySQL server with the `memcached -S` option encoded in the `daemon_memcached_option` configuration parameter:

```
mysqld ... --daemon_memcached_option="-S"
```

6. To test the setup, use an SASL-enabled client such as [SASL-enabled libmemcached](#).

```
memcp --servers=localhost:11211 --binary --username=testname
--password=testpasswd myfile.txt

memcat --servers=localhost:11211 --binary --username=testname
--password=testpasswd myfile.txt
```

If you specify an incorrect user name or password, the operation is rejected with a `memcache error AUTHENTICATION FAILURE` message. In this case, examine the cleartext password set in the `memcached-sasl-db` file to verify that the credentials you supplied are correct.

There are other methods to test SASL authentication with `memcached`, but the method described above is the most straightforward.

## 15.20.5 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the [InnoDB memcached](#) plugin involves some degree of rewriting or adapting existing code that uses MySQL or the [memcached](#) API.

- With the [daemon\\_memcached](#) plugin, instead of many traditional [memcached](#) servers running on low-powered machines, you will have the same number of [memcached](#) servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the [memcached](#) API, but adaptation is likely required due to the different server configuration.
- The data stored through the [daemon\\_memcached](#) plugin goes into [VARCHAR](#), [TEXT](#), or [BLOB](#) columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the [CAST\( \)](#) function in queries.
- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by [memcached](#) code likely have only a few or even a single column holding data values.
- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both [queries](#) (read) and [DML](#) (write) operations can be substantially faster when performed through the [InnoDB memcached](#) interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a web site.

The following sections explore these points in more detail.

### 15.20.5.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of [memcached](#) applications when adapting an existing MySQL schema or application to use the [daemon\\_memcached](#) plugin:

- [memcached](#) keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to [add\( \)](#), [set\( \)](#), [get\( \)](#), and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.
- If there is a short numeric [primary key](#) column in an [InnoDB](#) table, use it as the unique lookup key for [memcached](#) by converting the integer to a string value. If the [memcached](#) server is used for multiple applications, or with more than one [InnoDB](#) table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

#### Note

The [daemon\\_memcached](#) plugin supports inserts and reads on mapped [InnoDB](#) tables that have an [INTEGER](#) defined as the primary key.

- You cannot use a partitioned table for data queried or stored using [memcached](#).
- The [memcached](#) protocol passes numeric values around as strings. To store numeric values in the underlying [InnoDB](#) table, to implement counters that can be used in SQL functions such as [SUM\( \)](#) or [AVG\( \)](#), for example:
  - Use [VARCHAR](#) columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).

- In any query that performs arithmetic using column values, use the `CAST( )` function to convert the values from string to integer, or to some other numeric type. For example:

```
-- Alphabetic entries are returned as zero.
select cast(c2 as unsigned integer) from demo_test;
-- Since there could be numeric values of 0, can't disqualify them.
-- Test the string values to find the ones that are integers, and average only those.
select avg(cast(c2 as unsigned integer)) from demo_test
  where c2 between '0' and '9999999999';
-- Views let you hide the complexity of queries. The results are already converted;
-- no need to repeat conversion functions and WHERE clauses each time.
create view numbers as select c1 key, cast(c2 as unsigned integer) val
  from demo_test where c2 between '0' and '9999999999';
select sum(val) from numbers;
```

#### Note

Any alphabetic values in the result set are converted into 0 by the call to `CAST( )`. When using functions such as `AVG( )`, which depend on the number of rows in the result set, include `WHERE` clauses to filter out non-numeric values.

- If the `InnoDB` column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.
- To use an existing table with the `daemon_memcached` plugin, define an entry for it in the `innodb_memcache.containers` table. To make that table the default for all `memcached` requests, specify a value of `default` in the `name` column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of `memcached` data, set up multiple entries in the `innodb_memcache.containers` table with `name` values of your choice, then issue a `memcached` request in the form of `get @@name` or `set @@name` within the application to specify the table to be used for subsequent `memcached` requests.

For an example of using a table other than the predefined `test.demo_test` table, see [Example 15.22, “Using Your Own Table with an InnoDB memcached Application”](#). For the required table layout, see [Section 15.20.7, “InnoDB memcached Plugin Internals”](#).

- To use multiple `InnoDB` table column values with `memcached` key/value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the `value_columns` field of the `innodb_memcache.containers` entry for the `InnoDB` table. For example, specify `col1,col2,col3` or `col1|col2|col3` in the `value_columns` field.

Concatenate the column values into a single string using the pipe character as a separator before passing the string to `memcached add` or `set` calls. The string is unpacked automatically into the correct column. Each `get` call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

### Example 15.22 Using Your Own Table with an InnoDB memcached Application

This example shows how to use your own table with a sample Python application that uses `memcached` for data manipulation.

The example assumes that the `daemon_memcached` plugin is installed as described in [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#). It also assumes that your system is configured to run a Python script that uses the `python-memcache` module.

1. Create the `multicol` table which stores country information including population, area, and driver side data ('R' for right and 'L' for left).

```
mysql> USE test;

mysql> CREATE TABLE `multicol` (
  -> `country` varchar(128) NOT NULL DEFAULT '',
  -> `population` varchar(10) DEFAULT NULL,
  -> `area_sq_km` varchar(9) DEFAULT NULL,
  -> `drive_side` varchar(1) DEFAULT NULL,
  -> `c3` int(11) DEFAULT NULL,
  -> `c4` bigint(20) unsigned DEFAULT NULL,
  -> `c5` int(11) DEFAULT NULL,
  -> PRIMARY KEY (`country`)
  -> ) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

```
mysql> INSERT INTO innodb_memcache.containers
  -> (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
  ->  expire_time_column,unique_idx_name_on_key)
  -> VALUES
  -> ('bbb','test','multicol','country','population,area_sq_km,drive_side',
  ->  'c3','c4','c5','PRIMARY');

mysql> COMMIT;
```

- The `innodb_memcache.containers` record for the `multicol` table specifies a `name` value of `'bbb'`, which is the table identifier.

#### Note

If a single InnoDB table is used for all `memcached` applications, the `name` value can be set to `default` to avoid using `@@` notation to switch tables.

- The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.
  - The `db_table` column is set to `multicol`, which is the name of the InnoDB table.
  - `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.
  - Rather than a single InnoDB table column to hold a composite data value, data is divided among three table columns (`population`, `area_sq_km`, and `drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.
  - Values for the `flags`, `expire_time`, and `cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.
  - The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.
3. Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an `InnoDB` table through the `daemon_memcached` plugin.

```
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

def banner(message):
    print
    print "=" * len(message)
    print message
    print "=" * len(message)

country_data = [
    ("Canada", "34820000", "9984670", "R"),
    ("USA", "314242000", "9826675", "R"),
    ("Ireland", "6399152", "84421", "L"),
    ("UK", "62262000", "243610", "L"),
    ("Mexico", "113910608", "1972550", "R"),
    ("Denmark", "5543453", "43094", "R"),
    ("Norway", "5002942", "385252", "R"),
    ("UAE", "8264070", "83600", "R"),
    ("India", "1210193422", "3287263", "L"),
    ("China", "1347350000", "9640821", "R"),
]

def switch_table(memc, table):
    key = "@@" + table
    print "Switching default table to '" + table + "' by issuing GET for '" + key + "'."
    result = memc.get(key)

def insert_country_data(memc):
    banner("Inserting initial data via memcached interface")
    for item in country_data:
        country = item[0]
        population = item[1]
        area = item[2]
        drive_side = item[3]

        key = country
        value = "|".join([population, area, drive_side])
        print "Key = " + key
        print "Value = " + value

        if memc.add(key, value):
            print "Added new key, value pair."
        else:
            print "Updating value for existing key."
            memc.set(key, value)

def query_country_data(memc):
    banner("Retrieving data for all keys (country names)")
    for item in country_data:
        key = item[0]
        result = memc.get(key)
        print "Here is the result retrieved from the database for key " + key + ":"
        print result
        (m_population, m_area, m_drive_side) = result.split("|")
        print "Unpacked population value: " + m_population
        print "Unpacked area value      : " + m_area
        print "Unpacked drive side value: " + m_drive_side
```

```

if __name__ == '__main__':

    memc = connect_to_memcached()
    switch_table(memc, "bbb")
    insert_country_data(memc)
    query_country_data(memc)

    sys.exit(0)

```

Sample Python application notes:

- No database authorization is required to run the application, since data manipulation is performed through the `memcached` interface. The only required information is the port number on the local system where the `memcached` daemon listens.
- To make sure the application uses the `multicol` table, the `switch_table()` function is called, which performs a dummy `get` or `set` request using `@@` notation. The `name` value in the request is `bbb`, which is the `multicol` table identifier defined in the `innodb_memcache.containers.name` field.

A more descriptive `name` value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in `get @@...` requests.

- The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with `add` or `set` requests, and how to unpack the pipe-separated values returned by `get` requests. This extra processing is only required when mapping a single `memcached` value to multiple MySQL table columns.

#### 4. Run the sample Python application.

```
shell> python multicol.py
```

If successful, the sample application returns this output:

```

Connected to memcached.
Switching default table to 'bbb' by issuing GET for '@@bbb'.

```

5. Query the `innodb_memcache.containers` table to view the record you inserted earlier for the `multicol` table. The first record is the sample entry for the `demo_test` table that is created during

the initial `daemon_memcached` plugin setup. The second record is the entry you inserted for the `multicol` table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
      db_table: demo_test
    key_columns: c1
  value_columns: c2
        flags: c3
      cas_column: c4
  expire_time_column: c5
unique_idx_name_on_key: PRIMARY
***** 2. row *****
      name: bbb
    db_schema: test
      db_table: multicol
    key_columns: country
  value_columns: population,area_sq_km,drive_side
        flags: c3
      cas_column: c4
  expire_time_column: c5
unique_idx_name_on_key: PRIMARY
```

- Query the `multicol` table to view data inserted by the sample Python application. The data is available for MySQL [queries](#), which demonstrates how the same data can be accessed using SQL or through applications (using the appropriate [MySQL Connector or API](#)).

```
mysql> SELECT * FROM test.multicol;
```

country	population	area_sq_km	drive_side	c3	c4	c5
Canada	34820000	9984670	R	0	11	0
China	1347350000	9640821	R	0	20	0
Denmark	5543453	43094	R	0	16	0
India	1210193422	3287263	L	0	19	0
Ireland	6399152	84421	L	0	13	0
Mexico	113910608	1972550	R	0	15	0
Norway	5002942	385252	R	0	17	0
UAE	8264070	83600	R	0	18	0
UK	62262000	243610	L	0	14	0
USA	314242000	9826675	R	0	12	0

#### Note

Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a `VARCHAR` are truncated by removing some characters, which could produce nonsensical numeric values.

- Optionally, run report-type queries on the `InnoDB` table that stores the `memcached` data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the `country` key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of countries where people drive on the right, and the average size of countries whose names start with “U”:

```
mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
```

```

+-----+
| avg(population) |
+-----+
| 261304724.7142857 |
+-----+

mysql> SELECT SUM(area_sq_km) FROM multicol WHERE country LIKE 'U%';
+-----+
| sum(area_sq_km) |
+-----+
|          10153885 |
+-----+

```

Because the `population` and `area_sq_km` columns store character data rather than strongly typed numeric data, functions such as `AVG()` and `SUM()` work by converting each value to a number first. This approach *does not work* for operators such as `<` or `>`, for example, when comparing character-based values, `9 > 1000`, which is not expected from a clause such as `ORDER BY population DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue simple `SELECT *` queries from database applications, while ensuring that casting, filtering, and ordering is correct. The following example shows a view that can be queried to find the top three countries in descending order of population, with the results reflecting the latest data in the `multicol` table, and with population and area figures treated as numbers:

```

mysql> CREATE VIEW populous_countries AS
-> SELECT
->     country,
->     cast(population as unsigned integer) population,
->     cast(area_sq_km as unsigned integer) area_sq_km,
->     drive_side FROM multicol
-> ORDER BY CAST(population as unsigned integer) DESC
-> LIMIT 3;

mysql> SELECT * FROM populous_countries;
+-----+-----+-----+-----+
| country | population | area_sq_km | drive_side |
+-----+-----+-----+-----+
| China   | 1347350000 | 9640821    | R          |
| India   | 1210193422 | 3287263    | L          |
| USA     | 314242000  | 9826675    | R          |
+-----+-----+-----+-----+

mysql> DESC populous_countries;
+-----+-----+-----+-----+-----+-----+
| Field      | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| country    | varchar(128)        | NO   |     |         |       |
| population | bigint(10) unsigned | YES  |     | NULL    |       |
| area_sq_km | int(9) unsigned     | YES  |     | NULL    |       |
| drive_side | varchar(1)          | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+

```

### 15.20.5.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and InnoDB tables when adapting existing `memcached` applications to use the `daemon_memcached` plugin:

- If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment column as the **primary key** of the InnoDB table, and to create a unique **secondary index** on the column that contains the `memcached` key values. This is because InnoDB performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values).

Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.

- If you store several different classes of information using `memcached`, consider setting up a separate `InnoDB` table for each type of data. Define additional table identifiers in the `innodb_memcache.containers` table, and use the `@@table_id.key` notation to store and retrieve items from different tables. Physically dividing different types of information allows you tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable `compression` for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional `secondary indexes` on tables that are frequently used to generate reports using SQL.
- Preferably, configure a stable set of table definitions for use with the `daemon_memcached` plugin, and leave the tables in place permanently. Changes to the `innodb_memcache.containers` table take effect the next time the `innodb_memcache.containers` table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by `containers.name`) is requested using `@@` notation. Thus, new entries are visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.
- When you use the default `innodb_only` caching policy, calls to `add()`, `set()`, `incr()`, and so on can succeed but still trigger debugging messages such as `while expecting 'STORED', got unexpected response 'NOT_STORED'`. Debug messages occur because new and updated values are sent directly to the `InnoDB` table without being saved in the memory cache, due to the `innodb_only` caching policy.

### 15.20.5.3 Tuning InnoDB memcached Plugin Performance

Because using `InnoDB` in combination with `memcached` involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using `memcached` by itself. When using the `InnoDB memcached` plugin, focus tuning goals for `memcached` operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and `DML` operations (inserts, updates, and deletes) that use the `memcached` interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the `memcached` interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

### Adapting SQL Queries

The types of queries that are most suited to simple `GET` requests are those with a single clause or a set of `AND` conditions in the `WHERE` clause:

```
SQL:
SELECT col FROM tbl WHERE key = 'key_value';

memcached:
GET key_value

SQL:
SELECT col FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3;

memcached:
# Since you must always know these 3 values to look up the key,
```

```
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
GET key_value

SQL:
SELECT 'key exists!' FROM tbl
  WHERE EXISTS (SELECT coll FROM tbl WHERE KEY = 'key_value') LIMIT 1;

memcached:
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
GET key_value
```

## Using System Memory

For best performance, deploy the [daemon\\_memcached](#) plugin on machines that are configured as typical database servers, where the majority of system RAM is devoted to the [InnoDB buffer pool](#), through the [innodb\\_buffer\\_pool\\_size](#) configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of [innodb\\_buffer\\_pool\\_instances](#) for maximum throughput when most operations involve data that is already cached in memory.

## Reducing Redundant I/O

[InnoDB](#) has a number of settings that let you choose the balance between high reliability, in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the [innodb\\_doublewrite](#) to 0 and [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) to 2. Measure performance with different [innodb\\_flush\\_method](#) settings.

### Note

[innodb\\_support\\_xa](#) is deprecated and will be removed in a future release. As of MySQL 5.7.10, [InnoDB](#) support for two-phase commit in XA transactions is always enabled and disabling [innodb\\_support\\_xa](#) is no longer permitted.

For other ways to reduce or tune I/O for table operations, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

## Reducing Transactional Overhead

A default value of 1 for [daemon\\_memcached\\_r\\_batch\\_size](#) and [daemon\\_memcached\\_w\\_batch\\_size](#) is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent [commit](#) operations. On a busy system, you might increase [daemon\\_memcached\\_r\\_batch\\_size](#), knowing that changes to data made through SQL may not become visible to [memcached](#) immediately (that is, until *N* more [get](#) operations are processed). When processing data where every write operation must be reliably stored, leave [daemon\\_memcached\\_w\\_batch\\_size](#) set to 1. Increase the setting when processing large numbers of updates intended only for statistical analysis, where losing the last *N* updates in a crash is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze traffic patterns, changing [daemon\\_memcached\\_w\\_batch\\_size](#) from 1 to 100 reduces I/O overhead for commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an acceptable margin of error. If instead the application performed automated toll collection for each car, you

would set `daemon_memcached_w_batch_size` to 1 to ensure that each toll record is immediately saved to disk.

Because of the way InnoDB organizes `memcached` key values on disk, if you have a large number of keys to create, it may be faster to sort the data items by key value in the application and `add` them in sorted order, rather than create keys in arbitrary order.

The `memslap` command, which is part of the regular `memcached` distribution but not included with the `daemon_memcached` plugin, can be useful for benchmarking different configurations. It can also be used to generate sample key/value pairs to use in your own benchmarks. See [libmemcached Command-Line Utilities](#) for details.

#### 15.20.5.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional `memcached`, the `daemon_memcached` plugin allows you to control durability of data values produced through calls to `add`, `set`, `incr`, and so on. By default, data written through the `memcached` interface is stored to disk, and calls to `get` return the most recent value from disk. Although the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for InnoDB tables.

As you gain experience using the `daemon_memcached` plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

##### Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is [committed](#). If data is critical, it should be committed immediately so that it is safe in case of a crash or outage. If data is less critical, such as counters that are reset after a crash or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a `memcached` operation inserts, updates, or deletes data in the underlying InnoDB table, the change might be committed to the InnoDB table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if the `daemon_memcached_w_batch_size` value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size` to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the `memcached` API at regular intervals. The interval is controlled by the `innodb_api_bk_commit_interval` configuration option, which has a default setting of 5 seconds.

When a `memcached` operation inserts or updates data in the underlying InnoDB table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

##### Transaction Isolation

When a `memcached` operation such as `get` or `incr` causes a query or DML operation on the underlying InnoDB table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction [isolation level](#). Use the `innodb_api_trx_level` configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater [locking](#)

overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

## Disabling Row Locks for memcached DML Operations

The `innodb_api_disable_rowlock` option can be used to disable row locks when `memcached` requests through the `daemon_memcached` plugin cause DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in a MySQL configuration file.

## Allowing or Disallowing DDL

By default, you can perform DDL operations such as `ALTER TABLE` on tables used by the `daemon_memcached` plugin. To avoid potential slowdowns when these tables are used for high-throughput applications, disable DDL operations on these tables by enabling `innodb_api_enable_md1` at startup. This option is less appropriate when accessing the same tables through both `memcached` and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

## Storing Data on Disk, in Memory, or Both

The `innodb_memcache.cache_policies` table specifies whether to store data written through the `memcached` interface to disk (`innodb_only`, the default); in memory only, as with traditional `memcached` (`cache-only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the InnoDB table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache_only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the InnoDB table the next time the item is requested.

```
mysql> SELECT * FROM innodb_memcache.cache_policies;
+-----+-----+-----+-----+-----+
| policy_name | get_policy | set_policy | delete_policy | flush_policy |
+-----+-----+-----+-----+-----+
| cache_policy | innodb_only | innodb_only | innodb_only | innodb_only |
+-----+-----+-----+-----+-----+

mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
-> WHERE policy_name = 'cache_policy';
```

`innodb_memcache.cache_policies` values are only read at startup. After changing values in this table, uninstall and reinstall the `daemon_memcached` plugin to ensure that changes take effect.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

### 15.20.5.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the `daemon_memcached` plugin speeds up [DML](#) operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focussing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the `daemon_memcached` plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into `memcached` operations. `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. These operations are guaranteed to only affect one row when issued through the `memcached` interface, because the `key` is unique within the table.

In the following SQL examples, `t1` refers to the table used for `memcached` operations, based on the configuration in the `innodb_memcache.containers` table. `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`.

```
INSERT INTO t1 (key,val) VALUES (some_key,some_value);
SELECT val FROM t1 WHERE key = some_key;
UPDATE t1 SET val = new_value WHERE key = some_key;
UPDATE t1 SET val = val + x WHERE key = some_key;
DELETE FROM t1 WHERE key = some_key;
```

The following `TRUNCATE TABLE` and `DELETE` statements, which remove all rows from the table, correspond to the `flush_all` operation, where `t1` is configured as the table for `memcached` operations, as in the previous example.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

### 15.20.5.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying `InnoDB` table (which is `test.demo_test` by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the `memcached` interface, remember that `memcached` operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the `daemon_memcached_w_batch_size` option. If this option is set to a value greater than 1, use `READ UNCOMMITTED` queries to find rows that were just inserted.

```
mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
```

```
mysql> SELECT * FROM demo_test;
```

cx	cy	c1	cz	c2	ca	CB	c3	cu	c4	C5
NULL	NULL	a11	NULL	123456789	NULL	NULL	10	NULL	3	NULL

- When modifying a table using SQL that is also accessed through the `memcached` interface, you can configure `memcached` operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the `daemon_memcached_r_batch_size` option. If this option is set to a value greater than 1, changes made to the table using SQL are not immediately visible to `memcached` operations.
- The `InnoDB` table is either IS (intention shared) or IX (intention exclusive) locked for all operations in a transaction. If you increase `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` substantially from their default value of 1, the table is most likely locked between each operation, preventing `DDL` statements on the table.

## 15.20.6 The InnoDB memcached Plugin and Replication

Because the `daemon_memcached` plugin supports the MySQL [binary log](#), updates made on a [master server](#) through the `memcached` interface can be replicated for backup, balancing intensive read workloads, and high availability. All `memcached` commands are supported with binary logging.

You do not need to set up the `daemon_memcached` plugin on [slave servers](#). The primary advantage of this configuration is increased write throughput on the master. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the `daemon_memcached` plugin with MySQL replication. It is assumed that you have completed the setup described in [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

### Enabling the InnoDB memcached Binary Log

1. To use the `daemon_memcached` plugin with the MySQL [binary log](#), enable the `innodb_api_enable_binlog` configuration option on the [master server](#). This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the `--log-bin` option. You can add these options to the MySQL configuration file, or on the `mysqld` command line.

```
mysqld ... --log-bin --innodb_api_enable_binlog=1
```

2. Configure the master and slave server, as described in [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#).
3. Use `mysqldump` to create a master data snapshot, and sync the snapshot to the slave server.

```
master shell> mysqldump --all-databases --lock-all-tables > dbdump.db
slave shell> mysql < dbdump.db
```

4. On the master server, issue `SHOW MASTER STATUS` to obtain the master binary log coordinates.

```
mysql> SHOW MASTER STATUS;
```

5. On the slave server, use a `CHANGE MASTER TO` statement to set up a slave server using the master binary log coordinates.

```
mysql> CHANGE MASTER TO
      MASTER_HOST='localhost',
      MASTER_USER='root',
      MASTER_PASSWORD='',
      MASTER_PORT = 13000,
      MASTER_LOG_FILE='0.000001',
      MASTER_LOG_POS=114;
```

6. Start the slave.

```
mysql> START SLAVE;
```

If the error log prints output similar to the following, the slave is ready for replication.

```
2013-09-24T13:04:38.639684Z 49 [Note] Slave I/O thread: connected to
master 'root@localhost:13000', replication started in log '0.000001'
```

at position 114

## Testing the InnoDB memcached Replication Configuration

This example demonstrates how to test the [InnoDB memcached](#) replication configuration using the [memcached](#) and telnet to insert, update, and delete data. A MySQL client is used to verify results on the master and slave servers.

The example uses the [demo\\_test](#) table, which was created by the [innodb\\_memcached\\_config.sql](#) configuration script during the initial setup of the [daemon\\_memcached](#) plugin. The [demo\\_test](#) table contains a single example record.

1. Use the [set](#) command to insert a record with a key of [test1](#), a flag value of [10](#), an expiration value of [0](#), a cas value of [1](#), and a value of [t1](#).

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 1
t1
STORED
```

2. On the master server, check that the record was inserted into the [demo\\_test](#) table. Assuming the [demo\\_test](#) table was not previously modified, there should be two records. The example record with a key of [AA](#), and the record you just inserted, with a key of [test1](#). The [c1](#) column maps to the key, the [c2](#) column to the value, the [c3](#) column to the flag value, the [c4](#) column to the cas value, and the [c5](#) column to the expiration time. The expiration time was set to 0, since it is unused.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| AA    | HELLO, HELLO | 8     | 0     | 0     |
| test1 | t1          | 10    | 1     | 0     |
+-----+-----+-----+-----+-----+
```

3. Check to verify that the same record was replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| AA    | HELLO, HELLO | 8     | 0     | 0     |
| test1 | t1          | 10    | 1     | 0     |
+-----+-----+-----+-----+-----+
```

4. Use the [set](#) command to update the key to a value of [new](#).

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2
new
STORED
```

The update is replicated to the slave server (notice that the [cas](#) value is also updated).

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
```

c1	c2	c3	c4	c5
AA	HELLO, HELLO	8	0	0
test1	new	10	2	0

5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the `delete` operation is replicated to the slave, the `test1` record on the slave is also deleted.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+
```

6. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

7. Telnet to the master server and enter two new records.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test2 10 0 4
again
STORED
set test3 10 0 5
again1
STORED
```

8. Confirm that the two records were replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| test2 | again | 10 | 4 | 0 |
| test3 | again1 | 10 | 5 | 0 |
+-----+-----+-----+-----+
```

9. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
```

```
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

10. Check to ensure that the `flush_all` operation was replicated on the slave server.

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

## InnoDB memcached Binary Log Notes

Binary Log Format:

- Most `memcached` operations are mapped to `DML` statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging, which is independent of any server `binlog_format` setting.
- The `memcached flush_all` command is mapped to the `TRUNCATE TABLE` command. Since `DDL` commands can only use statement-based logging, the `flush_all` command is replicated by sending a `TRUNCATE TABLE` statement.

Transactions:

- The concept of `transactions` has not typically been part of `memcached` applications. For performance considerations, `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` are used to control the batch size for read and write transactions. These settings do not affect replication. Each SQL operation on the underlying `InnoDB` table is replicated after successful completion.
- The default value of `daemon_memcached_w_batch_size` is `1`, which means that each `memcached` write operation is committed immediately. This default setting incurs a certain amount of performance overhead to avoid inconsistencies in the data that is visible on the master and slave servers. The replicated records are always available immediately on the slave server. If you set `daemon_memcached_w_batch_size` to a value greater than `1`, records inserted or updated through `memcached` are not immediately visible on the master server; to view the records on the master server before they are committed, issue `SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED`.

## 15.20.7 InnoDB memcached Plugin Internals

### InnoDB API for the InnoDB memcached Plugin

The `InnoDB memcached` engine accesses `InnoDB` through `InnoDB` APIs, most of which are directly adopted from embedded `InnoDB`. `InnoDB` API functions are passed to the `InnoDB memcached` engine as callback functions. `InnoDB` API functions access the `InnoDB` tables directly, and are mostly DML operations with the exception of `TRUNCATE TABLE`.

`memcached` commands are implemented through the `InnoDB memcached` API. The following table outlines how `memcached` commands are mapped to DML or DDL operations.

**Table 15.15 memcached Commands and Associated DML or DDL Operations**

memcached Command	DML or DDL Operations
<code>get</code>	a read/fetch command

memcached Command	DML or DDL Operations
<code>set</code>	a search followed by an <code>INSERT</code> or <code>UPDATE</code> (depending on whether or not a key exists)
<code>add</code>	a search followed by an <code>INSERT</code> or <code>UPDATE</code>
<code>replace</code>	a search followed by an <code>UPDATE</code>
<code>append</code>	a search followed by an <code>UPDATE</code> (appends data to the result before <code>UPDATE</code> )
<code>prepend</code>	a search followed by an <code>UPDATE</code> (prepends data to the result before <code>UPDATE</code> )
<code>incr</code>	a search followed by an <code>UPDATE</code>
<code>decr</code>	a search followed by an <code>UPDATE</code>
<code>delete</code>	a search followed by a <code>DELETE</code>
<code>flush_all</code>	<code>TRUNCATE TABLE</code> (DDL)

## InnoDB memcached Plugin Configuration Tables

This section describes configuration tables used by the `daemon_memcached` plugin. The `cache_policies` table, `config_options` table, and `containers` table are created by the `innodb_memcached_config.sql` configuration script in the `innodb_memcache` database.

```
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies             |
| config_options             |
| containers                 |
+-----+
```

### cache\_policies Table

The `cache_policies` table defines a cache policy for the InnoDB memcached installation. You can specify individual policies for `get`, `set`, `delete`, and `flush` operations, within a single cache policy. The default setting for all operations is `innodb_only`.

- `innodb_only`: Use InnoDB as the data store.
- `cache-only`: Use the memcached engine as the data store.
- `caching`: Use both InnoDB and the memcached engine as data stores. In this case, if memcached cannot find a key in memory, it searches for the value in an InnoDB table.
- `disable`: Disable caching.

**Table 15.16** `cache_policies` Columns

Column	Description
<code>policy_name</code>	Name of the cache policy. The default cache policy name is <code>cache_policy</code> .
<code>get_policy</code>	The cache policy for get operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .

Column	Description
<code>set_policy</code>	The cache policy for set operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .
<code>delete_policy</code>	The cache policy for delete operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .
<code>flush_policy</code>	The cache policy for flush operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .

## config\_options Table

The `config_options` table stores `memcached`-related settings that can be changed at runtime using SQL. Supported configuration options are `separator` and `table_map_delimiter`.

**Table 15.17 config\_options Columns**

Column	Description
Name	<p>Name of the <code>memcached</code>-related configuration option. The following configuration options are supported by the <code>config_options</code> table:</p> <ul style="list-style-type: none"> <li><code>separator</code>: Used to separate values of a long string into separate values when there are multiple <code>value_columns</code> defined. By default, the <code>separator</code> is a <code> </code> character. For example, if you define <code>col1</code>, <code>col2</code> as value columns, and you define <code> </code> as the separator, you can issue the following <code>memcached</code> command to insert values into <code>col1</code> and <code>col2</code>, respectively:</li> </ul> <pre>set keyx 10 0 19 valuecolx valuecoly</pre> <p><code>valuecol1x</code> is stored in <code>col1</code> and <code>valuecoly</code> is stored in <code>col2</code>.</p> <ul style="list-style-type: none"> <li><code>table_map_delimiter</code>: The character separating the schema name and the table name when you use the <code>@@</code> notation in a key name to access a key in a specific table. For example, <code>@@t1.some_key</code> and <code>@@t2.some_key</code> have the same key value, but are stored in different tables.</li> </ul>
Value	The value assigned to the <code>memcached</code> -related configuration option.

## containers Table

The `containers` table is the most important of the three configuration tables. Each `InnoDB` table that is used to store `memcached` values must have an entry in the `containers` table. The entry provides a mapping between `InnoDB` table columns and container table columns, which is required for `memcached` to work with `InnoDB` tables.

The `containers` table contains a default entry for the `test.demo_test` table, which is created by the `innodb_memcached_config.sql` configuration script. To use the `daemon_memcached` plugin with your own InnoDB table, you must create an entry in the `containers` table.

**Table 15.18 containers Columns**

Column	Description
<code>name</code>	The name given to the container. If an InnoDB table is not requested by name using @@ notation, the <code>daemon_memcached</code> plugin uses the InnoDB table with a <code>containers.name</code> value of <code>default</code> . If there is no such entry, the first entry in the <code>containers</code> table, ordered alphabetically by <code>name</code> (ascending), determines the default InnoDB table.
<code>db_schema</code>	The name of the database where the InnoDB table resides. This is a required value.
<code>db_table</code>	The name of the InnoDB table that stores <code>memcached</code> values. This is a required value.
<code>key_columns</code>	The column in the InnoDB table that contains lookup key values for <code>memcached</code> operations. This is a required value.
<code>value_columns</code>	The InnoDB table columns (one or more) that store <code>memcached</code> data. Multiple columns can be specified using the separator character specified in the <code>innodb_memcached.config_options</code> table. By default, the separator is a pipe character (" "). To specify multiple columns, separate them with the defined separator character. For example: <code>col1 col2 col3</code> . This is a required value.
<code>flags</code>	The InnoDB table columns that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for <code>memcached</code> . A flag value can be used as a column specifier for some operations (such as <code>incr</code> , <code>prepend</code> ) if a <code>memcached</code> value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a <code>value_columns</code> to three InnoDB table columns, and only want the increment operation performed on one columns, use the <code>flags</code> column to specify the column. If you do not use the <code>flags</code> column, set a value of 0 to indicate that it is unused.
<code>cas_column</code>	The InnoDB table column that stores compare-and-swap (cas) values. The <code>cas_column</code> value is related to the way <code>memcached</code> hashes requests to different servers and caches data in memory. Because the InnoDB <code>memcached</code> plugin is tightly integrated with a single <code>memcached</code> daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that it is unused.

Column	Description
<code>expire_time_column</code>	The InnoDB table column that stores expiration values. The <code>expire_time_column</code> value is related to the way memcached hashes requests to different servers and caches data in memory. Because the InnoDB memcached plugin is tightly integrated with a single memcached daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that the column is unused. As of MySQL 5.7.8, maximum expire time is defined as <code>INT_MAX32</code> or 2147483647 seconds (approximately 68 years).
<code>unique_idx_name_on_key</code>	The name of the index on the key column. It must be a unique index. It can be the <a href="#">primary key</a> or a <a href="#">secondary index</a> . Preferably, use the primary key of the InnoDB table. Using the primary key avoids a lookup that is performed when using a secondary index. You cannot make a <a href="#">covering index</a> for memcached lookups; InnoDB returns an error if you try to define a composite secondary index over both the key and value columns.

### containers Table Column Constraints

- You must supply a value for `db_schema`, `db_name`, `key_columns`, `value_columns` and `unique_idx_name_on_key`. Specify 0 for `flags`, `cas_column`, and `expire_time_column` if they are unused. Failing to do so could cause your setup to fail.
- `key_columns`: The maximum limit for a memcached key is 250 characters, which is enforced by memcached. The mapped key must be a non-Null `CHAR` or `VARCHAR` type.
- `value_columns`: Must be mapped to a `CHAR`, `VARCHAR`, or `BLOB` column. There is no length restriction and the value can be NULL.
- `cas_column`: The `cas` value is a 64 bit integer. It must be mapped to a `BIGINT` of at least 8 bytes. If you do not use this column, set a value of 0 to indicate that it is unused.
- `expiration_time_column`: Must mapped to an `INTEGER` of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed 60\*60\*24\*30 (the number of seconds in 30 days). If the number sent by a client is larger, the server considers it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set a value of 0 to indicate that it is unused.
- `flags`: Must be mapped to an `INTEGER` of at least 32-bits and can be NULL. If you do not use this column, set a value of 0 to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If mismatches are found, the plugin will not load.

### Multiple Value Column Mapping

- During plugin initialization, when InnoDB memcached is configured with information defined in the `containers` table, each mapped column defined in `containers.value_columns` is verified against

the mapped [InnoDB](#) table. If multiple [InnoDB](#) table columns are mapped, there is a check to ensure that each column exists and is the right type.

- At run-time, for [memcached](#) insert operations, if there are more delimited values than the number of mapped columns, only the number of mapped values are taken. For example, if there are six mapped columns, and seven delimited values are provided, only the first six delimited values are taken. The seventh delimited value is ignored.
- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be set to NULL, insert operations will fail.
- If a table has more columns than mapped values, the extra columns do not affect results.

## The demo\_test Example Table

The [innodb\\_memcached\\_config.sql](#) configuration script creates a [demo\\_test](#) table in the [test](#) database, which can be used to verify [InnoDB memcached](#) plugin installation immediately after setup.

The [innodb\\_memcached\\_config.sql](#) configuration script also creates an entry for the [demo\\_test](#) table in the [innodb\\_memcache.containers](#) table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
      db_table: demo_test
    key_columns: c1
  value_columns: c2
        flags: c3
      cas_column: c4
  expire_time_column: c5
unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+
```

## 15.20.8 Troubleshooting the InnoDB memcached Plugin

This section describes issues that you may encounter when using the [InnoDB memcached](#) plugin.

- If you encounter the following error in the MySQL error log, the server might fail to start:

```
failed to set rlimit for open files. Try running as root or requesting
smaller maxconns value.
```

The error message is from the [memcached](#) daemon. One solution is to raise the OS limit for the number of open files. The commands for checking and increasing the open file limit varies by operating system. This example shows commands for Linux and OS X:

```
# Linux
shell> ulimit -n
1024
shell> ulimit -n 4096
shell> ulimit -n
4096

# OS X
```

```
shell> ulimit -n
256
shell> ulimit -n 4096
shell> ulimit -n
4096
```

The other solution is to reduce the number of concurrent connections permitted for the `memcached` daemon. To do so, encode the `-c memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. The `-c` option has a default value of 1024.

```
[mysqld]
...
loose-daemon_memcached_option='-c 64'
```

- To troubleshoot problems where the `memcached` daemon is unable to store or retrieve `InnoDB` table data, encode the `-vvv memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. Examine the MySQL error log for debug output related to `memcached` operations.

```
[mysqld]
...
loose-daemon_memcached_option='-vvv'
```

- If columns specified to hold `memcached` values are the wrong data type, such as a numeric type instead of a string type, attempts to store key/value pairs will fail with no specific error code or message.
- If the `daemon_memcached` plugin causes MySQL server startup issues, you can temporarily disable the `daemon_memcached` plugin while troubleshooting by adding this line under the `[mysqld]` group in the MySQL configuration file:

```
daemon_memcached=OFF
```

For example, if you run the `INSTALL PLUGIN` statement before running the `innodb_memcached_config.sql` configuration script to set up the necessary database and tables, the server might crash and fail to start. The server could also fail to start if you incorrectly configure an entry in the `innodb_memcache.containers` table.

To uninstall the `memcached` plugin for a MySQL instance, issue the following statement:

```
mysql> UNINSTALL PLUGIN daemon_memcached;
```

- If you run more than one instance of MySQL on the same machine with the `daemon_memcached` plugin enabled in each instance, use the `daemon_memcached_option` configuration parameter to specify a unique `memcached` port for each `daemon_memcached` plugin.
- If an SQL statement cannot find the `InnoDB` table or finds no data in the table, but `memcached` API calls retrieve the expected data, you may be missing an entry for the `InnoDB` table in the `innodb_memcache.containers` table, or you may have not switched to the correct `InnoDB` table by issuing a `get` or `set` request using `@@table_id` notation. This problem could also occur if you change an existing entry in the `innodb_memcache.containers` table without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value such as `col1|col2|col3` may still work, even if the daemon is using the `test.demo_test` table which stores values in a single column.
- When defining your own `InnoDB` table for use with the `daemon_memcached` plugin, and columns in the table are defined as `NOT NULL`, ensure that values are supplied for the `NOT NULL` columns

when inserting a record for the table into the `innodb_memcached.containers` table. If the `INSERT` statement for the `innodb_memcached.containers` record contains fewer delimited values than there are mapped columns, unfilled columns are set to `NULL`. Attempting to insert a `NULL` value into a `NOT NULL` column causes the `INSERT` to fail, which may only become evident after you reinitialize the `daemon_memcached` plugin to apply changes to the `innodb_memcached.containers` table.

- If `cas_column` and `expire_time_column` fields of the `innodb_memcached.containers` table are set to `NULL`, the following error will be returned when attempting to load the `memcached` plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in
database 'innodb_memcached' has an invalid NULL value.
```

The `memcached` plugin rejects usage of `NULL` in the `cas_column` and `expire_time_column` columns. Set the value of these columns to `0` when the columns are unused.

- As the length of the `memcached` key and values increase, you might encounter size and length limits.
  - When the key exceeds 250 bytes, `memcached` operations return an error. This is currently a fixed limit within `memcached`.
  - `InnoDB` table limits may be encountered if values exceed 768 bytes in size, 3072 bytes in size, or half of the `innodb_page_size` value. These limits primarily apply if you intend to create an index on a value column to run report-generating queries on that column using SQL. See [Section 15.8.8, “Limits on InnoDB Tables”](#) for details.
  - The maximum size for the key-value combination is 1 MB.
- If you share configuration files across MySQL servers of different versions, using the latest configuration options for the `daemon_memcached` plugin could cause startup errors on older MySQL versions. To avoid compatibility problems, use the `loose` prefix with option names. For example, use `loose-daemon_memcached_option='-c 64'` instead of `daemon_memcached_option='-c 64'`.
- There is no restriction or check in place to validate character set settings. `memcached` stores and retrieves keys and values in bytes and is therefore not character set sensitive. However, you must ensure that the `memcached` client and the MySQL table use the same character set.
- `memcached` connections are blocked from accessing tables that contain an indexed virtual column. Accessing an indexed virtual column requires a callback to the server, but a `memcached` connection does not have access to the server code.

## 15.21 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 6.4.2, “The Error Log”](#)). [Section B.3, “Server Error Codes and Messages”](#) provides troubleshooting information for some of the common `InnoDB`-specific errors that you may encounter.
- If the failure is related to a `deadlock`, run with the `innodb_print_all_deadlocks` option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see [Section 15.5.5, “Deadlocks in InnoDB”](#).
- Issues relating to the `InnoDB` data dictionary include failed `CREATE TABLE` statements (orphan table files), inability to open `InnoDB` files, and `system cannot find the path specified` errors. For information about these sorts of problems and errors, see [Section 15.21.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).

- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Enable the [InnoDB Monitors](#) to obtain information about a problem (see [Section 15.17, “InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of [InnoDB](#). If the problem is with locks, enable the Lock Monitor. If the problem is with table creation, tablespaces, or data dictionary operations, refer to the [InnoDB Information Schema system tables](#) to examine contents of the [InnoDB](#) internal data dictionary.

[InnoDB](#) temporarily enables standard [InnoDB](#) Monitor output under the following conditions:

- A long semaphore wait
- [InnoDB](#) cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

### 15.21.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for [InnoDB](#) I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

#### Initialization Problems

If something goes wrong when [InnoDB](#) attempts to initialize its tablespace or its log files, delete all files created by [InnoDB](#): all `ibdata` files and all `ib_logfile` files. If you already created some [InnoDB](#) tables, also delete the corresponding `.frm` files for these tables, and any `.ibd` files if you are using multiple tablespaces, from the MySQL database directories. Then try the [InnoDB](#) database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

#### Runtime Problems

If [InnoDB](#) prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the [InnoDB](#) data file directory and the [InnoDB](#) log directory exist.
- Make sure `mysqld` has access rights to create files in those directories.
- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

### 15.21.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM tbl_name` statements or InnoDB background operations to crash or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

### Warning

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on separate physical copy of your database. When forcing InnoDB recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. As of MySQL 5.7.3, an `innodb_force_recovery` setting of 4 or greater places InnoDB in read-only mode.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

Lets the server run even if it detects a corrupt page. Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (`SRV_FORCE_NO_BACKGROUND`)

Prevents the master thread and any purge threads from running. If a crash would occur during the purge operation, this recovery value prevents it.

- 3 (`SRV_FORCE_NO_TRX_UNDO`)

Does not run transaction rollbacks after crash recovery.

- 4 (`SRV_FORCE_NO_IBUF_MERGE`)

Prevents insert buffer merge operations. If they would cause a crash, does not do them. Does not calculate table statistics. This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. As of MySQL 5.7.3, sets InnoDB to read-only.

- 5 (SRV\_FORCE\_NO\_UNDO\_LOG\_SCAN)

Does not look at [undo logs](#) when starting the database: [InnoDB](#) treats even incomplete transactions as committed. This value can permanently corrupt data files. As of MySQL 5.7.3, sets [InnoDB](#) to read-only.

- 6 (SRV\_FORCE\_NO\_LOG\_REDO)

Does not do the [redo log](#) roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. As of MySQL 5.7.3, sets [InnoDB](#) to read-only.

You can [SELECT](#) from tables to dump them. With an [innodb\\_force\\_recovery](#) value of 3 or less you can [DROP](#) or [CREATE](#) tables. As of MySQL 5.7.9, [DROP TABLE](#) is also supported with an [innodb\\_force\\_recovery](#) value greater than 3.

If you know that a given table is causing a crash on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or [ALTER TABLE](#), you can kill the [mysqld](#) process and set [innodb\\_force\\_recovery](#) to 3 to bring the database up without the rollback, and then [DROP](#) the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an [ORDER BY primary\\_key DESC](#) clause might be able to dump the portion of the table after the corrupted part.

If a high [innodb\\_force\\_recovery](#) value is required to start [InnoDB](#), there may be corrupted data structures that could cause complex queries (queries containing [WHERE](#), [ORDER BY](#), or other clauses) to fail. In this case, you may only be able to run basic [SELECT \\* FROM t](#) queries.

## 15.21.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored both in the [.frm](#) files, and in the [InnoDB data dictionary](#). If you move [.frm](#) files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting [InnoDB](#), see [Section 15.21.2, “Forcing InnoDB Recovery”](#) for information about manual recovery.

### CREATE TABLE Failure Due to Orphan Table

A symptom of an out-of-sync data dictionary is that a [CREATE TABLE](#) statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the [InnoDB](#) internal data dictionary, you have an orphan table inside the [InnoDB](#) tablespace files that has no corresponding [.frm](#) file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphan table by following the instructions given in the error message. If you are still unable to use [DROP TABLE](#) successfully, the problem may be due to name completion in the [mysql](#) client.

To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

## Cannot Open File Error

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open an InnoDB file:

```
ERROR 1016: Can't open file: 'child2.ibd'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphan `.frm` file without a corresponding table inside InnoDB. You can drop the orphan `.frm` file by deleting it manually.

## Orphan Intermediate Tables

If MySQL exits in the middle of an in-place `ALTER TABLE` operation (`ALGORITHM=INPLACE`), you may be left with an orphan intermediate table that takes up space on your system. Also, an orphan intermediate table in an otherwise empty `general tablespace` will prevent you from dropping the general tablespace. This section describes how to identify and remove orphan intermediate tables.

Intermediate table names begin with an `#sql-ib` prefix (e.g., `#sql-ib87-856498050`). The accompanying `.frm` file has an `#sql-*` prefix and is named differently (e.g., `#sql-36ab_2.frm`).

To identify orphan intermediate tables on your system, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original table resides in a `file-per-table` tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan intermediate table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '#sql%';
```

To remove an orphan intermediate table, perform the following steps:

1. In the database directory, rename the `#sql-*.frm` file to match the base name of the orphan intermediate table:

```
shell> mv #sql-36ab_2.frm #sql-ib87-856498050.frm
```

### Note

If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan intermediate table (it must have the same columns and indexes) and must be placed in the database directory of the orphan intermediate table.

2. Drop the orphan intermediate table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-ib87-856498050`;
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as “#”.

#### Note

If a crash occurs during an in-place `ALTER TABLE` operation that was moving a table to a different tablespace, the recovery process restores the table to its original location but leaves an orphan intermediate table in the destination tablespace.

## Orphan Temporary Tables

If MySQL exits in the middle of a table-copying `ALTER TABLE` operation (`ALGORITHM=COPY`), you may be left with an orphan temporary table that takes up space on your system. Also, an orphan temporary table in an otherwise empty `general tablespace` will prevent you from dropping the general tablespace. This section describes how to identify and remove orphan temporary tables.

Orphan temporary table names begin with an `#sql-` prefix (e.g., `#sql-540_3`). The accompanying `.frm` file has the same base name as the orphan temporary table.

#### Note

If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan temporary table (it must have the same columns and indexes) and must be placed in the database directory of the orphan temporary table.

To identify orphan temporary tables on your system, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original table resides in a `file-per-table` tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan temporary table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

To remove an orphan temporary table, drop the table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-540_3`;
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as “#”.

## Tablespace Does Not Exist

With `innodb_file_per_table` enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.
2. Issue `DROP TABLE` for the original table. That should successfully drop the table and InnoDB should print a warning to the error log that the `.ibd` file was missing.

## Restoring Orphan File-Per-Table ibd Files

This procedure describes how to restore orphan `file-per-table .ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure is not supported for `general tablespace .ibd` files.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphan `.ibd` files, and that `.ibd` file backups are clean. See [Section 15.8.4, “Moving or Copying InnoDB Tables to Another Machine”](#) for information about creating clean backups.

Tablespace copying limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#) are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

```
mysql> CREATE DATABASE sakila;

mysql> USE sakila;

mysql> CREATE TABLE actor (
->   actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
->   first_name VARCHAR(45) NOT NULL,
->   last_name VARCHAR(45) NOT NULL,
->   last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
->   PRIMARY KEY (actor_id),
->   KEY idx_actor_last_name (last_name)
-> )ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

2. Discard the tablespace of the newly created table.

```
mysql> ALTER TABLE sakila.actor DISCARD TABLESPACE;
```

3. Copy the orphan `.ibd` file from your backup directory to the new database directory.

```
shell> cp /backup_directory/actor.ibd path/to/mysql-5.7/data/sakila/
```

4. Ensure that the `.ibd` file has the necessary file permissions.
5. Import the orphan `.ibd` file. A warning is issued indicating that InnoDB will attempt to import the file without schema verification.

```
mysql> ALTER TABLE sakila.actor IMPORT TABLESPACE; SHOW WARNINGS;
Query OK, 0 rows affected, 1 warning (0.15 sec)

Warning | 1810 | InnoDB: IO Read error: (2, No such file or directory)
Error opening './sakila/actor.cfg', will attempt to import
without schema verification
```

6. Query the table to verify that the `.ibd` file was successfully restored.

```
mysql> SELECT COUNT(*) FROM sakila.actor;
+-----+
```

```
| count(*) |
+-----+
|      200 |
+-----+
```

## 15.21.4 InnoDB Error Handling

The following items describe how [InnoDB](#) performs error handling. [InnoDB](#) sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a [tablespace](#), a MySQL [Table is full](#) error occurs and [InnoDB](#) rolls back the SQL statement.
- A transaction [deadlock](#) causes [InnoDB](#) to [roll back](#) the entire [transaction](#). Retry the whole transaction when this happens.

A lock wait timeout causes [InnoDB](#) to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was [START TRANSACTION](#) or [BEGIN](#) statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of [COMMIT](#), [ROLLBACK](#), or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the [IGNORE](#) option in your statement.
- A [row too long error](#) rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the [InnoDB](#) storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit [ROLLBACK](#) SQL statement, [SHOW PROCESSLIST](#) displays [Rolling back](#) in the [State](#) column for the relevant connection.

16.11.2 The Common Database Server Layer .....	2720

Storage engines are MySQL components that handle the SQL operations for different table types. [InnoDB](#) is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The [CREATE TABLE](#) statement in MySQL 5.7 creates [InnoDB](#) tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the [SHOW ENGINES](#) statement. The value in the [Support](#) column indicates whether an engine can be used. A value of [YES](#), [NO](#), or [DEFAULT](#) indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
  XA: NO
  Savepoints: NO
***** 2. row *****
  Engine: InnoDB
  Support: DEFAULT
```

```
      Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
      XA: YES
Savepoints: YES
***** 3. row *****
      Engine: MRG_MYISAM
      Support: YES
      Comment: Collection of identical MyISAM tables
Transactions: NO
      XA: NO
Savepoints: NO
***** 4. row *****
      Engine: BLACKHOLE
      Support: YES
      Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
      XA: NO
Savepoints: NO
***** 5. row *****
      Engine: MyISAM
      Support: YES
      Comment: MyISAM storage engine
Transactions: NO
      XA: NO
Savepoints: NO
...
```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default [InnoDB](#) storage engine or the [NDB](#) storage engine which are covered in [Chapter 15, The InnoDB Storage Engine](#), and [Chapter 20, MySQL NDB Cluster 7.5](#). For advanced users, this chapter also contains a description of the pluggable storage engine architecture (see [Section 16.11, “Overview of MySQL Storage Engine Architecture”](#)).

For information about storage engine support offered in commercial MySQL Server binaries, see [MySQL Enterprise Server 5.7](#), on the MySQL Web site. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 5.7 FAQ: Storage Engines”](#).

## MySQL 5.7 Supported Storage Engines

- [InnoDB](#): The default storage engine in MySQL 5.7. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints. For more information about [InnoDB](#), see [Chapter 15, The InnoDB Storage Engine](#).
- [MyISAM](#): These tables have a small footprint. [Table-level locking](#) limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.
- [Memory](#): Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the [HEAP](#) engine. Its use cases are decreasing; [InnoDB](#) with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and [NDBCLUSTER](#) provides fast key-value lookups for huge distributed data sets.
- [CSV](#): Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format.

Because CSV tables are not indexed, you typically keep the data in [InnoDB](#) tables during normal operation, and only use CSV tables during the import or export stage.

- [Archive](#): These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- [Blackhole](#): The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to slave servers, but the master server does not keep its own copy of the data.
- [NDB](#) (also known as [NDBCLUSTER](#)): This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.
- [Merge](#): Enables a MySQL DBA or developer to logically group a series of identical [MyISAM](#) tables and reference them as one object. Good for VLDB environments such as data warehousing.
- [Federated](#): Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- [Example](#): This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly [InnoDB](#) tables, with one [CSV](#) table for exporting data to a spreadsheet and a few [MEMORY](#) tables for temporary workspaces.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL:

**Table 16.1 Storage Engines Feature Summary**

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Storage limits	256TB	RAM	64TB	None	384EB
Transactions	No	No	Yes	No	Yes
Locking granularity	Table	Table	Row	Row	Row
MVCC	No	No	Yes	No	No
Geospatial data type support	Yes	No	Yes	Yes	Yes
Geospatial indexing support	Yes	No	Yes <sup>a</sup>	No	No
B-tree indexes	Yes	Yes	Yes	No	No
T-tree indexes	No	No	No	No	Yes

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Hash indexes	No	Yes	No <sup>b</sup>	No	Yes
Full-text search indexes	Yes	No	Yes <sup>c</sup>	No	No
Clustered indexes	No	No	Yes	No	No
Data caches	No	N/A	Yes	No	Yes
Index caches	Yes	N/A	Yes	No	Yes
Compressed data	Yes <sup>d</sup>	No	Yes <sup>e</sup>	Yes	No
Encrypted data <sup>f</sup>	Yes	Yes	Yes	Yes	Yes
Cluster database support	No	No	No	No	Yes
Replication support <sup>g</sup>	Yes	Yes	Yes	Yes	Yes
Foreign key support	No	No	Yes	No	No
Backup / point-in-time recovery <sup>h</sup>	Yes	Yes	Yes	Yes	Yes
Query cache support	Yes	Yes	Yes	Yes	Yes
Update statistics for data dictionary	Yes	Yes	Yes	Yes	Yes

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and higher.

<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.

<sup>d</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>e</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>f</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>g</sup>Implemented in the server, rather than in the storage engine.

<sup>h</sup>Implemented in the server, rather than in the storage engine.

## 16.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 5.7. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for `TEMPORARY` tables created with `CREATE TEMPORARY TABLE` can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See [Section 14.1.18, “CREATE TABLE Syntax”](#), and [Section 14.1.8, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your master server uses `InnoDB` tables for maximum safety, but the slave servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever `CREATE TABLE` or `ALTER TABLE` cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See [Section 6.1.8, “Server SQL Modes”](#).

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 10.2.3, “Mapping of Identifiers to File Names”](#).

## 16.2 The MyISAM Storage Engine

`MyISAM` is based on the older (and no longer available) `ISAM` storage engine but has many useful extensions.

**Table 16.2** `MyISAM` Storage Engine Features

Storage limits	256TB	Transactions	No	Locking granularity	Table
----------------	-------	--------------	----	---------------------	-------

<b>MVCC</b>	No	<b>Geospatial data type support</b>	Yes	<b>Geospatial indexing support</b>	Yes
<b>B-tree indexes</b>	Yes	<b>T-tree indexes</b>	No	<b>Hash indexes</b>	No
<b>Full-text search indexes</b>	Yes	<b>Clustered indexes</b>	No	<b>Data caches</b>	No
<b>Index caches</b>	Yes	<b>Compressed data</b>	Yes <sup>a</sup>	<b>Encrypted data<sup>b</sup></b>	Yes
<b>Cluster database support</b>	No	<b>Replication support<sup>c</sup></b>	Yes	<b>Foreign key support</b>	No
<b>Backup / point-in-time recovery<sup>d</sup></b>	Yes	<b>Query cache support</b>	Yes	<b>Update statistics for data dictionary</b>	Yes

<sup>a</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>b</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

<sup>d</sup>Implemented in the server, rather than in the storage engine.

Each [MyISAM](#) table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` ([MYData](#)) extension. The index file has an `.MYI` ([MYIndex](#)) extension.

To specify explicitly that you want a [MyISAM](#) table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 5.7, it is normally necessary to use `ENGINE` to specify the [MyISAM](#) storage engine because [InnoDB](#) is the default engine.

You can check or repair [MyISAM](#) tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress [MyISAM](#) tables with `myisampack` to take up much less space. See [Section 5.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), and [Section 5.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

[MyISAM](#) tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of  $(2^{32})^2$  (1.844E+19) rows in a [MyISAM](#) table.
- The maximum number of indexes per [MyISAM](#) table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one `AUTO_INCREMENT` column per table is supported. `MyISAM` automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 9.11.3, “Concurrent Inserts”](#).
- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 14.1.18, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Section 11.1, “Character Set Support”](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover-options` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

## Additional Resources

- A forum dedicated to the `MyISAM` storage engine is available at <http://forums.mysql.com/list.php?21>.

## 16.2.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 6.1.4, “Server Command Options”](#).

**Table 16.3** `MyISAM` Option/Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<a href="#">bulk_insert_buffer_size</a>	Yes	Yes	Yes		Both	Yes
<a href="#">concurrent_insert</a>	Yes	Yes	Yes		Global	Yes
<a href="#">delay-key-write</a>	Yes	Yes			Global	Yes
- Variable: <a href="#">delay_key_write</a>			Yes		Global	Yes
<a href="#">have_rtree_keys</a>			Yes		Global	No
<a href="#">key_buffer_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">log-isam</a>	Yes	Yes				
<a href="#">myisam-block-size</a>	Yes	Yes				
<a href="#">myisam_data_pointer_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">myisam_max_sort_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">myisam_mmap_size</a>	Yes	Yes	Yes		Global	No
<a href="#">myisam-recover-options</a>	Yes	Yes				
- Variable: <a href="#">myisam_recover_options</a>						
<a href="#">myisam_recover_options</a>			Yes		Global	No
<a href="#">myisam_repair_threads</a>	Yes	Yes	Yes		Both	Yes
<a href="#">myisam_sort_buffer_size</a>	Yes	Yes	Yes		Both	Yes
<a href="#">myisam_stats_method</a>	Yes	Yes	Yes		Both	Yes
<a href="#">myisam_use_mmap</a>	Yes	Yes	Yes		Global	Yes
<a href="#">skip-concurrent-insert</a>	Yes	Yes				
- Variable: <a href="#">concurrent_insert</a>						
<a href="#">tmp_table_size</a>	Yes	Yes	Yes		Both	Yes

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed `MyISAM` tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any `MyISAM` table.

### Note

If you do this, you should not access `MyISAM` tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in

use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of [MyISAM](#) tables. For additional information, see [Section 6.1.5, “Server System Variables”](#).

- [bulk\\_insert\\_buffer\\_size](#)

The size of the tree cache used in bulk insert optimization.

**Note**

This is a limit *per thread*!

- [myisam\\_max\\_sort\\_file\\_size](#)

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during [REPAIR TABLE](#), [ALTER TABLE](#), or [LOAD DATA INFILE](#)). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- [myisam\\_sort\\_buffer\\_size](#)

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a [MyISAM](#) table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify [FORCE](#) in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify [FORCE](#), a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes [BACKUP](#), the recovery process creates files with names of the form [tbl\\_name-datetime.BAK](#). You should have a [cron](#) script that automatically moves these files from the database directories to backup media.

## 16.2.2 Space Needed for Keys

MyISAM tables use B-tree indexes. You can roughly calculate the size for the index file as  $(key\_length + 4) / 0.67$ , summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In MyISAM tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 16.2.3 MyISAM Table Storage Formats

MyISAM supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 5.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 14.1.18, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed MyISAM tables using `myisamchk --unpack`; see [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

### 16.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. MyISAM table indexes can always be reconstructed based on the data rows.

#### Note

Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.

- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.
- The expected row length in bytes for static-sized rows is calculated using the following expression:

```
row length = 1
             + (sum of column lengths)
             + (number of NULL columns + delete_flag + 7)/8
             + (number of variable-length columns)
```

`delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

### 16.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a `MyISAM` table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.

- The expected row length for dynamic-sized rows is calculated using the following expression:

```

3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8

```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 16.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

#### Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

### 16.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

### 16.2.4.1 Corrupted MyISAM Tables

Even though the [MyISAM](#) table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or [MyISAM](#) code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a [MyISAM](#) table using the `CHECK TABLE` statement, and repair a corrupted [MyISAM](#) table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 14.7.2.2, “CHECK TABLE Syntax”](#), [Section 14.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 27.5, “Debugging and Porting MySQL”](#).

### 16.2.4.2 Problems from Tables Not Being Closed Properly

Each [MyISAM](#) index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.

- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 6.6, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

## 16.3 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

**Table 16.4** `MEMORY` Storage Engine Features

<b>Storage limits</b>	RAM	<b>Transactions</b>	No	<b>Locking granularity</b>	Table
<b>MVCC</b>	No	<b>Geospatial data type support</b>	No	<b>Geospatial indexing support</b>	No
<b>B-tree indexes</b>	Yes	<b>T-tree indexes</b>	No	<b>Hash indexes</b>	Yes
<b>Full-text search indexes</b>	No	<b>Clustered indexes</b>	No	<b>Data caches</b>	N/A
<b>Index caches</b>	N/A	<b>Compressed data</b>	No	<b>Encrypted data<sup>a</sup></b>	Yes
<b>Cluster database support</b>	No	<b>Replication support<sup>b</sup></b>	Yes	<b>Foreign key support</b>	No
<b>Backup / point-in-time recovery<sup>c</sup></b>	Yes	<b>Query cache support</b>	Yes	<b>Update statistics for data dictionary</b>	Yes

<sup>a</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

**When to Use MEMORY or MySQL Cluster.** Developers looking to deploy applications that use the `MEMORY` storage engine for important, highly available, or frequently updated data should consider whether MySQL Cluster is a better choice. A typical use case for the `MEMORY` engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in `MEMORY` tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.

- A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the [MEMORY](#) engine with higher performance levels, and provides additional features not available with [MEMORY](#):

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including [BLOB](#) and [TEXT](#)) not supported by [MEMORY](#).

For a white paper with more detailed comparison of the [MEMORY](#) storage engine and MySQL Cluster, see [Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine](#). This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing [MEMORY](#) users can migrate to MySQL Cluster.

## Performance Characteristics

[MEMORY](#) performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for [MEMORY](#) tables, they are not necessarily faster than [InnoDB](#) tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of [MEMORY](#) tables from multiple sessions.

Depending on the kinds of queries performed on a [MEMORY](#) table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

## Physical Characteristics of MEMORY Tables

The [MEMORY](#) storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of `.frm`.

[MEMORY](#) tables have the following characteristics:

- Space for [MEMORY](#) tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. [MEMORY](#) tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- [MEMORY](#) tables use a fixed-length row-storage format. Variable-length types such as [VARCHAR](#) are stored using a fixed length.

- [MEMORY](#) tables cannot contain [BLOB](#) or [TEXT](#) columns.
- [MEMORY](#) includes support for [AUTO\\_INCREMENT](#) columns.
- Non-[TEMPORARY MEMORY](#) tables are shared among all clients, just like any other non-[TEMPORARY](#) table.

## DDL Operations for MEMORY Tables

To create a [MEMORY](#) table, specify the clause [ENGINE=MEMORY](#) on the [CREATE TABLE](#) statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, [MEMORY](#) tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in [MEMORY](#) tables are lost. The tables themselves continue to exist because their definitions are stored in [.frm](#) files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a [MEMORY](#) table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
->     SELECT ip,SUM(downloads) AS down
->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of [MEMORY](#) tables is limited by the [max\\_heap\\_table\\_size](#) system variable, which has a default value of 16MB. To enforce different size limits for [MEMORY](#) tables, change the value of this variable. The value in effect for [CREATE TABLE](#), or a subsequent [ALTER TABLE](#) or [TRUNCATE TABLE](#), is the value used for the life of the table. A server restart also sets the maximum size of existing [MEMORY](#) tables to the global [max\\_heap\\_table\\_size](#) value. You can set the size for individual tables as described later in this section.

## Indexes

The [MEMORY](#) storage engine supports both [HASH](#) and [BTREE](#) indexes. You can specify one or the other for a given index by adding a [USING](#) clause as shown here:

```
CREATE TABLE lookup
(id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 9.3.1, “How MySQL Uses Indexes”](#).

[MEMORY](#) tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a [MEMORY](#) table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a [BTREE](#) index to avoid this problem.

[MEMORY](#) tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain `NULL` values.

## User-Created and Temporary Tables

`MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).
- User-created `MEMORY` tables are never converted to disk tables.

## Loading Data

To populate a `MEMORY` table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 6.1.4, “Server Command Options”](#), and [Section 14.2.6, “LOAD DATA INFILE Syntax”](#).

## MEMORY Tables and Replication

A server's `MEMORY` tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave `MEMORY` tables, when a `MEMORY` table is used on a master for the first time since it was started, a `DELETE` statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the `MEMORY` table on the master at startup.

## Managing Memory Use

The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a `MEMORY` table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a `MEMORY` table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable

before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

## Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

## 16.4 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i    | c          |
+-----+-----+
| 1    | record one |
| 2    | record two |
+-----+-----+
2 rows in set (0.00 sec)
```

Creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

## 16.4.1 Repairing and Checking CSV Tables

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | error    | Corrupt  |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | warning  | Table is marked as crashed |
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
```

```

| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.02 sec)

```

### Warning

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

## 16.4.2 CSV Limitations

The [CSV](#) storage engine does not support indexing.

Partitioning is not supported for tables using the [CSV](#) storage engine.

All tables that you create using the [CSV](#) storage engine must have the [NOT NULL](#) attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

## 16.5 The ARCHIVE Storage Engine

The [ARCHIVE](#) storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

**Table 16.5** [ARCHIVE](#) Storage Engine Features

<b>Storage limits</b>	None	<b>Transactions</b>	No	<b>Locking granularity</b>	Row
<b>MVCC</b>	No	<b>Geospatial data type support</b>	Yes	<b>Geospatial indexing support</b>	No
<b>B-tree indexes</b>	No	<b>T-tree indexes</b>	No	<b>Hash indexes</b>	No
<b>Full-text search indexes</b>	No	<b>Clustered indexes</b>	No	<b>Data caches</b>	No
<b>Index caches</b>	No	<b>Compressed data</b>	Yes	<b>Encrypted data<sup>a</sup></b>	Yes
<b>Cluster database support</b>	No	<b>Replication support<sup>b</sup></b>	Yes	<b>Foreign key support</b>	No
<b>Backup / point-in-time recovery<sup>c</sup></b>	Yes	<b>Query cache support</b>	Yes	<b>Update statistics for data dictionary</b>	Yes

<sup>a</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

The [ARCHIVE](#) storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke [CMake](#) with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the [ARCHIVE](#) engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the [ARCHIVE](#) storage engine is available with the [SHOW ENGINES](#) statement.

When you create an [ARCHIVE](#) table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all

having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 12.5.1, “Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

The `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

`ARCHIVE` does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading.

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 14.7.2.4, “OPTIMIZE TABLE Syntax”](#), [Section 14.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 14.7.5.36, “SHOW TABLE STATUS Syntax”](#).

## Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

## 16.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the [BLACKHOLE](#) storage engine if you build MySQL from source, invoke [CMake](#) with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the [BLACKHOLE](#) engine, look in the `sql` directory of a MySQL source distribution.

When you create a [BLACKHOLE](#) table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The [BLACKHOLE](#) storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the [BLACKHOLE](#) storage engine is available with the `SHOW ENGINES` statement.

Inserts into a [BLACKHOLE](#) table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

#### Note

When using the row based format for the binary log, updates and deletes are skipped, and neither logged nor applied. For this reason, you should use `STATEMENT` for the binary logging format, and not `ROW` or `MIXED`.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is [BLACKHOLE](#), depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

### Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

### Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the [BLACKHOLE](#) engine. This is carried out in a way similar to how master table filtering is achieved - by using the [BLACKHOLE](#) engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

## 16.7 The MERGE Storage Engine

The [MERGE](#) storage engine, also known as the [MRG\\_MyISAM](#) engine, is a collection of identical [MyISAM](#) tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge [MyISAM](#) tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the [MyISAM](#) tables can be compressed with [myisampack](#). See [Section 5.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as [AVG\\_ROW\\_LENGTH](#), [MAX\\_ROWS](#), or [PACK\\_KEYS](#) do not matter.

An alternative to a [MERGE](#) table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the [MyISAM](#) storage engine. For more information, see [Chapter 21, Partitioning](#).

When you create a [MERGE](#) table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An [.frm](#) file stores the table format, and an [.MRG](#) file contains the names of the underlying [MyISAM](#) tables that should be used as one. The tables do not have to be in the same database as the [MERGE](#) table.

You can use [SELECT](#), [DELETE](#), [UPDATE](#), and [INSERT](#) on [MERGE](#) tables. You must have [SELECT](#), [DELETE](#), and [UPDATE](#) privileges on the [MyISAM](#) tables that you map to a [MERGE](#) table.

### Note

The use of [MERGE](#) tables entails the following security issue: If a user has access to [MyISAM](#) table *t*, that user can create a [MERGE](#) table *m* that accesses *t*. However, if the user's privileges on *t* are subsequently revoked, the user can continue to access *t* by doing so through *m*.

Use of [DROP TABLE](#) with a [MERGE](#) table drops only the [MERGE](#) specification. The underlying tables are not affected.

To create a [MERGE](#) table, you must specify a [UNION=\(list-of-tables\)](#) option that indicates which [MyISAM](#) tables to use. You can optionally specify an [INSERT\\_METHOD](#) option to control how inserts into the [MERGE](#) table take place. Use a value of [FIRST](#) or [LAST](#) to cause inserts to be made in the first or last underlying table, respectively. If you specify no [INSERT\\_METHOD](#) option or if you specify it with a value of [NO](#), inserts into the [MERGE](#) table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+-----+
| a | message |
+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+-----+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.
- The column order in the underlying table and the `MERGE` table must match.
- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:

- The column type in the underlying table and the [MERGE](#) table must be equal.
- The column length in the underlying table and the [MERGE](#) table must be equal.
- The column of the underlying table and the [MERGE](#) table can be [NULL](#).
- The underlying table must have at least as many indexes as the [MERGE](#) table. The underlying table may have more indexes than the [MERGE](#) table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the [MERGE](#) table and the underlying [MyISAM](#) table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the [MERGE](#) table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the [MERGE](#) table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
  - Check whether index parts can be [NULL](#).

If a [MERGE](#) table cannot be opened or used because of a problem with an underlying table, [CHECK TABLE](#) displays information about which table caused the problem.

## Additional Resources

- A forum dedicated to the [MERGE](#) storage engine is available at <http://forums.mysql.com/list.php?93>.

### 16.7.1 MERGE Table Advantages and Disadvantages

[MERGE](#) tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with [myisampack](#), and then create a [MERGE](#) table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A [MERGE](#) table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a [MERGE](#) table for others. You can even have many different [MERGE](#) tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a [MERGE](#) table than to repair a single large table.

- Instantly map many tables as one. A [MERGE](#) table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, [MERGE](#) table collections are *very* fast to create or remap. (You must still specify the index definitions when you create a [MERGE](#) table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a [MERGE](#) table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each [MyISAM](#) table is bound by this limit, but a collection of [MyISAM](#) tables is not.
- You can create an alias or synonym for a [MyISAM](#) table by defining a [MERGE](#) table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of [MERGE](#) tables are:

- You can use only identical [MyISAM](#) tables for a [MERGE](#) table.
- Some [MyISAM](#) features are unavailable in [MERGE](#) tables. For example, you cannot create [FULLTEXT](#) indexes on [MERGE](#) tables. (You can create [FULLTEXT](#) indexes on the underlying [MyISAM](#) tables, but you cannot search the [MERGE](#) table with a full-text search.)
- If the [MERGE](#) table is nontemporary, all underlying [MyISAM](#) tables must be nontemporary. If the [MERGE](#) table is temporary, the [MyISAM](#) tables can be any mix of temporary and nontemporary.
- [MERGE](#) tables use more file descriptors than [MyISAM](#) tables. If 10 clients are using a [MERGE](#) table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the [MERGE](#) storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the [MERGE](#) storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes [MERGE](#) indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 14.8.2, “EXPLAIN Syntax”](#).

## 16.7.2 MERGE Table Problems

The following are known problems with [MERGE](#) tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child [MyISAM](#) tables.

From versions 5.1.23, [MERGE](#) children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the [MyISAM](#) tables corrupted them.

- If you use `ALTER TABLE` to change a [MERGE](#) table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying [MyISAM](#) tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a [MERGE](#) table indicates which underlying [MyISAM](#) table to use for inserts into the [MERGE](#) table. However, use of the `AUTO_INCREMENT` table option for that [MyISAM](#) table has no effect for inserts into the [MERGE](#) table until at least one row has been inserted directly into the [MyISAM](#) table.

- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.
- The definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.
- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.
- The maximum number of rows in a `MERGE` table is  $2^{64}$  (~1.844E+19; the same as for a `MyISAM` table). It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.

- Use of underlying [MyISAM](#) tables of differing row formats with a parent [MERGE](#) table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary [MERGE](#) table when [LOCK TABLES](#) is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;  
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;  
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary [MERGE](#) table.

- You cannot create a [MERGE](#) table with [CREATE ... SELECT](#), neither as a temporary [MERGE](#) table, nor as a nontemporary [MERGE](#) table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: *tbl\_name* is not [BASE TABLE](#).

- In some cases, differing [PACK\\_KEYS](#) table option values among the [MERGE](#) and underlying tables cause unexpected results if the underlying tables contain [CHAR](#) or [BINARY](#) columns. As a workaround, use [ALTER TABLE](#) to ensure that all involved tables have the same [PACK\\_KEYS](#) value. (Bug #50646)

## 16.8 The FEDERATED Storage Engine

The [FEDERATED](#) storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local [FEDERATED](#) table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the [FEDERATED](#) storage engine if you build MySQL from source, invoke [CMake](#) with the [-DWITH\\_FEDERATED\\_STORAGE\\_ENGINE](#) option.

The [FEDERATED](#) storage engine is not enabled by default in the running server; to enable [FEDERATED](#), you must start the MySQL server binary using the [--federated](#) option.

To examine the source for the [FEDERATED](#) engine, look in the [storage/federated](#) directory of a MySQL source distribution.

### 16.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as [MyISAM](#), [CSV](#) or [InnoDB](#)), the table consists of the table definition and the associated data. When you create a [FEDERATED](#) table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A [FEDERATED](#) table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the [.frm](#) file) and the associated table. The table type of the remote table may be any type supported by the remote [mysqld](#) server, including [MyISAM](#) or [InnoDB](#).
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the [.frm](#) file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a [FEDERATED](#) table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote

server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a **FEDERATED** table setup is shown in [Figure 16.1, “FEDERATED Table Structure”](#).

**Figure 16.1 FEDERATED Table Structure**

When a client issues an SQL statement that refers to a **FEDERATED** table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the **FEDERATED** table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the **FEDERATED** engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

## 16.8.2 How to Create FEDERATED Tables

To create a **FEDERATED** table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
```

```

    other INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;

```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

### Important

When you create the local table it *must* have an identical field definition to the remote table.

### Note

You can improve the performance of a [FEDERATED](#) table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the [WHERE](#) clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

## 16.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the [CONNECTION](#) string after the engine type in a [CREATE TABLE](#) statement. For example:

```

CREATE TABLE federated_table (
    id INT(20) NOT NULL AUTO_INCREMENT,
    name VARCHAR(32) NOT NULL DEFAULT '',
    other INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';

```

### Note

[CONNECTION](#) replaces the [COMMENT](#) used in some previous versions of MySQL.

The [CONNECTION](#) string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server [remote\\_host](#), using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```

scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name

```

Where:

- *scheme*: A recognized connection protocol. Only `mysql` is supported as the *scheme* value at this point.
- *user\_name*: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- *password*: (Optional) The corresponding password for *user\_name*.
- *host\_name*: The host name or IP address of the remote server.
- *port\_num*: (Optional) The port number for the remote server. The default is 3306.
- *db\_name*: The name of the database holding the remote table.
- *tbl\_name*: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 16.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The *server\_name* is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see [Section 14.1.17, “CREATE SERVER Syntax”](#).

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Connection scheme	<code>scheme</code>	<code>wrapper_name</code>	<code>Wrapper</code>
Remote user	<code>user_name</code>	<code>USER</code>	<code>Username</code>
Remote password	<code>password</code>	<code>PASSWORD</code>	<code>Password</code>
Remote host	<code>host_name</code>	<code>HOST</code>	<code>Host</code>
Remote port	<code>port_num</code>	<code>PORT</code>	<code>Port</code>
Remote database	<code>db_name</code>	<code>DATABASE</code>	<code>Db</code>

### 16.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns will fail. The following definition in `MyISAM` is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the **FEDERATED** engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED  
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses **SELECT**, **INSERT**, **UPDATE**, and **DELETE**, but not **HANDLER**.
- The **FEDERATED** storage engine supports **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE TABLE**, and indexes. It does not support **ALTER TABLE**, or any Data Definition Language statements that directly affect the structure of the table, other than **DROP TABLE**. The current implementation does not use prepared statements.
- **FEDERATED** accepts **INSERT ... ON DUPLICATE KEY UPDATE** statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a **FEDERATED** table when performing bulk inserts (for example, on a **INSERT INTO ... SELECT ...** statement) is slower than with other table types because each selected row is treated as an individual **INSERT** statement on the **FEDERATED** table.
- Transactions are not supported.
- **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
  - Bulk-insert handling does not occur for **INSERT ... ON DUPLICATE KEY UPDATE**.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a **CONNECTION** string, you cannot use an '@' character in the password. You can get round this limitation by using the **CREATE SERVER** statement to create a server connection.
- The **insert\_id** and **timestamp** options are not propagated to the data provider.
- Any **DROP TABLE** statement issued against a **FEDERATED** table drops only the local table, not the remote table.
- **FEDERATED** tables do not work with the query cache.
- User-defined partitioning is not supported for **FEDERATED** tables.

## 16.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the **FEDERATED** storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

## 16.9 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

## 16.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [MySQL Internals: Writing a Custom Storage Engine](#).

## 16.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

### 16.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

#### Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

#### Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

### 16.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

Data is the currency of today's web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. **Availability** refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. [Scalability](#) refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: [Chapter 18, Replication](#).
- MySQL Fabric. Learn more: [MySQL Fabric](#).
- MySQL Cluster. Learn more: [Chapter 20, MySQL NDB Cluster 7.5](#).
- Oracle MySQL Cloud Service. [Learn more about MySQL Cloud Service](#).
- Oracle Clusterware Agent for MySQL. [Learn more about Oracle Clusterware](#).

- MySQL with Solaris Cluster. [Learn more about Solaris Cluster.](#)

Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

**Figure 17.1 Tradeoffs: Cost and Complexity versus Availability**

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

**Table 17.1 Feature Comparison of MySQL HA Solutions**

Requirement	MySQL Replication	MySQL Cluster
<b>Availability</b>		
Platform Support	All Supported by MySQL Server ( <a href="http://www.mysql.com/">http://www.mysql.com/</a> )	All Supported by MySQL Cluster ( <a href="http://www.mysql.com/support/supportedplatforms/cluster.html">http://www.mysql.com/support/supportedplatforms/cluster.html</a> )

Requirement	MySQL Replication	MySQL Cluster
	<a href="#">support/supportedplatforms/database.html</a> )	
Automated IP Failover	No	Depends on Connector and Configuration
Automated Database Failover	No	Yes
Automatic Data Resynchronization	No	Yes
Typical Failover Time	User / Script Dependent	1 Second and Less
Synchronous Replication	No, Asynchronous and Semisynchronous	Yes
Shared Storage	No, Distributed	No, Distributed
Geographic redundancy support	Yes	Yes, via MySQL Replication
Update Schema On-Line	No	Yes
<b>Scalability</b>		
Number of Nodes	One Master, Multiple Slaves	255
Built-in Load Balancing	Reads, via MySQL Replication	Yes, Reads and Writes
Supports Read-Intensive Workloads	Yes	Yes
Supports Write-Intensive Workloads	Yes, via Application-Level Sharding	Yes, via Auto-Sharding
Scale On-Line (add nodes, repartition, etc.)	No	Yes

## 17.1 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as [Chapter 18, Replication](#).

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at [/scratchpool](#):

```

Filesystem                size      used   avail capacity  Mounted on
/dev/dsk/c0d0s0           4.6G      3.7G    886M     82%      /
/devices                   0K         0K       0K        0%      /devices
ctfs                       0K         0K       0K        0%      /system/contract
proc                       0K         0K       0K        0%      /proc
mnttab                     0K         0K       0K        0%      /etc/mnttab
swap                      1.4G      892K     1.4G       1%      /etc/svc/volatile
objfs                      0K         0K       0K        0%      /system/object
/usr/lib/libc/libc_hwcapi.so.1
                           4.6G      3.7G    886M     82%      /lib/libc.so.1
fd                         0K         0K       0K        0%      /dev/fd
swap                      1.4G      40K     1.4G       1%      /tmp

```

swap	1.4G	28K	1.4G	1%	/var/run
/dev/dsk/c0d0s7	26G	913M	25G	4%	/export/home
scratchpool	16G	24K	16G	1%	/scratchpool

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x  31 root    bin           50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root    bin           5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root    sys           16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000    1000         40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1    0      -    24.5K  -
scratchpool@snap2    0      -    24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

## 17.1.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x  6 root    root      7 Nov  8 09:13 ./
drwxr-xr-x 29 root    root      34 Nov  9 07:06 ../
drwxr-xr-x 31 root    bin       50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root    bin       5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root    sys      16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000   1000     40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

## 17.1.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send/ zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

## 17.1.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On `MyISAM` tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

## 17.2 Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see [Section 17.2.2, “Using `memcached`”](#)

Benefits of using `memcached` include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.
- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.
- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information is not in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 17.2, “`memcached` Architecture Overview”](#).

**Figure 17.2 `memcached` Architecture Overview**

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.

## 17.2.1 Installing `memcached`

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

### Installing `memcached` from a Binary Distribution

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

#### Note

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

### Building `memcached` from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached Web site](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you might specify to the `configure`:

- `--prefix`

To specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see [Section 17.2.2.8, “memcached Thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 17.2.2.6, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

## 17.2.2 Using `memcached`

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

### Note

You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211

- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

### 17.2.2.1 `memcached` Command-Line Options

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

#### Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
kthr    memory              page            disk              faults              cpu
r  b  w   swap free  re  mf pi po fr de sr sl s2 -- --  in  sy  cs us sy id
0  0  0  5170504 3450392 2   7   2  0  0  0  4  0  0  0  0  296  54 199  0  0 100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

**Note**

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- `-s socket`

Specify a Unix socket to listen on.

If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

Specify the number of threads to use when processing incoming requests.

By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

**Note**

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

Print the help message and exit.

- `-i`

Print the `memcached` and `libevent` license.

- `-I mem`

Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- `-b`

Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

Save the process ID of the `memcached` instance into `file`.

- `-f`

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see [Section 17.2.2.9, “memcached Logs”](#).

- `-n bytes`

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

Disable the use of compare and swap (CAS) operations.

This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see [Section 17.2.4, “Getting memcached Statistics”](#)). The default is the colon (`:`). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in `memcached` 1.4.0.

### 17.2.2.2 `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must be capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.
- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.
- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 17.2.2.5, “`memcached` Hashing/Distribution Types”](#).

### 17.2.2.3 Using Namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieved from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

**Note**

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

**17.2.2.4 Data Expiry**

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 17.2.4, “Getting `memcached` Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

**17.2.2.5 `memcached` Hashing/Distribution Types**

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];  
$value = hash('myid');  
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 ( $7009 \% 3 = 1$ ), and store or retrieve the key and value with that server.

**Note**

This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in [Figure 17.3, “memcached Hash Selection”](#).

**Figure 17.3** `memcached` Hash Selection

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).
- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

**Note**

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

- A new `memcached` instance has been added to the list of available instances
- A `memcached` instance has been removed from the list of available instances
- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

**Figure 17.4** `memcached` Hash Selection with New `memcached` instance

This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can

add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

### 17.2.2.6 Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see [Section 17.2.1, "Installing `memcached`"](#).

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid`: The connection ID.

- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid`: The connection ID.

- `conn-create(ptr)`

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:

- `ptr`: A pointer to the connection. object
- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr`: A pointer to the connection object.
- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid`: The connection ID.
- `threadid`: The thread ID.
- `slabs-allocate(size, slabclass, slabsize, ptr)`

Allocate memory from the slab allocator.

Arguments:

- `size`: The requested size.
- `slabclass`: The allocation is fulfilled in this class.
- `slabsize`: The size of each item in this class.
- `ptr`: A pointer to allocated memory.
- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `size`: The requested size.
- `slabclass`: The class that failed to fulfill the request.
- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space.

Arguments:

- `slabclass`: The class that needs more memory.
- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `slabclass`: The class that failed to grab more memory.
- `slabs-free(size, slabclass, ptr)`

Release memory.

Arguments:

- `size`: The amount of memory to release, in bytes.
- `slabclass`: The class the memory belongs to.
- `ptr`: A pointer to the memory to release.
- `assoc-find(key, depth)`

Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

Arguments:

- `key`: The key searched for.
- `depth`: The depth in the list of hash table.
- `assoc-insert(key, nokeys)`

Fired when a new item has been inserted.

Arguments:

- `key`: The key just inserted.
- `nokeys`: The total number of keys currently being stored, including the key for which insert was called.
- `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key`: The key just deleted.
- `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.
- `item-link(key, size)`

Fired when an item is being linked in the cache.

Arguments:

- `key`: The items key.
- `size`: The size of the data.

- `item-unlink(key, size)`  
Fired when an item is being deleted.  
Arguments:
  - `key`: The items key.
  - `size`: The size of the data.
- `item-remove(key, size)`  
Fired when the refcount for an item is reduced.  
Arguments:
  - `key`: The item's key.
  - `size`: The size of the data.
- `item-update(key, size)`  
Fired when the "last referenced" time is updated.  
Arguments:
  - `key`: The item's key.
  - `size`: The size of the data.
- `item-replace(oldkey, oldsize, newkey, newsize)`  
Fired when an item is being replaced with another item.  
Arguments:
  - `oldkey`: The key of the item to replace.
  - `oldsize`: The size of the old item.
  - `newkey`: The key of the new item.
  - `newsize`: The size of the new item.
- `process-command-start(connid, request, size)`  
Fired when the processing of a command starts.  
Arguments:
  - `connid`: The connection ID.
  - `request`: The incoming request.
  - `size`: The size of the request.
- `process-command-end(connid, response, size)`  
Fired when the processing of a command is done.

Arguments:

- `connid`: The connection ID.
- `response`: The response to send back to the client.
- `size`: The size of the response.
- `command-get(connid, key, size)`

Fired for a `get` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `command-gets(connid, key, size, casid)`

Fired for a `gets` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The casid for the item.
- `command-add(connid, key, size)`

Fired for a `add` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).
- `command-set(connid, key, size)`

Fired for a `set` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-replace(connid, key, size)`

Fired for a `replace` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-prepend(connid, key, size)`

Fired for a `prepend` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-append(connid, key, size)`

Fired for a `append` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-cas(connid, key, size, casid)`

Fired for a `cas` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The cas ID requested.

- `command-incr(connid, key, val)`

Fired for `incr` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.

- `val`: The new value.
- `command-decr(connid, key, val)`  
Fired for `decr` command.  
Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `val`: The new value.
- `command-delete(connid, key, exptime)`  
Fired for a `delete` command.  
Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `exptime`: The expiry time.

### 17.2.2.7 Memory Allocation within `memcached`

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 17.5, “Memory Allocation in `memcached`”](#).

**Figure 17.5 Memory Allocation in `memcached`**

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for  $104 \times 1.25$ , or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 17.2.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

### 17.2.2.8 `memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

### 17.2.2.9 memcached Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by memcached includes details of the operations being performed.

Without the verbose options, memcached normally produces no output during normal operating.

- **Output when using `-v`**

The lowest verbosity level shows you:

- Errors and warnings
- Transient errors
- Protocol and socket errors, including exhausting available connections
- Each registered client connection, including the socket descriptor number and the protocol used.

For example:

```
32: Client using the ascii protocol
33: Client using the ascii protocol
```

The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```
<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d
```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of memcached with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
```

```

slab class 1: chunk size      80 perslab 13107
slab class 2: chunk size     104 perslab 10082
slab class 3: chunk size     136 perslab  7710
slab class 4: chunk size     176 perslab  5957
slab class 5: chunk size     224 perslab  4681
slab class 6: chunk size     280 perslab  3744
slab class 7: chunk size     352 perslab  2978
slab class 8: chunk size     440 perslab  2383
slab class 9: chunk size     552 perslab  1899
slab class 10: chunk size    696 perslab  1506
slab class 11: chunk size    872 perslab  1202
slab class 12: chunk size   1096 perslab   956
slab class 13: chunk size   1376 perslab   762
slab class 14: chunk size   1720 perslab   609
slab class 15: chunk size   2152 perslab   487
slab class 16: chunk size   2696 perslab   388
slab class 17: chunk size   3376 perslab   310
slab class 18: chunk size   4224 perslab   248
slab class 19: chunk size   5280 perslab   198
slab class 20: chunk size   6600 perslab   158
slab class 21: chunk size   8256 perslab   127
slab class 22: chunk size  10320 perslab   101
slab class 23: chunk size  12904 perslab    81
slab class 24: chunk size  16136 perslab    64
slab class 25: chunk size  20176 perslab    51
slab class 26: chunk size  25224 perslab    41
slab class 27: chunk size  31536 perslab    33
slab class 28: chunk size  39424 perslab    26
slab class 29: chunk size  49280 perslab    21
slab class 30: chunk size  61600 perslab    17
slab class 31: chunk size  77000 perslab    13
slab class 32: chunk size  96256 perslab    10
slab class 33: chunk size 120320 perslab     8
slab class 34: chunk size 150400 perslab     6
slab class 35: chunk size 188000 perslab     5
slab class 36: chunk size 235000 perslab     4
slab class 37: chunk size 293752 perslab     3
slab class 38: chunk size 367192 perslab     2
slab class 39: chunk size 458992 perslab     2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)

```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```

shell> memcached -f 4 -m 1g -vv
slab class 1: chunk size      80 perslab 13107
slab class 2: chunk size     320 perslab  3276
slab class 3: chunk size    1280 perslab   819
slab class 4: chunk size    5120 perslab   204
slab class 5: chunk size   20480 perslab    51
slab class 6: chunk size   81920 perslab    12
slab class 7: chunk size  327680 perslab     3

```

...

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```

32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545

```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the `memcached` server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```

<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol

```

```
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

### 17.2.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

#### 17.2.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- `get(key)`: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])`: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days ( $30 \times 24 \times 60 \times 60$ ), or an absolute time (epoch) if larger than this value.
- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.
- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.
- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.
- `incr(key, value)`: Increments the item associated with the `key` by the specified `value`.

- `decr(key , value)`: Decrements the item associated with the `key` by the specified `value`.
- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

### 17.2.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the `InnoDB buffer pool` and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

#### Caution

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached` instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the `memcached` ports to a select set of hosts.

You can introduce `memcached` to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using `memcached` in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 17.6, “Typical `memcached` Application Flowchart”](#).

**Figure 17.6 Typical `memcached` Application Flowchart**

### Adapting Database Best Practices to `memcached` Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a [primary key](#). Because of the uniqueness requirements for `memcached` keys, make sure your database schema makes appropriate use of primary keys and [unique constraints](#).

If you combine multiple column values into a single `memcached` item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to `memcached` lookups are those with a single `WHERE` clause, using an `=` or `IN` operator. For complicated `WHERE` clauses, or those using operators such as `<`, `>`, `BETWEEN`, or `LIKE`, `memcached` does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

#### 17.2.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Key stored successfully\n");
    else
        fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));

    return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
```

```
Added server successfully
Key stored successfully
```

## `libmemcached` Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

## `libmemcached` Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
memcached_server_add (memcached_st *ptr,
                     char *hostname,
                     unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
memcached_server_add_unix_socket (memcached_st *ptr,
                                char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
    memcached_server_push (memcached_st *ptr,
                          memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
    memcached_server_list_append (memcached_server_st *ptr,
                                char *hostname,
                                unsigned int port,
                                memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

## libmemcached Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```
memcached_return
    memcached_set (memcached_st *ptr,
                  const char *key,
                  size_t key_length,
                  const char *value,
                  size_t value_length,
                  time_t expiration,
                  uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see [Controlling libmemcached Behaviors](#).

This table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

libmemcached Function	Equivalent Core Function
<code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>set()</code> operation.
<code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>add()</code> function.
<code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>replace()</code> .
<code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>	Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .
<code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>	Appends the specified <code>value</code> after the current value of the specified <code>key</code> .
<code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>	Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.
<code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>add()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_prepend()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_append()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_cas()</code> , but has the option of an additional master key that can be used to identify an individual server.

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
```

```
const char *master_key,
size_t master_key_length,
const char *key,
size_t key_length,
const char *value,
size_t value_length,
time_t expiration,
uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

## `libmemcached` Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                    const char *key, size_t key_length,
                    size_t *value_length,
                    uint32_t *flags,
                    memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
               char **keys, size_t *key_length,
               unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                     const char *key, size_t *key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
```

```

{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;

    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;

    memc = memcached_create(NULL);

    servers = memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc = memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    for(x = 0; x < 3; x++)
    {
        key_length[x] = strlen(keys[x]);
        value_length[x] = strlen(values[x]);

        rc = memcached_set(memc, keys[x], key_length[x], values[x],
                           value_length[x], (time_t)0, (uint32_t)0);
        if (rc == MEMCACHED_SUCCESS)
            fprintf(stderr, "Key %s stored successfully\n", keys[x]);
        else
            fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));
    }

    rc = memcached_mget(memc, keys, key_length, 3);

    if (rc == MEMCACHED_SUCCESS)
    {
        while ((return_value = memcached_fetch(memc, return_key, &return_key_length,
                                                &return_value_length, &flags, &rc)) != NULL)
        {
            if (rc == MEMCACHED_SUCCESS)
            {
                fprintf(stderr, "Key %s returned %s\n", return_key, return_value);
            }
        }
    }

    return 0;
}

```

Running the above application produces the following output:

```

shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green

```

## Controlling `libmemcached` Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```
memcached_return
memcached_behavior_set (memcached_st *ptr,
                        memcached_behavior flag,
                        uint64_t data);
```

To get the current behavior setting:

```
uint64_t
memcached_behavior_get (memcached_st *ptr,
                        memcached_behavior flag);
```

The following table describes `libmemcached` behavior flags.

Behavior	Description
<code>MEMCACHED_BEHAVIOR_NO_BLOCK</code>	Caused <code>libmemcached</code> to use asynchronous I/O.
<code>MEMCACHED_BEHAVIOR_TCP_NODELAY</code>	Turns on no-delay for network sockets.
<code>MEMCACHED_BEHAVIOR_HASH</code>	Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include <code>MEMCACHED_HASH_DEFAULT</code> , <code>MEMCACHED_HASH_MD5</code> , <code>MEMCACHED_HASH_CRC</code> , <code>MEMCACHED_HASH_FNV1_64</code> , <code>MEMCACHED_HASH_FNV1A_64</code> , <code>MEMCACHED_HASH_FNV1_32</code> , and <code>MEMCACHED_HASH_FNV1A_32</code> .
<code>MEMCACHED_BEHAVIOR_DISTRIBUTION</code>	Changes the method of selecting the server used to store a given value. The default method is <code>MEMCACHED_DISTRIBUTION_MODULA</code> . You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> . <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> .
<code>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</code>	Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.
<code>MEMCACHED_BEHAVIOR_SUPPORT_CAS</code>	Support CAS operations. By default, this is disabled because it imposes a performance penalty.
<code>MEMCACHED_BEHAVIOR_KETAMA</code>	Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code> .
<code>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</code>	Modify the timeout value used by <code>poll()</code> . Supply a signed <code>int</code> pointer for the timeout value.
<code>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</code>	Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.
<code>MEMCACHED_BEHAVIOR_VERIFY_KEY</code>	Forces <code>libmemcached</code> to verify that a specified key is valid.

Behavior	Description
<code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code>	If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.
<code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code>	In nonblocking mode this changes the value of the timeout during socket connection.

## `libmemcached` Command-Line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file name as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

### 17.2.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using [CPAN](#):

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

### Note

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

Cache::Memcached Function	Equivalent Generic Method
<code>get()</code>	Generic <code>get()</code> .
<code>get_multi(keys)</code>	Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code> .

Cache::Memcached Function	Equivalent Generic Method
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filename = shift or die "Must specify the film name\n";
my $filmkey = $filename;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
    $filmdata = load_filmdata($filename);

    if (defined($filmdata))
    {
        # Set the data into the cache, using the key

        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filename\n";
    }
}
else
{

```

```

    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmdname) = @_ ;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila', 'password');

    my ($filmdbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                    $dbh->quote($filmdname)));

    if (!defined($filmdname))
    {
        return (undef);
    }

    $filmdbase->{stars} =
    $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                    'from film_actor left join (actor) ' .
                                    'on (film_actor.actor_id = actor.actor_id) ' .
                                    'where film_id=%s',
                                    $dbh->quote($filmdbase->{film_id})));

    return($filmdbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to [memcached](#). When calling it for a film does not exist, you get this result:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached

```

When accessing a film that has already been added to the cache:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached

```

### 17.2.3.5 Using MySQL and [memcached](#) with Python

The Python [memcache](#) module interfaces to [memcached](#) servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```

python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43

```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. When you store Python data structures as `memcached` items, they are automatically serialized (turned into string values) using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class. For example, if the `memcached` daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each `memcached` instance to use. To enable debugging, set the optional `debug` parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is `crc32`. To change the function used, set the value of `memcache.serverHashFunction` to the alternate function to use. For example:

```
from zlib import Adler32
memcache.serverHashFunction = Adler32
```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

Python <code>memcache</code> Function	Equivalent Generic Function
<code>get()</code>	Generic <code>get()</code> .
<code>get_multi(keys)</code>	Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code> .
<code>set_multi(dict [, expiry [, key_prefix]])</code>	Sets multiple key/value pairs from the supplied <code>dict</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>prepend(key, value [, expiry])</code>	Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>append(key, value [, expiry])</code>	Appends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>delete_multi(keys [, expiry [, key_prefix]] )</code>	Deletes all the keys from the hash matching each string in the array <code>keys</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

#### Note

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a [memcache](#) instance, loading the raw data from MySQL:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the [memcached](#) server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using [cPickle/pickle](#), when you load the data back from [memcached](#), you can use the object directly. In the example above, the information stored to [memcached](#) is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from [memcached](#) and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

### 17.2.3.6 Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

Configuration option	Default	Description
<code>memcache.allow_failover</code>	1	Specifies whether another server in the list should be queried if the first server selected fails.
<code>memcache.max_failover_attempts</code>	20	Specifies the number of servers to try before returning a failure.
<code>memcache.chunk_size</code>	8192	Defines the size of network chunks used to exchange data with the <code>memcached</code> server.
<code>memcache.default_port</code>	11211	Defines the default port to use when communicating with the <code>memcached</code> servers.
<code>memcache.hash_strategy</code>	standard	Specifies which hash strategy to use. Set to <code>consistent</code> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code> , an older (modula) strategy is used that potentially uses different servers for storage.
<code>memcache.hash_function</code>	crc32	Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the memcache object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                        [, int $weight [, int $timeout [, int $retry_interval
```

```
[, bool $status [, callback $failure_callback
]]]]]] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php

$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table:

PECL <code>memcache</code> Function	Generic Function
<code>get()</code>	Generic <code>get()</code> .
<code>set()</code>	Generic <code>set()</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>increment()</code>	Generic <code>incr()</code> .
<code>decrement()</code>	Generic <code>decr()</code> .

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php

$memc = new Memcache;
$memc->addServer('localhost',11211);

if(empty($_POST['film'])) {
?>
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Simple Memcache Lookup</title>
</head>
<body>
```

```

    <form method="post">
        <p><b>Film</b>: <input type="text" size="20" name="film"></p>
        <input type="submit">
    </form>
    <hr/>
<?php
} else {

    echo "Loading data...\n";

    $film    = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }
    } else {

        $mysqli = mysqli('localhost','sakila','password','sakila');

        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);

        if (!$result) {
            sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }

        $row = $result->fetch_assoc();

        $memc->set($row['title'], $row);

        printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8'));
    }
}
?>
</body>
</html>

```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 17.2.3.7 Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn] y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

Ruby <code>MemCache</code> Method	Equivalent <code>memcached</code> API Functions
<code>get()</code>	Generic <code>get()</code> .
<code>get_hash(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values.
<code>set()</code>	Generic <code>set()</code> .
<code>set_many(pairs)</code>	Set the values of the keys and values in the hash <code>pairs</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .

Ruby <code>MemCache</code> Method	Equivalent <code>memcached</code> API Functions
<code>delete()</code>	Generic <code>delete()</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

### 17.2.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <https://github.com/gwhalin/Memcached-Java-Client/downloads>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {

        String[] servers =
            {
                "localhost:11211",
            };

        Integer[] weights = { 1 };

        SockIOPool pool = SockIOPool.getInstance();

        pool.setServers( servers );
        pool.setWeights( weights );
    }
}
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
```

```
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modular hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

Java <code>com.danga.MemCached</code> Method	Equivalent Generic Method
<code>get()</code>	Generic <code>get()</code> .
<code>getMulti(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values.
<code>set()</code>	Generic <code>set()</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

### 17.2.3.9 Using the `memcached` TCP Text Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with `memcached`, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (`cas`):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- `command`: The command name.
  - `set`: Store value against key
  - `add`: Store this value against key if the key does not already exist
  - `replace`: Store this value against key if the key already exists
  - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
- `key`: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- `flags`: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- `exptime`: The expiry time, or zero for no expiry.
- `length`: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
- `casunique`: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- `noreply`: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see [Table 17.3, “memcached Protocol Responses”](#).

- **Retrieval commands:** `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 .... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key`: The key name.
- `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.
- `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- `casunique`: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands:** `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- `key`: The key name.
- `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- `noreply`: Tells the server not to reply to the command.

Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr`, `decr`

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- `key`: The key name.
- `value`: An integer to be used as the increment or decrement value.
- `noreply`: Tells the server not to reply to the command.

The response is:

- `NOT_FOUND`: The specified key could not be located.
- `value`: The new value associated with the specified key.

Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands:** `stats`

The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- `name`: The optional name of the statistics to return. If not specified, the general statistics are returned.
- `value`: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see [Section 17.2.4, “Getting `memcached` Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

**Table 17.2** `memcached` Command Reference

Command	Command Formats
<code>set</code>	<code>set key flags exptime length, set key flags exptime length noreply</code>
<code>add</code>	<code>add key flags exptime length, add key flags exptime length noreply</code>
<code>replace</code>	<code>replace key flags exptime length, replace key flags exptime length noreply</code>
<code>append</code>	<code>append key length, append key length noreply</code>
<code>prepend</code>	<code>prepend key length, prepend key length noreply</code>
<code>cas</code>	<code>cas key flags exptime length casunique, cas key flags exptime length casunique noreply</code>
<code>get</code>	<code>get key1 [key2 ... keyn]</code>
<code>gets</code>	
<code>delete</code>	<code>delete key, delete key noreply, delete key expiry, delete key expiry noreply</code>
<code>incr</code>	<code>incr key, incr key noreply, incr key value, incr key value noreply</code>
<code>decr</code>	<code>decr key, decr key noreply, decr key value, decr key value noreply</code>
<code>stat</code>	<code>stat, stat name, stat name value</code>

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 17.3** `memcached` Protocol Responses

String	Description
<code>STORED</code>	Value has successfully been stored.
<code>NOT_STORED</code>	The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code> ), or where the item has already been set to be deleted.
<code>EXISTS</code>	When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.
<code>NOT_FOUND</code>	The item you are trying to store, update or delete does not exist or has already been deleted.
<code>ERROR</code>	You submitted a nonexistent command name.
<code>CLIENT_ERROR</code> <code>errorstring</code>	There was an error in the input line, the detail is contained in <code>errorstring</code> .
<code>SERVER_ERROR</code> <code>errorstring</code>	There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.
<code>VALUE</code> <code>keys</code> <code>flags</code> <code>length</code>	The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block are returned, of the specified <code>length</code> .
<code>DELETED</code>	The requested key was deleted from the server.
<code>STAT</code> <code>name</code> <code>value</code>	A line of statistics data.

String	Description
<code>END</code>	The end of the statistics data.

## 17.2.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the [Section 17.2.4.2, “memcached Slabs Statistics”](#) and [Section 17.2.4.1, “memcached General Statistics”](#) information. For more information, see [Section 17.2.4.6, “Using memcached-tool”](#).

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
```

```
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
  'hosts' => {
    'localhost:11211' => {
      'misc' => {
        'bytes' => '2421',
        'curr_connections' => '3',
        'connection_structures' => '56',
        'pointer_size' => '32',
        'time' => '1211440166',
        'total_items' => '410956',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'evictions' => '0',
        'curr_items' => '31',
        'pid' => '23599',
        'limit_maxbytes' => '67108864',
        'uptime' => '1254',
        'rusage_user' => '9.857805',
        'cmd_get' => '838451',
        'rusage_system' => '34.096988',
        'version' => '1.2.5',
        'get_hits' => '581511',
        'bytes_read' => '46665716',
        'threads' => '1',
        'total_connections' => '3104',
        'get_misses' => '256940'
      },
      'sizes' => {
        '128' => '16',
        '64' => '15'
      }
    }
  },
  'self' => {},
  'total' => {
    'cmd_get' => 838451,
    'bytes' => 2421,
    'get_hits' => 581511,
    'connection_structures' => 56,
    'bytes_read' => 46665716,
    'total_items' => 410956,
    'total_connections' => 3104,
    'cmd_set' => 588167,
    'bytes_written' => 35715151,
    'curr_items' => 31,
    'get_misses' => 256940
  }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 17.2.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 17.2.4.2, “memcached Slabs Statistics”](#).

- Item statistics (`items`), see [Section 17.2.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 17.2.4.4, “memcached Size Statistics”](#).
- Detailed status (`detail`), see [Section 17.2.4.5, “memcached Detail Statistics”](#).

### 17.2.4.1 `memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u:32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

Statistic	Data type	Description	Version
<code>pid</code>	<code>32u</code>	Process ID of the <code>memcached</code> instance.	
<code>uptime</code>	<code>32u</code>	Uptime (in seconds) for this <code>memcached</code> instance.	
<code>time</code>	<code>32u</code>	Current time (as epoch).	
<code>version</code>	string	Version string of this instance.	
<code>pointer_size</code>	string	Size of pointers for this host specified in bits (32 or 64).	
<code>rusage_user</code>	<code>32u:32u</code>	Total user time for this instance (seconds:microseconds).	
<code>rusage_system</code>	<code>32u:32u</code>	Total system time for this instance (seconds:microseconds).	
<code>curr_items</code>	<code>32u</code>	Current number of items stored by this instance.	
<code>total_items</code>	<code>32u</code>	Total number of items stored during the life of this instance.	
<code>bytes</code>	<code>64u</code>	Current number of bytes used by this server to store items.	
<code>curr_connections</code>	<code>32u</code>	Current number of open connections.	
<code>total_connections</code>	<code>32u</code>	Total number of connections opened since the server started running.	
<code>connection_structures</code>	<code>32u</code>	Number of connection structures allocated by the server.	
<code>cmd_get</code>	<code>64u</code>	Total number of retrieval requests ( <code>get</code> operations).	
<code>cmd_set</code>	<code>64u</code>	Total number of storage requests ( <code>set</code> operations).	
<code>get_hits</code>	<code>64u</code>	Number of keys that have been requested and found present.	
<code>get_misses</code>	<code>64u</code>	Number of items that have been requested and not found.	
<code>delete_hits</code>	<code>64u</code>	Number of keys that have been deleted and found present.	1.3.x
<code>delete_misses</code>	<code>64u</code>	Number of items that have been delete and not found.	1.3.x

Statistic	Data type	Description	Version
<code>incr_hits</code>	64u	Number of keys that have been incremented and found present.	1.3.x
<code>incr_misses</code>	64u	Number of items that have been incremented and not found.	1.3.x
<code>decr_hits</code>	64u	Number of keys that have been decremented and found present.	1.3.x
<code>decr_misses</code>	64u	Number of items that have been decremented and not found.	1.3.x
<code>cas_hits</code>	64u	Number of keys that have been compared and swapped and found present.	1.3.x
<code>cas_misses</code>	64u	Number of items that have been compared and swapped and not found.	1.3.x
<code>cas_badvalue</code>	64u	Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value.	1.3.x
<code>evictions</code>	64u	Number of valid items removed from cache to free memory for new items.	
<code>bytes_read</code>	64u	Total number of bytes read by this server from network.	
<code>bytes_written</code>	64u	Total number of bytes sent by this server to network.	
<code>limit_maxbytes</code>	32u	Number of bytes this server is permitted to use for storage.	
<code>threads</code>	32u	Number of worker threads requested.	
<code>conn_yields</code>	64u	Number of yields for connections (related to the <code>-R</code> option).	1.4.0

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

#### 17.2.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
```

```

STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END

```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

Statistic	Description	Version
<code>chunk_size</code>	Space allocated to each chunk within this slab class.	
<code>chunks_per_page</code>	Number of chunks within a single page for this slab class.	
<code>total_pages</code>	Number of pages allocated to this slab class.	
<code>total_chunks</code>	Number of chunks allocated to the slab class.	
<code>used_chunks</code>	Number of chunks allocated to an item..	
<code>free_chunks</code>	Number of chunks not yet allocated to items.	
<code>free_chunks_end</code>	Number of free chunks at the end of the last allocated page.	
<code>get_hits</code>	Number of get hits to this chunk	1.3.x
<code>cmd_set</code>	Number of set commands on this chunk	1.3.x
<code>delete_hits</code>	Number of delete hits to this chunk	1.3.x
<code>incr_hits</code>	Number of increment hits to this chunk	1.3.x
<code>decr_hits</code>	Number of decrement hits to this chunk	1.3.x
<code>cas_hits</code>	Number of CAS hits to this chunk	1.3.x
<code>cas_badval</code>	Number of CAS hits on this chunk where the existing value did not match	1.3.x
<code>mem_requested</code>	The true amount of memory of memory requested within this chunk	1.4.1

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

Statistic	Description	Version
<code>active_slabs</code>	Total number of slab classes allocated.	
<code>total_malloced</code>	Total amount of memory allocated to slab pages.	

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

### 17.2.4.3 memcached Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

Statistic	Description	
<code>number</code>	The number of items currently stored in this slab class.	
<code>age</code>	The age of the oldest item within the slab class, in seconds.	
<code>evicted</code>	The number of items evicted to make way for new entries.	
<code>evicted_time</code>	The time of the last evicted entry	
<code>evicted_nonzero</code>	The time of the last evicted non-zero entry	1.4.0
<code>outofmemory</code>	The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect).	
<code>tailrepairs</code>	Number of times the entries for a particular ID need repairing	

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

### 17.2.4.4 memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the

nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

### Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

## 17.2.4.5 `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the `get`, `set`, and `del` operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail off
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

#### 17.2.4.6 Using `memcached-tool`

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
```

#	Item_Size	Max_age	Pages	Count	Full?	Evicted	Evict_Time	OOM
1	80B	93s	1	20	no	0	0	0
2	104B	93s	1	16	no	0	0	0
3	136B	1335s	1	28	no	0	0	0
4	176B	1335s	1	24	no	0	0	0
5	224B	1335s	1	32	no	0	0	0
6	280B	1335s	1	34	no	0	0	0
7	352B	1335s	1	36	no	0	0	0
8	440B	1335s	1	46	no	0	0	0
9	552B	1335s	1	58	no	0	0	0
10	696B	1335s	1	66	no	0	0	0
11	872B	1335s	1	89	no	0	0	0
12	1.1K	1335s	1	112	no	0	0	0
13	1.3K	1335s	1	145	no	0	0	0
14	1.7K	1335s	1	123	no	0	0	0
15	2.1K	1335s	1	198	no	0	0	0
16	2.6K	1335s	1	199	no	0	0	0
17	3.3K	1335s	1	229	no	0	0	0
18	4.1K	1335s	1	248	yes	36	2	0
19	5.2K	1335s	2	328	no	0	0	0
20	6.4K	1335s	2	316	yes	387	1	0
21	8.1K	1335s	3	381	yes	492	1	0
22	10.1K	1335s	3	303	yes	598	2	0
23	12.6K	1335s	5	405	yes	605	1	0
24	15.8K	1335s	6	384	yes	766	2	0
25	19.7K	1335s	7	357	yes	908	170	0
26	24.6K	1336s	7	287	yes	1012	1	0
27	30.8K	1336s	7	231	yes	1193	169	0
28	38.5K	1336s	4	104	yes	1323	169	0
29	48.1K	1336s	1	21	yes	1287	1	0
30	60.2K	1336s	1	17	yes	1093	169	0
31	75.2K	1337s	1	13	yes	713	168	0
32	94.0K	1337s	1	10	yes	278	168	0
33	117.5K	1336s	1	3	no	0	0	0

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
# Item_Size Max_age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0
2 104B 93s 1 16 no 0 0 0
...
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab
- `Count`: The number of items in this slab
- `Full?`: Whether the slab is fully populated
- `Evicted`: The number of objects evicted from this slab
- `Evict_Time`: The time (in seconds) since the last eviction
- `OOM`: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211 Field Value
accepting_conns 1
bytes 162
bytes_read 485
bytes_written 6820
cas_badval 0
cas_hits 0
cas_misses 0
cmd_flush 0

### 17.2.5.1 Can memcached be run on a Windows environment?

No. Currently [memcached](#) is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

### 17.2.5.2 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In [memcached](#) 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile [memcached](#). You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In [memcached](#) 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. [memcached](#) is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

### 17.2.5.3 Is it true [memcached](#) will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

**17.2.5.4** Are there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with `memcached`, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

**17.2.5.5** How is an event such as a crash of one of the `memcached` servers handled by the `memcached` client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 17.2.2.5, “memcached Hashing/Distribution Types”](#).

**17.2.5.6** What is a recommended hardware configuration for a `memcached` server?

`memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. A `memcached` server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

To build and deploy a dedicated `memcached` server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

**17.2.5.7** Is `memcached` more effective for video and audio as opposed to textual read/writes?

`memcached` works equally well for all kinds of data. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` is 1MB, but can be configured to be larger by using the `-I` option in `memcached` 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using `memcached` with audio and video content, you will probably want to increase the maximum object size. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**17.2.5.8** Can `memcached` work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# `memcached` library. For more information, see <https://sourceforge.net/projects/memcacheddotnet/>.

**17.2.5.9** How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a `memcached` instance to reduce the latency. Connection pooling

would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

**17.2.5.10** How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

**17.2.5.11** How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

**17.2.5.12** Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

**17.2.5.13** Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

**17.2.5.14** What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the memcached servers, and there is no complex configuration; just add more servers to the list and let the client API and the memcached servers make the decisions.

---

Replication enables data from one MySQL database server (the master) to be copied to one or more MySQL database servers (the slaves). Replication is asynchronous by default; slaves do not need to be connected permanently to receive updates from the master. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.

- Long-distance data distribution - you can use replication to create a local copy of data for a remote site to use, without permanent access to the master.

For information on how to use replication in such scenarios, see [Section 18.3, “Replication Solutions”](#).

MySQL 5.7 supports different methods of replication. The traditional method is based on replicating events from the master's binary log, and requires the log files and positions in them to be synchronized between master and slave. The newer method based on *global transaction identifiers* (GTIDs) is transactional and therefore does not require working with log files or positions within these files, which greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency between master and slave as long as all transactions committed on the master have also been applied on the slave. For more information about GTIDs and GTID-based replication in MySQL, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#). For information on using binary log file position based replication, see [Section 18.1, “Configuring Replication”](#).

Replication in MySQL supports different types of synchronization. The original type of synchronization is one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see [Chapter 20, MySQL NDB Cluster 7.5](#)). In MySQL 5.7, semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction; see [Section 18.3.9, “Semisynchronous Replication”](#). MySQL 5.7 also supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time; see [Section 18.3.10, “Delayed Replication”](#). For scenarios where *synchronous* replication is required, use MySQL Cluster (see [Chapter 20, MySQL NDB Cluster 7.5](#)).

There are a number of solutions available for setting up replication between servers, and the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You can also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 18.2.1, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. For more information, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 18.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and potential problems and their resolution, see [Section 18.4, “Replication Notes and Tips”](#). For answers to some questions often asked by those who are new to MySQL Replication, see [Section A.13, “MySQL 5.7 FAQ: Replication”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see [Section 18.2, “Replication Implementation”](#).

## 18.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and includes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication using binary log file positions, [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#), deals with the configuration of the servers and provides methods for copying data between the master and slaves.
- For a guide to setting up two or more servers for replication using GTID transactions, [Section 18.1.3, “Replication with Global Transaction Identifiers”](#), deals with the configuration of the servers.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 18.2.1, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 18.1.7, “Common Replication Administration Tasks”](#).

### 18.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

#### Important

You cannot configure the master to log only certain events.

Each slave keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave records the current position within the binary log, it is possible for slaves to be disconnected, reconnect and then resume processing.

The master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's master info repository, which can be either a file or a table (see [Section 18.2.4, “Replication Relay and Status Logs”](#)).

### 18.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#).
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Setting the Replication Slave Configuration](#).
- Optionally, create a separate user for your slaves to use during authentication with the master when reading the binary log for replication. See [Section 18.1.2.2, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, on the master you should record the current position in the binary log. You need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on the master and want to use it to synchronize the slave, you need to create a data snapshot to copy the data to the slave. The storage engine you are using has an impact on how you create the snapshot. When you are using [MyISAM](#), you must stop processing statements on the master to obtain a read-lock, then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information will not match, resulting in inconsistent or corrupted databases on the slaves. For more information on replicating a [MyISAM](#) master, see [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#). If you are using [InnoDB](#), you do not need a read-lock and a transaction that is long enough to transfer the data snapshot is sufficient. For more information, see [Section 15.19, “InnoDB and MySQL Replication”](#).
- Configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Setting the Master Configuration on the Slave](#).

**Note**

Certain steps within the setup process require the [SUPER](#) privilege. If you do not have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a master and slaves that contain no data, see [Setting Up Replication between a New Master and Slaves](#).
- To set up replication of a new master using the data from an existing MySQL server, see [Setting Up Replication with Existing Data](#).
- To add replication slaves to an existing replication environment, see [Section 18.1.2.6, “Adding Slaves to a Replication Environment”](#).

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in [Section 14.4.1, “SQL Statements for Controlling Master Servers”](#), and [Section 14.4.2, “SQL Statements for Controlling Slave Servers”](#). Also familiarize yourself with the replication startup options described in [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

### 18.1.2.1 Setting the Replication Master Configuration

To configure a master to use binary log file position based replication, you must enable binary logging and establish a unique server ID. If this has not already been done, a server restart is required.

Binary logging *must* be enabled on the master because the binary log is the basis for replicating changes from the master to its slaves. If binary logging is not enabled on the master using the [log-bin](#) option, replication is not possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and  $(2^{32})-1$ . How you organize and select the numbers is your choice.

To configure the binary log and server ID options, shut down the MySQL server and edit the `my.cnf` or `my.ini` file. Within the `[mysqld]` section of the configuration file, add the `log-bin` and `server-id` options. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

#### Note

The following options have an impact on this procedure:

- if you omit `server-id` (or set it explicitly to its default value of 0), the master refuses any connections from slaves.
- For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.
- Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, the slave can not communicate with the master and replication fails.

### 18.1.2.2 Creating a User for Replication

Each slave connects to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each slave, or connect to the master using the same account for each slave.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the master info repository file or table (see [Section 18.2.4.2, “Slave Status Logs”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%mydomain.com';
```

See [Section 14.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

### 18.1.2.3 Obtaining the Replication Master Binary Log Coordinates

To configure the slave to start the replication process at the correct point, you need the master's current coordinates within its binary log.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` are empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ( `' '` ) and `4`.

If the master has been binary logging previously, use this procedure to obtain the master binary log coordinates:

#### Warning

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for `InnoDB` tables.

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

#### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.000003 | 73      | test        | manual,mysql      |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log file and the `Position` column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

The next step depends on whether you have existing data on the master. Choose one of the following options:

- If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so that the data copied to the slave is in synchrony with the master. Proceed to [Section 18.1.2.4, "Choosing a Method for Data Snapshots"](#).
- If you are setting up a new master and slave replication group, you can exit the first session to release the read lock. See [Setting Up Replication between a New Master and Slaves](#) for how to proceed.

### 18.1.2.4 Choosing a Method for Data Snapshots

If the master database contains existing data it is necessary to copy this data to each slave. There are different ways to dump the data from the master database. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

- Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using `InnoDB`.
- If your database is stored in binary portable files, you can copy the raw data files to a slave. This can be more efficient than using `mysqldump` and importing the file on each slave, because it skips the overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as `InnoDB` this is not recommended.

#### Creating a Data Snapshot Using `mysqldump`

To create a snapshot of the data in an existing master database, use the `mysqldump` tool. Once the data dump has been completed, import this data into the slave before starting the replication process.

The following example dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

#### Note

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).

It is possible to exclude certain databases from the dump using the `mysqldump` tool. If you want to choose which databases to include in the dump, do not use `--all-databases`. Choose one of these options:

- Exclude all the tables in the database using `--ignore-table` option.
- Name only those databases which you want dumped using the `--databases` option.

For more information, see [Section 5.5.4, “mysqldump — A Database Backup Program”](#).

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

#### Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the slave. MySQL Enterprise Backup is a commercial product

that is included as part of a MySQL Enterprise subscription. See [Section 28.2, “MySQL Enterprise Backup Overview”](#) for detailed information.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the [cold backup](#) technique to obtain a reliable binary snapshot of [InnoDB](#) tables: do a [slow shutdown](#) of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of [MyISAM](#) tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`. If you are replicating only certain databases, copy only those files that relate to those tables. For [InnoDB](#), all tables in all databases are stored in the [system tablespace](#) files, unless you have the `innodb_file_per_table` option enabled.

The following files are not required for replication:

- Files relating to the `mysql` database.
- The master info repository file, if used (see [Section 18.2.4, “Replication Relay and Status Logs”](#)).
- The master's binary log files.
- Any relay log files.

Depending on whether you are using [InnoDB](#) tables or not, choose one of the following:

If you are using [InnoDB](#) tables, and also to get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using [InnoDB](#) tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

### 18.1.2.5 Setting Up Replication Slaves

The following sections describe how to set up slaves. Before you proceed, ensure that you have:

- Configured the MySQL master with the necessary configuration properties. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#).
- Obtained the master status information. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
- On the master, released the read lock:

```
mysql> UNLOCK TABLES;
```

### Setting the Replication Slave Configuration

Each replication slave *must* have a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, shut down the slave server and edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from any of the other slaves.

#### Note

If you omit `server-id` (or set it explicitly to its default value of 0), the slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be set up. However, if you enable binary logging on the slave, you can use the slave's binary log for data backups and crash recovery, and also use the slave as part of a more complex replication topology. For example, where this slave then acts as a master to other slaves.

### Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, configure the slave with the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

**Note**

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#).

The next steps depend on whether you have existing data to import to the slave or not. See [Section 18.1.2.4, “Choosing a Method for Data Snapshots”](#) for more information. Choose one of the following:

- If you do not have a snapshot of a database to import, see [Setting Up Replication between a New Master and Slaves](#).
- If you have a snapshot of a database to import, see [Setting Up Replication with Existing Data](#).

## Setting Up Replication between a New Master and Slaves

When there is no snapshot of a previous database to import, configure the slave to start the replication from the new master.

To set up replication between a master and a new slave:

1. Start up the MySQL slave and connect to it.
2. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Setting the Master Configuration on the Slave](#).

Perform these slave setup steps on each slave.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data is automatically replicated to the slaves.

If you are setting up a new replication environment using the data from a different existing database server to create a new master, run the dump file generated from that server on the new master. The database updates are automatically propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

## Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the master to the slave before starting replication. The process for importing data to the slave depends on how you created the snapshot of data on the master.

Choose one of the following:

If you used `mysqldump`:

1. Start the slave, using the `--skip-slave-start` option so that replication does not start.
2. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

1. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

2. Start the slave, using the `--skip-slave-start` option so that replication does not start.
3. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Setting the Master Configuration on the Slave](#).
4. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave connects to the master and replicates any updates that have occurred on the master since the snapshot was taken.

If the `server-id` option for the master is not correctly set, slaves cannot connect to it. Similarly, if you have not set the `server-id` option correctly for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

The slave stores information about the master you have configured in its master info repository. The master info repository can be in the form of files or a table, as determined by the value set for `--master-info-repository`. When a slave uses `--master-info-repository=FILE`, two files are stored in the data directory, named `master.info` and `relay-log.info`. If `--master-info-repository=TABLE` instead, this information is saved in the `master_slave_info` table in the `mysql` database. In either case, do *not* remove or edit the files or table. Always use the `CHANGE MASTER TO` statement to change replication parameters. The slave can use the values specified in the statement to update the status files automatically. See [Section 18.2.4, "Replication Relay and Status Logs"](#), for more information.

#### Note

The contents of the master info repository override some of the server options specified on the command line or in `my.cnf`. See [Section 18.1.6, "Replication and Binary Logging Options and Variables"](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

### 18.1.2.6 Adding Slaves to a Replication Environment

You can add another slave to an existing replication configuration without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This situation can occur if the `--relay-log` option is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#), for more information about these options.

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`. If this is not possible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new slave after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.  
  
If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
  - b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
  - c. Proceed with the remaining steps in this section.
3. Copy the master info and relay log info repositories (see [Section 18.2.4, “Replication Relay and Status Logs”](#)) from the existing slave to the new slave. These hold the current log coordinates for the master's binary log and the slave's relay log.

4. Start the existing slave.
5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.
6. Start the new slave. The slave uses the information in its master info repository to start the replication process.

### 18.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any slaves; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether masters and slaves are consistent; as long as all transactions committed on a master are also committed on a slave, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see [Section 18.2.1, “Replication Formats”](#)); however, for best results, we recommend that you use the row-based format.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in the MySQL Server (see [Section 18.1.3.1, “GTID Concepts”](#)).
- A general procedure for setting up and starting GTID-based replication (see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#)).
- Suggested methods for provisioning new replication servers when using GTIDs (see [Section 18.1.3.3, “Using GTIDs for Failover and Scaleout”](#)).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see [Section 18.1.3.4, “Restrictions on Replication with GTIDs”](#)).

For information about MySQL Server options and variables relating to GTID-based replication, see [Section 18.1.6.5, “Global Transaction ID Options and Variables”](#). See also [Section 13.17, “Functions Used with Global Transaction IDs”](#), which describes SQL functions supported by MySQL 5.7 for use with GTIDs.

#### 18.1.3.1 GTID Concepts

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (master). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication setup. There is a 1-to-1 mapping between all transactions and all GTIDs.

The following paragraphs provide a basic description of GTIDs. More advanced concepts are covered later in the following sections:

- [GTID Sets](#)
- [mysql.gtid\\_executed Table](#)
- [mysql.gtid\\_executed Table Compression](#)

A GTID is represented as a pair of coordinates, separated by a colon character (:), as shown here:

```
GTID = source_id:transaction_id
```

The *source\_id* identifies the originating server. Normally, the server's *server\_uuid* is used for this purpose. The *transaction\_id* is a sequence number determined by the order in which the transaction was committed on this server; for example, the first transaction to be committed has *1* as its *transaction\_id*, and the tenth transaction to be committed on the same originating server is assigned a *transaction\_id* of *10*. It is not possible for a transaction to have *0* as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID *3E11FA47-71CA-11E1-9E33-C80AA9429562* has this GTID:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
```

This format is used to represent GTIDs in the output of statements such as `SHOW SLAVE STATUS` as well as in the binary log. They can also be seen when viewing the log file with `mysqlbinlog --base64-output=DECODE-ROWS` or in the output from `SHOW BINLOG EVENTS`.

As written in the output of statements such as `SHOW MASTER STATUS` or `SHOW SLAVE STATUS`, a sequence of GTIDs originating from the same server may be collapsed into a single expression, as shown here.

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The example just shown represents the first through fifth transactions originating on the MySQL Server whose *server\_uuid* is *3E11FA47-71CA-11E1-9E33-C80AA9429562*.

This format is also used to supply the argument required by the `START SLAVE` options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`.

## GTID Sets

A GTID set is a set of global transaction identifiers which is represented as shown here:

```
gtid_set:
    uuid_set [, uuid_set] ...
    | ''

uuid_set:
    uuid:interval[:interval]...

uuid:
    hhhh-hhhh-hhhh-hhhh-hhhh-hhhh-hhhh-hhhh

h:
    [0-9|A-F]

interval:
    n[-n]

(n >= 1)
```

GTID sets are used in the MySQL Server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are represented as GTID sets. In addition, the functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input. When GTID sets are returned from server variables, UUIDs are in alphabetical order and numeric intervals are merged and in ascending order.

GTIDs are always preserved between master and slave. This means that you can always determine the source for any transaction applied on any slave by examining its binary log. In addition, once a transaction

with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the master can be applied no more than once on the slave, which helps to guarantee consistency.

When GTIDs are in use, the slave has no need for any nonlocal data, such as the name of a file on the master and a position within that file. All necessary information for synchronizing with the master is obtained directly from the replication data stream. GTIDs replace the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between master and slave. therefore, do not include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct a slave to replicate from a given master; instead it is necessary only to enable the `MASTER_AUTO_POSITION` option. For the exact steps needed to configure and start masters and slaves using GTID-based replication, see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#).

The generation and life cycle of a GTID consist of the following steps:

1. A transaction is executed and committed on the master.

This transaction is assigned a GTID using the master's UUID and the smallest nonzero transaction sequence number not yet used on this server; the GTID is written to the master's binary log (immediately preceding the transaction itself in the log).

2. After the binary log data is transmitted to the slave and stored in the slave's relay log (using established mechanisms for this process—see [Section 18.2, “Replication Implementation”](#), for details), the slave reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the slave that the next transaction must be logged using this GTID.

It is important to note that the slave sets `gtid_next` in a session context.

3. The slave verifies that this GTID has not already been used to log a transaction in its own binary log. If this GTID has not been used, the slave then writes the GTID, applies the transaction, and writes the transaction to its binary log. By reading and checking the transaction's GTID first, before processing the transaction itself, the slave guarantees not only that no previous transaction having this GTID has been applied on the slave, but also that no other session has already read this GTID but has not yet committed the associated transaction. In other words, multiple clients are not permitted to apply the same transaction concurrently.
4. Because `gtid_next` is not empty, the slave does not attempt to generate a GTID for this transaction but instead writes the GTID stored in this variable—that is, the GTID obtained from the master—immediately preceding the transaction in its binary log.

## mysql.gtid\_executed Table

Beginning with MySQL 5.7.5, GTIDs are stored in a table named `gtid_executed`, in the `mysql` database. A row in this table contains, for each GTID or set of GTIDs that it represents, the UUID of the originating server, and the starting and ending transaction IDs of the set; for a row referencing only a single GTID, these last two values are the same.

The `mysql.gtid_executed` table is created (if it does not already exist) when the MySQL Server is installed or upgraded, using a `CREATE TABLE` statement similar to that shown here:

```
CREATE TABLE gtid_executed (
  source_uuid CHAR(36) NOT NULL,
  interval_start BIGINT(20) NOT NULL,
  interval_end BIGINT(20) NOT NULL,
  PRIMARY KEY (source_uuid, interval_start)
)
```

**Warning**

As with other MySQL system tables, do not attempt to create or modify this table yourself.

GTIDs are stored in the `mysql.gtid_executed` table only when `gtid_mode` is `ON` or `ON_PERMISSIVE`. GTIDs are stored in this table without regard to whether binary logging is enabled. However, the manner in which they are stored differs depending on whether `log_bin` is `ON` or `OFF`:

- If binary logging is disabled (`log_bin` is `OFF`), the server stores the GTID belonging to each transaction together with the transaction in the table.

In addition, when binary logging is disabled, this table is compressed periodically at a user-configurable rate; see [mysql.gtid\\_executed Table Compression](#), for more information.

- If binary logging is enabled (`log_bin` is `ON`), then in addition to storing the GTIDs in `mysql.gtid_executed`, whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log into the new binary log.

In the event of the server stopping unexpectedly, the set of GTIDs from the previous binary log is not saved in the `mysql.gtid_executed` table. In this case, these GTIDs are added to the table and to the set of GTIDs in the `gtid_executed` system variable during recovery.

The `mysql.gtid_executed` table is reset by `RESET MASTER`.

## mysql.gtid\_executed Table Compression

Over the course of time, the `mysql.gtid_executed` table can become filled with many rows referring to individual GTIDs that originate on the same server, and whose transaction IDs make up a sequence, similar to what is shown here:

```
mysql> SELECT * FROM mysql.gtid_executed;
```

source_uuid	interval_start	interval_end
3E11FA47-71CA-11E1-9E33-C80AA9429562	37	37
3E11FA47-71CA-11E1-9E33-C80AA9429562	38	38
3E11FA47-71CA-11E1-9E33-C80AA9429562	39	39
3E11FA47-71CA-11E1-9E33-C80AA9429562	40	40
3E11FA47-71CA-11E1-9E33-C80AA9429562	41	41
3E11FA47-71CA-11E1-9E33-C80AA9429562	42	42
3E11FA47-71CA-11E1-9E33-C80AA9429562	43	43
...		

Considerable space can be saved if this table is compressed periodically by replacing each such set of rows with a single row that spans the entire interval of transaction identifiers, like this:

source_uuid	interval_start	interval_end
3E11FA47-71CA-11E1-9E33-C80AA9429562	37	43
...		

When GTIDs are enabled, the server performs this type of compression on the `mysql.gtid_executed` table periodically. You can control the number of transactions that are allowed to elapse before the table is compressed, and thus the compression rate, by setting the `executed_gtids_compression_period` system variable. This variable's default value is 1000; this means that, by default, compression of the

table is performed after each 1000 transactions. Setting `executed_gtid_compression_period` to 0 prevents the compression from being performed at all; however, you should be prepared for a potentially large increase in the amount of disk space that may be required by the `gtid_executed` table if you do this.

#### Note

When binary logging is enabled, the value of `executed_gtid_compression_period` is *not* used and the `mysql.gtid_executed` table is compressed on each binary log rotation.

Compression of the `mysql.gtid_executed` table is performed by a dedicated foreground thread that is created whenever GTIDs are enabled on the server. This thread is not listed in the output of `SHOW PROCESSLIST`, but it can be viewed as a row in the `threads` table, as shown here:

```
mysql> SELECT * FROM PERFORMANCE_SCHEMA.THREADS WHERE NAME LIKE '%gtid%\G
***** 1. row *****
      THREAD_ID: 21
        NAME: thread/sql/compress_gtid_table
         TYPE: FOREGROUND
PROCESSLIST_ID: 139635685943104
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Daemon
PROCESSLIST_TIME: 611
PROCESSLIST_STATE: Suspending
PROCESSLIST_INFO: NULL
PARENT_THREAD_ID: 1
          ROLE: NULL
    INSTRUMENTED: YES
```

This thread has the name `thread/sql/compress_gtid_table`, and normally sleeps until `executed_gtid_compression_period` transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table as described previously. It then sleeps until another `executed_gtid_compression_period` transactions have taken place, then wakes up to perform the compression again, repeating this loop indefinitely. Setting this value to 0 when binary logging is disabled means that the thread always sleeps and never wakes up.

### 18.1.3.2 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 5.7. This is a “cold start” procedure that assumes either that you are starting the replication master for the first time, or that it is possible to stop it; for information about provisioning replication slaves using GTIDs from a running master, see [Section 18.1.3.3, “Using GTIDs for Failover and Scaleout”](#). For information about changing GTID mode on servers online, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

The key steps in this startup process for the simplest possible GTID replication topology—consisting of one master and one slave—are as follows:

1. If replication is already running, synchronize both servers by making them read-only.
2. Stop both servers.
3. Restart both servers with GTIDs enabled and the correct options configured.

The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

**Note**

`server_uuid` must exist for GTIDs to function correctly.

4. Instruct the slave to use the master as the replication data source and to use auto-positioning, and then start the slave.

The SQL statements needed to accomplish this step are described in the example that follows later in this section.

5. Enable read mode again on both servers, so that they can accept updates.

In the following example, two servers are already running as master and slave, using MySQL's binary log position-based replication protocol. If you are starting with new servers, see [Section 18.1.2.2, “Creating a User for Replication”](#) for information about adding a specific user for replication connections and [Section 18.1.2.1, “Setting the Replication Master Configuration”](#) for information about setting the server-id. The following examples show how to use startup options when running `mysqld`. Alternatively you can store startup options in an option file, see [Section 5.2.6, “Using Option Files”](#) for more information.

Most of the steps that follow require the use of the MySQL `root` account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.

**Step 1: Synchronize the servers.** Make the servers read-only. To do this, enable the `read_only` system variable by executing the following statement on both servers:

```
mysql> SET @@global.read_only = ON;
```

Then, allow the slave to catch up with the master. *It is extremely important that you make sure the slave has processed all updates before continuing.*

**Step 2: Stop both servers.** Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

```
shell> mysqladmin -uusername -p shutdown
```

Then supply this user's password at the prompt.

**Step 3: Restart both servers with GTIDs enabled.** To enable GTID-based replication, each server must be started with GTID mode enabled, by setting the `--gtid-mode` option to `ON`, and with the `--enforce-gtid-consistency` option enabled to ensure that only statements which are safe for GTID-based replication are logged. In addition, you should start the slave with the `--skip-slave-start` option before configuring the slave settings. For more information on GTID related options, see [Section 18.1.6.5, “Global Transaction ID Options and Variables”](#).

It is not mandatory to have binary logging enabled in order to use GTIDs due to the addition of the `mysql.gtid_executed` Table in MySQL 5.7.5. This means that you can have slave servers using GTIDs but without binary logging. Masters *must* always have binary logging enabled in order to be able to replicate. For example, to start a slave with GTIDs enabled but without binary logging, use at least these options:

```
shell> mysqld --gtid-mode=ON --enforce-gtid-consistency &
```

In MySQL 5.7.4 and earlier, binary logging is required to use GTIDs and both master and slave servers must be started with at least these options:

```
shell> mysqld --gtid-mode=ON --log-bin --enforce-gtid-consistency &
```

Depending on your configuration, supply additional options to `mysqld`.

**Step 4: Direct the slave to use the master.** Tell the slave to use the master as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Execute a `CHANGE MASTER TO` statement on the slave, using the `MASTER_AUTO_POSITION` option to tell the slave that transactions will be identified by GTIDs.

You may also need to supply appropriate values for the master's host name and port number as well as the user name and password for a replication user account which can be used by the slave to connect to the master; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

```
mysql> CHANGE MASTER TO
>     MASTER_HOST = host,
>     MASTER_PORT = port,
>     MASTER_USER = user,
>     MASTER_PASSWORD = password,
>     MASTER_AUTO_POSITION = 1;
```

Neither the `MASTER_LOG_FILE` option nor the `MASTER_LOG_POS` option may be used with `MASTER_AUTO_POSITION` set equal to 1. Attempting to do so causes the `CHANGE MASTER TO` statement to fail with an error.

Assuming that the `CHANGE MASTER TO` statement has succeeded, you can then start the slave, like this:

```
mysql> START SLAVE;
```

**Step 5: Disable read-only mode.** Allow the master to begin accepting updates once again by running the following statement:

```
mysql> SET @@global.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the master as before. [Section 18.1.3.3, “Using GTIDs for Failover and Scaleout”](#), discusses creation of new slaves when using GTIDs.

### 18.1.3.3 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) for provisioning a new slave which can then be used for scaleout, being promoted to master as necessary for failover. This section describes the following techniques:

- [Simple replication](#)
- [Copying data and transactions to the slave](#)
- [Injecting empty transactions](#)
- [Excluding transactions with `gtid\_purged`](#)
- [Restoring GTID mode slaves](#)

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying

changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a slave that is immediately available as a candidate to become a new master on failover or switchover.

**Simple replication.** The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the slave of a master that has the entire execution history, and enable global transaction identifiers on both servers. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#), for more information.

Once replication is started, the new server copies the entire binary log from the master and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the slave to read the binary log from the master; it can sometimes take a comparatively long time for the new slave to catch up with the master, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the master by copying binary log files to the new server.

**Copying data and transactions to the slave.** Playing back the entire transaction history can be time-consuming, and represents a major bottleneck when setting up a new replication slave. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the master contains is imported to the slave. The binary log is played back, after which replication can be started, allowing the slave to become current with any remaining transactions.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the slave, as outlined here:

Data Set	Transaction History
<ul style="list-style-type: none"> <li>Use the <code>mysql</code> client to import a dump file created with <code>mysqldump</code>. Use the <code>--master-data</code> option to include binary logging information and <code>--set-gtid-purged</code> to <code>AUTO</code> (the default) or <code>ON</code>, to include information about executed transactions. You should have <code>--gtid-mode=ON</code> while importing the dump on the slave.</li> <li>Stop the slave, copy the contents of the master's data directory to the slave's data directory, then restart the slave.</li> </ul>	<p>If <code>gtid_mode</code> is not <code>ON</code>, restart the server with GTID mode enabled.</p> <ul style="list-style-type: none"> <li>Import the binary log using <code>mysqlbinlog</code>, with the <code>--read-from-remote-server</code> and <code>--read-from-remote-master</code> options.</li> <li>Copy the master's binary log files to the slave. You can make copies from the slave using <code>mysqlbinlog --read-from-remote-server --raw</code>. These can be read in to the slave in either of the following ways: <ul style="list-style-type: none"> <li>Update the slave's <code>binlog.index</code> file to point to the copied log files. Then execute a <code>CHANGE MASTER TO</code> statement in the <code>mysql</code> client to point to the first log file, and <code>START SLAVE</code> to read them.</li> <li>Use <code>mysqlbinlog &gt; file</code> (without the <code>--raw</code> option) to export the binary log files to SQL files that can be processed by the <code>mysql</code> client.</li> </ul> </li> </ul>

See also [Section 5.6.7.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing master. This means that the slave's availability is not instantaneous—but only a relatively short amount of time should be required for the slave to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the master in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new slave discussed in this section use other means to transfer information about transactions to the new slave.

**Injecting empty transactions.** The master's global `gtid_executed` variable contains the set of all transactions executed on the master. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the master's `gtid_executed`, like this:

```
SET GTID_NEXT= 'aaa-bbb-ccc-ddd:N' ;

BEGIN;
COMMIT;

SET GTID_NEXT= 'AUTOMATIC' ;
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the slave's binary logs, as shown here, where `N` is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'master-bin.00000N';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to master. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a master as its binary log history converges with that of the replication stream (that is, as it catches up with the master or masters). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with `gtid_purged`.** The master's global `gtid_purged` variable contains the set of all transactions that have been purged from the master's binary log. As with the method discussed previously (see [Injecting empty transactions](#)), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the slave directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a master as its binary log history converges with that of the replication master or group.

**Restoring GTID mode slaves.** When restoring a slave in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.

Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.GTID_NEXT`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the slave and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/*!*/;`, so set it back:

```
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```
mysql> SET GTID_NEXT=automatic;  
mysql> RESET SLAVE;  
mysql> START SLAVE;
```

### 18.1.3.4 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

**Updates involving nontransactional storage engines.** When using GTIDs, updates to tables using nontransactional storage engines such as `MyISAM` cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as `InnoDB`.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the master and the slave use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

**CREATE TABLE ... SELECT statements.** `CREATE TABLE ... SELECT` is not safe for statement-based replication. When using row-based replication, this statement is actually logged as two separate events—one for the creation of the table, and another for the insertion of rows from the source table into the new table just created. When this statement is executed within a transaction, it is possible in some cases for these two events to receive the same transaction identifier, which means that the transaction containing the inserts is skipped by the slave. Therefore, `CREATE TABLE ... SELECT` is not supported when using GTID-based replication.

**Temporary tables.** `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are not supported inside transactions when using GTIDs (that is, when the server was started with the `--enforce-gtid-consistency` option). It is possible to use these statements with GTIDs enabled, but only outside of any transaction, and only with `autocommit=1`.

**Preventing execution of unsupported statements.** To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

For information about other required startup options when enabling GTIDs, see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#).

`sql_slave_skip_counter` is not supported when using GTIDs. If you need to skip transactions, use the value of the master's `gtid_executed` variable instead; see [Injecting empty transactions](#), for more information.

**GTID mode and mysqldump.** It is possible to import a dump made using `mysqldump` into a MySQL Server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

**GTID mode and mysql\_upgrade.** It is not recommended to use `mysql_upgrade` with the `--write-binlog` option on a MySQL Server running with `--gtid-mode=ON` because `mysql_upgrade` can make changes to system tables that use the `MyISAM` storage engine, which is non-transactional.

## 18.1.4 MySQL Multi-Source Replication

This section describes MySQL Multi-Source Replication, included in MySQL 5.7.6 and later. Multi-source replication enables you to replicate from multiple immediate masters in parallel. This section describes multi-source replication, and how to configure, monitor and troubleshoot it.

### 18.1.4.1 MySQL Multi-Source Replication Overview

MySQL Multi-Source Replication enables a replication slave to receive transactions from multiple sources simultaneously. Multi-source replication can be used to back up multiple servers to a single server, to merge table shards, and consolidate data from multiple servers to a single server. Multi-source replication does not implement any conflict detection or resolution when applying the transactions, and those tasks are left to the application if required. In a multi-source replication topology, a slave creates a replication channel for each master that it should receive transactions from. See [Section 18.2.3, “Replication Channels”](#). The following sections describe how to set up multi-source replication.

### 18.1.4.2 Multi-Source Replication Tutorials

This section provides tutorials on how to configure masters and slaves for multi-source replication, and how to start, stop and reset multi-source slaves.

## Configuring Multi-Source Replication

This section explains how to configure a multi-source replication topology, and provides details about configuring masters and slaves. Such a topology requires at least two masters and one slave configured.

Masters in a multi-source replication topology can be configured to use either global transaction identifier (GTID) based replication, or binary log position-based replication. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#) for how to configure a master using GTID based replication. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#) for how to configure a master using file position based replication.

Slaves in a multi-source replication topology require `TABLE` based repositories. Multi-source replication is not compatible with `FILE` based repositories. The type of repository being used by `mysqld` can be configured either at startup, or dynamically.

To configure the type of repository used by a replication slave at startup, start `mysqld` with the following options:

```
--master-info-repository=TABLE --relay-log-info-repository=TABLE
```

To modify an existing replication slave that is using a [FILE](#) repository to use [TABLE](#) repositories, convert the existing replication repositories dynamically by running the following commands:

```
STOP SLAVE;
SET GLOBAL master_info_repository = 'TABLE';
SET GLOBAL relay_log_info_repository = 'TABLE';
```

## Adding a GTID Based Master to a Multi-Source Replication Slave

This section assumes you have enabled GTID based transactions on the master using `gtid_mode=ON`, enabled a replication user, and ensured that the slave is using [TABLE](#) based replication repositories. Use the [CHANGE MASTER TO](#) statement to add a new master to a channel by using a [FOR CHANNEL \*channel\*](#) clause. For more information on replication channels, see [Section 18.2.3, “Replication Channels”](#)

For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='', \
MASTER_AUTO_POSITION = 1 FOR CHANNEL 'master-1';
```

Multi-source replication is compatible with auto-positioning. See [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#) for more information.

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

## Adding a Binary Log Based Master to a Multi-Source Replication Slave

This section assumes you have enabled binary logging on the master using `--log-bin`, enabled a replication user, noted the current binary log position, and ensured that the slave is using [TABLE](#) based replication repositories. You need to know the current [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POSITION](#). Use the [CHANGE MASTER TO](#) statement to add a new master to a channel by specifying a [FOR CHANNEL \*channel\*](#) clause. For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='' \
MASTER_LOG_FILE='master1-bin.000006', MASTER_LOG_POS=628 FOR CHANNEL 'master-1';
```

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

## Starting Multi-Source Replication Slaves

Once you have added all of the channels you want to use as replication masters, use a [START SLAVE \*thread\\_types\*](#) statement to start replication. When you have enabled multiple channels on a slave, you can choose to either start all channels, or select a specific channel to start.

- To start all currently configured replication channels:

```
START SLAVE thread_types;
```

- To start only a named channel, use a [FOR CHANNEL \*channel\*](#) clause:

```
START SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to start on the slave. See [Section 14.4.2.6, “START SLAVE Syntax”](#) for more information.

## Stopping Multi-Source Replication Slaves

The `STOP SLAVE` statement can be used to stop a multi-source replication slave. By default, if you use the `STOP SLAVE` statement on a multi-source replication slave all channels are stopped. Optionally, use the `FOR CHANNEL channel` clause to stop only a specific channel.

- To stop all currently configured replication channels:

```
STOP SLAVE thread_types;
```

- To stop only a named channel, use a `FOR CHANNEL channel` clause:

```
STOP SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to stop on the slave. See [Section 14.4.2.7, “STOP SLAVE Syntax”](#) for more information.

## Resetting Multi-Source Replication Slaves

The `RESET SLAVE` statement can be used to reset a multi-source replication slave. By default, if you use the `RESET SLAVE` statement on a multi-source replication slave all channels are reset. Optionally, use the `FOR CHANNEL channel` clause to reset only a specific channel.

- To reset all currently configured replication channels:

```
RESET SLAVE;
```

- To reset only a named channel, use a `FOR CHANNEL channel` clause:

```
RESET SLAVE FOR CHANNEL channel;
```

See [Section 14.4.2.4, “RESET SLAVE Syntax”](#) for more information.

### 18.1.4.3 Multi-Source Replication Monitoring

To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is `Channel_Name`. This enables you to write complex queries based on `Channel_Name` as a key. See [Section 24.10.11, “Performance Schema Replication Tables”](#).
- Using `SHOW SLAVE STATUS FOR CHANNEL channel_name`. By default, if the `FOR CHANNEL channel_name` clause is not used, this statement shows the slave status for all channels with one row per channel. The identifier `channel_name` is added as a column in the result set. If a `FOR CHANNEL channel_name` clause is provided, the results show the status of only the named replication channel.

#### Note

The `SHOW VARIABLES` statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a `SHOW VARIABLES` statement in a topology with multiple channels shows the status of only the default channel.

## Monitoring Channels Using Performance Schema Tables

This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```
mysql> SELECT * FROM replication_connection_status\G;
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24

LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
***** 2. row *****
CHANNEL_NAME: master2
GROUP_NAME:
SOURCE_UUID: 7475e474-a223-11e4-a978-0811960cc264
THREAD_ID: 26
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 7475e474-a223-11e4-a978-0811960cc264:4-6
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
2 rows in set (0.00 sec)
```

In the above output there are two channels enabled, and as shown by the `CHANNEL_NAME` field they are called `master1` and `master2`.

The addition of the `CHANNEL_NAME` field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a `WHERE channel_name=channel` clause:

```
mysql> SELECT * FROM replication_connection_status WHERE channel_name='master1'\G
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
1 row in set (0.00 sec)
```

Similarly, the `WHERE channel_name=channel` clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see [Section 24.10.11, “Performance Schema Replication Tables”](#).

### 18.1.4.4 Multi-Source Replication Error Messages

New error codes and messages have been added to MySQL 5.7.6 to provide information about errors encountered in a multi-source replication topology. These error codes and messages are only emitted when multi-source replication is enabled, and provide information related to the channel which generated the error. For example:

`Slave is already running` and `Slave is already stopped` have been replaced with `Replication thread(s) for channel channel_name are already running` and `Replication threads(s) for channel channel_name are already stopped` respectively.

The server log messages have also been changed to indicate which channel the log messages relate to. This makes debugging and tracing easier.

## 18.1.5 Changing Replication Modes on Online Servers

This section describes how to change the mode of replication being used without having to take the server offline. This is new functionality added in MySQL 5.7.6.

### 18.1.5.1 Replication Mode Concepts

To be able to safely configure the replication mode of an online server it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying transactions which are logged. The types of transactions used by replication are as follows:

- GTID transactions are identified by a global transaction identifier (GTID) in the form `UUID:NUMBER`. Every GTID transaction in a log is always preceded by a `Gtid_log_event`. GTID transactions can be addressed using either the GTID or using the file name and position.
- Anonymous transactions do not have a GTID assigned, and MySQL 5.7.6 and later ensures that every anonymous transaction in a log is preceded by an `Anonymous_gtid_log_event`. In previous versions, anonymous transactions were not preceded by any particular event. Anonymous transactions can only be addressed using file name and position.

When using GTIDs you can take advantage of auto-positioning and automatic fail-over, as well as use `WAIT_FOR_EXECUTED_GTID_SET()`, `session_track_gtids`, and monitor replicated transactions using Performance Schema tables. With GTIDs enabled you cannot use `sql_slave_skip_counter`, instead use empty transactions.

The changes introduced by MySQL 5.7.6 mean that transactions in a relay log that was received from a master running a previous version of MySQL may not be preceded by any particular event at all, but after being replayed and logged in the slave's binary log, they are preceded with an `Anonymous_gtid_log_event`.

The ability to configure the replication mode online means that the `gtid_mode` and `enforce_gtid_consistency` variables are now both dynamic and can be set by `SUPER` from a top-level statement. In previous versions, both of these variables could only be configured using the appropriate option at server start, meaning that changes to the replication mode required a server restart. In all versions `gtid_mode` could be set to `ON` or `OFF`, which corresponded to whether GTIDs were used to identify transactions or not. When `gtid_mode=ON` it is not possible to replicate anonymous transactions, and when `gtid_mode=OFF` only anonymous transactions can be replicated. As of MySQL 5.7.6, the `gtid_mode` variable has two additional states, `OFF_PERMISSIVE` and `ON_PERMISSIVE`. When `gtid_mode=OFF_PERMISSIVE` then *new* transactions are anonymous while permitting replicated transactions to be either GTID or anonymous transactions. When `gtid_mode=ON_PERMISSIVE` then

*new* transactions use GTIDs while permitting replicated transactions to be either GTID or anonymous transactions. This means it is possible to have a replication topology that has servers using both anonymous and GTID transactions. For example a master with `gtid_mode=ON` could be replicating to a slave with `gtid_mode=ON_PERMISSIVE`. The valid values for `gtid_mode` are as follows and in this order:

- `OFF`
- `OFF_PERMISSIVE`
- `ON_PERMISSIVE`
- `ON`

It is important to note that the state of `gtid_mode` can only be changed by one step at a time based on the above order. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`. This is to ensure that the process of changing from anonymous transactions to GTID transactions online is correctly handled by the server. When you switch between `gtid_mode=ON` and `gtid_mode=OFF`, the GTID state (in other words the value of `gtid_executed`) is persistent. This ensures that the GTID set that has been applied by the server is always retained, regardless of changes between types of `gtid_mode`.

As part of the changes introduced by MySQL 5.7.6, the fields related to GTIDs have been modified so that they display the correct information regardless of the currently selected `gtid_mode`. This means that fields which display GTID sets, such as `gtid_executed`, `gtid_purged`, `RECEIVED_TRANSACTION_SET` in the `replication_connection_status` Performance Schema table, and the GTID related results of `SHOW SLAVE STATUS`, now return the empty string when there are no GTIDs present. Fields that display a single GTID, such as `CURRENT_TRANSACTION` in the `replication_applier_status_by_worker` Performance Schema table, now display `ANONYMOUS` when GTID transactions are not being used.

Replication from a master using `gtid_mode=ON` provides the ability to use auto-positioning, configured using the `CHANGE MASTER TO MASTER_AUTO_POSITION = 1;` statement. The replication topology being used impacts on whether it is possible to enable auto-positioning or not, as this feature relies on GTIDs and is not compatible with anonymous transactions. An error is generated if auto-positioning is enabled and an anonymous transaction is encountered. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning, see [Section 18.1.5.2, “Enabling GTID Transactions Online”](#). The valid combinations of `gtid_mode` and auto-positioning on master and slave are shown in the following table, where the master's `gtid_mode` is shown on the horizontal and the slave's `gtid_mode` is on the vertical:

**Table 18.1 Valid Combinations of Master and Slave `gtid_mode`**

Master/Slave <code>gtid_mode</code>	<code>OFF</code>	<code>OFF_PERMISSIVE</code>	<code>ON_PERMISSIVE</code>	<code>ON</code>
<code>OFF</code>	Y	Y	N	N
<code>OFF_PERMISSIVE</code>	Y	Y	Y	Y*
<code>ON_PERMISSIVE</code>	Y	Y	Y	Y*
<code>ON</code>	N	N	Y	Y*

In the above table, the entries are:

- **Y:** the `gtid_mode` of master and slave is compatible
- **N:** the `gtid_mode` of master and slave is not compatible

- \*: auto-positioning can be used

The currently selected `gtid_mode` also impacts on the `gtid_next` variable. The following table shows the behavior of the server for the different values of `gtid_mode` and `gtid_next`.

**Table 18.2 Valid Combinations of `gtid_mode` and `gtid_next`**

<code>gtid_next</code>	<b>AUTOMATIC</b>		<b>ANONYMOUS</b>	<b>UUID:NUMBER</b>
	<b>binary log on</b>	<b>binary log off</b>		
<b>OFF</b>	ANONYMOUS	ANONYMOUS	ANONYMOUS	Error
<b>OFF_PERMISSIVE</b>	ANONYMOUS	ANONYMOUS	ANONYMOUS	UUID:NUMBER
<b>ON_PERMISSIVE</b>	New GTID	ANONYMOUS	ANONYMOUS	UUID:NUMBER
<b>ON</b>	New GTID	ANONYMOUS	Error	UUID:NUMBER

In the above table, the entries are:

- **ANONYMOUS**: generate an anonymous transaction.
- **Error**: generate an error and fail to execute `SET GTID_NEXT`.
- **UUID:NUMBER**: generate a GTID with the specified UUID:NUMBER.
- **New GTID**: generate a GTID with an automatically generated number.

When the binary log is off and `gtid_next` is set to **AUTOMATIC**, then no GTID is generated. This is consistent with the behavior of previous versions.

### 18.1.5.2 Enabling GTID Transactions Online

This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot enable GTID transactions online on any single server unless *all* servers which are in the topology are using this version.
- All servers have `gtid_mode` set to the default value **OFF**.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of [Section 18.1.5.3, “Disabling GTID Transactions Online”](#), the online procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

#### Note

It is crucial that you complete every step before continuing to the next step.

To enable GTID transactions:

1. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = WARN;
```

Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

### Important

This is the first important step. You must ensure that no warnings are being generated in the error logs before going to the next step.

2. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

It does not matter which server executes this statement first, but it is important that all servers complete this step before any server begins the next step.

4. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

It does not matter which server executes this statement first.

5. On each server, wait until the status variable `ONGOING_ANONYMOUS_TRANSACTION_COUNT` is zero. This can be checked using:

```
SHOW STATUS LIKE 'ONGOING_ANONYMOUS_TRANSACTION_COUNT';
```

### Note

On a replication slave, it is theoretically possible that this shows zero and then non-zero again. This is not a problem, it suffices that it shows zero once.

6. Wait for all transactions generated up to step 5 to replicate to all servers. You can do this without stopping updates: the only important thing is that all anonymous transactions get replicated.

See [Section 18.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.

7. If you use binary logs for anything other than replication, for example point in time backup and restore, wait until you do not need the old binary logs having transactions without GTIDs.

For instance, after step 6 has completed, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 6 was completed. Also wait for any backup taken before step 6 to expire.

### Important

This is the second important point. It is vital to understand that binary logs containing anonymous transactions, without GTIDs cannot be used after the

next step. After this step, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

8. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON;
```

9. On each server, add `gtid-mode=ON` to `my.cnf`.

You are now guaranteed that all transactions have a GTID (except transactions generated in step 5 or earlier, which have already been processed). To start using the GTID protocol so that you can later perform automatic fail-over, execute the following on each slave. Optionally, if you use multi-source replication, do this for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

### 18.1.5.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot disable GTID transactions online on any single server unless *all* servers which are in the topology are using this version.
  - All servers have `gtid_mode` set to `ON`.
1. Execute the following on each slave, and if you using multi-source replication, do it for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \
MASTER_LOG_POS = position [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

2. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

4. On each server, wait until the variable `@@GLOBAL.GTID_OWNED` is equal to the empty string. This can be checked using:

```
SELECT @@GLOBAL.GTID_OWNED;
```

On a replication slave, it is theoretically possible that this is empty and then nonempty again. This is not a problem, it suffices that it is empty once.

5. Wait for all transactions that currently exist in any binary log to replicate to all slaves. See [Section 18.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.
6. If you use binary logs for anything else than replication, for example to do point in time backup or restore: wait until you do not need the old binary logs having GTID transactions.

For instance, after step 5 has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 5 was completed. Also wait for any backup taken before step 5 to expire.

### Important

This is the one important point during this procedure. It is important to understand that logs containing GTID transactions cannot be used after the next step. Before proceeding you must be sure that GTID transactions do not exist anywhere in the topology.

7. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF;
```

8. On each server, set `gtid-mode=OFF` in `my.cnf`.

If you want to set `enforce_gtid_consistency=OFF`, you can do so now. After setting it, you should add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

## 18.1.5.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: if you are sure that the slave never lags more than N seconds, just wait for a bit more than N seconds. Or wait for a day, or whatever time period you consider safe for your deployment.

A safer method in the sense that it does not depend on timing: if you only have a master with one or more slaves, do the following:

1. On the master, execute:

```
SHOW MASTER STATUS;
```

Note down the values in the `File` and `Position` column.

2. On every slave, use the file and position information from the master to execute:

```
SELECT MASTER_POS_WAIT(file, position);
```

If you have a master and multiple levels of slaves, or in other words you have slaves of slaves, repeat step 2 on each level, starting from the master, then all the direct slaves, then all the slaves of slaves, and so on.

If you use a circular replication topology where multiple servers may have write clients, perform step 2 for each master-slave connection, until you have completed the full circle. Repeat the whole process so that you do the full circle *twice*.

For example, suppose you have three servers A, B, and C, replicating in a circle so that A -> B -> C -> A. The procedure is then:

- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.
- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.

## 18.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `--server-id` option.

<b>Command-Line Format</b>	<code>--server-id=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>server_id</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 18.1.6.2, “Replication Master Options and Variables”](#), and [Section 18.1.6.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. For example, `server-id=3`.

In MySQL 5.7.2 and earlier, if you start a master server without using `--server-id` to set its ID, the default ID is 0. In this case, the master refuses connections from all slaves, slaves refuse to connect to the master, and the server sets the `server_id` system variable to 1. In MySQL 5.7.3 and later, the `--server-id` must be used if binary logging is enabled, and a value of 0 is not changed by the server. If you specify `--server-id` without an argument, the effect is the same as using 0. In either case, if the `server_id` is 0, binary logging takes place, but slaves cannot connect to the master, nor can any other servers connect to it as slaves. (Bug #11763963, Bug #56718)

For more information, see [Setting the Replication Slave Configuration](#).

### `server_uuid`

In MySQL 5.7, the server generates a true UUID in addition to the `--server-id` supplied by the user. This is available as the global, read-only variable `server_uuid`.

#### Note

The presence of the `server_uuid` system variable in MySQL 5.7 does not change the requirement for setting a unique `--server-id` for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

System Variable	Name	<code>server_uuid</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).
2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. In MySQL 5.7, `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

#### Important

The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, masters and slaves know each other's UUIDs. The value of a slave's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed, the value of the master's UUID is available on the slave in the output of `SHOW SLAVE STATUS`.

#### Note

Issuing a `STOP SLAVE` or `RESET SLAVE` statement does *not* reset the master's UUID as used on the slave.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

When starting, the slave I/O thread generates an error and aborts if its master's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the slave I/O thread generates a warning if either of the following is true:

- No master having the expected `server_uuid` exists.
- The master's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

### 18.1.6.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 18.3 Summary of Replication options and variables in MySQL 5.7**

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<code>abort-slave-event-count</code>		
Yes	No	No
Yes		No
DESCRIPTION: Option used by mysql-test for debugging and testing of replication		
<code>binlog_gtid_simple_recovery</code>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Controls how binary logs are iterated during GTID recovery		
<code>Com_change_master</code>		
No	No	Yes
No	Both	No
DESCRIPTION: Count of CHANGE MASTER TO statements		
<code>Com_show_master_status</code>		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW MASTER STATUS statements		
<code>Com_show_new_master</code>		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW NEW MASTER statements

Yes	No	No
Yes		No
DESCRIPTION: Whether to write the replication SQL thread's location in the relay logs to a file or a table.		
<code>relay-log-recovery</code>		
Yes	No	No
Yes		No
DESCRIPTION: Enables automatic recovery of relay log files from master at startup		
<code>relay_log_basename</code>		
No	Yes	No
No	Global	No
DESCRIPTION: Complete path to relay log, including filename		
<code>relay_log_index</code>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: The name of the relay log index file		
<code>relay_log_info_file</code>		
Yes	Yes	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Global	No
DESCRIPTION: The name of the file in which the slave records information about the relay logs <a href="#">relay_log_info_repository</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Whether to write the replication SQL thread's location in the relay logs to a file or a table <a href="#">relay_log_purge</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Determines whether relay logs are purged <a href="#">relay_log_recovery</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Whether automatic recovery of relay log files from master at startup is enabled; must be enabled for a crash-safe slave. <a href="#">relay_log_space_limit</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Maximum space to use for all relay logs <a href="#">replicate-do-db</a>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave SQL thread to restrict replication to the specified database <a href="#">replicate-do-table</a>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave SQL thread to restrict replication to the specified table <a href="#">replicate-ignore-db</a>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave SQL thread not to replicate to the specified database <a href="#">replicate-ignore-table</a>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave SQL thread not to replicate to the specified table		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">replicate-rewrite-db</a>		
Yes	No	No
Yes		No
DESCRIPTION: Updates to a database with a different name than the original		
<a href="#">replicate-same-server-id</a>		
Yes	No	No
Yes		No
DESCRIPTION: In replication, if set to 1, do not skip events having our server id		
<a href="#">replicate-wild-do-table</a>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave thread to restrict replication to the tables that match the specified wildcard pattern		
<a href="#">replicate-wild-ignore-table</a>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave thread not to replicate to the tables that match the given wildcard pattern		
<a href="#">report-host</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Host name or IP of the slave to be reported to the master during slave registration		
<a href="#">report-password</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: An arbitrary password that the slave server should report to the master. Not the same as the password for the MySQL replication user account.		
<a href="#">report-port</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Port for connecting to slave reported to the master during slave registration		
<a href="#">report-user</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: An arbitrary user name that a slave server should report to the master. Not the same as the name used with the MySQL replication user account.		
<a href="#">Rpl_semi_sync_master_clients</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of semisynchronous slaves <a href="#">rpl_semi_sync_master_enabled</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Whether semisynchronous replication is enabled on the master <a href="#">Rpl_semi_sync_master_net_avg_wait_time</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The average time the master waited for a slave reply <a href="#">Rpl_semi_sync_master_net_wait_time</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The total time the master waited for slave replies <a href="#">Rpl_semi_sync_master_net_waits</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of times the master waited for slave replies <a href="#">Rpl_semi_sync_master_no_times</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times the master turned off semisynchronous replication <a href="#">Rpl_semi_sync_master_no_tx</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of commits not acknowledged successfully <a href="#">Rpl_semi_sync_master_status</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Whether semisynchronous replication is operational on the master <a href="#">Rpl_semi_sync_master_timefunc_failures</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times the master failed when calling time functions		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">rpl_semi_sync_master_timeout</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Number of milliseconds to wait for slave acknowledgment		
<a href="#">rpl_semi_sync_master_trace_level</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: The semisynchronous replication debug trace level on the master		
<a href="#">Rpl_semi_sync_master_tx_avg_wait_time</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The average time the master waited for each transaction		
<a href="#">Rpl_semi_sync_master_tx_wait_time</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The total time the master waited for transactions		
<a href="#">Rpl_semi_sync_master_tx_waits</a>

DESCRIPTION: Whether semisynchronous replication is operational on slave <a href="#">rpl_semi_sync_slave_trace_level</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: The semisynchronous replication debug trace level on the slave <a href="#">rpl_stop_slave_timeout</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Set the number of seconds that STOP SLAVE waits before timing out. <a href="#">server_uuid</a>		
No	Yes	No
No	Global	No
DESCRIPTION: The server's globally unique ID, automatically (re)generated at server start <a href="#">show-slave-auth-info</a>		
Yes	No	No
Yes		No
DESCRIPTION: Show user name and password in SHOW SLAVE HOSTS on this master		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<code>simplified_binlog_gtid_recovery</code>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Controls how binary logs are iterated during GTID recovery		
<code>skip-slave-start</code>		
Yes	No	No
Yes		No
DESCRIPTION: If set, slave is not autostarted		
<code>slave-checkpoint-group</code>		
Yes	No	No
Yes		No
DESCRIPTION: Maximum number of transactions processed by a multi-threaded slave before a checkpoint operation is called to update progress status. Not supported by MySQL Cluster.		
<code>slave-checkpoint-period</code>		
Yes	No	No
Yes		No
DESCRIPTION: Update progress status of multi-threaded slave and flush relay log info to disk after this number of milliseconds. Not supported by MySQL Cluster.		
<code>slave-load-tmpdir</code>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: The location where the slave should put its temporary files when replicating a LOAD DATA INFILE statement		
<code>slave-max-allowed-packet</code>		
Yes	No	No
Yes		No
DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.		
<code>slave_net_timeout</code>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Number of seconds to wait for more data from a master/slave connection before aborting the read		
<code>slave-parallel-type</code>		
Yes	No	No
Yes		No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
DESCRIPTION: Tells the slave to use database partitioning (DATABASE) or timestamp information (LOGICAL_CLOCK) from the master to parallelize transactions. The default is DATABASE.		
<a href="#">slave-parallel-workers</a>		
Yes	No	No
Yes		No
DESCRIPTION: Number of worker threads for executing events in parallel. Set to 0 (the default) to disable slave multi-threading. Not supported by MySQL Cluster.		
<a href="#">slave-pending-jobs-size-max</a>		
Yes	No	No
No		No
DESCRIPTION: Maximum size of slave worker queues holding events not yet applied.		
<a href="#">slave-rows-search-algorithms</a>		
Yes	No	No
Yes		No
DESCRIPTION: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN; the default is TABLE_SCAN, INDEX_SCAN.		
<a href="#">slave-skip-errors</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Tells the slave thread to continue replication when a query returns an error from the provided list		
<a href="#">slave_checkpoint_group</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Maximum number of transactions processed by a multi-threaded slave before a checkpoint operation is called to update progress status. Not supported by MySQL Cluster.		
<a href="#">slave_checkpoint_period</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Update progress status of multi-threaded slave and flush relay log info to disk after this number of milliseconds. Not supported by MySQL Cluster.		
<a href="#">slave_compressed_protocol</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Use compression on master/slave protocol		
<a href="#">slave_exec_mode</a>		
Yes	Yes	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Global	Yes
DESCRIPTION: Allows for switching the slave thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for MySQL Cluster, where IDEMPOTENT is always used		
<a href="#">Slave_heartbeat_period</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The slave's replication heartbeat interval, in seconds		
<a href="#">slave_max_allowed_packet</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.		
<a href="#">Slave_open_temp_tables</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of temporary tables that the slave SQL thread currently has open		
<a href="#">slave_parallel_type</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Tells the slave to use database partitioning (DATABASE) or information (LOGICAL_CLOCK) from master to parallelize transactions. The default is DATABASE.		
<a href="#">slave_parallel_workers</a>		
Yes	Yes	No
No	Global	Yes
DESCRIPTION: Number of worker threads for executing events in parallel. Set to 0 (the default) to disable slave multi-threading. Not supported by MySQL Cluster.		
<a href="#">slave_pending_jobs_size_max</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Maximum size of slave worker queues holding events not yet applied.		
<a href="#">slave_preserve_commit_order</a>		
Yes	Yes	No
No	Global	Yes
DESCRIPTION: Ensures that all commits by slave workers happen in the same order as on the master to maintain consistency when using parallel worker threads.		
<a href="#">Slave_retried_transactions</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of times since startup that the replication slave SQL thread has retried transactions		
<a href="#">slave_rows_search_algorithms</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN; the default is TABLE_SCAN, INDEX_SCAN.		
<a href="#">Slave_running</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The state of this server as a replication slave (slave I/O thread status)		
<a href="#">slave_transaction_retries</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping		
<a href="#">slave_type_conversions</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave.		
<a href="#">sql_slave_skip_counter</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Number of events from the master that a slave server should skip. Not compatible with GTID replication.		
<a href="#">sync_binlog</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronously flush binary log to disk after every #th event		
<a href="#">sync_master_info</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronize master.info to disk after every #th event.		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">sync_relay_log</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronize relay log to disk after every #th event.		
<a href="#">sync_relay_log_info</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronize relay.info file to disk after every #th event.		

[Section 18.1.6.2, “Replication Master Options and Variables”](#), provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see [Section 18.1.6.3, “Replication Slave Options and Variables”](#).

**Table 18.4 Summary of Binary Logging options and variables in MySQL 5.7**

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">binlog-checksum</a>		
Yes	No	No
Yes		No
DESCRIPTION: Enable/disable binary log checksums		
<a href="#">binlog-do-db</a>		
Yes	No	No
Yes		No
DESCRIPTION: Limits binary logging to specific databases		
<a href="#">binlog_format</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies the format of the binary log		
<a href="#">binlog-ignore-db</a>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the master that updates to the given database should not be logged to the binary log		
<a href="#">binlog-row-event-max-size</a>		
Yes	No	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes		No
DESCRIPTION: Binary log max event size <a href="#">binlog-rows-query-log-events</a>		
Yes	No	No
Yes		No
DESCRIPTION: Enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6.2 slaves/readers. <a href="#">Binlog_cache_disk_use</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions that used a temporary file instead of the binary log cache <a href="#">binlog_cache_size</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Size of the cache to hold the SQL statements for the binary log during a transaction <a href="#">Binlog_cache_use</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions that used the temporary binary log cache <a href="#">binlog_checksum</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Enable/disable binary log checksums <a href="#">binlog_direct_non_transactional_updates</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using. <a href="#">binlog_error_action</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Controls what happens when the server cannot write to the binary log. <a href="#">binlog_group_commit_sync_delay</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Sets the number of microseconds to wait before synchronizing transactions to disk.		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">binlog_group_commit_sync_no_delay_count</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Sets the maximum number of transactions to wait for before aborting the current delay specified by binlog_group_commit_sync_delay.		
<a href="#">binlog_max_flush_queue_time</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: How long to read transactions before flushing to binary log		
<a href="#">binlog_order_commits</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Whether to commit in same order as writes to binary log		
<a href="#">binlog_row_image</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Use full or minimal images when logging row changes. Allowed values are full, minimal, and noblob.		
<a href="#">binlog_rows_query_log_events</a>		
No	Yes	No
No	Both	Yes
DESCRIPTION: When TRUE, enables logging of rows query log events in row-based logging mode. FALSE by default. Do not enable when producing logs for pre-5.6.2 replication slaves or other readers.		
<a href="#">Binlog_stmt_cache_disk_use</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of nontransactional statements that used a temporary file instead of the binary log statement cache		
<a href="#">binlog_stmt_cache_size</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Size of the cache to hold nontransactional statements for the binary log during a transaction		
<a href="#">Binlog_stmt_cache_use</a>		
No	No	Yes
No	Global	No

Option or Variable Name		
Command Line	System Variable	Status Variable

<b>Notes</b>		
DESCRIPTION: Number of statements that used the temporary binary log statement cache		
<a href="#">binlogging_impossible_mode</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Deprecated and will be removed in a future version. Use the renamed binlog_error_action instead.		
<a href="#">Com_show_binlog_events</a>		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW BINLOG EVENTS statements		
<a href="#">Com_show_binlogs</a>		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW BINLOGS statements		
<a href="#">log-bin-use-v1-row-events</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Use version 1 binary log row events		
<a href="#">log_bin_basename</a>		
No	Yes	No
No	Global	No
DESCRIPTION: Complete path to binary log, including filename		
<a href="#">log_bin_use_v1_row_events</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Shows whether server is using version 1 binary log row events		
<a href="#">master-verify-checksum</a>		
Yes	No	No
Yes		No
DESCRIPTION: Cause master to examine checksums when reading from the binary log		
<a href="#">master_verify_checksum</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Cause master to read checksums from binary log.		
<a href="#">max-binlog-dump-events</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	No	No
Yes		No
DESCRIPTION: Option used by mysql-test for debugging and testing of replication <a href="#">max_binlog_cache_size</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Can be used to restrict the total size used to cache a multi-statement transaction <a href="#">max_binlog_size</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Binary log will be rotated automatically when size exceeds this value <a href="#">max_binlog_stmt_cache_size</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Can be used to restrict the total size used to cache all nontransactional statements during a transaction <a href="#">slave-sql-verify-checksum</a>		
Yes	No	No
Yes		No
DESCRIPTION: Cause slave to examine checksums when reading from the relay log <a href="#">slave_sql_verify_checksum</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Cause slave to examine checksums when reading from relay log. <a href="#">sporadic-binlog-dump-fail</a>		
Yes	No	No
Yes		No
DESCRIPTION: Option used by mysql-test for debugging and testing of replication		

[Section 18.1.6.4, “Binary Logging Options and Variables”](#), provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see [Section 6.4.4, “The Binary Log”](#).

For information about the [sql\\_log\\_bin](#) and [sql\\_log\\_off](#) variables, see [Section 6.1.5, “Server System Variables”](#).

For a table showing *all* command-line options, system and status variables used with [mysqld](#), see [Section 6.1.3, “Server Option and Variable Reference”](#).

### 18.1.6.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the [server-id](#) option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other replication master or slave. Example: [server-id=3](#).

For options used on the master for controlling binary logging, see [Section 18.1.6.4, “Binary Logging Options and Variables”](#).

#### System Variables Used on Replication Masters

The following system variables are used to control replication masters:

- [auto\\_increment\\_increment](#)

<b>System Variable</b>	<b>Name</b>	<a href="#">auto_increment_increment</a>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<a href="#">1</a>
	<b>Min Value</b>	<a href="#">1</a>
	<b>Max Value</b>	<a href="#">65535</a>

[auto\\_increment\\_increment](#) and [auto\\_increment\\_offset](#) are intended for use with master-to-master replication, and can be used to control the operation of [AUTO\\_INCREMENT](#) columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of [auto\\_increment\\_increment](#) or [auto\\_increment\\_offset](#) to a noninteger value produces an error, and the actual value of the variable remains unchanged.

#### Note

[auto\\_increment\\_increment](#) is also supported for use with [NDB](#) tables.

These two variables affect [AUTO\\_INCREMENT](#) column behavior as follows:

- [auto\\_increment\\_increment](#) controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

```

| auto_increment_increment | 1 |
| auto_increment_offset   | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 10    |
| auto_increment_offset   | 1     |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
4 rows in set (0.00 sec)

```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```

mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 10    |
| auto_increment_offset   | 5     |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5   |

```

```

| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)

```

When the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |

```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 18.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `auto_increment_offset`

<b>System Variable</b>	<b>Name</b>	<code>auto_increment_offset</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	65535

This variable has a default value of 1. For more information, see the description for `auto_increment_increment`.

#### Note

`auto_increment_offset` is also supported for use with `NDB` tables.

### 18.1.6.3 Replication Slave Options and Variables

This section explains the server options and system variables that apply to slave replication servers and contains the following:

[Startup Options for Replication Slaves](#)

[Options for Logging Slave Status to Tables](#)

[System Variables Used on Replication Slaves](#)

Specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. Specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

## Startup Options for Replication Slaves

This section explains startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--log-slave-updates`

<b>Command-Line Format</b>	<code>--log-slave-updates</code>	
<b>System Variable</b>	<b>Name</b>	<code>log_slave_updates</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Normally, a slave does not write any updates that are received from a master server to its own binary log. This option causes the slave to write the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, **A** serves as the master for the slave **B**, and **B** serves as the master for the slave **C**. For this to work, **B** must be both a master *and* a slave. You must start both **A** and **B** with `--log-bin` to enable binary logging, and **B** with the `--log-slave-updates` option so that updates received from **A** are logged by **B** to its binary log.

- `--log-slow-slave-statements`

<b>Removed</b>	5.7.1	
<b>Command-Line Format</b>	<code>--log-slow-slave-statements</code> (5.7.0)	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

This command-line option was removed in MySQL 5.7.1 and replaced by the `log_slow_slave_statements` system variable. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- `--log-warnings[=level]`

<b>Deprecated</b>	5.7.2	
<b>Command-Line Format</b>	<code>--log-warnings[=#]</code>	
<b>System Variable</b>	<b>Name</b>	<code>log_warnings</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms, <= 5.7.1)	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (32-bit platforms, >= 5.7.2)	<b>Type</b>	integer
	<b>Default</b>	2
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms, <= 5.7.1)	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615
<b>Permitted Values</b> (64-bit platforms, >= 5.7.2)	<b>Type</b>	integer
	<b>Default</b>	2
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615

**Note**

As of MySQL 5.7.2, the `log_error_verbosity` system variable is preferred over, and should be used instead of, the `--log-warnings` option or `log_warnings` system variable. For more information, see the descriptions of `log_error_verbosity` and `log_warnings`. The `--log-warnings` command-line option and `log_warnings` system variable are deprecated and will be removed in a future MySQL release.

Causes the server to record more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network or connection failure, and provides information about how each slave thread started. This variable is enabled by default (the default is 1 before MySQL 5.7.2, 2 as of 5.7.2). To disable it, set it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

**Note**

The effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-info-file=file_name`

<b>Command-Line Format</b>	<code>--master-info-file=file_name</code>	
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<code>master.info</code>

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see [Section 18.2.4.2, “Slave Status Logs”](#).

- `--master-retry-count=count`

<b>Deprecated</b>	5.6.1	
<b>Command-Line Format</b>	<code>--master-retry-count=#</code>	
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<code>86400</code>
	<b>Min Value</b>	0
	<b>Max Value</b>	<code>4294967295</code>
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<code>86400</code>
	<b>Min Value</b>	0
	<b>Max Value</b>	<code>18446744073709551615</code>

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

This option is deprecated and will be removed in a future MySQL release. Applications should be updated to use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.

- `--max-relay-log-size=size`

<b>Command-Line Format</b>	<code>--max_relay_log_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>max_relay_log_size</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	1073741824

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see [Section 18.2.4.1, “The Slave Relay Log”](#).

- `--relay-log=file_name`

<b>Command-Line Format</b>	<code>--relay-log=file_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name

The base name for the relay log. For the default replication channel, the default base name for relay logs is `host_name-relay-bin`. For non-default replication channels, the default base name for relay logs is `host_name-channel-relay-bin`, where `channel` is the name of the replication channel recorded in this relay log. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 5.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previously, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.

- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `--relay-log-index=file_name`

<b>Command-Line Format</b>	<code>--relay-log-index=file_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log_index</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the server. For the default replication channel, the default name is `host_name-relay-bin.index`. For non-default replication channels, the default name is `host_name-channel-relay-bin.index`, where `channel` is the name of the replication channel recorded in this relay log index.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 5.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

<b>Command-Line Format</b>	<code>--relay-log-info-file=file_name</code>	
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<code>relay-log.info</code>

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see [Section 18.2.4.2, “Slave Status Logs”](#).

- `--relay-log-purge={0|1}`

<b>Command-Line Format</b>	<code>--relay_log_purge</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log_purge</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	TRUE

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when using the `--relay-log-recovery` option puts data consistency at risk.

- `--relay-log-recovery={0|1}`

<b>Command-Line Format</b>	<code>--relay-log-recovery</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This should be used following an unexpected halt of a replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

This variable can be set to 1 to make a slave resilient to unexpected halts, see [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#) for more information. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency.

When using a multi-threaded slave (in other words `slave_parallel_workers` is greater than 0), inconsistencies such as gaps can occur in the sequence of transactions that have been executed from the relay log. Enabling the `--relay-log-recovery` option when there are inconsistencies causes an error and the option has no effect. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, which brings the server to a more consistent state, then issue `RESET SLAVE` to remove the relay logs. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `--relay-log-space-limit=size`

<b>Command-Line Format</b>	<code>--relay_log_space_limit=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log_space_limit</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	0

<b>Min Value</b>	0
<b>Max Value</b>	18446744073709551615

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit”. This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

<b>Command-Line Format</b>	<code>--replicate-do-db=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

Creates a replication filter using the name of a database. In MySQL 5.7.3 and later, such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_DO_DB`. The precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the

slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

<b>Command-Line Format</b>	<code>--replicate-ignore-db=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

Creates a replication filter using the name of a database. In MySQL 5.7.3 and later, such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_IGNORE_DB`. As with `--replicate-do-db`, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

<b>Command-Line Format</b>	<code>--replicate-do-table=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

Creates a replication filter by telling the slave SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_DO_TABLE` statement.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

<b>Command-Line Format</b>	<code>--replicate-ignore-table=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

Creates a replication filter by telling the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_IGNORE_TABLE` statement.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

<b>Command-Line Format</b>	<code>--replicate-rewrite-db=old_name-&gt;new_name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

Tells the slave to create a replication filter that translates the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
shell> mysql --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

<b>Command-Line Format</b>	<code>--replicate-same-server-id</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

<b>Command-Line Format</b>	<code>--replicate-wild-do-table=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

Creates a replication filter by telling the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE` statement.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `mylownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

<b>Command-Line Format</b>	<code>--replicate-wild-ignore-table=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

Creates a replication filter which keeps the slave thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE` statement.

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

<b>Command-Line Format</b>	<code>--report-host=host_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>report_host</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master.

#### Note

It is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

<b>Command-Line Format</b>	<code>--report-password=name</code>	
<b>System Variable</b>	<b>Name</b>	<code>report_password</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

<b>Command-Line Format</b>	<code>--report-port=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>report_port</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>[slave_port]</code>
	<b>Min Value</b>	0
	<b>Max Value</b>	65535

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the slave (Bug #13333431). This is also the default value displayed by `SHOW SLAVE HOSTS`.

- `--report-user=user_name`

<b>Command-Line Format</b>	<code>--report-user=name</code>	
<b>System Variable</b>	<b>Name</b>	<code>report_user</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info`

<b>Command-Line Format</b>	<code>--show-slave-auth-info</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--slave-checkpoint-group=#`

<b>Command-Line Format</b>	<code>--slave-checkpoint-group=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>512</code>
	<b>Min Value</b>	<code>32</code>
	<b>Max Value</b>	<code>524280</code>
	<b>Block Size</b>	<code>8</code>

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this option. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This option works in combination with the `--slave-checkpoint-period` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `--slave-checkpoint-period=#`

<b>Command-Line Format</b>	<code>--slave-checkpoint-period=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>300</code>
	<b>Min Value</b>	<code>1</code>
	<b>Max Value</b>	<code>4G</code>

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this option. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This option works in combination with the `--slave-checkpoint-group` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `--slave-parallel-workers`

<b>Command-Line Format</b>	<code>--slave-parallel-workers=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	1024

Sets the number of slave applier threads for executing replication transactions in parallel. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier threads. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread.

A multi-threaded slave provides parallel execution by using a coordinator thread and the number of applier threads configured by this option. The way which transactions are distributed among applier threads is configured by `--slave-parallel-type`. For more information about multi-threaded slaves see [slave-parallel-workers](#).

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this option. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

- `--slave-pending-jobs-size-max=#`

<b>Command-Line Format</b>	<code>--slave-pending-jobs-size-max=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	16M
	<b>Min Value</b>	1024
	<b>Max Value</b>	

	<b>Max Value</b>	18EB
	<b>Block Size</b>	1024

For multi-threaded slaves, this option sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this option has no effect on slaves for which multi-threading is not enabled.

The minimum possible value for this option is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

### Important

The value for this option must not be less than the master's value for `max_allowed_packet`; otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `--skip-slave-start`

<b>Command-Line Format</b>	<code>--skip-slave-start</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

<b>Command-Line Format</b>	<code>--slave_compressed_protocol</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_compressed_protocol</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

<b>Command-Line Format</b>	<code>--slave-load-tmpdir=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_load_tmpdir</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
		2861

<b>Permitted Values</b>	<b>Type</b>	directory name
	<b>Default</b>	<code>/tmp</code>

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `slave-max-allowed-packet=bytes`

<b>Command-Line Format</b>	<code>--slave-max-allowed-packet=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>1073741824</code>
	<b>Min Value</b>	<code>1024</code>
	<b>Max Value</b>	<code>1073741824</code>

This option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--slave-net-timeout=seconds`

<b>Command-Line Format</b>	<code>--slave-net-timeout=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_net_timeout</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>3600</code>
	<b>Min Value</b>	<code>1</code>

<b>Permitted Values</b> (>= 5.7.7)	<b>Type</b>	integer
	<b>Default</b>	60
	<b>Min Value</b>	1

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. Prior to MySQL 5.7.7, the default was 3600 seconds (one hour). In MySQL 5.7.7 and later the default is 60 (one minute).

- `--slave-parallel-type=type`

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--slave-parallel-type=type</code>	
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	DATABASE
	<b>Valid Values</b>	DATABASE LOGICAL_CLOCK

When using a multi-threaded slave (`slave_parallel_workers` is greater than 0), this option specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The possible values are:

- **DATABASE**: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. Only recommended if there are no cross-database constraints, as such constraints may be violated on the slave.
- **LOGICAL\_CLOCK**: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. There are no cross-database constraints, and data does not need to be partitioned into multiple databases.

Regardless of the value of this variable, there is no special configuration required on the master. When `slave_preserve_commit_order=1`, you can only use **LOGICAL\_CLOCK**. If your replication topology uses multiple levels of slaves, **LOGICAL\_CLOCK** may achieve less parallelization for each level the slave is away from the master.

- `slave-rows-search-algorithms=list`

<b>Command-Line Format</b>	<code>--slave-rows-search-algorithms=list</code>	
<b>Permitted Values</b>	<b>Type</b>	set
	<b>Default</b>	TABLE_SCAN, INDEX_SCAN
	<b>Valid Values</b>	TABLE_SCAN, INDEX_SCAN
		INDEX_SCAN, HASH_SCAN
		TABLE_SCAN, HASH_SCAN
		TABLE_SCAN, INDEX_SCAN, HASH_SCAN (equivalent to INDEX_SCAN, HASH_SCAN)

When preparing batches of rows for row-based logging and replication, this option controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or no key at all. This option takes a comma-separated list of any 2 (or possibly 3) values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The list need not be quoted, but must contain no spaces, whether or not quotes are used. Possible combinations (lists) and their effects are shown in the following table:

Index used / option value	<code>INDEX_SCAN,HASH_SCAN</code> or <code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code>	<code>INDEX_SCAN, TABLE_SCAN</code>	<code>TABLE_SCAN, HASH_SCAN</code>
Primary key or unique key	Index scan	Index scan	Hash scan over index
(Other) Key	Hash scan over index	Index scan	Hash scan over index
No index	Hash scan	Table scan	Hash scan

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously). The default value is `TABLE_SCAN, INDEX_SCAN`, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`. To use hashing for any searches that does not use a primary or unique key, set this option to `INDEX_SCAN, HASH_SCAN`. To force hashing for *all* searches, set it to `TABLE_SCAN, HASH_SCAN`.

#### Note

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

Command-Line Format	<code>--slave-skip-errors=name</code>	
System Variable	Name	<code>slave_skip_errors</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string
	Default	<code>OFF</code>
	Valid Values	<code>OFF</code> [list of error codes]

		all
		ddl_exist_errors
Permitted Values	Type	string
	Default	OFF
	Valid Values	OFF
		[list of error codes]
		all
		ddl_exist_errors
Permitted Values	Type	string
	Default	OFF
	Valid Values	OFF
		[list of error codes]
		all
		ddl_exist_errors

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This option causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

MySQL 5.7 supports an additional shorthand value `ddl_exist_errors`, which is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}`

Command-Line Format	<code>--slave-sql-verify-checksum=value</code>	
Permitted Values	Type	boolean
	Default	0

	<b>Valid Values</b>	0
		1

When this option is enabled, the slave examines checksums read from the relay log, in the event of a mismatch, the slave stops with an error. Disabled by default.

The following options are used internally by the MySQL test suite for replication testing and debugging. They are not intended for use in a production setting.

- `--abort-slave-event-count`

<b>Command-Line Format</b>	<code>--abort-slave-event-count=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0

When this option is set to some positive integer *value* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *value* log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays *Yes* in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

- `--disconnect-slave-event-count`

<b>Command-Line Format</b>	<code>--disconnect-slave-event-count=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0

## Options for Logging Slave Status to Tables

MySQL 5.7 supports logging of replication slave status information to tables rather than files. Writing of the master info log and the relay log info log can be configured separately using the two server options listed here:

- `--master-info-repository={FILE|TABLE}`

<b>Command-Line Format</b>	<code>--master-info-repository=FILE TABLE</code>	
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	FILE
	<b>Valid Values</b>	FILE
		TABLE

This option causes the server to write its master info log to a file or a table. The name of the file defaults to `master.info`; you can change the name of the file using the `--master-info-file` server option.

The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_master_info` table in the `mysql` database.

- `--relay-log-info-repository={FILE|TABLE}`

<b>Command-Line Format</b>	<code>--relay-log-info-repository=FILE TABLE</code>	
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	FILE
	<b>Valid Values</b>	FILE TABLE

This option causes the server to log its relay log info to a file or a table. The name of the file defaults to `relay-log.info`; you can change the name of the file using the `--relay-log-info-file` server option.

The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_relay_log_info` table in the `mysql` database.

These options can be used to make replication slaves resilient to unexpected halts. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#), for more information.

The info log tables and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

For more information, see [Section 18.2.4, “Replication Relay and Status Logs”](#).

## System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

<b>Command-Line Format</b>	<code>--init-slave=name</code>	
<b>System Variable</b>	<b>Name</b>	<code>init_slave</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START SLAVE` statements.

### Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 14.4.2.6, “START SLAVE Syntax”](#), for more information.

- `log_slow_slave_statements`

<b>Introduced</b>	5.7.1
-------------------	-------

<b>System Variable</b>	<b>Name</b>	<code>log_slow_slave_statements</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave. This variable was added in MySQL 5.7.1. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

- `master_info_repository`

<b>Command-Line Format</b>	<code>--master-info-repository=FILE TABLE</code>	
<b>System Variable</b>	<b>Name</b>	<code>master_info_repository</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<code>FILE</code>
	<b>Valid Values</b>	<code>FILE</code> <code>TABLE</code>

The setting of this variable determines whether the slave logs master status and connection information to a `FILE` (`master.info`), or to a `TABLE` (`mysql.slave_master_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_master_info` system variable; see that variable's description for further information.

This variable must be set to `TABLE` before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to `FILE`.

- `relay_log`

<b>Command-Line Format</b>	<code>--relay-log=file_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name

The base name of the relay log file, with no paths and no file extension. By default `relay-log`. The file name of individual files for the default replication channel is `relay-log.XXXXXXX`, and for additional replication channels is `relay-log-channel.XXXXXXX`.

- `relay_log_basename`

<b>System Variable</b>	<b>Name</b>	<code>relay_log_basename</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<code>datadir + '/' + hostname + '-relay-bin'</code>

Holds the name and complete path to the relay log file.

- `relay_log_index`

<b>Command-Line Format</b>	<code>--relay-log-index</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log_index</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<code>*host_name*-relay-bin.index</code>

The name of the relay log index file for the default replication channel. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

<b>Command-Line Format</b>	<code>--relay-log-info-file=file_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log_info_file</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<code>relay-log.info</code>

The name of the file in which the slave records information about the relay logs, when `relay_log_info_repository=FILE`. If `relay_log_info_repository=TABLE`, it is the file name that would be used in case the repository was changed to `FILE`). The default name is `relay-log.info` in the data directory.

- `relay_log_info_repository`

<b>System Variable</b>	<b>Name</b>	<code>relay_log_info_repository</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	FILE
	<b>Valid Values</b>	FILE TABLE

This variable determines whether the slave's position in the relay logs is written to a [FILE](#) (`relay-log.info`) or to a [TABLE](#) (`mysql.slave_relay_log_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable; see that variable's description for further information.

This variable must be set to [TABLE](#) before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to [FILE](#).

- `relay_log_recovery`

<b>Command-Line Format</b>	<code>--relay-log-recovery</code>	
<b>System Variable</b>	<b>Name</b>	<code>relay_log_recovery</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. In MySQL 5.7, this global variable is read-only; its value can be changed by starting the slave with the `--relay-log-recovery` option, which should be used following an unexpected halt of a replication slave to ensure that no possibly corrupted relay logs are processed. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#) for more information.

This variable also interacts with `relay-log-purge`, which controls purging of logs when they are no longer needed. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency.

When `relay_log_recovery` is enabled and the slave has stopped due to errors encountered while running in multi-threaded mode, you can use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `rpl_stop_slave_timeout`

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--rpl-stop-slave-timeout=seconds</code>	
<b>System Variable</b>	<b>Name</b>	<code>rpl_stop_slave_timeout</code>

<b>Permitted Values</b>	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
	<b>Type</b>	integer
	<b>Default</b>	31536000
	<b>Min Value</b>	2
	<b>Max Value</b>	31536000

In MySQL 5.7.2 and later, you can control the length of time (in seconds) that **STOP SLAVE** waits before timing out by setting this variable. This can be used to avoid deadlocks between **STOP SLAVE** and other slave SQL statements using different client connections to the slave. The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent **STOP SLAVE** statements. This variable affects only the client that issues a **STOP SLAVE** statement. When the timeout is reached, the issuing client stops waiting for the slave threads to stop, but the slave threads continue to try to stop.

- `slave_checkpoint_group`

<b>Command-Line Format</b>	<code>--slave-checkpoint-group=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_checkpoint_group=#</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	512
	<b>Min Value</b>	32
	<b>Max Value</b>	524280
	<b>Block Size</b>	8

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent **START SLAVE** commands.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this variable. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_period`

<b>Command-Line Format</b>	<code>--slave-checkpoint-period=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_checkpoint_period=#</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	300
	<b>Min Value</b>	1
	<b>Max Value</b>	4G

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this variable. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `slave_compressed_protocol`

<b>Command-Line Format</b>	<code>--slave_compressed_protocol</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_compressed_protocol</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Whether to use compression of the slave/master protocol if both the slave and the master support it. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START SLAVE` statement, as well as reconnections made by a running I/O thread (for example after issuing a `CHANGE MASTER TO MASTER_RETRY_COUNT` statement).

- `slave_exec_mode`

<b>Command-Line Format</b>	<code>--slave-exec-mode=mode</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_exec_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	STRICT (ALL)
	<b>Default</b>	IDEMPOTENT (NDB)
	<b>Valid Values</b>	IDEMPOTENT STRICT

Controls how a slave thread resolves conflicts and errors during replication. `STRICT` mode is the default, and is suitable for most cases. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. This mode should only be used with MySQL Cluster Replication in some special scenarios, such as multi-master replication, and circular replication. (See [Section 20.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”](#), and [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.) Setting this variable takes effect for all replication channels immediately, including running channels.

#### Warning

The `mysqld` supplied with MySQL Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as `IDEMPOTENT`.

`IDEMPOTENT` mode is supported only by `NDB` and is used when replicating `NDB` to `InnoDB`.

- `slave_load_tmpdir`

<b>Command-Line Format</b>	<code>--slave-load-tmpdir=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_load_tmpdir</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	directory name
	<b>Default</b>	<code>/tmp</code>

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements. Setting this variable takes effect for all replication channels immediately, including running channels.

- `slave_max_allowed_packet`

<b>System Variable</b>	<b>Name</b>	<code>slave_max_allowed_packet</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>1073741824</code>
	<b>Min Value</b>	<code>1024</code>
	<b>Max Value</b>	<code>1073741824</code>

This variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. Setting this variable takes effect for all replication channels immediately, including running channels.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_net_timeout`

<b>Command-Line Format</b>	<code>--slave-net-timeout=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_net_timeout</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	<code>3600</code>
	<b>Min Value</b>	<code>1</code>
	<b>Max Value</b>	
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	integer
	<b>Default</b>	<code>60</code>
	<b>Min Value</b>	<code>1</code>
	<b>Max Value</b>	

The number of seconds to wait for more data from a master/slave connection before aborting the read. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

- `slave_parallel_type=type`

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--slave-parallel-type=type</code>	
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>DATABASE</code>
	<b>Valid Values</b>	<code>DATABASE</code>
		<code>LOGICAL_CLOCK</code>

When using a multi-threaded slave (`slave_parallel_workers` is greater than 0), this variable specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. See `--slave-parallel-type` for more information.

- `slave_parallel_workers`

<b>Command-Line Format</b>	<code>--slave-parallel-workers=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_parallel_workers</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	1024

Sets the number of slave applier threads for executing replication transactions in parallel. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier threads. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread. Setting `slave_parallel_workers` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this variable. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

A multi-threaded slave provides parallel execution by using a coordinator thread and the number of applier threads configured by this variable. The way which transactions are distributed among applier threads is configured by `slave_parallel_type`. The transactions that the slave applies in parallel may commit out of order, unless `slave_preserve_commit_order=1`. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the master

have been executed on the slave. This has implications for logging and recovery when using a multi-threaded slave. For example, on a multi-threaded slave the `START SLAVE UNTIL` statement only supports using `SQL_AFTER_MTS_GAPS`.

In MySQL 5.7.5 and later, retrying of transactions is supported when multi-threading is enabled on a slave. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multi-threaded slaves.

- `slave_pending_jobs_size_max`

<b>System Variable</b>	<b>Name</b>	<code>slave_pending_jobs_size_max</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	16M
	<b>Min Value</b>	1024
	<b>Max Value</b>	18EB
	<b>Block Size</b>	1024

For multi-threaded slaves, this variable sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The minimum possible value for this variable is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

#### Important

The value of this variable must not be less than the master's value for `max_allowed_packet`; otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `slave_preserve_commit_order`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--slave-preserve-commit-order=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_preserve_commit_order</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	0

	<b>Valid Values</b>	0
		1

For multi-threaded slaves, enabling this variable ensures that transactions are externalized on the slave in the same order as they appear in the slave's relay log. Setting this variable has no effect on slaves for which multi-threading is not enabled. All replication threads (for all replication channels if you are using multiple replication channels) must be stopped before changing this variable. `--log-bin` and `--log-slave-updates` must be enabled on the slave. In addition `--slave-parallel-type` must be set to `LOGICAL_CLOCK`.

Once a multi-threaded slave has been started, transactions can begin to execute in parallel. With `slave_preserve_commit_order` enabled, the executing thread waits until all previous transactions are committed before committing. While the slave thread is waiting for other workers to commit their transactions it reports its status as `Waiting for preceding transaction to commit`. (Prior to MySQL 5.7.8, this was shown as `Waiting for its turn to commit`.) Enabling this mode on a multi-threaded slave ensures that it never enters a state that the master was not in. This makes it well suited to using replication for read scale-out. See [Section 18.3.4, “Using Replication for Scale-Out”](#).

When using a multi-threaded slave, if `slave_preserve_commit_order` is not enabled, there is a chance of gaps in the sequence of transactions that have been executed from the slave's relay log. When this option is enabled, there is not this chance of gaps, but `Exec_master_log_pos` may be behind the position up to which has been executed. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `slave_rows_search_algorithms`

<b>System Variable</b>	<b>Name</b>	<code>slave_rows_search_algorithms=list</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	set
	<b>Default</b>	<code>TABLE_SCAN, INDEX_SCAN</code>
	<b>Valid Values</b>	<code>TABLE_SCAN, INDEX_SCAN</code>
		<code>INDEX_SCAN, HASH_SCAN</code>
		<code>TABLE_SCAN, HASH_SCAN</code>
		<code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN, HASH_SCAN</code> )

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, using some other key, or using no key at all. Setting this variable takes effect for all replication channels immediately, including running channels.

This variable takes a comma-separated list of at least 2 values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The value expected as a string, so the value must be quoted. In addition, the value must not contain any spaces. Possible combinations (lists) and their effects are shown in the following table:

Index used / option value	INDEX_SCAN, HASH_SCAN or INDEX_SCAN, TABLE_SCAN, HASH_SCAN	INDEX_SCAN, TABLE_SCAN, HASH_SCAN	TABLE_SCAN, HASH_SCAN
Primary key or unique key	Index scan	index scan	Index hash
(Other) Key	Index hash	Index scan	Index hash
No index	Table hash	Table scan	Table hash

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement, as shown here:

```
mysql> SET GLOBAL slave_rows_search_algorithms = "INDEX_SCAN, TABLE_SCAN";
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE '%algorithms%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_rows_search_algorithms | TABLE_SCAN, INDEX_SCAN |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET GLOBAL slave_rows_search_algorithms = "TABLE_SCAN, INDEX_SCAN";
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE '%algorithms%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_rows_search_algorithms | TABLE_SCAN, INDEX_SCAN |
+-----+-----+
1 row in set (0.00 sec)
```

The default value is `TABLE_SCAN, INDEX_SCAN`, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`. To use hashing for any searches that does not use a primary or unique key, set this variable to `INDEX_SCAN, HASH_SCAN`. To force hashing for *all* searches, set it to `TABLE_SCAN, HASH_SCAN`.

- `slave_skip_errors`

<b>Command-Line Format</b>	<code>--slave-skip-errors=name</code>	
<b>System Variable</b>	<b>Name</b>	<code>slave_skip_errors</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<code>OFF</code>
	<b>Valid Values</b>	<code>OFF</code>
		[list of error codes]

		all
		ddl_exist_errors
Permitted Values	Type	string
	Default	OFF
	Valid Values	OFF
		[list of error codes]
		all
		ddl_exist_errors
Permitted Values	Type	string
	Default	OFF
	Valid Values	OFF
		[list of error codes]
		all
		ddl_exist_errors

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This variable causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value. The setting of this variable takes effect immediately, even for running replication threads.

- `slave_sql_verify_checksum`

System Variable	Name	<code>slave_sql_verify_checksum</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	1
	Valid Values	0
		1

Cause the slave SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the slave stops with an error. Setting this variable takes effect for all replication channels immediately, including running channels.

#### Note

The slave I/O thread always reads checksums if possible when accepting events from over the network.

- `slave_transaction_retries`

Command-Line Format	<code>--slave_transaction_retries=#</code>
System Variable	Name <code>slave_transaction_retries</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	10
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	10
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615

If a replication slave SQL thread fails to execute a transaction because of an [InnoDB](#) deadlock or because the transaction's execution time exceeded [InnoDB's innodb\\_lock\\_wait\\_timeout](#) or [NDB's TransactionDeadlockDetectionTimeout](#) or [TransactionInactiveTimeout](#), it automatically retries [slave\\_transaction\\_retries](#) times before stopping with an error. The default value is 10. Setting this variable takes effect for all replication channels immediately, including running channels.

As of MySQL 5.7.5, retrying of transactions is supported when multi-threading is enabled on a slave. In previous versions, [slave\\_transaction\\_retries](#) was treated as equal to 0 when using multi-threaded slaves.

- [slave\\_type\\_conversions](#)

<b>Command-Line Format</b>	<code>--slave_type_conversions=set</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">slave_type_conversions</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b> (<= 5.7.1)	<b>Type</b>	set
	<b>Default</b>	
	<b>Valid Values</b>	<a href="#">ALL_LOSSY</a>
		<a href="#">ALL_NON_LOSSY</a>
<b>Permitted Values</b> (>= 5.7.2)	<b>Type</b>	set
	<b>Default</b>	
	<b>Valid Values</b>	<a href="#">ALL_LOSSY</a>
		<a href="#">ALL_NON_LOSSY</a>
		<a href="#">ALL_SIGNED</a>
		<a href="#">ALL_UNSIGNED</a>

Controls the type conversion mode in effect on the slave when using row-based replication. In MySQL 5.7.2 and later, its value is a comma-delimited set of zero or more elements from the list: [ALL\\_LOSSY](#), [ALL\\_NON\\_LOSSY](#), [ALL\\_SIGNED](#), [ALL\\_UNSIGNED](#). Set this variable to an empty string to disallow type conversions between the master and the slave. Setting this variable takes effect for all replication channels immediately, including running channels.

[ALL\\_SIGNED](#) and [ALL\\_UNSIGNED](#) were added in MySQL 5.7.2 (Bug#15831300). For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

- `sql_slave_skip_counter`

<b>System Variable</b>	<b>Name</b>	<code>sql_slave_skip_counter</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer

The number of events from the master that a slave server should skip. Setting the option has no immediate effect. The variable applies to the next `START SLAVE` statement; the next `START SLAVE` statement also changes the value back to 0. When this variable is set to a non-zero value and there are multiple replication channels configured, the `START SLAVE` statement can only be used with the `FOR CHANNEL channel` clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `--gtid-mode=ON`. In MySQL 5.7.1 and later, trying to do so is specifically disallowed. (Bug #15833516) If you need to skip transactions when employing GTIDs, use `gtid_executed` from the master instead. See [Injecting empty transactions](#), for information about how to do this.

#### Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 14.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

- `sync_master_info`

<b>Command-Line Format</b>	<code>--sync-master-info=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>sync_master_info</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (32-bit platforms)</b>	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0

	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615

The effects of this variable on a replication slave depend on whether the slave's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

**master\_info\_repository = FILE.** If the value of `sync_master_info` is greater than 0, the slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

**master\_info\_repository = TABLE.** If the value of `sync_master_info` is greater than 0, the slave updates its master info repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

- `sync_relay_log`

<b>Command-Line Format</b>	<code>--sync-relay-log=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>sync_relay_log</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

<b>Command-Line Format</b>	<code>--sync-relay-log-info=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>sync_relay_log_info</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615

The effects of this variable on the slave depend on the server's `relay_log_info_repository` setting (`FILE` or `TABLE`), and if this is `TABLE`, additionally on whether the storage engine used by the relay log info table is transactional (such as `InnoDB`) or not (`MyISAM`). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are shown in the following table:

<code>sync_relay_log_info</code>	<code>relay_log_info_repository</code>		
	<code>FILE</code>	<code>TABLE</code>	
		Transactional	Nontransactional
$N > 0$	The slave synchronizes its <code>relay-log.info</code> file to disk (using <code>fdatasync()</code> ) after every $N$ transactions.	The table is updated after each transaction. ( $N$ is effectively ignored.)	The table is updated after every $N$ events.
0	The MySQL server performs no synchronization of the <code>relay-log.info</code> file to disk; instead, the server relies on the operating system to flush		The table is never updated.

sync_relay_log_info	relay_log_info_repository		
	FILE	TABLE	
		Transactional	Nontransactional
	its contents periodically as with any other file.		

The default value for `sync_relay_log_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

### 18.1.6.4 Binary Logging Options and Variables

#### Startup Options Used with Binary Logging

#### System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 6.4.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 6.1.4, “Server Command Options”](#), and [Section 6.1.5, “Server System Variables”](#).

#### Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

Command-Line Format	<code>--binlog-row-event-max-size=#</code>	
Permitted Values (32-bit platforms)	Type	integer
	Default	8192
	Min Value	256
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	8192
	Min Value	256
	Max Value	18446744073709551615

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 8192. See [Section 18.2.1, “Replication Formats”](#).

- `--log-bin[=base_name]`

Command-Line Format	<code>--log-bin</code>	
System Variable	Name	<code>log_bin</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 6.4.4, “The Binary Log”](#).

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see [Section B.5.7, “Known Issues in MySQL”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

When the server reads an entry from the index file, it checks whether the entry contains a relative path, and if it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. (In older versions of MySQL, manual intervention was required whenever relocating the binary log or relay log files.) (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. The binary log file name (with path) is available as the `log_bin_basename` system variable.

In MySQL 5.7.3 and later, if you specify this option without also specifying a `--server-id`, the server is not allowed to start. (Bug #11763963, Bug #56739)

- `--log-bin-index[=file_name]`

<b>Command-Line Format</b>	<code>--log-bin-index=file_name</code>	
<b>Permitted Values</b>	<b>Type</b>	file name

The index file for binary log file names. See [Section 6.4.4, “The Binary Log”](#). If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

<b>Command-Line Format</b>	<code>--log-bin-trust-function-creators</code>	
<b>System Variable</b>	<b>Name</b>	<code>log_bin_trust_function_creators</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to `1`. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 22.7, “Binary Logging of Stored Programs”](#).

- `--log-bin-use-vl-row-events[={0|1}]`

<b>Command-Line Format</b>	<code>--log-bin-use-v1-row-events[={0 1}]</code>	
<b>System Variable</b>	<b>Name</b>	<code>log_bin_use_v1_row_events</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	0

MySQL 5.7 uses Version 2 binary log row events, which cannot be read by MySQL Server releases prior to MySQL 5.6.6. Setting this option to 1 causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves. Setting `--log-bin-use-v1-row-events` to 0 (the default) causes `mysqld` to use Version 2 binary log events.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 18.1.6.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

<b>Command-Line Format</b>	<code>--binlog-do-db=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

<b>Command-Line Format</b>	<code>--binlog-ignore-db=name</code>	
<b>Permitted Values</b>	<b>Type</b>	string

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Prior to MySQL 5.7.2, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.7.2 and later, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.** MySQL 5.7 supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

<b>Command-Line Format</b>	<code>--binlog-checksum=type</code>	
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	CRC32
	<b>Valid Values</b>	NONE CRC32

Enabling this option causes the master to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported, and CRC32 is the default.

- `--master-verify-checksum={0|1}`

<b>Command-Line Format</b>	<code>--master-verify-checksum=name</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enabling this option causes the master to verify events from the binary log using checksums, and to stop with an error in the event of a mismatch. Disabled by default.

To control reading of checksums by the slave (from the relay) log, use the `--slave-sql-verify-checksum` option.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

<b>Command-Line Format</b>	<code>--max-binlog-dump-events=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

<b>Command-Line Format</b>	<code>--sporadic-binlog-dump-fail</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	FALSE

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--binlog-rows-query-log-events`

<b>Command-Line Format</b>	<code>--binlog-rows-query-log-events</code>	
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>

This option enables `binlog_rows_query_log_events`.

## System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see [Section 6.1.5, “Server System Variables”](#).

- `binlog_cache_size`

<b>Command-Line Format</b>	<code>--binlog_cache_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_cache_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (32-bit platforms)</b>	<b>Type</b>	integer
	<b>Default</b>	<code>32768</code>
	<b>Min Value</b>	<code>4096</code>
	<b>Max Value</b>	<code>4294967295</code>
<b>Permitted Values (64-bit platforms)</b>	<b>Type</b>	integer
	<b>Default</b>	<code>32768</code>
	<b>Min Value</b>	<code>4096</code>
	<b>Max Value</b>	<code>18446744073709551615</code>

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 6.4.4, “The Binary Log”](#).

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

<b>System Variable</b>	<b>Name</b>	<code>binlog_checksum</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<code>CRC32</code>
	<b>Valid Values</b>	<code>NONE</code>
		<code>CRC32</code>

When enabled, this variable causes the master to write a checksum for each event in the binary log. `binlog_checksum` supports the values `NONE` (disabled) and `CRC32`. The default is `CRC32`.

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

Setting this variable on the master to a value unrecognized by the slave causes the slave to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older slaves is a concern, you may want to set the value explicitly to `NONE`.

- `binlog_direct_non_transactional_updates`

<b>Command-Line Format</b>	<code>--binlog_direct_non_transactional_updates[=value]</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_direct_non_transactional_updates</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

*`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format`*

is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

### Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

In MySQL 5.7, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- `binlog_error_action`

<b>Introduced</b>	5.7.6	
<b>Command-Line Format</b>	<code>--binlog_error_action[=value]</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_error_action</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>IGNORE_ERROR</code>
	<b>Valid Values</b>	<code>IGNORE_ERROR</code> <code>ABORT_SERVER</code>
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>ABORT_SERVER</code>
	<b>Valid Values</b>	<code>IGNORE_ERROR</code> <code>ABORT_SERVER</code>

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the master's log to become inconsistent and replication slaves to lose synchronization.

In MySQL 5.7.7 and later, this variable defaults to `ABORT_SERVER`, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. Upon server restart, all of the previously prepared and binary logged transactions are committed, while any transactions which were prepared but not binary logged due to the error are aborted.

When `binlog_error_action` is set to `IGNORE_ERROR`, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again. This provides backward compatibility with older versions of MySQL.

In previous releases this variable was named `binlogging_impossible_mode`.

- `binlog_format`

<b>Command-Line Format</b>	<code>--binlog-format=format</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_format</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>STATEMENT</code>
	<b>Valid Values</b>	<code>ROW</code>
		<code>STATEMENT</code>
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>ROW</code>
	<b>Valid Values</b>	<code>ROW</code>
		<code>STATEMENT</code>
		<code>MIXED</code>

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See [Section 18.2.1, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

#### Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

Prior to MySQL 5.7.7, the default format was `STATEMENT`. In MySQL 5.7.7 and later the default is `ROW`. *Exception:* In MySQL Cluster, the default is `MIXED`; statement-based replication is not supported for MySQL Cluster.

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#).

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.

- From within a transaction.

Trying to switch the format in those cases results in an error.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlog_group_commit_sync_delay`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--binlog-group-commit-sync-delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_group_commit_sync_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	1000000

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default `binlog-group-commit-sync-delay` is set to 0, meaning that there is no delay. Setting `binlog-group-commit-sync-delay` to a microsecond delay enables more transactions to be synchronized together to disk at once, reducing the overall time to commit a group of transactions because the larger groups require fewer time units per group. With the correct tuning, this can increase slave performance without compromising the master's throughput.

- `binlog_group_commit_sync_no_delay_count`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--binlog-group-commit-sync-no-delay-count=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_group_commit_sync_no_delay_count</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer

	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	1000000

The maximum number of transactions to wait for before aborting the current delay as specified by `binlog-group-commit-sync-delay`. If `binlog-group-commit-sync-delay` is set to 0, then this option has no effect.

- `binlogging_impossible_mode`

<b>Introduced</b>	5.7.5	
<b>Deprecated</b>	5.7.6	
<b>Command-Line Format</b>	<code>--binlogging_impossible_mode[=value]</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlogging_impossible_mode</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>IGNORE_ERROR</code>
	<b>Valid Values</b>	<code>IGNORE_ERROR</code> <code>ABORT_SERVER</code>

This option is deprecated and will be removed in a future MySQL release. Use the renamed `binlog_error_action` to control what happens when the server cannot write to the binary log.

- `binlog_max_flush_queue_time`

<b>Deprecated</b>	5.7.9	
<b>System Variable</b>	<b>Name</b>	<code>binlog_max_flush_queue_time</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	100000

Formerly, this controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. In MySQL 5.7, this variable no longer has any effect.

`binlog_max_flush_queue_time` is deprecated as of MySQL 5.7.9, and is marked for eventual removal in a future MySQL release.

- `binlog_order_commits`

<b>System Variable</b>	<b>Name</b>	<code>binlog_order_commits</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>ON</code>

When this variable is enabled on a master (the default), transactions are externalized in the same order as they are written to the binary log. If disabled, transactions may be committed in parallel. In some cases, disabling this variable might produce a performance increment.

- `binlog_row_image`

<b>Command-Line Format</b>	<code>--binlog-row-image=image_type</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_row_image=image_type</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>full</code>
	<b>Valid Values</b>	<code>full</code> (Log all columns)
		<code>minimal</code> (Log only changed columns, and columns needed to identify rows)
		<code>noblob</code> (Log all columns, except for unneeded BLOB and TEXT columns)

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

#### Note

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or

columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are `NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- `full`: Log all columns in both the before image and the after image.
- `minimal`: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image that are actually changed.
- `noblob`: Log all columns (same as `full`), except for `BLOB` and `TEXT` columns that are not required to identify rows, or that have not changed.

#### Note

This variable is not supported by MySQL Cluster; setting it has no effect on the logging of `NDB` tables.

The default value is `full`.

In MySQL 5.5 and earlier, full row images are always used for both before images and after images. If you need to replicate from a newer master to a slave running MySQL 5.5 or earlier, the master should always use this value.

When using `minimal` or `noblob`, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the master and slave silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is `STATEMENT`. When `binlog_format` is `MIXED`, the setting for `binlog_row_image` is applied to changes that are logged using row-based format, but this setting no effect on changes logged as statements.

Setting `binlog_row_image` on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- `binlog_rows_query_log_events`

System Variable	Name	<code>binlog_rows_query_log_events</code>
	Variable Scope	Global, Session

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<a href="#">FALSE</a>

The [binlog\\_rows\\_query\\_log\\_events](#) system variable affects row-based logging only. When enabled, it causes the MySQL Server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes; such as obtaining the original query issued on the master when it cannot be reconstructed from the row updates.

These events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using mysqlbinlog's [--verbose](#) option twice, either as "-vv" or "--verbose --verbose".

- [binlog\\_stmt\\_cache\\_size](#)

<b>Command-Line Format</b>	<a href="#">--binlog_stmt_cache_size=#</a>	
<b>System Variable</b>	<b>Name</b>	<a href="#">binlog_stmt_cache_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (32-bit platforms)</b>	<b>Type</b>	integer
	<b>Default</b>	<a href="#">32768</a>
	<b>Min Value</b>	<a href="#">4096</a>
	<b>Max Value</b>	<a href="#">4294967295</a>
<b>Permitted Values (64-bit platforms)</b>	<b>Type</b>	integer
	<b>Default</b>	<a href="#">32768</a>
	<b>Min Value</b>	<a href="#">4096</a>
	<b>Max Value</b>	<a href="#">18446744073709551615</a>

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. Separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled ([--log-bin](#) option). If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The [Binlog\\_stmt\\_cache\\_use](#) and [Binlog\\_stmt\\_cache\\_disk\\_use](#) status variables can be useful for tuning the size of this variable. See [Section 6.4.4, “The Binary Log”](#).

The [binlog\\_cache\\_size](#) system variable sets the size for the transaction cache.

- [log\\_bin](#)

<b>System Variable</b>	<b>Name</b>	<a href="#">log_bin</a>
------------------------	-------------	-------------------------

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See [Section 6.4.4, “The Binary Log”](#).

- `log_bin_basename`

<b>System Variable</b>	<b>Name</b>	<code>log_bin_basename</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name
	<b>Default</b>	<code>datadir + '/' + hostname + '-bin'</code>

Holds the name and complete path to the binary log file. Unlike the `log_bin` system variable, `log_bin_basename` reflects the name set with the `--log-bin` server option.

- `log_bin_index`

<b>System Variable</b>	<b>Name</b>	<code>log_bin_index</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	file name

The index file for binary log file names.

- `log_bin_use_v1_row_events`

<b>Command-Line Format</b>	<code>--log-bin-use-v1-row-events[={0 1}]</code>	
<b>System Variable</b>	<b>Name</b>	<code>log_bin_use_v1_row_events</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	0

Shows whether Version 2 binary logging is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and

thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of MySQL Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB $EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

#### Note

MySQL Cluster NDB 7.5 uses Version 2 binary log row events by default. You should keep this mind when planning upgrades or downgrades, and for setups using MySQL Cluster Replication.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `log_slave_updates`

<b>Command-Line Format</b>	<code>--log-slave-updates</code>	
<b>System Variable</b>	<b>Name</b>	<code>log_slave_updates</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

- `log_statements_unsafe_for_binlog`

<b>Introduced</b>	5.7.11	
<b>System Variable</b>	<b>Name</b>	<code>log_statements_unsafe_for_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>ON</code>

If error 1592 is encountered, controls whether the generated warnings are added to the error log or not.

- `master_verify_checksum`

<b>System Variable</b>	<b>Name</b>	<code>master_verify_checksum</code>
------------------------	-------------	-------------------------------------

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enabling this variable causes the master to examine checksums when reading from the binary log. `master_verify_checksum` is disabled by default; in this case, the master uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- `max_binlog_cache_size`

<b>Command-Line Format</b>	<code>--max_binlog_cache_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>max_binlog_cache_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	18446744073709551615
	<b>Min Value</b>	4096
	<b>Max Value</b>	18446744073709551615

If a transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

`max_binlog_cache_size` sets the size for the transaction cache only; the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

In MySQL 5.7, the visibility to sessions of `max_binlog_cache_size` matches that of the `binlog_cache_size` system variable; in other words, changing its value effects only new sessions that are started after the value is changed.

- `max_binlog_size`

<b>Command-Line Format</b>	<code>--max_binlog_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>max_binlog_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer

	<b>Default</b>	1073741824
	<b>Min Value</b>	4096
	<b>Max Value</b>	1073741824

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

<b>Command-Line Format</b>	<code>--max_binlog_stmt_cache_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>max_binlog_stmt_cache_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	18446744073709547520
	<b>Min Value</b>	4096
	<b>Max Value</b>	18446744073709547520

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `sync_binlog`

<b>Command-Line Format</b>	<code>--sync-binlog=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>sync_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	0

	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

Controls the number of binary log commit groups to collect before synchronizing the binary log to disk. When `sync_binlog=0`, the binary log is never synchronized to disk, and when `sync_binlog` is set to a value greater than 0 this number of binary log commit groups is periodically synchronized to disk. When `sync_binlog=1`, all transactions are synchronized to the binary log before they are committed. Therefore, even in the event of an unexpected restart, any transactions that are missing from the binary log are only in prepared state. This causes the server's automatic recovery routine to roll back those transactions. This guarantees that no transaction is lost from the binary log, and is the safest option. However this can have a negative impact on performance because of an increased number of disk writes. Using a higher value improves performance, but with the increased risk of data loss.

When `sync_binlog=0` or `sync_binlog` is greater than 1, transactions are committed without having been synchronized to disk. Therefore, in the event of a power failure or operating system crash, it is possible that the server has committed some transactions that have not been synchronized to the binary log. Therefore it is impossible for the recovery routine to recover these transactions and they will be lost from the binary log.

Prior to MySQL 5.7.7, the default value of `sync_binlog` was 0, which configures no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. MySQL 5.7.7 and later use a default value of 1, which is the safest choice, but as noted above can impact performance.

### 18.1.6.5 Global Transaction ID Options and Variables

#### Startup Options Used with GTID Replication

#### System Variables Used with GTID Replication

The MySQL Server options and system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs).

For additional information, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

### Startup Options Used with GTID Replication

The following server startup options are used with GTID-based replication:

- `--enforce-gtid-consistency`

<b>Command-Line Format</b>	<code>--enforce-gtid-consistency[=value]</code>	
<b>System Variable</b> (<= 5.7.5)	<b>Name</b>	<code>enforce_gtid_consistency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>System Variable</b> (>= 5.7.6)	<b>Name</b>	<code>enforce_gtid_consistency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (<= 5.7.5)	<b>Type</b>	boolean
	<b>Default</b>	<code>false</code>
<b>Permitted Values</b> (>= 5.7.6)	<b>Type</b>	enumeration
	<b>Default</b>	<code>OFF</code>
	<b>Valid Values</b>	<code>OFF</code>
		<code>ON</code>
		<code>WARN</code>

When enabled, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this option to `ON` before enabling GTID based replication.

The values that `--enforce-gtid-consistency` can be configured to are:

- `OFF`: all transactions are allowed to violate GTID consistency.
- `ON`: no transaction is allowed to violate GTID consistency.
- `WARN`: all transactions are allowed to violate GTID consistency, but a warning is generated in this case. Added in MySQL 5.7.6.

Setting `--enforce-gtid-consistency` without a value is an alias for `--enforce-gtid-consistency=ON`. This impacts on the behavior of the variable, see `enforce_gtid_consistency`.

Only statements that can be logged using GTID safe statements can be logged when `enforce-gtid-consistency` is set to `ON`, so the operations listed here cannot be used with this option:

- `CREATE TABLE ... SELECT` statements
- `CREATE TEMPORARY TABLE` or `DROP TEMPORARY TABLE` statements inside transactions
- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all *nontransactional* tables are temporary.

For more information, see [Section 18.1.3.4, “Restrictions on Replication with GTIDs”](#).

- `--executed-gtids-compression-period`

<b>Introduced</b>	5.7.5	
<b>Deprecated</b>	5.7.6	
<b>Command-Line Format</b>	<code>--executed-gtids-compression-period=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `--gtid-mode`

<b>Command-Line Format</b>	<code>--gtid-mode=MODE</code>	
<b>System Variable (&lt;= 5.7.5)</b>	<b>Name</b>	<code>gtid_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>System Variable (&gt;= 5.7.6)</b>	<b>Name</b>	<code>gtid_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.5)</b>	<b>Type</b>	enumeration
	<b>Default</b>	OFF
	<b>Valid Values</b>	OFF
		<code>UPGRADE_STEP_1</code>
		<code>UPGRADE_STEP_2</code>
<b>Permitted Values (&gt;= 5.7.6)</b>	<b>Type</b>	enumeration
	<b>Default</b>	OFF
	<b>Valid Values</b>	OFF
		<code>OFF_PERMISSIVE</code>
		<code>ON_PERMISSIVE</code>
		ON

This option specifies whether global transaction identifiers (GTIDs) are used to identify transactions. Setting this option to `--gtid-mode=ON` requires that `enforce-gtid-consistency` be set to `ON`. Prior to MySQL 5.7.6 the `gtid_mode` variable which this option controls could only be set at server startup. In MySQL 5.7.6 and later the `gtid_mode` variable is dynamic and enables GTID based

replication to be configured online. Before using this feature, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

Prior to MySQL 5.7.5, starting the server with `--gtid-mode=ON` required that the server also be started with the `--log-bin`, `--log-slave-updates`, options. In versions of MySQL 5.7.5 and later this is not a requirement. See [mysql.gtid\\_executed Table](#).

- `--gtid-executed-compression-period`

<b>Introduced</b>	5.7.6	
<b>Command-Line Format</b>	<code>--gtid-executed-compression-period=#</code>	
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

Compress the `mysql.gtid_executed` table each time this many transactions have taken place. A setting of 0 means that this table is not compressed. No compression of the table occurs when binary logging is enabled, therefore the option has no effect unless `log_bin` is `OFF`.

See [mysql.gtid\\_executed Table Compression](#), for more information.

In MySQL version 5.7.5, this variable was added as `executed_gtid_compression_period` and in MySQL version 5.7.6 it was renamed to `gtid_executed_compression_period`.

## System Variables Used with GTID Replication

The following system variables are used with GTID-based replication:

- `binlog_gtid_simple_recovery`

<b>Introduced</b>	5.7.6	
<b>Command-Line Format</b>	<code>--binlog-gtid-simple-recovery</code>	
<b>System Variable</b>	<b>Name</b>	<code>binlog_gtid_simple_recovery</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>TRUE</code>

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts. In MySQL version 5.7.5, this variable was added as `simplified_binlog_gtid_recovery` and in MySQL version 5.7.6 it was renamed to `binlog_gtid_simple_recovery`.

When `binlog_gtid_simple_recovery=FALSE`, the method of iterating the binary log files is:

- To initialize `gtid_executed`, binary log files are iterated from the newest file, stopping at the first binary log that has any `Previous_gtid_log_event`. All GTIDs from `Previous_gtid_log_event` and `Gtid_log_events` are read from this binary log file. This GTID set is stored internally and called `gtids_in_binlog`. The value of `gtid_executed` is computed as the union of this set and the GTIDs stored in the `mysql.gtid_executed` table.

This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

- To initialize `gtid_purged`, binary log files are iterated from the oldest to the newest, stopping at the first binary log that contains either a `Previous_gtid_log_event` that is non-empty (that has at least one GTID) or that has at least one `Gtid_log_event`. From this binary log it reads `Previous_gtid_log_event`. This GTID set is subtracted from `gtids_in_binlog` and the result stored in the internal variable `gtids_in_binlog_not_purged`. The value of `gtid_purged` is initialized to the value of `gtid_executed`, minus `gtids_in_binlog_not_purged`.

When `binlog_gtid_simple_recovery=TRUE`, which is the default in MySQL 5.7.7 and later, the server iterates only the oldest and the newest binary log files and the values of `gtid_purged` and `gtid_executed` are computed based only on `Previous_gtid_log_event` or `Gtid_log_event` found in these files. This ensures only two binary log files are iterated during server restart or when binary logs are being purged.

#### Note

If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:

- The newest binary log was generated by MySQL 5.7.5 or older, and `gtid_mode` was `ON` for some binary logs but `OFF` for the newest binary log.
- A `SET GTID_PURGED` statement was issued on a MySQL version prior to 5.7.7, and the binary log that was active at the time of the `SET GTID_PURGED` has not yet been purged.

If an incorrect GTID set is computed in either situation, it will remain incorrect even if the server is later restarted, regardless of the value of this option.

- `enforce_gtid_consistency`

Command-Line Format	<code>--enforce-gtid-consistency[=value]</code>	
<b>System Variable</b> (<= 5.7.5)	<b>Name</b>	<code>enforce_gtid_consistency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>System Variable</b> (>= 5.7.6)	<b>Name</b>	<code>enforce_gtid_consistency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (<= 5.7.5)	<b>Type</b>	boolean

	<b>Default</b>	false
<b>Permitted Values</b> (>= 5.7.6)	<b>Type</b>	enumeration
	<b>Default</b>	OFF
	<b>Valid Values</b>	OFF
		ON
		WARN

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this variable to **ON** before enabling GTID based replication.

The values that `enforce_gtid_consistency` can be configured to are:

- **OFF**: all transactions are allowed to violate GTID consistency.
- **ON**: no transaction is allowed to violate GTID consistency.
- **WARN**: all transactions are allowed to violate GTID consistency, but a warning is generated in this case. Added in MySQL 5.7.6.

For more information on statements that can be logged using GTID based replication, see `--enforce-gtid-consistency`.

Prior to MySQL 5.7.6, the boolean `enforce-gtid-consistency` defaulted to **OFF**. To maintain compatibility with previous versions, in MySQL 5.7.6 the enumeration defaults to **OFF**, and setting `--enforce-gtid-consistency` without a value is interpreted as setting the value to **ON**. The variable also has multiple textual aliases for the values: `0=OFF=FALSE`, `1=ON=TRUE`, `2=WARN`. This differs from other enumeration types but maintains compatibility with the boolean type used in previous versions. These changes impact on what is returned by the variable. Using `SELECT @@ENFORCE_GTID_CONSISTENCY`, `SHOW VARIABLES LIKE 'ENFORCE_GTID_CONSISTENCY'`, and `SELECT * FROM INFORMATION_SCHEMA.VARIABLES WHERE 'VARIABLE_NAME' = 'ENFORCE_GTID_CONSISTENCY'`, all return the textual form, not the numeric form. This is an incompatible change, since `@@ENFORCE_GTID_CONSISTENCY` returns the numeric form for booleans but returns the textual form for `SHOW` and the Information Schema.

- `executed_gtids_compression_period`

<b>Introduced</b>	5.7.5	
<b>Deprecated</b>	5.7.6	
<b>System Variable</b> (>= 5.7.5)	<b>Name</b>	<code>executed_gtids_compression_period</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `gtid_executed`

<b>System Variable</b>	<b>Name</b>	<code>gtid_executed</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	No
<b>System Variable (&gt;= 5.7.7)</b>	<b>Name</b>	<code>gtid_executed</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a `SET gtid_purged` statement. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, `@@global.gtid_executed` is initialized. See [binlog\\_gtid\\_simple\\_recovery](#) for more information on how binary logs are iterated to populate `gtid_executed`. GTIDs are then added to the set as transactions are executed, or if any `SET gtid_purged` statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@global.gtid_executed, @@global.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`.

Prior to MySQL 5.7.7, this variable could also be used with session scope, where it contained a representation of the set of transactions that are written to the cache in the current session. The session scope was deprecated in MySQL 5.7.7.

- `gtid_executed_compression_period`

<b>Introduced</b>	5.7.6	
<b>System Variable (&gt;= 5.7.6)</b>	<b>Name</b>	<code>gtid_executed_compression_period</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1000

	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

Compress the `mysql.gtid_executed` table each time this many transactions have been processed. A setting of 0 means that this table is not compressed. Since no compression of the table occurs when using the binary log, setting the value of the variable has no effect unless binary logging is disabled.

See [mysql.gtid\\_executed Table Compression](#), for more information.

In MySQL version 5.7.5, this variable was added as `executed_gtid_compression_period` and in MySQL version 5.7.6 it was renamed to `gtid_executed_compression_period`.

- `gtid_mode`

<b>System Variable</b> (<= 5.7.5)	<b>Name</b>	<code>gtid_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>System Variable</b> (>= 5.7.6)	<b>Name</b>	<code>gtid_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (<= 5.7.5)	<b>Type</b>	enumeration
	<b>Default</b>	OFF
	<b>Valid Values</b>	OFF
		UPGRADE_STEP_1
		UPGRADE_STEP_2
<b>Permitted Values</b> (>= 5.7.6)	<b>Type</b>	enumeration
		ON
	<b>Default</b>	OFF
	<b>Valid Values</b>	OFF
		OFF_PERMISSIVE
		ON_PERMISSIVE
	<b>Valid Values</b>	ON
		ON

Controls whether GTID based logging is enabled and what type of transactions the logs can contain. Prior to MySQL 5.7.6 this variable was read-only and was set using the `--gtid-mode` option only. MySQL 5.7.6 enables this variable to be set dynamically. You must have the `SUPER` privilege to set this variable. `enforce_gtid_consistency` must be true before you can set `gtid_mode=ON`. Before modifying this variable, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

Transactions logged in MySQL 5.7.6 and later can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID transactions have

a unique identifier that is used to refer to transactions. The `OFF_PERMISSIVE` and `ON_PERMISSIVE` modes added in MySQL 5.7.6 permit a mix of these transaction types in the topology. The different modes are now:

- `OFF`: Both new and replicated transactions must be anonymous.
- `OFF_PERMISSIVE`: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.
- `ON_PERMISSIVE`: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.
- `ON`: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`.

In MySQL 5.7.6 and later, the values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values. In MySQL 5.7.5 and earlier, the values of `gtid_purged` and `gtid_executed` are not persistent while `gtid_mode=OFF`. Therefore, after changing `gtid_mode` to `OFF`, once all binary logs containing GTIDs are purged, the values of these variables are lost.

- `gtid_next`

<b>System Variable</b>	<b>Name</b>	<code>gtid_next</code>
	<b>Variable Scope</b>	Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>AUTOMATIC</code>
	<b>Valid Values</b>	<code>AUTOMATIC</code>
		<code>ANONYMOUS</code>
		<code>UUID:NUMBER</code>

This variable is used to specify whether and how the next GTID is obtained. `gtid_next` can take any of the following values:

- `AUTOMATIC`: Use the next automatically-generated global transaction ID.
- `ANONYMOUS`: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in `UUID:NUMBER` format.

Exactly which of the above options are valid depends on the setting of `gtid_mode`, see [Section 18.1.5.1, “Replication Mode Concepts”](#) for more information. Setting this variable has no effect if `gtid_mode` is `OFF`.

After this variable has been set to `UUID:NUMBER`, and a transaction has been committed or rolled back, an explicit `SET GTID_NEXT` statement must again be issued before any other statement.

In MySQL 5.7.5 and later, `DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines. Prior to MySQL 5.7.5, when GTIDs were enabled but `gtid_next` was not `AUTOMATIC`, `DROP TABLE` did not work correctly when used with either of these combinations of tables. (Bug #17620053)

In MySQL 5.7.1, you cannot execute any of the statements `CHANGE MASTER TO`, `START SLAVE`, `STOP SLAVE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE SERVER`, `ALTER SERVER`, `DROP SERVER`, `CACHE INDEX`, `LOAD INDEX INTO CACHE`, `FLUSH`, or `RESET` when `gtid_next` is set to any value other than `AUTOMATIC`; in such cases, the statement fails with an error. Such statements are *not* disallowed in MySQL 5.7.2 and later. (Bug #16062608, Bug #16715809, Bug #69045) (Bug #16062608)

- `gtid_owned`

<b>System Variable</b>	<b>Name</b>	<code>gtid_owned</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

- `gtid_purged`

<b>System Variable</b>	<b>Name</b>	<code>gtid_purged</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in `gtid_executed`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, the global value of `gtid_purged` is initialized to a set of GTIDs. See [binlog\\_gtid\\_simple\\_recovery](#) for more information on how binary logs are iterated to populate `gtid_purged`. Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

It is possible to update the value of this variable, but only when `gtid_executed` is the empty string, and therefore `gtid_purged` is the empty string. This can occur either when replication has not been started previously, or when replication was not previously using GTIDs. Prior to MySQL 5.7.6, this variable was settable only when `gtid_mode=ON`. In MySQL 5.7.6 and later, this variable is settable regardless of the value of `gtid_mode`.

If all existing binary logs were generated using MySQL 5.7.6 or later, after issuing a `SET gtid_purged` statement, `binlog_gtid_simple_recovery=TRUE` (the default setting in MySQL 5.7.7 and later) can safely be used. If binary logs from MySQL 5.7.7 or earlier exist, there is a chance that `gtid_purged`

may be computed incorrectly. See [binlog\\_gtid\\_simple\\_recovery](#) for more information. If you are using MySQL 5.7.7 or earlier, after issuing a `SET gtid_purged` statement note down the current binary log file name, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=FALSE` to avoid `gtid_purged` or `gtid_executed` being computed incorrectly.

- [simplified\\_binlog\\_gtid\\_recovery](#)

<b>Introduced</b>	5.7.5	
<b>Deprecated</b>	5.7.6	
<b>Command-Line Format</b>	<code>--simplified-binlog-gtid-recovery</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">simplified_binlog_gtid_recovery</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>FALSE</code>

This option is deprecated and will be removed in a future MySQL release. Use the renamed [binlog\\_gtid\\_simple\\_recovery](#) to control how MySQL iterates through binary log files after a crash.

## 18.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication and how to pause a slave.

### 18.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: master1
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 60
      Master_Log_File: mysql-bin.000004
      Read_Master_Log_Pos: 931
      Relay_Log_File: slave1-relay-bin.000056
      Relay_Log_Pos: 950
      Relay_Master_Log_File: mysql-bin.000004
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
      Last_Errno: 0
      Last_Error:
```

```

        Skip_Counter: 0
    Exec_Master_Log_Pos: 931
        Relay_Log_Space: 1365
        Until_Condition: None
        Until_Log_File:
        Until_Log_Pos: 0
    Master_SSL_Allowed: No
    Master_SSL_CA_File:
    Master_SSL_CA_Path:
    Master_SSL_Cert:
    Master_SSL_Cipher:
    Master_SSL_Key:
    Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
        Last_IO_Errno: 0
        Last_IO_Error:
        Last_SQL_Errno: 0
        Last_SQL_Error:
    Replicate_Ignore_Server_Ids: 0

```

The key fields from the status report to examine are:

- **Slave\_IO\_State**: The current status of the slave. See [Section 9.14.5, “Replication Slave I/O Thread States”](#), and [Section 9.14.6, “Replication Slave SQL Thread States”](#), for more information.
- **Slave\_IO\_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP SLAVE**.
- **Slave\_SQL\_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.
- **Last\_IO\_Error**, **Last\_SQL\_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- **Seconds\_Behind\_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for **Seconds\_Behind\_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave\_net\_timeout** has not yet elapsed.

It is also possible that transient values for **Seconds\_Behind\_Master** may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, **Seconds\_Behind\_Master** displays 0; but when the slave I/O thread is still queuing up a new event, **Seconds\_Behind\_Master** may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute **SHOW SLAVE STATUS** several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (**Master\_Log\_file**, **Read\_Master\_Log\_Pos**): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (**Relay\_Master\_Log\_File**, **Exec\_Master\_Log\_Pos**): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.

- ([Relay\\_Log\\_File](#), [Relay\\_Log\\_Pos](#)): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using [SHOW PROCESSLIST](#) to examine the list of running processes. Slave connections have [Binlog Dump](#) in the [Command](#) field:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
   Id: 10
  User: root
   Host: slave1:58371
    db: NULL
Command: Binlog Dump
   Time: 777
   State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the [--report-host](#) option and are connected to the master, the [SHOW SLAVE HOSTS](#) statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the [--report-host](#) option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
|          10 | slave1 | 3306 |          0         |          1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

### 18.1.7.2 Pausing Replication on the Slave

You can stop and start replication on the slave using the [STOP SLAVE](#) and [START SLAVE](#) statements.

To stop processing of the binary log from the master, use [STOP SLAVE](#):

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the [START SLAVE](#) statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

## 18.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 18.2.2, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 9.14, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 18.2.4, “Replication Relay and Status Logs”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

### 18.2.1 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the master writes SQL statements to the binary log. Replication of the master to the slave works by executing the SQL statements on the slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard MySQL statement-based binary logging format. Replication capabilities in MySQL version 5.1.4 and earlier used this format exclusively.
- When using row-based logging, the master writes *events* to the binary log that indicate how individual table rows are changed. Replication of the master to the slave works by copying the events representing the changes to the table rows to the slave. This is called *row-based replication* (often abbreviated as *RBR*).
- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called *mixed-format logging*. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 6.4.4.3, “Mixed Binary Logging Format”](#).

Prior to MySQL 5.7.7, statement-based format was the default. In MySQL 5.7.7 and later, row-based format is the default.

**MySQL Cluster.** The default binary logging format in MySQL Cluster NDB 7.5 is `MIXED`. You should note that MySQL Cluster Replication always uses row-based replication, and that the `NDB` storage engine is incompatible with statement-based replication. See [Section 20.6.2, “General Requirements for NDB Cluster Replication”](#), for more information.

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 6.4.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#).

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See [Section 6.4.4.2, “Setting The Binary Log Format”](#).

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 22.7, “Binary Logging of Stored Programs”](#).

### 18.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when

performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

### Advantages of statement-based replication

- Proven technology.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

### Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**  
Not all statements which modify data (such as [INSERT](#), [DELETE](#), [UPDATE](#), and [REPLACE](#) statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 18.4.1.12, “Replication of Invoked Features”](#), for more information.
  - [DELETE](#) and [UPDATE](#) statements that use a [LIMIT](#) clause without an [ORDER BY](#) are nondeterministic. See [Section 18.4.1.17, “Replication and LIMIT”](#).
  - Deterministic UDFs must be applied on the slaves.
- Statements using any of the following functions cannot be replicated properly using statement-based replication:
  - [LOAD\\_FILE\(\)](#)
  - [UUID\(\)](#), [UUID\\_SHORT\(\)](#)
  - [USER\(\)](#)
  - [FOUND\\_ROWS\(\)](#)
  - [SYSDATE\(\)](#) (unless both the master and the slave are started with the `--sysdate-is-now` option)
  - [GET\\_LOCK\(\)](#)
  - [IS\\_FREE\\_LOCK\(\)](#)
  - [IS\\_USED\\_LOCK\(\)](#)

- `MASTER_POS_WAIT()`
- `RAND()`
- `RELEASE_LOCK()`
- `SLEEP()`
- `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see [Section 18.4.1.16, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 18.4.1.28, “Slave Errors During Replication”](#).
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

### Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

#### Note

Statements that update the information in the `mysql` database—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`
  - `INSERT` statements with `AUTO_INCREMENT`
  - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

### Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot see on the slave what statements were received from the master and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

#### 18.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.

For additional information, see [Section 18.2.1, “Replication Formats”](#), and [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#).

- **Row-based logging of temporary tables.** As noted in [Section 18.4.1.24, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format. When using mixed format logging, “safe” statements involving temporary tables are logged using statement-based format. For more information, see [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

In MySQL 5.7, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists for a given client session when that session ends. While this means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF EXISTS` option.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. Depending on the engine used for the slave's copy of the table, this may or may not be effective.
- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 14.7.6.1, “BINLOG Syntax”](#)). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see [Section 5.6.7.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and slave\_exec\_mode.** Using `slave_exec_mode=IDEMPOTENT` is generally only useful with MySQL NDB Cluster replication, for which `IDEMPOTENT` is the default value. (See [Section 20.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”](#)). When `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 6.1.5, “Server System Variables”](#).

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

- **Lack of binary log checksums.** RBL does not use checksums, so network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network

corruption use SSL for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#), for general information about setting up MySQL with SSL.

- **Filtering based on server ID not supported.** In MySQL 5.7, you can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats. Another method to filter out changes on some slaves is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.
- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).
- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format. Use of `STOP SLAVE` or `STOP SLAVE SQL_THREAD` prior to shutting down the slave MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

### 18.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL Replication, refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see [Section 18.4.1.13, “Replication and Floating-Point Values”](#)).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.
- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. Formerly, if a large number of such statements were executed on the master, this could lead to excessively large error log files. To prevent this, MySQL 5.7 provides a warning suppression mechanism, which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to

the error log; instead, for each 50 warnings of this type, a note `The last warning was repeated N times in last S seconds` is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see [Section 18.2.1, “Replication Formats”](#).

#### Statements considered unsafe.

Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.**

These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `PASSWORD()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

**Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

For more information, see [Section 18.4.1.16, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See [Section 18.4.1.38, “Replication and Variables”](#). For exceptions, see [Section 6.4.4.3, “Mixed Binary Logging Format”](#).
- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.
- **Fulltext plugin.** This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe in MySQL 5.7.1 and later. (Bug #11756280, Bug #48183)
- **Trigger or stored program updates a table having an `AUTO_INCREMENT` column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

For more information, see [Section 18.4.1.1, “Replication and `AUTO\_INCREMENT`”](#).

- **`INSERT ... ON DUPLICATE KEY UPDATE` statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

- **Updates using `LIMIT`.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See [Section 18.4.1.17, “Replication and `LIMIT`”](#).

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe. For more information, see [Section 18.4.1.33, “Replication and Transactions”](#).
- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **LOAD DATA INFILE statements.** `LOAD DATA INFILE` is treated as unsafe and when `binlog_format=mixed` the statement is logged in row-based format. When `binlog_format=statement` `LOAD DATA INFILE` does not generate a warning, unlike other unsafe statements.

For additional information, see [Section 18.4.1, “Replication Features and Issues”](#).

## 18.2.2 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 9.14.4, “Replication](#)

Master Thread States". For slave states, see [Section 9.14.5, "Replication Slave I/O Thread States"](#), and [Section 9.14.6, "Replication Slave SQL Thread States"](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
  Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread that services a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
  User: system user
  Host:
  db: NULL
  Command: Connect
  Time: 11
  State: Waiting for master to send event
  Info: NULL
***** 2. row *****
  Id: 11
  User: system user
  Host:
  db: NULL
  Command: Connect
  Time: 11
  State: Has read all relay log; waiting for the slave I/O
        thread to update it
  Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section A.13, "MySQL 5.7 FAQ: Replication"](#). If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 6.1.5, "Server System Variables"](#).

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See [Section 18.1.7.1, "Checking Replication Status"](#).

## 18.2.3 Replication Channels

MySQL 5.7.6 introduces the concept of a replication channel, which represents the path of transactions flowing from a master to a slave. This section describes how channels can be used in a replication topology, and the impact they have on single-source replication.

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string ( " "). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older slaves function as expected (see [Section 18.2.3.2, “Compatibility with Previous Replication Statements”](#)). Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

A replication channel encompasses the path of transactions transmitted from a master to a slave. In multi-source replication a slave opens multiple channels, one per master, and each channel has its own relay log and applier (SQL) threads. Once transactions are received by a replication channel's receiver (I/O) thread, they are added to the channel's relay log file and passed through to an applier thread. This enables channels to function independently.

A replication channel is also associated with a host name and port. You can assign multiple channels to the same combination of host name and port; in MySQL 5.7, the maximum number of channels that can be added to one slave in a multi-source replication topology is 256. Each replication channel must have a unique (nonempty) name (see [Section 18.2.3.4, “Replication Channel Naming Conventions”](#)). Channels can be configured independently.

### 18.2.3.1 Commands for Operations on a Single Channel

To enable existing MySQL replication statements to act on individual replication channels, MySQL 5.7.6 introduces the `FOR CHANNEL channel_name` option for use with the following replication statements in managing a replication channel independently of other channels:

- `CHANGE MASTER TO`
- `START SLAVE`
- `STOP SLAVE`
- `SHOW RELAYLOG EVENTS`
- `FLUSH RELAY LOGS`
- `SHOW SLAVE STATUS`
- `RESET SLAVE`

Similarly, an additional `channel_name` parameter is introduced for the following functions:

- `MASTER_POS_WAIT( )`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS( )`

Beginning with MySQL 5.7.9, the following statements are disallowed for the `group_replication_recovery` channel.

- `START SLAVE`
- `STOP SLAVE`

### 18.2.3.2 Compatibility with Previous Replication Statements

When a replication slave has multiple channels and a `FOR CHANNEL channel_name` option is not specified, a valid statement generally acts on all available channels.

For example, the following statements behave as expected:

- `START SLAVE` starts replication threads for all channels. (In MySQL 5.7.9 and later, this does not include the `group_replication_recovery` channel.)
- `STOP SLAVE` stops replication threads for all the channels. (In MySQL 5.7.9 and later, this does not include the `group_replication_recovery` channel.)
- `SHOW SLAVE STATUS` reports the status for all channels.
- `FLUSH RELAY LOGS` flushes the relay logs for all channels.
- `RESET SLAVE` resets all channels.

#### Warning

Use `RESET SLAVE` with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 `Multiple channels exist on the slave. Please provide channel name as an argument.` is generated. The following statements and functions generate this error when used in a multi-source replication topology and a `FOR CHANNEL channel_name` option is not used to specify which channel to act on:

- `SHOW RELAYLOG EVENTS`
- `CHANGE MASTER TO`
- `MASTER_POS_WAIT( )`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS( )`
- `WAIT_FOR_EXECUTED_GTID_SET( )`

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

### 18.2.3.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup options *must* be configured correctly to use multi-source replication.

- `--relay-log-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

- `--master-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

The following startup options now affect *all* channels in a replication topology.

- `--log-slave-updates`

All transactions received by the slave (even from multiple sources) are written in the binary log.

- `--relay-log-purge`

When set, each channel purges its own relay log automatically.

- `--slave_transaction_retries`

Applier threads of all channels retry transactions.

- `--skip-slave-start`

No replication threads start on any channels.

- `--slave-skip-errors`

Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are `mysqld` startup options, they are applied on every channel.

- `--max-relay-log-size=size`

Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- `--relay-log-space-limit=size`

Upper limit for the total size of all relay logs combined, for each individual channel. For *N* channels, the combined size of these logs is limited to `relay_log_space_limit * N`.

- `--slave-parallel-workers=value`

Number of slave parallel workers per channel.

- `--slave-checkpoint-group`

Waiting time by an I/O thread for each source.

- `--relay-log-index=filename`

Base name for each channel's relay log index file. See [Section 18.2.3.4, “Replication Channel Naming Conventions”](#).

- `--relay-log=filename`

Denotes the base name of each channel's relay log file. See [Section 18.2.3.4, “Replication Channel Naming Conventions”](#).

- `--slave_net_timeout=N`

This value is set per channel, so that each channel waits for *N* seconds to check for a broken connection.

- `--slave-skip-counter=N`

This value is set per channel, so that each channel skips *N* events from its master.

### 18.2.3.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case insensitive. Because channel names are used in slave tables, the character set used for these is always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- `group_replication_applier`
- `group_replication_recovery`

The name you choose for a replication channel also influences the file names used by a multi-source replication slave. The relay log files and index files for each channel are named `base_name-relay-bin-channel_name.0000x`, where `base_name` is generally a host name (if not specified using `--log-bin`) and `channel_name` is the name of the channel logged to this file.

## 18.2.4 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

This log can be written to the `mysql.slave_master_info` table instead of a file, by starting the slave with `--master-info-repository=TABLE`.

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *relay log info log* holds status information about the execution point within the slave's relay log.

This log can be written to the `mysql.slave_relay_log_info` table instead of a file by starting the slave with `--relay-log-info-repository=TABLE`.

In MySQL 5.7, setting `relay_log_info_repository` and `master_info_repository` to `TABLE` can improve resilience to unexpected halts (crash-safe replication). See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#). When using this configuration, a warning is given if `mysqld` is unable to initialize the replication logging tables, but the slave is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support slave logging tables to one in which they are supported.

### Important

Do not attempt to update or insert rows in the `slave_master_info` or `slave_relay_log_info` table manually. Doing so can cause undefined behavior, and is not supported.

Execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing, while statements that perform only reads are permitted at any time.

### 18.2.4.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 5.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 18.2.4.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. In MySQL 5.7, either or both of these logs can also be written to tables in the `mysql` database by starting the server with the appropriate option: use `--master-info-repository` to have the master info log written

to the `mysql.slave_master_info` table, and use `--relay-log-info-repository` to have the relay log info log written to the `mysql.slave_relay_log_info` table. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 14.4.2, “SQL Statements for Controlling Slave Servers”](#). Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log file or table should be protected because it contains the password for connecting to the master. See [Section 7.1.2.3, “Passwords and Logging”](#).

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file, the columns in the `mysql.slave_master_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

Line in <code>master.info</code> File	<code>slave_master_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	Description
1	<code>Number_of_lines</code>	[None]	Number of lines in the file, or columns in the table
2	<code>Master_log_name</code>	<code>Master_Log_File</code>	The name of the master binary log currently being read from the master
3	<code>Master_log_pos</code>	<code>Read_Master_Log_Pos</code>	The current position within the master binary log that have been read from the master
4	<code>Host</code>	<code>Master_Host</code>	The host name of the master
5	<code>User_name</code>	<code>Master_User</code>	The user name used to connect to the master
6	<code>User_password</code>	Password (not shown by <code>SHOW SLAVE STATUS</code> )	The password used to connect to the master
7	<code>Port</code>	<code>Master_Port</code>	The network port used to connect to the master
8	<code>Connect_retry</code>	<code>Connect_Retry</code>	The period (in seconds) that the slave will wait before trying to reconnect to the master

Line in master.info File	slave_master_info Table Column	SHOW SLAVE STATUS Column	Description
9	Enabled_ssl	Master_SSL_Allowed	Indicates whether the server supports SSL connections
10	Ssl_ca	Master_SSL_CA_File	The file used for the Certificate Authority (CA) certificate
11	Ssl_capath	Master_SSL_CA_Path	The path to the Certificate Authority (CA) certificates
12	Ssl_cert	Master_SSL_Cert	The name of the SSL certificate file
13	Ssl_cipher	Master_SSL_Cipher	The list of possible ciphers used in the handshake for the SSL connection
14	Ssl_key	Master_SSL_Key	The name of the SSL key file
15	Ssl_verify_server_cert	Master_SSL_Verify_Server_Cert	Whether to verify the server certificate
16	Heartbeat	[None]	Interval between replication heartbeats, in seconds
17	Bind	Master_Bind	Which of the slave's network interfaces should be used for connecting to the master
18	Ignored_server_ids	Replicate_Ignore_Server_Ids	The list of server IDs to be ignored. Note that for <code>Ignored_server_ids</code> the list of server IDs is preceded by the total number of server IDs to ignore.

Line in <code>master.info</code> File	<code>slave_master_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	Description
19	<code>Uuid</code>	<code>Master_UUID</code>	The master's unique ID
20	<code>Retry_count</code>	<code>Master_Retry_Count</code>	Maximum number of reconnection attempts permitted
21	<code>Ssl_crl</code>	[None]	Path to an ssl certificate revocation list file
22	<code>Ssl_crl_path</code>	[None]	Path to a directory containing ssl certificate revocation list files
23	<code>Enabled_auto_position</code>	<code>Auto_position</code>	If autopositioning is in use or not
24	<code>Channel_name</code>	<code>Channel_name</code>	The name of the replication channel

The slave SQL thread updates the relay log info log. In MySQL 5.7, the `relay-log.info` file includes a line count and a replication delay value. The following table shows the correspondence between the lines in the `relay-log.info` file, the columns in the `mysql.slave_relay_log_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

Line in <code>relay-log.info</code>	<code>slave_relay_log_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	Description
1	<code>Number_of_lines</code>	[None]	Number of lines in the file or columns in the table
2	<code>Relay_log_name</code>	<code>Relay_Log_File</code>	The name of the current relay log file
3	<code>Relay_log_pos</code>	<code>Relay_Log_Pos</code>	The current position within the relay log file; events up to this position have been executed on the slave database
4	<code>Master_log_name</code>	<code>Relay_Master_Log_File</code>	The name of the master binary log file from which the

Line in relay-log.info	slave_relay_log_info Table Column	SHOW SLAVE STATUS Column	Description
			events in the relay log file were read
5	Master_log_pos	Exec_Master_Log_Pos	The equivalent position within the master's binary log file of events that have already been executed
6	Sql_delay	SQL_Delay	The number of seconds that the slave must lag the master
7	Number_of_workers	[None]	The number of slave worker threads for executing replication events (transactions) in parallel
8	Id	[None]	ID used for internal purposes; currently this is always 1
9	Channel_name	Channel_name	The name of the replication channel

In older versions of MySQL (prior to MySQL 5.6), the `relay-log.info` file does not include a line count or a delay value (and the `slave_relay_log_info` table is not available).

Line	Status Column	Description
1	Relay_Log_File	The name of the current relay log file
2	Relay_Log_Pos	The current position within the relay log file; events up to this position have been executed on the slave database
3	Relay_Master_Log_File	The name of the master binary log file from which the events in the relay log file were read
4	Exec_Master_Log_Pos	The equivalent position within the master's binary log file of events that have already been executed

#### Note

If you downgrade a slave server to a version older than MySQL 5.6, the older server does not read the `relay-log.info` file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, you can

use `SHOW SLAVE STATUS`, or query the `slave_master_info` and `slave_relay_log_info` tables if you are writing the status logs to tables.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

## 18.2.5 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).) In MySQL 5.7.3 and later, the filters governed by these options can also be set dynamically using the `CHANGE REPLICATION FILTER` statement. The rules governing such filters are the same whether they are created on startup using `--replicate-*` options or while the slave server is running by `CHANGE REPLICATION FILTER`.

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 18.2.5.2, “Evaluation of Table-Level Replication Options”](#), for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement `CREATE DATABASE dbx` was not replicated if the slave had been started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. (Bug #46110)

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

### Note

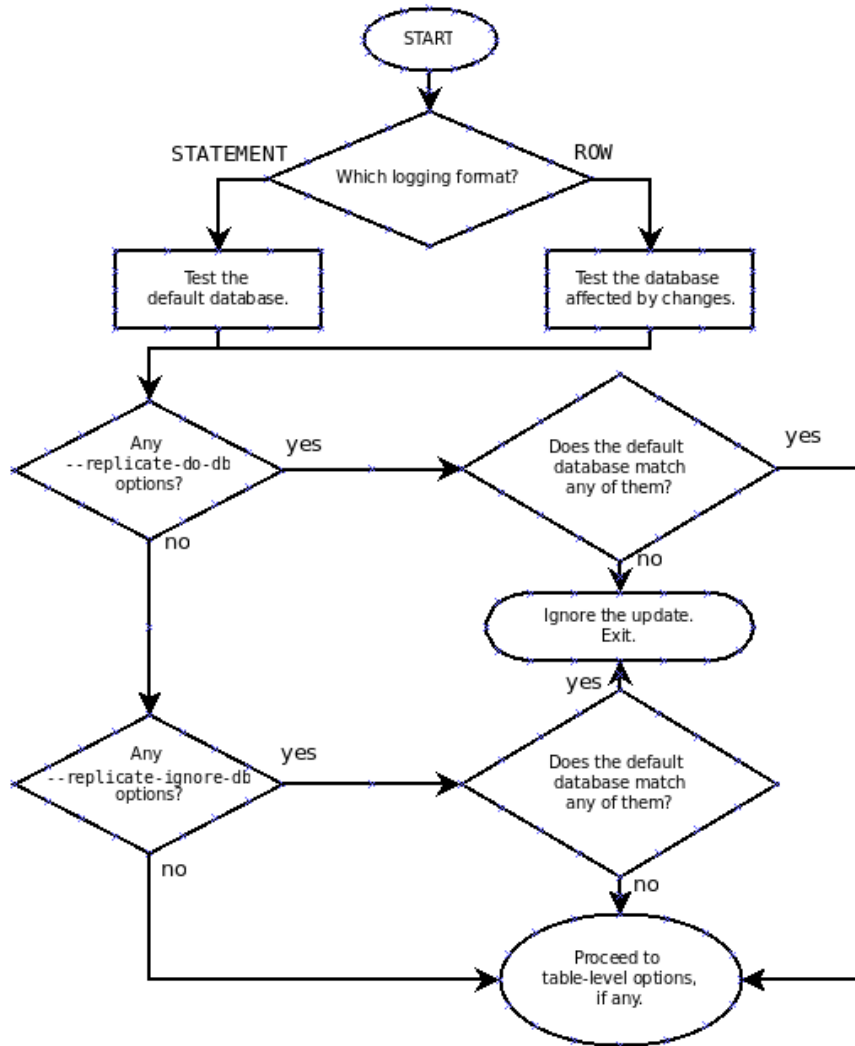

In MySQL 5.7, all replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.

■ This is a change from previous versions of MySQL. (Bug #51639)

### 18.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
  - **Yes.** Do any of them match the database?
  - **Yes.** Execute the statement and exit.
  - **No.** Ignore the statement and exit.

- **No.** Continue to step 2.
2. Are there any `--replicate-ignore-db` options?
    - **Yes.** Do any of them match the database?
      - **Yes.** Ignore the statement and exit.
      - **No.** Continue to step 3.
    - **No.** Continue to step 3.
  3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 18.2.5.2, “Evaluation of Table-Level Replication Options”](#).

**Important**

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

**Important**

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

### 18.2.5.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

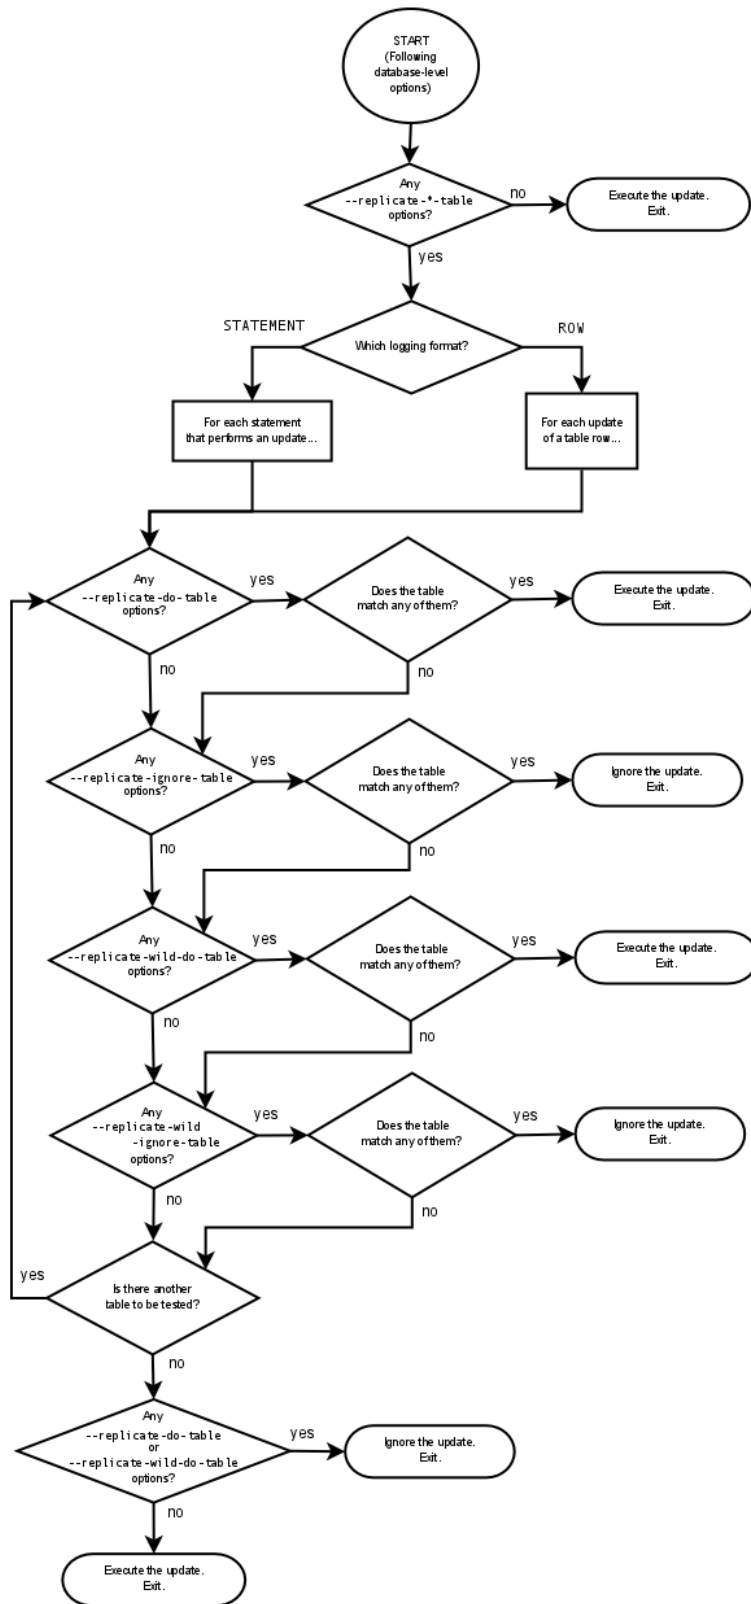

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

#### Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.

The following steps describe this evaluation in more detail:

1. Are there any table options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 5.
  - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 6.
  - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
  - **Yes.** Ignore the event and exit.
  - **No.** Execute the event and exit.

### 18.2.5.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No <code>--replicate-*</code> options at all:	The slave executes all events that it receives from the master.
<code>--replicate-*-db</code> options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.
<code>--replicate-*-table</code> options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

## 18.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 18.3.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 18.3.3, “Using Replication with Different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 18.3.4, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 18.3.5, “Replicating Different Databases to Different Slaves”](#)

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see [Section 18.3.6, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 18.3.7, “Switching Masters During Failover”](#).

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see [Section 18.3.8, “Setting Up Replication to Use Secure Connections”](#).

## 18.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 18.3.1.1, “Backing Up a Slave Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 18.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 18.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

### 18.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 5.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 18.1.7.1, "Checking Replication Status"](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 18.3.5, "Replicating Different Databases to Different Slaves"](#).

### 18.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in

addition to the slave's data, you should also back up the slave status files, the master info and relay log info repositories, and the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

### 18.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

#### Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 5.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

#### Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

### Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

## 18.3.2 Handling an Unexpected Halt of a Replication Slave

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the slave to recover its state before halting. This section describes the impact

of an unexpected halt of a slave during replication and how to configure a slave for the best chance of recovery to continue replication.

After an unexpected halt of a slave, upon restart the I/O thread must recover the information about which transactions have been received, and the SQL thread must recover which transactions have been executed already. For information on the slave logs required for recovery, see [Section 18.2.4, “Replication Relay and Status Logs”](#). The information required for recovery was traditionally stored in files, which had the risk of losing synchrony with the master depending at which stage of processing a transaction the slave halted at, or even corruption of the files themselves. In MySQL 5.7 you can instead use tables to store this information. These tables are created using [InnoDB](#), and by using this transactional storage engine the information is always recoverable upon restart. To configure MySQL 5.7 to store the replication information in tables, set [relay\\_log\\_info\\_repository](#) and [master\\_info\\_repository](#) to `TABLE`. The server then stores information required for the recovery of the I/O thread in the `mysql.slave_master_info` table and information required for the recovery of the SQL thread in the `mysql.slave_relay_log_info` table.

Exactly how a replication slave recovers from an unexpected halt is influenced by the chosen method of replication, whether the slave is single-threaded or multi-threaded, the setting of variables such as [relay\\_log\\_recovery](#), and whether features such as [MASTER\\_AUTO\\_POSITION](#) are being used.

The following table shows the impact of these different factors on how a single-threaded slave recovers from an unexpected halt.

**Table 18.5 Factors Influencing Single-threaded Replication Slave Recovery**

GTID	MASTER_AUTO_POSITION	relay_log_recovery	relay_log_info_repository	Crash type	Recovery guaranteed	Relay log impact
OFF	Any	1	TABLE	Any	Yes	Lost
OFF	Any	1	TABLE	Server	Yes	Lost
OFF	Any	1	Any	OS	No	Lost
OFF	Any	0	TABLE	Server	Yes	Remains
OFF	Any	0	TABLE	OS	No	Remains
ON	ON	Any	Any	Any	Yes	Lost
ON	OFF	0	TABLE	Server	Yes	Remains
ON	OFF	0	Any	OS	No	Remains

As the table shows, when using a single-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and [MASTER\\_AUTO\\_POSITION](#), set [relay\\_log\\_recovery=0](#). With this configuration the setting of [relay\\_log\\_info\\_repository](#) and other variables does not impact on recovery.
- When using file position based replication, set [relay\\_log\\_recovery=1](#) and [relay\\_log\\_info\\_repository=TABLE](#).

#### Note

During recovery the relay log is lost.

The following table shows the impact of these different factors on how a multi-threaded slave recovers from an unexpected halt.

**Table 18.6 Factors Influencing Multi-threaded Replication Slave Recovery**

GTID	<code>sync_relay_log</code>	<code>MASTER_AUTO_POSITION</code>	<code>relay_log_recovery</code>	<code>relay_log_info_repository</code>	Crash type	Recovery guaranteed	Relay log impact
OFF	1	Any	1	TABLE	Any	Yes	Lost
OFF	>1	Any	1	TABLE	Server	Yes	Lost
OFF	>1	Any	1	Any	OS	No	Lost
OFF	1	Any	0	TABLE	Server	Yes	Remains
OFF	1	Any	0	TABLE	OS	No	Remains
ON	Any	ON	Any	Any	Any	Yes	Lost
ON	1	OFF	0	TABLE	Server	Yes	Remains
ON	1	OFF	0	Any	OS	No	Remains

As the table shows, when using a multi-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=0`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery.
- When using file position based replication, set `relay_log_recovery=1`, `sync_relay_log=1`, and `relay_log_info_repository=TABLE`.

**Note**

During recovery the relay log is lost.

It is important to note the impact of `sync_relay_log=1`, which requires a write of to the relay log per transaction. Although this setting is the most resilient to an unexpected halt, with at most one unwritten transaction being lost, it also has the potential to greatly increase the load on storage. Without `sync_relay_log=1`, the effect of an unexpected halt depends on how the relay log is handled by the operating system. Also note that when `relay_log_recovery=0`, the next time the slave is started after an unexpected halt the relay log is processed as part of recovery. After this process completes, the relay log is deleted.

An unexpected halt of a multi-threaded replication slave using the recommended file position based replication configuration above may result in a relay log with transaction inconsistencies (gaps in the sequence of transactions) caused by the unexpected halt. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#). In MySQL 5.7.13 and later, if the relay log recovery process encounters such transaction inconsistencies they are filled and the recovery process continues automatically. In MySQL versions prior to MySQL 5.7.13, this process is not automatic and requires starting the server with `relay_log_recovery=0`, starting the slave with `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to fix any transaction inconsistencies and then restarting the slave with `relay_log_recovery=1`.

When you are using multi-source replication and `relay_log_recovery=1`, after restarting due to an unexpected halt all replication channels go through the relay log recovery process. Any inconsistencies found in the relay log due to an unexpected halt of a multi-threaded slave are filled.

### 18.3.3 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 18.3.4, “Using Replication for Scale-Out”](#)), you want to use [InnoDB](#) tables on the master to take advantage of the transactional functionality, but use [MyISAM](#) on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the [Archive](#) storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used [mysqldump](#) to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for [mysqldump](#) is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the [--skip-federated](#) option on your slave to disable the [FEDERATED](#) engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually [MyISAM](#). (This requires that the [NO\\_ENGINE\\_SUBSTITUTION](#) SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use [ALTER TABLE](#) to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an [ALTER TABLE ... ENGINE='engine\\_type'](#) for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the [default\\_storage\\_engine](#) variable is not replicated, be aware that [CREATE TABLE](#) and [ALTER TABLE](#) statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to [MyISAM](#), even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the [default\\_storage\\_engine](#) variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

### 18.3.4 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 18.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 18.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`

- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 18.3.5 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 18.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#).

**Figure 18.2 Using Replication to Replicate Databases to Separate Replication Slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

#### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 18.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

#### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

## 18.3.6 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 18.3, “Using an Additional Replication Host to Improve Performance”](#).

**Figure 18.3 Using an Additional Replication Host to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

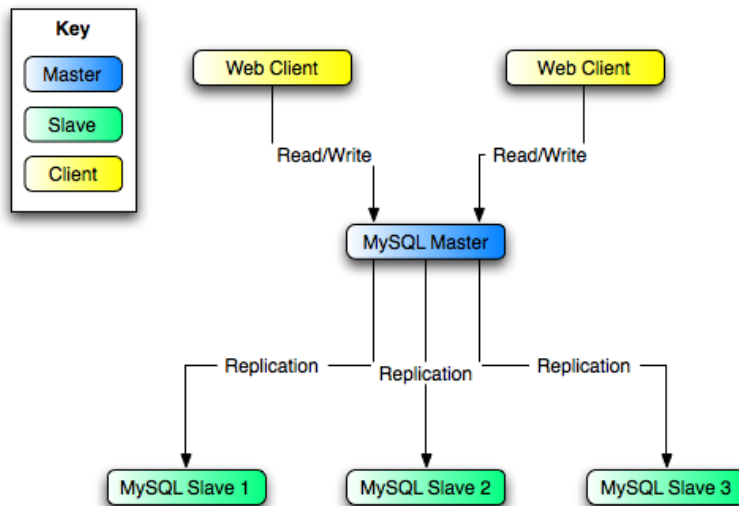

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 18.3.5, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 18.3.3, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

## 18.3.7 Switching Masters During Failover

When using replication with GTIDs (see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#)), you can provide failover between master and slaves in the event of a failure using `mysqlfailover`, which is provided by the MySQL Utilities; see [mysqlfailover — Automatic replication health monitoring and failover](#), for more information. If you are not using GTIDs and therefore cannot use `mysqlfailover`, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change to another master in case of failure. This section discusses some of the issues encountered when setting up failover in this way.

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the `--log-bin` option, and if not using GTIDs then they should also be run without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in [Figure 18.4, “Redundancy Using Replication, Initial Structure”](#).

**Figure 18.4 Redundancy Using Replication, Initial Structure**

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 18.3.4, “Using Replication for Scale-Out”](#).

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 18.5, “Redundancy Using Replication, After Master Failure”](#).

**Figure 18.5 Redundancy Using Replication, After Master Failure**

When **Master** becomes available again, you should make it a slave of **Slave 1**. To do this, issue on **Master** the same `CHANGE MASTER TO` statement as that issued on **Slave 2** and **Slave 3** previously. **Master** then becomes a slave of **Slave 1** and picks up the **Web Client** writes that it missed while it was offline.

To make **Master** a master again, use the preceding procedure as if **Slave 1** was unavailable and **Master** was to be the new master. During this procedure, do not forget to run `RESET MASTER` on **Master** before making **Slave 1**, **Slave 2**, and **Slave 3** slaves of **Master**. If you fail to do this, the slaves may pick up stale writes from the **Web Client** applications dating from before the point at which **Master** became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

### 18.3.8 Setting Up Replication to Use Secure Connections

To use a secure connection for encrypting the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support secure connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up secure connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for secure connections, see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

To enable secure connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, there are two ways to specify the information required for connecting securely to the master. You can either name the slave certificate and key files in the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement:

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to connect securely:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1;
```

- To specify the certificate and key names using the `CHANGE MASTER TO` statement, append the appropriate `MASTER_SSL_xxx` options:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1,
-> MASTER_SSL_CA = 'ca_file_name',
-> MASTER_SSL_CAPATH = 'ca_directory_name',
-> MASTER_SSL_CERT = 'cert_file_name',
```

```
-> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that a secure connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce the use of secure connections during replication, create a user and use the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass'
-> REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%.mydomain.com';
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%.mydomain.com' REQUIRE SSL;
```

## 18.3.9 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.7 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

As of MySQL 5.7.3, the number of slave acknowledgments the master must receive per transaction before proceeding is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable. The default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks for each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.
- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous master receives acknowledgment from the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count`, the transaction is on hold and not committed.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync.

Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.

- **AFTER\_COMMIT**: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With **AFTER\_SYNC**, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With **AFTER\_COMMIT**, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

### 18.3.9.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:

- `rpl_semi_sync_master_enabled`

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- `rpl_semi_sync_master_timeout`

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_XXX` system variables are described at [Section 6.1.5, “Server System Variables”](#).

- Status variables enable semisynchronous replication monitoring. Some examples:

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_xxx` status variables are described at [Section 6.1.7, “Server Status Variables”](#).

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

### 18.3.9.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.
- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see [Section 18.1, “Configuring Replication”](#).
- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See [Section 18.2.3, “Replication Channels”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from <http://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE '%semi%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| rpl_semi_sync_master | ACTIVE |
+-----+-----+
```

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value *N* is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
STOP SLAVE IO_THREAD;  
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]  
rpl_semi_sync_master_enabled=1  
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]  
rpl_semi_sync_slave_enabled=1
```

### 18.3.9.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

## 18.3.10 Delayed Replication

MySQL 5.7 supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time. The default delay is 0 seconds. Use the `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay to *N* seconds:

```
CHANGE MASTER TO MASTER_DELAY = N;
```

An event received from the master is not executed until at least *N* seconds later than its execution on the master. The exceptions are that there is no delay for format description events or log file rotation events, which affect only the internal state of the SQL thread.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the master. A DBA can roll back a delayed slave to the time just before the disaster.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.
- To inspect what the database looked like long ago, without having to reload a backup. For example, if the delay is one week and the DBA needs to see what the database looked like before the last few days' worth of development, the delayed slave can be inspected.

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

`SHOW SLAVE STATUS` has three fields that provide information about the delay:

- `SQL_Delay`: A nonnegative integer indicating the number of seconds that the slave must lag the master.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the slave SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

## 18.4 Replication Notes and Tips

### 18.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.7 (or later), you cannot replicate to a slave that uses MySQL 5.6 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the [SLEEP\(\)](#) function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.7 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 22.7, “Binary Logging of Stored Programs”](#). For more information about row-based logging and row-based replication, see [Section 6.4.4.1, “Binary Logging Formats”](#), and [Section 18.2.1, “Replication Formats”](#).

For additional information specific to replication and [InnoDB](#), see [Section 15.19, “InnoDB and MySQL Replication”](#). For information relating to replication with MySQL Cluster, see [Section 20.6, “NDB Cluster Replication”](#).

### 18.4.1.1 Replication and AUTO\_INCREMENT

Statement-based replication of [AUTO\\_INCREMENT](#), [LAST\\_INSERT\\_ID\(\)](#), and [TIMESTAMP](#) values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.7.1, [AUTO\\_INCREMENT](#) columns in tables on the slave must match the same columns on the master; that is, [AUTO\\_INCREMENT](#) columns must be replicated to [AUTO\\_INCREMENT](#) columns.
- A statement invoking a trigger or function that causes an update to an [AUTO\\_INCREMENT](#) column is not replicated correctly using statement-based replication. In MySQL 5.7, such statements are marked as unsafe. (Bug #45677)
- An [INSERT](#) into a table that has a composite primary key that includes an [AUTO\\_INCREMENT](#) column that is not the first column of this composite key is not safe for statement-based logging or replication. In MySQL 5.7 and later, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the [InnoDB](#) storage engine, since an [InnoDB](#) table with an [AUTO\\_INCREMENT](#) column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an [AUTO\\_INCREMENT](#) column to a table with [ALTER TABLE](#) might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an [AUTO\\_INCREMENT](#) number. Assuming that you want to add an

`AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

### Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

## 18.4.1.2 Replication and BLACKHOLE Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. In MySQL 5.7.2 and later, a warning is logged whenever this occurs (Bug #13004581)

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

## 18.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

## 18.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

## 18.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 18.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.7, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

### 18.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

MySQL 5.7 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. Some older versions of MySQL permitted these statements to do so; this means that, when using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. To prevent this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 5.7. (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement fails following the upgrade unless it is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 14.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL 5.7 ignores the statement completely; nothing is inserted or logged. The handling of such statements in this regard has changed considerably in previous MySQL releases; if you are replicating from a MySQL 5.5.6 or older master to a newer slave, see [Replication of CREATE ... IF NOT EXISTS Statements](#), for more information.

### 18.4.1.7 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.7, the statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

### 18.4.1.8 Replication of `CURRENT_USER()`

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. `CURRENT_USER()` or `CURRENT_USER` is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`.

### 18.4.1.9 Replication of `DROP ... IF EXISTS` Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

### 18.4.1.10 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

**Note**

Replication between tables which are partitioned differently from one another is not supported. See [Section 18.4.1.19, “Replication and Partitioning”](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

## Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

(This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (  
    c1 INT,  
    c2 INT,  
    c3 INT  
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 12.7, “Data Type Default Values”](#).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging

format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

### Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.7.1, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the master and the slave; otherwise, updates could be applied to the wrong table on the slave. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.** Row-based replication in MySQL 5.7 supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

**Type conversion modes (slave\_type\_conversions variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

Mode	Effect
<code>ALL_LOSSY</code>	<p>In this mode, type conversions that would mean loss of information are permitted.</p> <p>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.</p>
<code>ALL_NON_LOSSY</code>	<p>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.</p> <p>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only</p>

Mode	Effect
	<code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code> , then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code> , or <code>CHAR(25)</code> to <code>VARCHAR(20)</code> ) causes the slave to stop with an error.
<code>ALL_LOSSY, ALL_NON_LOSSY</code>	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
<code>ALL_SIGNED</code>	Treat promoted integer types as signed values (the default behavior).
<code>ALL_UNSIGNED</code>	Treat promoted integer types as unsigned values.
<code>ALL_SIGNED, ALL_UNSIGNED</code>	Treat promoted integer types as signed if possible, otherwise as unsigned.
[empty]	When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.  This mode is the default.

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. Beginning with MySQL 5.7.2, you can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. (Bug#15831300) `ALL_SIGNED` tells the slave to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $D' \geq D$  and  $(M' - D') \geq (M - D)$  is non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 13.21.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* characters of the string on the slave, where *N* is the width of the target column.

**Important**

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* bytes of the string on the slave, where *N* is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where *M'* > *M*, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the *M* bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where *M'* < *M*, the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

#### 18.4.1.11 Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 6.1.8, “Server SQL Modes”](#).

#### 18.4.1.12 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`

- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

#### Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 23.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), and [Section 14.7.5.18, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where *event\_name* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *master\_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
```

```
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

#### 18.4.1.13 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 13.2, “Type Conversion in Expression Evaluation”](#), and [Section B.5.4.8, “Problems with Floating-Point Values”](#).

#### 18.4.1.14 Replication and Fractional Seconds Support

MySQL 5.7 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 12.3.6, “Fractional Seconds in Time Values”](#).

There may be problems replicating from a master server that understands fractional seconds to an older slave (MySQL 5.6.3 and earlier) that does not:

- For `CREATE TABLE` statements containing columns that have an *fsp* (fractional seconds precision) value greater than 0, replication will fail due to parser errors.
- Statements that use temporal data types with an *fsp* value of 0 will work for with statement-based logging but not row-based logging. In the latter case, the data types have binary formats and type codes on the master that differ from those on the slave.
- Some expression results will differ on master and slave. Examples: On the master, the `timestamp` system variable returns a value that includes a microseconds fractional part; on the slave, it returns an integer. On the master, functions that return a result that includes the current time (such as `CURTIME()`, `SYSDATE()`, or `UTC_TIMESTAMP()`) interpret an argument as an *fsp* value and the return value

includes a fractional seconds part of that many digits. On the slave, these functions permit an argument but ignore it.

### 18.4.1.15 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 14.7.6.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 18.4.1.16 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 18.2.1, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 18.4.1.8, “Replication of CURRENT\\_USER\(\)”](#).) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also [Section 18.4.1.32, “Replication and Time Zones”](#)

To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have

been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 18.4.1.32, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES (GET_LOCK(...))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.7.3, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the slave. (Bug #17234370, BUG# 69861)

#### 18.4.1.17 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

#### 18.4.1.18 Replication and LOAD DATA INFILE

In MySQL 5.7, `LOAD DATA INFILE` is considered unsafe (see [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)).

#### 18.4.1.19 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#)).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

### 18.4.1.20 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 18.4.1.21 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 18.4.1.24, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

#### 18.4.1.22 Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

#### 18.4.1.23 Replication and `MEMORY` Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'.`
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in MySQL Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 18.4.1.38, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See [Section 16.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

#### 18.4.1.24 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever `binlog_format` is `STATEMENT` or `MIXED`, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

#### 18.4.1.25 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

#### 18.4.1.26 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 18.4.1.17, “Replication and LIMIT”](#), for a detailed discussion of these.

#### 18.4.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `virtual` on a 5.6 master that is replicating to a 5.7 or higher slave because `VIRTUAL` is a reserved word beginning in MySQL 5.7. Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 10.2, “Schema Object Names”](#).

#### 18.4.1.28 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

#### 18.4.1.29 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see [Section 14.8.3, “HELP Syntax”](#)). These tables can be loaded manually as described at [Section 6.1.10, “Server-Side Help”](#).

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.6 help content into a MySQL 5.6 master server, but not necessarily replicate that content to a MySQL 5.7 slave server for which 5.7 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that the help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from <http://dev.mysql.com/doc/index-other.html>.

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.
2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.

## Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version (enter the command on one line):

```
mysql --init-command="SET sql_log_bin=0"  
mysql < fill_help_tables.sql
```

Use the `--init-command` option on each server, including the slaves, in case a slave also acts as a master to other slaves in your replication topology. The `SET` statement suppresses binary logging. After the command has been run on each server to be upgraded, you are done.

### Note

As of MySQL 5.7.5, the `fill_help_tables.sql` file includes the `SET` statement to cause the file contents not to replicate. Thus, for 5.7.5 and higher, the command is simpler:

```
mysql mysql < fill_help_tables.sql
```

## Loading Help Table Content With Replication to Slaves

### Note

As mentioned previously, `fill_help_tables.sql` in MySQL 5.7.5 and up includes a `SET` statement to suppress binary logging of the file contents. If you want to replicate help table contents for MySQL 5.7.5 or later, you must edit

`fill_help_tables.sql` to remove the `SET` statement. This should rarely be desirable because help table contents are specific to the version of the server into which they are loaded, which may differ for master and slave.

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

TABLE_NAME	COLUMN_NAME	COLUMN_TYPE
help_category	url	char(128)
help_topic	url	char(128)

For tables with the new structure, the statement produces this result:

TABLE_NAME	COLUMN_NAME	COLUMN_TYPE
help_category	url	text
help_topic	url	text

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.
- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

```
SET sql_log_bin=0;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
```

Then run this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

### 18.4.1.30 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same [INSERT](#) statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 6.1.8, “Server SQL Modes”](#). In particular, see [SQL Mode Changes in MySQL 5.7](#), which describes changes in MySQL 5.7 so that you can assess whether your applications will be affected.

### 18.4.1.31 Replication Retries and Timeouts

The global system variable [slave\\_transaction\\_retries](#) affects replication as follows:

If the slave SQL thread fails to execute a transaction because of an [InnoDB](#) deadlock or because it exceeded the [InnoDB innodb\\_lock\\_wait\\_timeout](#) value, or the [NDB TransactionDeadlockDetectionTimeout](#) or [TransactionInactiveTimeout](#) value, the slave automatically retries the transaction [slave\\_transaction\\_retries](#) times before stopping with an error. The default value is 10. The total retry count can be seen in the output of [SHOW STATUS](#); see [Section 6.1.7, “Server Status Variables”](#).

### 18.4.1.32 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the [NOW\(\)](#) or [FROM\\_UNIXTIME\(\)](#) functions. Set the time zone in which MySQL server runs by using the [--timezone=timezone\\_name](#) option of the [mysqld\\_safe](#) script or by setting the [TZ](#) environment variable. See also [Section 18.4.1.16, “Replication and System Functions”](#).

### 18.4.1.33 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.**

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. In MySQL 5.7, a statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a “mixed” statement. (In previous MySQL release series, a statement that changed both nontransactional and transactional tables was considered mixed.) Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a transactional table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_trans_update` is `OFF`

For more information, see [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

**Note**

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

In MySQL 5.7, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases, an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such

transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** The `binlog_format` system variable is read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. In MySQL 5.7, this true is even for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

#### 18.4.1.34 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions.* A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps.* A gap is a transaction that has not been (fully) applied, even though some later transaction has been applied. Gaps can only appear when using a multi-threaded slave. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that `log-bin` and `log-slave-updates` are also enabled.
- *Gap-free low-watermark position.* Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have not been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. This can only happen on multi-threaded slaves. Enabling `slave_preserve_commit_order` does *not* prevent gap-free low-watermark positions.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and gap-free low-watermark position inconsistencies:

1. While slave threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded slave, the coordinator thread when using a multi-threaded slave). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multi-threaded slave, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP SLAVE` when using a multi-threaded slave. After issuing `STOP SLAVE`, the slave waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or gap-free low-watermark positions, unless any of the cases above applies (in other words, before `STOP SLAVE` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP SLAVE` returns successfully.)
6. If the last transaction in the relay log is only half-received and the multi-threaded slave coordinator has started to schedule the transaction to a worker, then `STOP SLAVE` waits up to 60 seconds for the

transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.

7. `STOP SLAVE` when using a single-threaded slave. If the ongoing transaction only updates transactional tables, it is rolled back and `STOP SLAVE` stops immediately. If the ongoing transaction is mixed, `STOP SLAVE` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP SLAVE` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The slave database is in a state that may never have existed on the master.
2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a "low-watermark". In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE MASTER TO` statements for that channel fail with an error, unless the applier threads are running and the `CHANGE MASTER TO` statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-slave`, it does not record the existence of gaps; thus it prints `CHANGE MASTER TO` with `RELAY_LOG_POS` set to the low-watermark position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-slave`).

If a replication channel has a gap-free low-watermark position, cases 2 to 5 above apply, but case 1 does not.

The gap-free low-watermark position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START SLAVE [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before `START SLAVE`, and even if `START SLAVE` is used with `UNTIL` clauses. `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` only applies as many transactions as needed in order to fill in the gaps. If `START SLAVE` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

#### Warning

`RESET SLAVE` removes the relay logs and resets the replication position. Thus issuing `RESET SLAVE` on a slave with gaps means the slave loses any information about the gaps, without correcting the gaps.

`slave-preserve-commit-order` ensures that there are no gaps. However, it is still possible that `Exec_master_log_pos` is just a gap-free low-watermark position in scenarios 1 to 4 above. That is, there may be transactions after `Exec_master_log_pos` which have been applied. Therefore the cases numbered 2 to 5 above (but not case 1) apply, even when `slave-preserve-commit-order` is enabled.

### 18.4.1.35 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an [AUTO\\_INCREMENT](#) column is not replicated correctly using statement-based replication. MySQL 5.7 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event ([INSERT](#), [UPDATE](#), [DELETE](#)) and action time ([BEFORE](#), [AFTER](#)), but before MySQL 5.7.2 cannot have multiple triggers that have the same trigger event and action time. MySQL 5.7.2 lifts this limitation and multiple triggers are permitted. This change has replication implications for upgrades and downgrades.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

**Upgrades.** Suppose that you upgrade an old server that does not support multiple triggers to MySQL 5.7.2 or higher. If the new server is a replication master and has old slaves that do not support multiple triggers, an error occurs on those slaves if a trigger is created on the master for a table that already has a trigger with the same trigger event and action time. To avoid this problem, upgrade the slaves first, then upgrade the master.

**Downgrades.** If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions remain in the [.TRG](#) file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about [.TRG](#) files, see [Table Trigger Storage](#).
- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's [.TRG](#) file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using [NEW](#) and [OLD](#) can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using [OUT](#) parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

### 18.4.1.36 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 14.1.34](#), “`TRUNCATE TABLE Syntax`” governing such tables. (Bug #36763)

### 18.4.1.37 Replication and User Name Length

The maximum length of MySQL user names was increased from 16 characters to 32 characters in MySQL 5.7.8. Replication of user names longer than 16 characters to a slave that supports only shorter user names will fail. However, this should occur only when replicating from a newer master to an older slave, which is not a recommended configuration.

### 18.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`

- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 6.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see [Section 18.4.1.23, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 18.2.1, “Replication Formats”](#).

In MySQL 5.7, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`

- `sql_auto_is_null`

**Important**

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems.

### 18.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.7.1 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

## 18.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.5 to a slave running MySQL 5.6, from a master running MySQL 5.6 to a slave running MySQL 5.7, and so on.

However, you may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, in MySQL 5.5, `CREATE TABLE ... SELECT` statements are permitted to change tables other than the one being created, but are no longer allowed to do so in MySQL 5.6 (see [Section 18.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#)).

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.7.1, MySQL 5.7.2, and MySQL 5.7.4 concurrently, although you could use any two of these releases together.

**Important**

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

This also has significant implications for upgrading replication servers; see [Section 18.4.3, “Upgrading a Replication Setup”](#), for more information.

- For more information about row-based replication, see [Section 18.2.1, “Replication Formats”](#).
- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 18.4.1, “Replication Features and Issues”](#).

### 18.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#)

When you upgrade a master to 5.7 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.7.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.7.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 5.7 format.

Changes affecting operations in strict SQL mode may result in replication failure on an updated slave. For example, as of MySQL 5.7.2, the server restricts insertion of a `DEFAULT` value of 0 for temporal data types in strict mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`). A resulting incompatibility for replication if you use statement-based logging (`binlog_format=STATEMENT`) is that if a slave is upgraded, a nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (`binlog_format=ROW`) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.7.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 5.7 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.7 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.7 format. These too are recognized by the 5.7 slaves.

In other words, when upgrading to MySQL 5.7, the slaves must be MySQL 5.7 before you can upgrade the master to 5.7. Note that downgrading from 5.7 to older versions does not work so simply: You must ensure that any 5.7 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binary log. See [Section 18.2.1, “Replication Formats”](#).

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.7”](#). It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all the requirements for GTID-based replication. For example `server_uuid`, which was added in MySQL 5.6, must exist for GTIDs to function correctly. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#), which contains information about converting existing replication setups to use GTID-based replication.

## 18.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 18.2.2, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.
  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.

- Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
- If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
- Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 18.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 18.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;  
mysql> START SLAVE;
```

The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID( )`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID( )` is that they take two events in the binary log of the master.

See also [Section 14.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 18.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the master
  - All binary log files from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

This chapter explains MySQL Group Replication and how to install, configure and monitor groups. MySQL Group Replication is a MySQL Server plugin that enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

The chapter is structured as follows:

- [Section 19.1, “Group Replication Background”](#) provides an introduction to groups and how Group Replication works.
- [Section 19.2, “Getting Started”](#) explains how to configure multiple MySQL Server instances to create a group.
- [Section 19.3, “Monitoring Group Replication”](#) explains how to monitor a group.
- [Section 19.5, “Group Replication Security”](#) explains how to secure a group.
- [Section 19.9, “Group Replication Technical Details”](#) provides in-depth information about how Group Replication works.

## 19.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided group communication protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group

of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication systems engine.

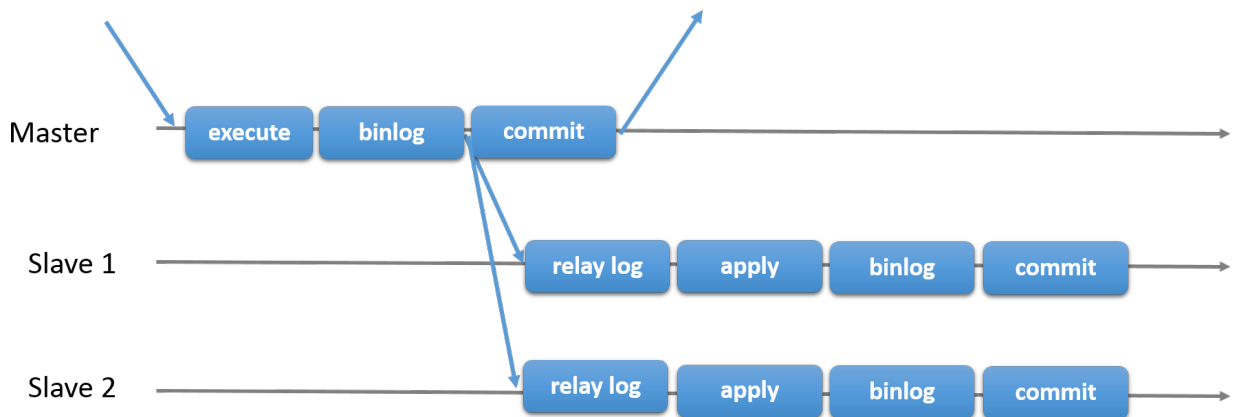

### 19.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

#### 19.1.1.1 Primary-Secondary Replication

Traditional MySQL Replication provides a simple Primary-Secondary approach to replication. There is a primary (master) and there is one or more secondaries (slaves). The primary executes transactions, commits them and then they are later (thus asynchronously) sent to the secondaries to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

**Figure 19.1 MySQL Asynchronous Replication**

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the Primary waits, at commit time, for the secondary to acknowledge that it has *received* the transaction. Only then does the Primary resume the commit operation.

**Figure 19.2 MySQL Semisynchronous Replication**

In the two pictures above, you can see a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). Blue arrows represent messages exchanged between servers or messages exchanged between servers and the client application.

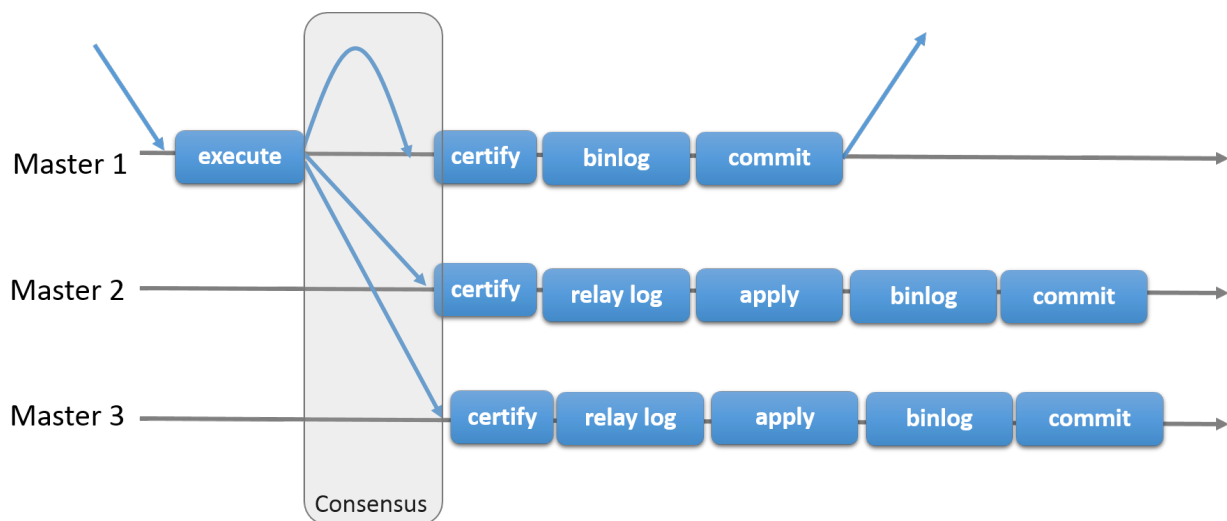

### 19.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. The replication group is a set of servers that interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-master update everywhere replication protocol. In essence, a replication group is formed by multiple servers and each server in the group may execute transactions independently. But all read-write (RW) transactions commit only after they have been approved by the group. Read-only (RO) transactions need no coordination within the group and thus commit immediately. In other words, for any RW transaction the group needs to decide whether it commits or not, thus the commit operation is not a unilateral decision from the originating server. To be precise, when a transaction is ready to commit at the originating server, the server atomically broadcasts the write values (rows changed) and the correspondent write set (unique identifiers of the rows that were updated). Then a global total order is established for that transaction. Ultimately, this means that all servers receive the same set of transactions in the same order. As a consequence, all servers apply the same set of changes in the same order, therefore they remain consistent within the group.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting the write sets of two different and concurrent transactions, in a process called *certification*. If two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The resolution procedure states that the transaction that was ordered first commits on all servers, whereas the transaction ordered second aborts, and thus is rolled back on the originating server and dropped by the other servers in the group. This is in fact a distributed first commit wins rule.

**Figure 19.3 MySQL Group Replication Protocol**

Finally, Group Replication is a shared-nothing replication scheme where each server has its own entire copy of the data.

The Figure above depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Note that some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

## 19.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state throughout a set of servers. Consequently, even if some of the servers fail, as long it is not all or a majority, the system is still available, and all it could have degraded performance or scalability, it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server fail-over, and the multi-master update everywhere nature ensures that not even updates are blocked in the event of a single server failure. Therefore MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of a server crash, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue.

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

### 19.1.2.1 Examples of Use Case Scenarios

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to Master-Slave replication* - In certain situations, using a single master server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

## 19.1.3 Group Replication Details

This section presents details about some of the services that Group Replication builds on.

### 19.1.3.1 Failure Detection

There is a failure detection mechanism provided that is able to find and report which servers are silent and as such assumed to be dead. At a high level, the failure detector is a distributed service that provides information about which servers may be dead (suspicions). Later if the group agrees that the suspicions are probably true, then the group decides that a given server has indeed failed. This means that the remaining members in the group take a coordinated decision to exclude a given member.

Suspicious are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised.

If a server gets isolated from the rest of the group, then it suspects that all others have failed. Being unable to secure agreement with the group (as it cannot secure a quorum), its suspicion does not have consequences. When a server is isolated from the group in this way, it is unable to execute any local transactions.

### 19.1.3.2 Group Membership

MySQL Group Replication relies on a group membership service. This is built into the plugin. It defines which servers are online and participating in the group. The list of online servers is often referred to as a *view*. Therefore, every server in the group has a consistent view of which are the members participating actively in the group at a given moment in time.

Servers have to agree not only on transaction commits, but also which is the current view. Therefore, if servers agree that a new server becomes part of the group, then the group itself is reconfigured to integrate that server in it, triggering a view change. The opposite also happens, if a server leaves the group, voluntarily or not, then the group dynamically rearranges its configuration and a view change is triggered.

Note though that when a member leaves voluntarily, it first initiates a dynamic group reconfiguration. This triggers a procedure, where all members have to agree on the new view without the leaving server. However, if a member leaves involuntarily (for example it has stopped unexpectedly or the network connection is down) then the failure detection mechanism realizes this fact and a reconfiguration of the group is proposed, this one without the failed member. As mentioned this requires agreement from the majority of servers in the group. If the group is not able to reach agreement (for example it partitioned in such a way that there is no majority of servers online), then the system is not be able to dynamically change the configuration and as such, blocks to prevent a split-brain situation. Ultimately, this means that the administrator needs to step in and fix this.

### 19.1.3.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers ( $n$ ) needed to tolerate  $f$  failures is then  $n = 2 \times f + 1$ .

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

Group Size	Majority	Instant Failures Tolerated
1	1	0
2	2	0
3	2	1
4	3	1
5	3	2
6	4	2

Group Size	Majority	Instant Failures Tolerated
7	4	3

The next Chapter covers technical aspects of Group Replication.

## 19.2 Getting Started

MySQL Group Replication is provided as a plugin to MySQL server, and each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three servers.

### 19.2.1 Deploying Group Replication in Single-Primary Mode

Each of the server instances in a group can run on an independent physical machine, or on the same machine. This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently.

**Figure 19.4 Group Architecture**

This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

#### 19.2.1.1 Deploying Instances for Group Replication

The first step is to deploy three instances of MySQL Server. Group Replication is a built-in MySQL plugin provided with MySQL Server 5.7.17 and later. For more background information on MySQL plugins, see

[Section 6.5, “MySQL Server Plugins”](#). Once you have download the MySQL Server package, unpack it and install the binaries. This procedure assumes that MySQL Server was downloaded and unpacked into the current directory, under the directory named `mysql-5.7`. As this tutorial uses one physical machine, each MySQL instance requires a specific data directory, which stores the data for the instance. Create the data directories in a directory named `data` and initialize each one.

```
mkdir data
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s1
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s2
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#).

### Warning

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see [Section 19.5, “Group Replication Security”](#).

## 19.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see [Section 19.7.2, “Limitations”](#).

### Group Replication Server Settings

To install and use the Group Replication plugin you must configure the MySQL Server instance correctly. It is recommended to store the configuration in your `my.cnf` file. See [Section 5.2.6, “Using Option Files”](#) for more information. Unless stated otherwise, what follows is the configuration for the first instance in the group, referred to as `s1` in this procedure. The following section shows an example server configuration.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-5.7/

port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

### Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

## Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
```

```

enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

```

These settings configure the server to use the unique identifier number 1, to enable global transaction identifiers and to store replication metadata in system tables instead of files. Additionally, it instructs the server to turn on binary logging, use row-based format and disable binary log event checksums. For more details see [Section 19.7.2, “Limitations”](#).

## Group Replication Settings

At this point the `my.cnf` file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```

transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24901"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off

```

### Note

The `loose-` prefix used for the `group_replication` variables above instructs the server to continue to start if the Group Replication plugin has not been loaded at the time the server is started.

- *Line 1* instructs the server that for each transaction it has to collect the write set and encode it as a hash using the XXHASH64 hashing algorithm.
- *Line 2* tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa".
- *Line 3* instructs the plugin to not start operations automatically when the server starts.
- *Line 4* tells the plugin to use the IP address 127.0.0.1, or localhost, and port 24901 for incoming connections from other members in the group.

### Important

The server listens on this port for member-to-member connections. This port must not be used for user applications at all, it must be reserved for inter-communication between different members of the group while running Group Replication.

The local address configured by `group_replication_local_address` must be accessible to all group members. For example, if each server instance is on a different machine use the IP and port of the machine, such as 10.0.0.1:33061. The recommended port for `group_replication_local_address` is 33061, but in this tutorial we use three server instances running on one machine, thus ports 24901 to 24903 are used.

- *Line 5* tells the plugin that the following members on those hosts and ports should be contacted in case it needs to join the group. These are seed members, which are used when this member wants to connect

to the group. Upon joining the server contacts one of them first (seed) and then it asks the group to reconfigure to allow the joiner to be accepted in the group. Note that this option does *not* need to list all members in the group, but rather a list of servers that should be contacted in case this server wishes to join the group.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. The second server joining asks the one and only member in the group to join and then the group expands. The third server joining can ask any of these two to join, and then the group expands again. Subsequent servers repeat this procedure when joining.

### Warning

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they may not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It may work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

- *Line 6* instructs the plugin whether to bootstrap the group or not.

### Important

This option must only be used on one server instance at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Disable this option after the first server instance comes online.

Configuration for all servers in the group is quite similar. You need to change the specifics about each server (for example `server_id`, `datadir`, `group_replication_local_address`). This is illustrated later in this tutorial.

## 19.2.1.3 User Credentials

Group Replication relies on the asynchronous replication protocol to be able to run distributed recovery. Therefore you need to set up a replication user to be able to establish direct member-to-member recovery channels.

Start the server:

```
mysql-5.7/bin/mysqld --defaults-file=data/s1/s1.cnf
```

Disable binary logging, create a user with the correct permissions and save the credentials for the Group Replication recovery channel.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@%' IDENTIFIED BY 'rpl_pass';
```

```
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
```

The final line seen above configures this server to use the given credentials next time it needs to recover its state from another member. Distributed recovery is the first step taken by a server that joins the group. If these credentials are not set properly, the server can not run the recovery protocol, and ultimately can not join the group.

### 19.2.1.4 Launching Group Replication

Assuming that server s1 has already been configured and started as instructed above, the next step is to install the Group Replication plugin. Connect to the server and issue the following command:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	PROPRIETARY
(...)				
group_replication	ACTIVE	GROUP REPLICATION	group_replication.so	PROPRIETARY

To start the group, instruct server s1 to bootstrap the group and then start Group Replication. This bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the bootstrap configuration option was not saved in the configuration file. If it is saved in the configuration file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`.

```
SET GLOBAL group_replication_bootstrap_group=ON;
START GROUP_REPLICATION;
SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATUS
group_replication_applier	ce9be252-2b71-11e6-b8f4-00212844f856	myhost	24801	ONLINE

1 row in set (0,00 sec)

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `myhost` listening for client connections on port `24801`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
Query OK, 1 row affected (0,00 sec)

mysql> use test
Database changed
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
Query OK, 0 rows affected (0,00 sec)

mysql> INSERT INTO t1 VALUES (1, 'Luis');
Query OK, 1 row affected (0,01 sec)
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
+-----+
| c1 | c2 |
+-----+
| 1 | Luis |
+-----+
1 row in set (0,00 sec)

mysql> SHOW BINLOG EVENTS;
+-----+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info |
+-----+-----+-----+-----+-----+-----+
| binlog.000001 | 4 | Format_desc | 1 | 123 | Server ver: 5.7.17-gr080-log, Binlog ver: 4 |
| binlog.000001 | 123 | Previous_gtid | 1 | 150 | |
| binlog.000001 | 150 | Gtid | 1 | 211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 211 | Query | 1 | 270 | BEGIN |
| binlog.000001 | 270 | View_change | 1 | 369 | view_id=14724817264259180:1 |
| binlog.000001 | 369 | Query | 1 | 434 | COMMIT |
| binlog.000001 | 434 | Gtid | 1 | 495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 495 | Query | 1 | 585 | CREATE DATABASE test |
| binlog.000001 | 585 | Gtid | 1 | 646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 646 | Query | 1 | 770 | use `test`; CREATE TABLE t1 (c1 INT PRIMARY |
| binlog.000001 | 770 | Gtid | 1 | 831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa |
| binlog.000001 | 831 | Query | 1 | 899 | BEGIN |
| binlog.000001 | 899 | Table_map | 1 | 942 | table_id: 108 (test.t1) |
| binlog.000001 | 942 | Write_rows | 1 | 984 | table_id: 108 flags: STMT_END_F |
| binlog.000001 | 984 | Xid | 1 | 1011 | COMMIT /* xid=38 */ |
+-----+-----+-----+-----+-----+-----+
15 rows in set (0,00 sec)
```

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log. The importance of the binary log entries is illustrated in the following section when the group grows and distributed recovery is executed as new members try to catch up and become online.

### 19.2.1.5 Adding Instances to the Group

At this point, the group has one member in it, server `s1`, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

#### Adding a Second Instance

In order to add a second instance, server `s2`, first create the configuration file for it. The configuration is similar to the one used for server `s1`, except for things such as the location of the data directory, the ports that `s2` is going to be listening on or its `server_id`. These different lines are highlighted in the listing below.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s2
basedir=<full_path_to_bin>/mysql-5.7/

port=24802
socket=<full_path_to_sock_dir>/s2.sock

#
# Replication configuration parameters
#
server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

#
# Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24902"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off
```

Similar to the procedure for server s1, with the configuration file in place you launch the server.

```
mysql-5.7/bin/mysqld --defaults-file=data/s2/s2.cnf
```

Then configure the recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group.

```
mysql> SET SQL_LOG_BIN=0;
Query OK, 0 rows affected (0,00 sec)

mysql> CREATE USER rpl_user@'%';
Query OK, 0 rows affected (0,00 sec)

mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@ '%' IDENTIFIED BY 'rpl_pass';
Query OK, 0 rows affected, 1 warning (0,00 sec)

mysql> FLUSH PRIVILEGES;
Query OK, 0 rows affected (0,00 sec)

mysql> SET SQL_LOG_BIN=1;
Query OK, 0 rows affected (0,00 sec)

mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
Query OK, 0 rows affected, 2 warnings (0,01 sec)
```

Install the Group Replication plugin and start the process of joining the server to the group. The following example installs the plugin in the same way as used while deploying server s1.

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
Query OK, 0 rows affected (0,01 sec)
```

Add server s2 to the group.

```
mysql> START GROUP_REPLICATION;
Query OK, 0 rows affected (44,88 sec)
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do *not* issue `SET GLOBAL group_replication_bootstrap_group=ON;` before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two *ONLINE* servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	myhost	24801	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	myhost	24802	ONLINE

2 rows in set (0,00 sec)

As server s2 is also marked as *ONLINE*, it must have already caught up with server s1 automatically. Verify that it has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
```

Database (test)
test

1 row in set (0,00 sec)

```
mysql> SELECT * FROM test.t1;
```

c1	c2
1	Luis

1 row in set (0,00 sec)

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	2	123	Server ver: 5.7.17-log, Binlog ver: 4
binlog.000001	123	Previous_gtid	2	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724832985483517:1
binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PRIMAR
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	831	Query	1	890	BEGIN
binlog.000001	890	Table_map	1	933	table_id: 108 (test.t1)
binlog.000001	933	Write_rows	1	975	table_id: 108 flags: STMT_END_F
binlog.000001	975	Xid	1	1002	COMMIT /* xid=30 */
binlog.000001	1002	Gtid	1	1063	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	1063	Query	1	1122	BEGIN

```

+-----+-----+-----+-----+-----+
| binlog.000001 | 1122 | View_change | 1 | 1261 | view_id=14724832985483517:2 |
| binlog.000001 | 1261 | Query | 1 | 1326 | COMMIT |
+-----+-----+-----+-----+-----+
19 rows in set (0,00 sec)

```

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. According to the distributed recovery procedure, this means that just after joining the group and immediately before being declared online, server s2 has connected to server s1 automatically and fetched the missing data from it. In other words, it copied transactions from the binary log of s1 that it was missing, up to the point in time that it joined the group.

## Adding a Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

### 1. Create the configuration file

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s3
basedir=<full_path_to_bin>/mysql-5.7/

port=24802
socket=<full_path_to_sock_dir>/s3.sock

#
# Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

#
# Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24903"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off
```

## 2. Start the server

```
mysql-5.7/bin/mysqld --defaults-file=data/s3/s3.cnf
```

### 3. Configure the recovery credentials for the group replication recovery channel.

```
SET SQL_LOG_BIN=0;
CREATE USER repl_user@'%';
GRANT REPLICATION SLAVE ON *.* TO repl_user@ '%' IDENTIFIED BY 'rpl_pass';
FLUSH PRIVILEGES;
```

```
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
```

#### 4. Install the Group Replication plugin and start it.

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
START GROUP_REPLICATION;
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	myhost	24801	ONLINE
group_replication_applier	7eb217ff-6df3-11e6-966c-00212844f856	myhost	24803	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	myhost	24802	ONLINE

3 rows in set (0,00 sec)

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has also caught up:

```
mysql> SHOW DATABASES LIKE 'test';
```

Database (test)
test

1 row in set (0,00 sec)

```
mysql> SELECT * FROM test.t1;
```

c1	c2
1	Luis

1 row in set (0,00 sec)

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	3	123	Server ver: 5.7.17-log, Binlog ver: 4
binlog.000001	123	Previous_gtid	3	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724832985483517:1
binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PRIMAR
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	831	Query	1	890	BEGIN
binlog.000001	890	Table_map	1	933	table_id: 108 (test.t1)
binlog.000001	933	Write_rows	1	975	table_id: 108 flags: STMT_END_F
binlog.000001	975	Xid	1	1002	COMMIT /* xid=29 */
binlog.000001	1002	Gtid	1	1063	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa

binlog.000001	1585	Query	1	1650	COMMIT
-----+-----+-----+-----+-----+-----					
23 rows in set (0,00 sec)					

## 19.3 Monitoring Group Replication

Use the Performance Schema tables to monitor Group Replication, assuming that MySQL has been compiled with the Performance Schema enabled. Group Replication adds the following two new P\_S tables:

- `performance_schema.replication_group_member_stats`
- `performance_schema.replication_group_members`

These existing P\_S replication tables also show information regarding Group Replication.

- `performance_schema.replication_connection_status`
- `performance_schema.replication_applier_status`

The replication channels created by the Group Replication plugin are named:

- `group_replication_recovery` - This channel is used for the replication changes that are related to the distributed recovery phase.
- `group_replication_applier` - This channel is used for the incoming changes from the group. This is the channel used to apply transactions coming directly from the group.

The following sections describe the information available in each of these tables.

### 19.3.1 Replication\_group\_member\_stats

Each member in a replication group certifies and applies transactions committed by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on. The table `performance_schema.replication_group_member_stats` provides the following information related to the certification process.

**Table 19.1** `replication_group_member_stats`

Field	Description
Channel_name	The name of the Group Replication channel.
Member_id	This gives the member server UUID to which we are currently connected to. This has a different value for each member in the group. This also serves a key since it is unique to each member.
Count_Transactions_in_queue	Number of transactions in queue pending conflict detection checks. Once checked for conflicts, and if they pass the check, they are queued to be applied as well.

Field	Description
Count_transactions_checked	Indicates the number of transactions that were checked for conflicts.
Count_conflicts_detected	Indicates the number of transactions that did not pass the conflict detection check.
Count_transactions_validating	Indicates the current size of the conflict detection database (against which each transaction is certified).
Transactions_committed_all_members	Indicates those transactions that have been successfully committed on all members of the current view. This is updated at a fixed time interval.
Last_conflict_free_transaction	Shows the transaction identifier of the last conflict free transaction checked.

These fields are important for monitoring the performance of the members connected in the group. For example, suppose that one of the group's members is delayed and is not able to keep up to date with the other members of the group. In this case you might see a large number of transactions in the queue. Based on this information, you could decide to either remove the member from the group or delay the processing of transactions on the other members of the group thus reducing the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin.

### 19.3.2 Replication\_group\_members

This table is used for monitoring the status of the different servers that are tracked in the current view, or in other words are part of the group and as such are tracked by the membership service.

**Table 19.2 replication\_group\_members**

Field	Description
Channel_name	The name of the Group Replication channel.
Member_id	This shows the member server UUID.
Member_host	The network address of the member.
Member_port	The MySQL connection port on which member is listening.
Member_state	This gives the status of the members of the group (whether they are ONLINE, RECOVERING, OFFLINE or UNREACHABLE)

### 19.3.3 Replication\_connection\_status

When connected to a group, some fields in this table show information regarding Group Replication. For instance, the transactions that have been received from the group and queued in the applier queue (the relay log).

**Table 19.3 replication\_connection\_status**

Field	Description
Channel_name	The name of the Group Replication channel.
Group_name	Shows the value of the name of the group. It is always a valid UUID.

Field	Description
Source_UUID	Shows the identifier for the group. It is similar to the group name and it is used as the UUID for all the transactions that are generated during group replication.
Service_state	Shows whether the member is a part of the group or not. The possible values of service state can be {ON, OFF and CONNECTING};
Received_transaction_set	Transactions in this GTID set have been received by this member of the group.

### 19.3.4 Replication\_applier\_status

The state of the Group Replication related channels and threads can be observed using the regular `replication_applier_status` table as well. If there are many different worker threads applying transactions, then the worker tables can also be used to monitor what each worker thread is doing.

**Table 19.4** `replication_applier_status`

Field	Description
Channel_name	The name of the Group Replication channel.
Service_state	Shows whether the applier service is ON or OFF.
Remaining_delay	Shows whether there is some applier delay configured.
Count_transactions_retries	The number of retries performed while applying a transaction.
Received_transaction_set	Transactions in this GTID set have been received by this member of the group.

### 19.3.5 Group Replication Server States

The table `replication_group_members` is updated whenever there is a view change, for example when the configuration of the group is dynamically changed. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together.

There are various states that a server instance can be in. If servers are communicating properly, all report the same states for all servers. However, if there is a network partition, or a server leaves the group, then different information may be reported, depending on which server is queried. Note that if the server has left the group then obviously it cannot report updated information about other servers' state. If there is a partition, such that quorum is lost, servers are not able to coordinate between themselves. As a consequence, they cannot guess what the status of different servers is. Therefore, instead of guessing their state they report that some servers are unreachable.

**Table 19.5** Server State

Field	Description	Group Synchronized
ONLINE	The member is ready to serve as a fully functional group member, meaning that the client can connect and start executing transactions.	Yes
RECOVERING	The member is in the process of becoming an active member of the group and is currently going through the recovery process, receiving state information from a donor.	No

Field	Description	Group Synchronized
OFFLINE	The plugin is loaded but the member does not belong to any group.	No
ERROR	The state of the local node. Whenever there is an error on the recovery phase or while applying changes, the server enters this state.	No
UNREACHABLE	Whenever the local failure detector suspects that a given server is not reachable, because maybe it has crashed or was disconnected involuntarily, it shows that server's state as 'unreachable'.	No

Note that Group Replication is *not* synchronous, but eventually synchronous. More precisely, transactions are delivered to all group members in the same order, but their execution is not synchronized, meaning that after a transaction is accepted to be committed, each member commits at its own pace.

## 19.4 Group Replication Operations

This section describes the different modes of deploying Group Replication, explains common operations for managing groups and provides information about how to tune your groups .

### 19.4.1 Deploying in Multi-Primary or Single-Primary Mode

Group Replication operates in the following different modes:

- single-primary mode
- multi-primary mode

The default mode is single-primary. It is not possible to have members of the group deployed in different modes, for example one configured in multi-primary mode while another one is in single-primary mode. To switch between modes, the group and not the server, needs to be restarted with a different operating configuration. Regardless of the deployed mode, Group Replication does not handle client-side fail-over, that must be handled by the application itself, a connector or a middleware framework such as a proxy or router.

When deployed in multi-primary mode, statements are checked to ensure they are compatible with the mode. The following checks are made when Group Replication is deployed in multi-master mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

These checks can be deactivated by setting the option `group_replication_enforce_update_everywhere_checks` to `FALSE`. When deploying in single-primary mode, this option *must* be set to `FALSE`.

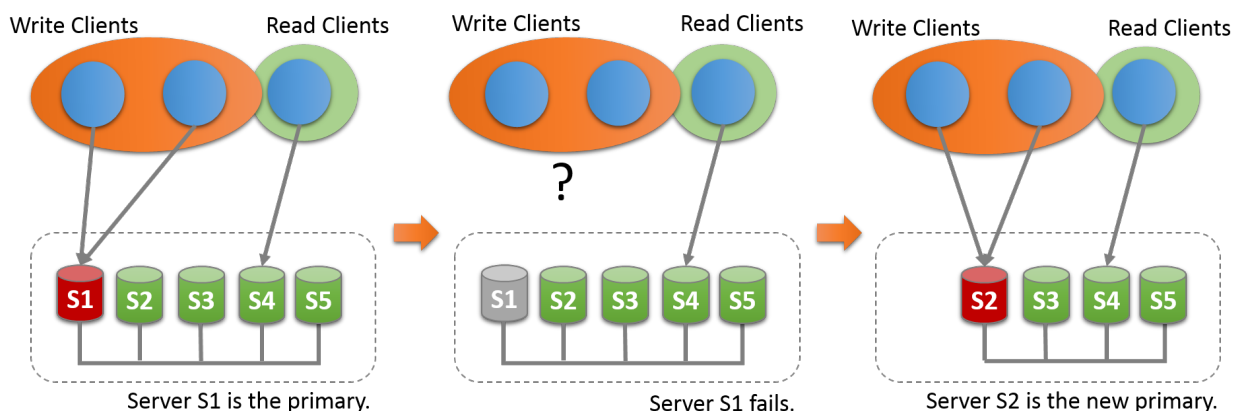

#### 19.4.1.1 Single-Primary Mode

In this mode the group has a single-primary server that is set to read-write mode. All the other members in the group are set to read-only mode (i.e., super-read-only ). This happens automatically. The primary

is typically the first server to bootstrap the group, all other servers that join automatically learn about the primary server and are set to read only.

**Figure 19.5 New Primary Election**

When in single-primary mode, some of the checks deployed in multi-primary mode are disabled, because the system enforces that only a single writer server is in the group at a time. For example, changes to tables that have cascading foreign keys are allowed, whereas in multi-primary mode are not. Upon primary member failure, an automatic leader election mechanism chooses the next primary member. The next primary is selected by ordering the remaining servers lexicographically (using their UUID) and picking the first member in the list.

In the event the primary member is removed from the group, then an election is performed and a new primary is chosen from the remaining servers in the group. This election is performed by looking at the new view, ordering the server UUIDs in lexicographical order and by picking the first one. Once a new primary is elected, it is automatically set to read-only and the other secondaries remain as secondaries, and as such, read-only.

It is a good practice to wait for the new primary to apply its replication related relay-log before re-routing the client applications to it.

### 19.4.1.2 Multi-Primary Mode

In multi-primary mode, there is no notion of a single primary. There is no need to engage an election procedure since there is no server playing any special role.

**Figure 19.6 Client Failover**

All servers are set to read-write mode when joining the group.

### 19.4.1.3 Finding the Primary

The following example shows how to find out which server is currently the primary when deployed in single-primary mode.

```
mysql> SELECT VARIABLE_VALUE FROM performance_schema.global_status WHERE VARIABLE_NAME= 'group_replication_pri
+-----+
| VARIABLE_VALUE |
+-----+
| 69e1a3b8-8397-11e6-8e67-bf68cbc061a4 |
+-----+
1 row in set (0,00 sec)
```

## 19.4.2 Tuning Recovery

Whenever a new member joins a replication group, it connects to a suitable donor and fetches the data that it has missed up until the point it is declared online. This critical component in Group Replication is fault tolerant and configurable. The following section explains how recovery works and how to tune the settings

### Donor Selection

A random donor is selected from the existing online members in the group. This way there is a good chance that the same server is not selected more than once when multiple members enter the group.

If the connection to the selected donor fails, a new connection is automatically attempted to a new candidate donor. Once the connection retry limit is reached the recovery procedure terminates with an error.

#### Note

A donor is picked randomly from the list of online members in the current view.

### Enhanced Automatic Donor Switchover

The other main point of concern in recovery as a whole is to make sure that it copes with failures. Hence, Group Replication provides robust error detection mechanisms. In earlier versions of Group Replication, when reaching out to a donor, recovery could only detect connection errors due to authentication issues or some other problem. The reaction to such problematic scenarios was to switch over to a new donor thus a new connection attempt was made to a different member.

This behavior was extended to also cover other failure scenarios:

- *Purged data scenarios* - If the selected donor contains some purged data that is needed for the recovery process then an error occurs. Recovery detects this error and a new donor is selected.
- *Duplicated data* - If a joiner already contains some data that conflicts with the data coming from the selected donor during recovery then an error occurs. This could be caused by some errant transactions present in the joiner.

One could argue that recovery should fail instead of switching over to another donor, but in heterogeneous groups there is chance that other members share the conflicting transactions and others do not. For that reason, upon error, recovery selects another donor from the group.

- *Other errors* - If any of the recovery threads fail (receiver or applier threads fail) then an error occurs and recovery switches over to a new donor.

**Note**

In case of some persistent failures or even transient failures recovery automatically retries connecting to the same or a new donor.

## Donor Connection Retries

The recovery data transfer relies on the binary log and existing MySQL replication framework, therefore it is possible that some transient errors could cause errors in the receiver or applier threads. In such cases, the donor switch over process has retry functionality, similar to that found in regular replication.

## Number of Attempts

The number of attempts a joiner makes when trying to connect to a donor from the pool of donors is 10. This is configured through the `group_replication_recovery_retry_count` plugin variable. The following command sets the maximum number of attempts to connect to a donor to 10.

```
SET GLOBAL group_replication_recovery_retry_count= 10;
```

Note that this accounts for the global number of attempts that the joiner makes connecting to each one of the suitable donors.

## Sleep Routines

The `group_replication_recovery_reconnect_interval` plugin variable defines how much time the recovery process should sleep between donor connection attempts. This variable has its default set to 60 seconds and you can change this value dynamically. The following command sets the recovery donor connection retry interval to 120 seconds.

```
SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

Note, however, that recovery does not sleep after every donor connection attempt. As the joiner is connecting to different servers and not to the same one over and over again, it can assume that the problem that affects server A maybe not affect server B. As such, recovery suspends only when it has gone through all the possible donors. Once the joiner has tried to connect to all the suitable donors in the group and none remains, the recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` variable.

### 19.4.3 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

**Note**

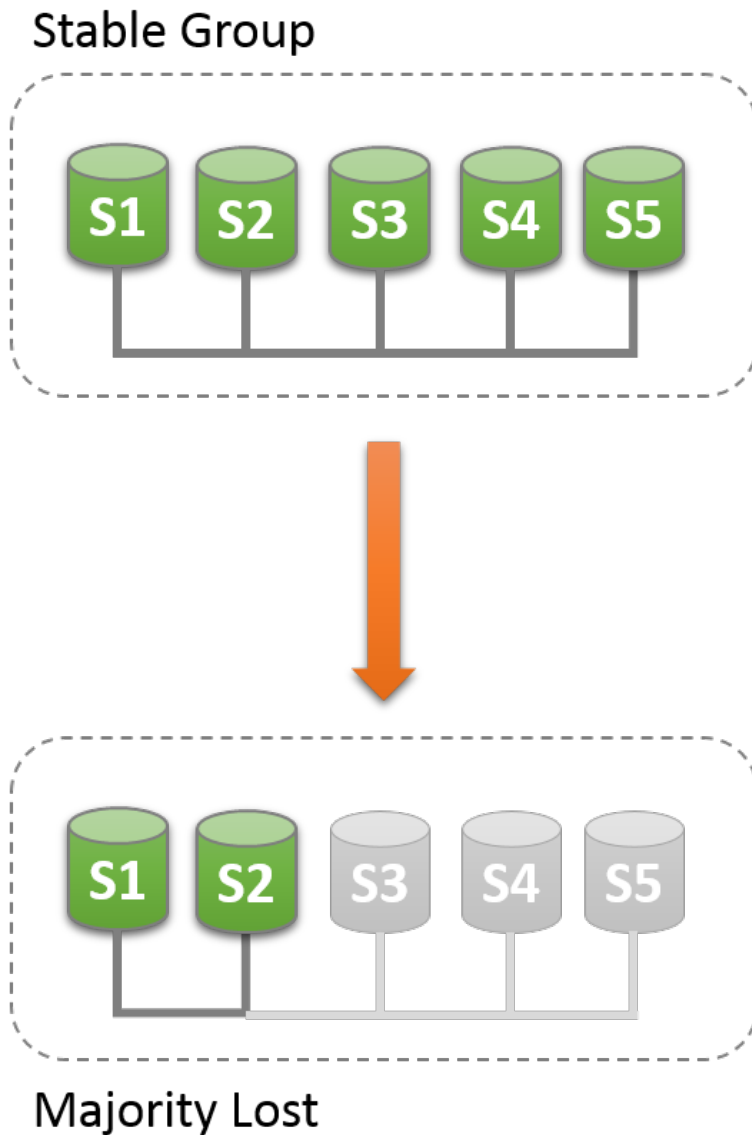

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

### 19.4.3.1 Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 19.7 Losing Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, lets assume that there is a group with these 5 servers in it:

- Server s1 with member identifier [199b2df7-4aaf-11e6-bb16-28b2bd168d07](#)
- Server s2 with member identifier [199bb88e-4aaf-11e6-babe-28b2bd168d07](#)
- Server s3 with member identifier [1999b9fb-4aaf-11e6-bb54-28b2bd168d07](#)
- Server s4 with member identifier [19ab72fc-4aaf-11e6-bb51-28b2bd168d07](#)
- Server s5 with member identifier [19b33846-4aaf-11e6-ba81-28b2bd168d07](#)

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	1999b9fb-4aaf-11e6-bb54-28b2bd168d07	127.0.0.1	13002	ONLINE
group_replication_applier	199b2df7-4aaf-11e6-bb16-28b2bd168d07	127.0.0.1	13001	ONLINE
group_replication_applier	199bb88e-4aaf-11e6-babe-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	19ab72fc-4aaf-11e6-bb51-28b2bd168d07	127.0.0.1	13003	ONLINE
group_replication_applier	19b33846-4aaf-11e6-ba81-28b2bd168d07	127.0.0.1	13004	ONLINE

5 rows in set (0,00 sec)

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	1999b9fb-4aaf-11e6-bb54-28b2bd168d07	127.0.0.1	13002	UNREACHABLE
group_replication_applier	199b2df7-4aaf-11e6-bb16-28b2bd168d07	127.0.0.1	13001	ONLINE
group_replication_applier	199bb88e-4aaf-11e6-babe-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	19ab72fc-4aaf-11e6-bb51-28b2bd168d07	127.0.0.1	13003	UNREACHABLE
group_replication_applier	19b33846-4aaf-11e6-ba81-28b2bd168d07	127.0.0.1	13004	UNREACHABLE

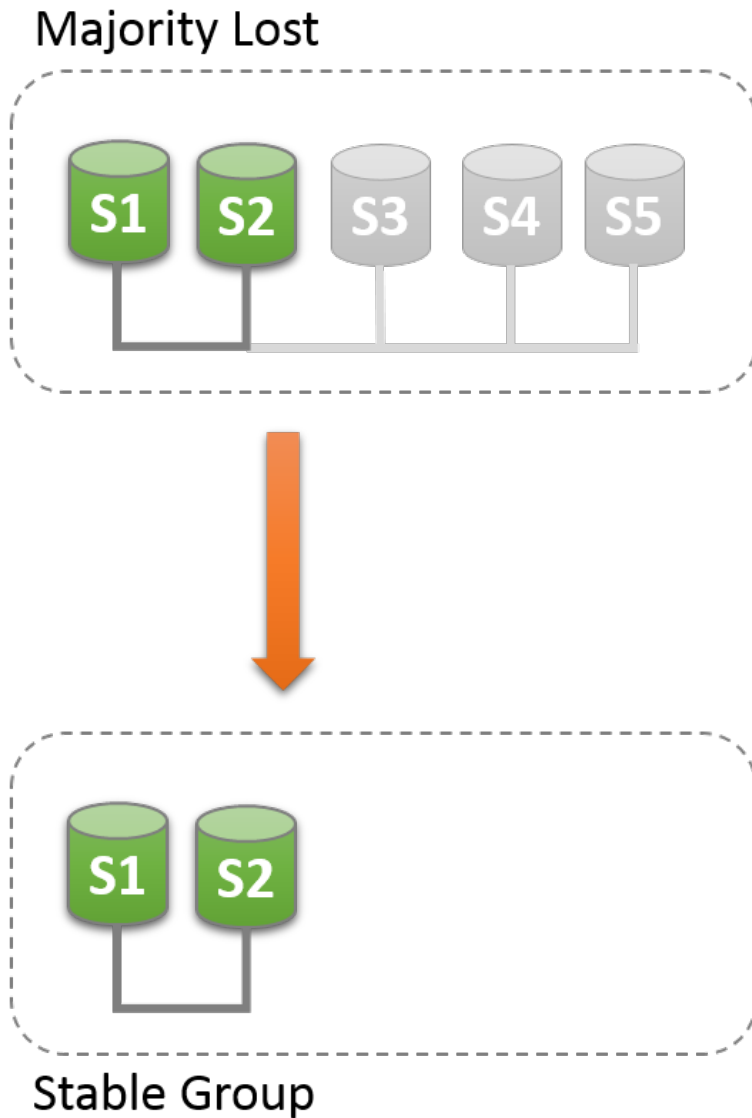

5 rows in set (0,00 sec)

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

### 19.4.3.2 Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could chose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

Figure 19.8 Forcing a New Membership

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

**Warning**

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	1999b9fb-4aaf-11e6-bb54-28b2bd168d07	127.0.0.1	13002	UNREACHABLE
group_replication_applier	199b2df7-4aaf-11e6-bb16-28b2bd168d07	127.0.0.1	13001	ONLINE
group_replication_applier	199bb88e-4aaf-11e6-babe-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	19ab72fc-4aaf-11e6-bb51-28b2bd168d07	127.0.0.1	13003	UNREACHABLE
group_replication_applier	19b33846-4aaf-11e6-ba81-28b2bd168d07	127.0.0.1	13004	UNREACHABLE

5 rows in set (0,00 sec)

The first thing to do is to check what is the peer address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
+-----+
| @@group_replication_local_address |
+-----+
| 127.0.0.1:10000 |
+-----+
1 row in set (0,00 sec)
```

Then log in to s2 and do the same thing:

```
mysql> SELECT @@group_replication_local_address;
+-----+
| @@group_replication_local_address |
+-----+
| 127.0.0.1:10001 |
+-----+
1 row in set (0,00 sec)
```

Once you know the group communication addresses of s1 (127.0.0.1:10000) and s2 (127.0.0.1:10001), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
Query OK, 0 rows affected (7,13 sec)
```

This unblocks the group by forcing a different configuration. Check [replication\\_group\\_members](#) on both s1 and s2 to verify the group membership after this change. First on s1.

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	b5ffe505-4ab6-11e6-b04b-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	b60907e7-4ab6-11e6-afb7-28b2bd168d07	127.0.0.1	13001	ONLINE

2 rows in set (0,00 sec)

And then on s2.

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	b5ffe505-4ab6-11e6-b04b-28b2bd168d07	127.0.0.1	13000	ONLINE
group_replication_applier	b60907e7-4ab6-11e6-afb7-28b2bd168d07	127.0.0.1	13001	ONLINE

2 rows in set (0,00 sec)

When forcing a new membership configuration, make sure that whatever servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shutdown and if they are not, shut them down before proceeding.

## 19.5 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using address whitelisting.

### 19.5.1 IP Address Whitelisting

The Group Replication plugin has a configuration option to determine from which hosts an incoming Group Communication connection can be accepted. This option is called `group_replication_ip_whitelist`. If you set this option on a server s1, then when server s2 is establishing a connection to s1 for the purpose of engaging group communication, then s1 first checks the whitelist before accepting the connection from s2. If s2 is in the whitelist, then s1 accepts the connection, otherwise s1 rejects the connection attempt by s2.

#### Note

By default, if not specified explicitly, the whitelist is automatically set to the private network addresses that the server has network interfaces on.

If you do not configure any whitelist, the server automatically sets the whitelist to the private networks that the server has an interface on. This means that a server, even if it has interfaces on public IPs, does not by default allow connections from external hosts.

Whenever the IP whitelist is set to AUTOMATIC, an entry in the error log can be emitted in such case, similar to:

```
2016-07-07T06:40:49.320686Z 4 [Note] Plugin group_replication reported: 'Added automatically \\
IP ranges 10.120.40.237/18,10.178.59.44/22,127.0.0.1/8 to the whitelist'
```

You can improve the security of the group further by manually setting the list of IP addresses permitted for group communication connections to come from. The list can be specified in CIDR notation or as simple IP addresses. A comma must separate each entry. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_whitelist="10.120.40.237/18,10.178.59.44/22,127.0.0.1/8";
mysql> START GROUP_REPLICATION;
```

#### Note

The localhost IP address (127.0.0.1) is always added to the whitelist. If not explicitly, it is implicitly and automatically added.

### 19.5.2 Secure Socket Layer Support (SSL)

MySQL Group Replication supports both OpenSSL and YaSSL builds of MySQL Server.

Group communication connections as well as recovery connections, are secured using SSL. The following sections explain how to configure connections.

## Configuring SSL for Recovery

Recovery is performed through a regular asynchronous replication connection. Once the donor is selected, the joiner establishes an asynchronous replication connection. This is all automatic.

However, a user that requires an SSL connection must have been created before the joiner connects to the donor. Typically, this is set up at the time one is provisioning a server to join the group.

```
donor> SET SQL_LOG_BIN=0;
donor> CREATE USER 'rec_ssl_user'@'%' REQUIRE SSL;
donor> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%%';
donor> SET SQL_LOG_BIN=1;
```

Assuming that all servers already in the group have a replication user set up to use SSL, you configure the joiner to use those credentials when connecting to the donor. That is done according to the values of the SSL options provided for the Group Replication plugin.

```
new_member> SET GLOBAL group_replication_recovery_use_ssl=1;
new_member> SET GLOBAL group_replication_recovery_ssl_ca= '.../cacert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_cert= '.../client-cert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_key= '.../client-key.pem';
```

And by configuring the recovery channel to use the credentials of the user that requires an SSL connection.

```
new_member> CHANGE MASTER TO MASTER_USER="rec_ssl_user" FOR CHANNEL "group_replication_recovery";
new_member> START GROUP_REPLICATION;
```

## Configuring SSL for Group Communication

Secure sockets can be used to establish communication between members in a group. The configuration for this depends on the server's SSL configuration. As such, if the server has SSL configured, the Group Replication plugin also has SSL configured. For more information on the options for configuring the server SSL, see [Section 7.4.5, "Command Options for Secure Connections"](#). The options which configure Group Replication are shown in the following table.

**Table 19.6 SSL Options**

Server Configuration	Plugin Configuration Description
ssl_key	Path of key file. To be used as client and server certificate.
ssl_cert	Path of certificate file. To be used as client and server certificate.
ssl_ca	Path of file with SSL CAs that are trusted.
ssl_capath	Path of directory containing certificates for SSL CAs that are trusted.
ssl_crl	Path of file containing the certificate revocation lists.
ssl_crlpath	Path of directory containing revoked certificate lists files.
ssl_cipher	Permitted ciphers to use while encrypting data over the connection.
tls_version	Secure communication will use this version and its protocols.

These options are MySQL Server configuration options which Group Replication relies on for its configuration. In addition there is the following Group Replication specific option to configure SSL on the plugin itself.

- `group_replication_ssl_mode` - specifies the security state of the connection between Group Replication members.

**Table 19.7 group\_replication\_ssl\_mode configuration values**

Value	Description
<code>DISABLED</code>	Establish an unencrypted connection ( <i>default</i> ).
<code>REQUIRED</code>	Establish a secure connection if the server supports secure connections.
<code>VERIFY_CA</code>	Like <code>REQUIRED</code> , but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.
<code>VERIFY_IDENTITY</code>	Like <code>VERIFY_CA</code> , but additionally verify that the server certificate matches the host to which the connection is attempted.

The following example shows an example `my.cnf` file section used to configure SSL on a server and how activate it for Group Replication.

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "/.../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "/.../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

The only plugin specific configuration option that is listed is `group_replication_ssl_mode`. This option activates the SSL communication between members of the group, by configuring the SSL framework with the `ssl_*` parameters that are provided to the server.

### 19.5.3 Virtual Private Networks (VPN)

There is nothing preventing Group Replication from operating over a virtual private network. At its core, it just relies on an IPv4 socket to establish connections between servers for the purpose of propagating messages between them.

## 19.6 Group Replication System Variables

These are the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with "group\_replication".

#### Important

Although most variables are described as dynamic and can be changed while the server is running, most changes only take effect upon restarting the Group Replication plugin. Variables which can be changed without requiring a restart of the plugin are specifically noted as such in this section.

- `group_replication_group_name`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-group-name=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_group_name</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The name of the group.

- `group_replication_start_on_boot`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-start-on-boot=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_start_on_boot</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Whether the server should start Group Replication or not during server start.

- `group_replication_local_address`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-local-address=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_local_address</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The local address in host:port formatted string.

- `group_replication_group_seeds`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-group-seeds=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_group_seeds</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

A list of peer addresses, comma separated list such as host1:port1,host2:port2.

- `group_replication_force_members`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-force-members=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_force_members</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

A list of peer addresses, comma separated list such as host1:port1,host2:port2. This option is used to force a new group membership, in which the excluded members do not receive a new view and are blocked. You need to manually kill the excluded servers.

- `group_replication_bootstrap_group`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-bootstrap-group=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_bootstrap_group</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Configure this server to bootstrap the group. This option must only be set on one server and only when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to OFF. It should be set to OFF both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- `group_replication_poll_spin_loops`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-poll-spin-loops=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_poll_spin_loops</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	33060
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	33060
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709547520

The number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- `group_replication_recovery_retry_count`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-retry-count=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_retry_count</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	33060
	<b>Min Value</b>	0
	<b>Max Value</b>	31536000

The number of times that the member that is joining tries to connect to the available donors before giving up.

- `group_replication_recovery_reconnect_interval`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-reconnect-interval=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_reconnect_interval</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	60

	<b>Min Value</b>	0
	<b>Max Value</b>	0

The sleep time, in seconds, between reconnection attempts when no donor was found in the group.

- `group_replication_recovery_use_ssl`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-use-ssl=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_use_ssl</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Whether Group Replication recovery connection should use SSL or not.

- `group_replication_recovery_ssl_ca`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-ca=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_ca</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The path to a file that contains a list of trusted SSL certificate authorities.

- `group_replication_recovery_ssl_capath`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-capath=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_capath</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The path to a directory that contains trusted SSL certificate authority certificates.

- `group_replication_recovery_ssl_cert`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-cert=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_cert</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The name of the SSL certificate file to use for establishing a secure connection.

- `group_replication_recovery_ssl_key`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-key=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_key</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The name of the SSL key file to use for establishing a secure connection.

- `group_replication_recovery_ssl_cipher`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-cipher=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_cipher</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

A list of permissible ciphers to use for SSL encryption.

- `group_replication_recovery_ssl_crl`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-crl=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_crl</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	<b>Type</b>	string
-------------------------	-------------	--------

The path to a directory that contains files containing certificate revocation lists.

- `group_replication_recovery_ssl_crlpath`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-crlpath=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_crlpath</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

The path to a directory that contains files containing certificate revocation lists.

- `group_replication_recovery_ssl_verify_server_cert`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-ssl-verify-server-cert=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ssl_verify_server_cert</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Make the recovery process check the server's Common Name value in the donor sent certificate.

- `group_replication_recovery_complete_at`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-recovery-complete-at=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_complete_at</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>OFF</code>
	<b>Valid Values</b>	<code>TRANSACTIONS_CERTIFIED</code> <code>TRANSACTIONS_APPLIED</code>

Recovery policies when handling cached transactions after state transfer. This option specifies whether a member is marked online after it has received all transactions that it missed before it joined the group (TRANSACTIONS\_CERTIFIED) or after it has received and applied them (TRANSACTIONS\_APPLIED).

- `group_replication_components_stop_timeout`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-components-stop-timeout=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_components_stop_timeout</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer

Timeout, in seconds, that the plugin waits for each of the components when shutting down.

- `group_replication_allow_local_lower_version_join`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-allow-local-lower-version-join=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_allow_local_lower_version_join</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Allow the current server to join the group even if it has a lower plugin version than the group.

- `group_replication_allow_local_disjoint_gtids_join`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-allow-local-disjoint-gtids-join=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_allow_local_disjoint_gtids_join</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	<code>OFF</code>

Allow the current server to join the group even if it has transactions not present in the group.

**Warning**

Use caution when enabling this option as incorrect usage could lead to inconsistencies in the group.

- `group_replication_auto_increment_increment`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-auto-increment-increment=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_auto_increment_increment</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	7
	<b>Min Value</b>	1
	<b>Max Value</b>	65535

Determines the interval between successive column values for transactions that execute on this server instance.

- `group_replication_compression_threshold`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-compression-threshold=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_compression_threshold</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	1000000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967296

The value in bytes above which (lz4) compression is enforced. When set to zero, deactivates compression.

- `group_replication_gtid_assignment_block_size`

<b>Introduced</b>	5.7.17
<b>Command-Line Format</b>	<code>--group-replication-gtid-assignment-block-size=value</code>

<b>System Variable</b>	<b>Name</b>	<code>group_replication_gtid_assignment_block_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<code>1000000</code>
	<b>Min Value</b>	<code>1</code>
	<b>Max Value</b>	<code>4294967295</code>
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	integer
	<b>Default</b>	<code>1000000</code>
	<b>Min Value</b>	<code>1</code>
	<b>Max Value</b>	<code>18446744073709547520</code>

The number of consecutive GTIDs that are reserved for each member. Each member consumes its blocks and reserve more when needed.

- `group_replication_ssl_mode`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-ssl-mode=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_ssl_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>DISABLED</code>
	<b>Valid Values</b>	<code>DISABLED</code>
		<code>REQUIRED</code>
		<code>VERIFY_CA</code>
		<code>VERIFY_IDENTITY</code>

Specifies the security state of the connection between Group Replication members.

- `group_replication_single_primary_mode`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-single-primary-mode=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_single_primary_mode</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

- `group_replication_enforce_update_everywhere_checks`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-enforce-update-everywhere-checks=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_enforce_update_everywhere_checks</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enable/Disable strict consistency checks for multi-master update everywhere.

- `group_replication_flow_control_mode`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-flow-control-mode=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_flow_control_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	QUOTA
	<b>Valid Values</b>	DISABLED
		QUOTA

Specifies the mode used for flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_certifier_threshold`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-flow-control-certifier-threshold=value</code>	

<b>System Variable</b>	<b>Name</b>	<code>group_replication_flow_control_certifier_threshold</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	25000
	<b>Min Value</b>	0
	<b>Max Value</b>	2147483648

Specifies the number of waiting transactions in the certifier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_applier_threshold`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-flow-control-applier-threshold=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_flow_control_applier_threshold</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	25000
	<b>Min Value</b>	0
	<b>Max Value</b>	2147483648

Specifies the number of waiting transactions in the applier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_ip_whitelist`

<b>Introduced</b>	5.7.17	
<b>Command-Line Format</b>	<code>--group-replication-ip-whitelist=value</code>	
<b>System Variable</b>	<b>Name</b>	<code>group_replication_recovery_ip_whitelist</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	AUTOMATIC

Specifies which hosts are permitted to connect to the group. By default set to [AUTOMATIC](#), which permits connections from private subnetworks active on the host. Active interfaces on the host are scanned and those with addresses on private subnetworks are automatically added to the permitted list. Alternatively you can specify the permitted hosts using a comma separated list of IPv4 addresses or subnet CIDR notation. For example 192.168.1.0/24,10.0.0.1.

**Note**

Address 127.0.0.1 is always permitted to connect, even when not specified using [group\\_replication\\_ip\\_whitelist](#).

## 19.7 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

### 19.7.1 Group Replication Requirements

Server instances that you want to use for Group Replication must satisfy the following requirements.

#### Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the [InnoDB](#) transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, [InnoDB](#) provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication.
- **Primary Keys.** Every table that is to be replicated by the group must have an explicit primary key defined. Primary keys play an extremely important role in determining which transactions conflict by identifying exactly which rows each transaction has modified.
- **IPv4 Network.** The group communication engine used by MySQL Group Replication only supports IPv4. Therefore, Group Replication requires an IPv4 network infrastructure.
- **Network Performance.** Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other, and is impacted by both network latency as well as network bandwidth.

#### Server Instance Configuration

The following options must be configured on server instances that are members of a group.

- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be turned on for it to operate. See [Section 6.4.4, “The Binary Log”](#).
- **Slave Updates Logged.** Set `--log-slave-updates`. Servers need to log binary logs that are applied through the replication applier. Servers in the group need to log all transactions that they receive and apply from the group. This is required because recovery is conducted by relying on binary logs from participants in the group. Therefore, copies of each transaction need to exist on every server, even for those transactions that were not initiated on the server itself.
- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on

row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. See [Section 18.2.1, “Replication Formats”](#).

- **Global Transaction Identifiers On.** Set `--gtid-mode=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).
- **Replication Information Repositories.** Set `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE`. The replication applier needs to have the master information and relay log metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin has consistent recoverability and transactional management of the replication metadata. See [Section 18.2.4.2, “Slave Status Logs”](#).
- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts.

## 19.7.2 Limitations

The following known limitations exist for Group Replication.

- **Replication Event Checksums.** Due to a design limitation of replication event checksums, Group Replication cannot currently make use of them. Therefore set `--binlog-checksum=NONE`.
- **Gap Locks.** The certification process does not take into account [gap locks](#), as information about gap locks is not available outside of [InnoDB](#). See [Gap Locks](#) for more information.

### Note

Unless you rely on [REPEATABLE READ](#) semantics in your applications, we recommend using the [READ COMMITTED](#) isolation level with Group Replication. InnoDB does not use gap locks in [READ COMMITTED](#), which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see [Section 14.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#)) or named locks (see [GET\\_LOCK\(\)](#)).
- **Savepoints Not Supported.** Transaction savepoints are not supported.
- **SERIALIZABLE Isolation Level.** [SERIALIZABLE](#) isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to [SERIALIZABLE](#) configures Group Replication to refuse to commit the transaction.
- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.

- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined `CASCADING foreign key constraints`. This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

## 19.8 Frequently Asked Questions

This section provides answers to frequently asked questions.

### What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused.

### How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group.

### What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

### How do I set credentials for the recovery procedure?

You pre-configure the Group Replication recovery channel credentials using the `CHANGE MASTER TO` statement.

### Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

---

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

## **Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?**

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

## **Can I deploy Group Replication across wide-area networks?**

This is not supported.

Fast networks with good bandwidth are a requirement for optimal performance. To improve tolerance to the effects of narrow bandwidth, you can turn ON compression for example. However, if the network drops packets, leading to retransmissions and higher end-to-end latency, then throughput and latency are negatively affected.

## **Do nodes automatically rejoin a group in case of temporary connectivity problems?**

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Once a server is removed from the group, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

## **When is a member excluded from a group?**

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

## **What happens when one node is significantly lagging behind?**

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

## **Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?**

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

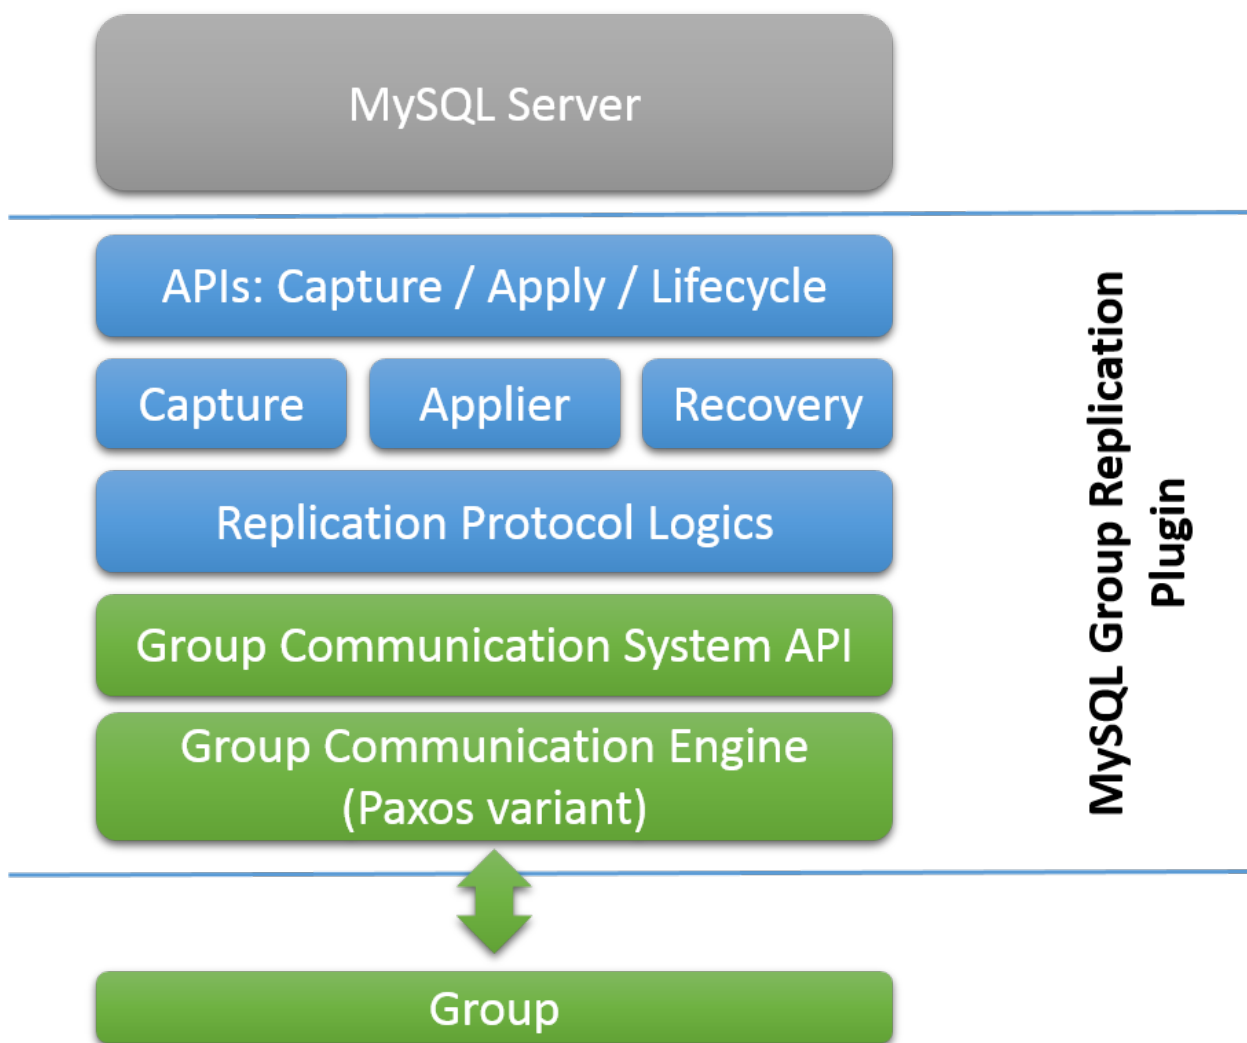

## 19.9 Group Replication Technical Details

This section provides more technical details about MySQL Group Replication.

### 19.9.1 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

**Figure 19.9 Group Replication Plugin Block Diagram**

Starting from the top of the figure, there is a set of APIs that control how the Group Replication plugin interacts with MySQL Server (the grey box). There are interfaces to make information flow from the

server to the plugin and vice versa. Such interfaces isolate the server core from the plugin and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications such as the server is starting, the server is recovering, the server is ready to accept connections, the server is about to commit a transaction, and so on. In the other direction, the plugin instructs the server to commit or abort ongoing transactions, queue transactions in the relay-log, and so on.

Below the API block is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery and is responsible for getting a server that is joining the group up to date by selecting the donor, orchestrating the catch up procedure and reacting on donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, receives and propagates transactions to the group.

The first green box is the Group Communication API. It is a high level API abstracting the properties required to build a replicated state machine (details in the Background chapter ). Therefore it decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The MySQL Group Replication plugin contains an implementation of a Paxos based group communication engine.

## 19.9.2 The Group

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. This state is transferred by means of Asynchronous MySQL replication. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically. The group membership service described at [Section 19.1.3.2, “Group Membership”](#) powers all of this.

## 19.9.3 Data Manipulation Statements

As there are no primary servers (masters) for any particular data set, every server in the group is allowed to execute transactions at any time, even transactions that change state (RW transactions).

Any server may execute a transaction without any *a priori* coordination. But, at commit time, it coordinates with the rest of the servers in the group to reach a decision on the fate of that transaction. This coordination serves two purposes: (i) check whether the transaction should commit or not; (ii) and propagate the changes so that other servers can apply the transaction as well.

As a transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. Conflict detection is carried out by inspecting and comparing write sets of transactions. Thus, they are detected at the row level. Conflict resolution follows the first committer wins rule. If t1 and t2 execute concurrently at different sites, because t2 is ordered before t1, and both changed the same row, then t2 wins the conflict and t1 aborts. In other words, t1 was trying to change data that had been rendered stale by t2.

### Note

If two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server. They then have a chance to synchronize on the local lock manager instead of aborting later in the replication protocol.

## 19.9.4 Data Definition Statements

Care needs to be taken when executing data definition statements also commonly known as data definition language (DDL). Given that MySQL does not support atomic or transactional DDL, one cannot optimistically execute DDL statements and later roll back if needs be. Consequently, the lack of atomicity does not fit directly into the optimistic replication paradigm that Group Replication is based on.

Therefore, more care needs to be taken when replicating data definition statements. Schema changes and changes to the data that the object contains need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so, may result in data inconsistency.

### Note

If the group is deployed in single-primary mode, then this is not a problem, because all changes are performed through the same server, the primary.

### Warning

MySQL DDL execution is not atomic or transactional. The server executes and commits without securing group agreement first. As such, you must route DDL and DML for the same object through the same server, while the DDL is executing and has not replicated everywhere yet.

## 19.9.5 Distributed Recovery

This section describes the process through which a joining member catches up with the remaining servers, called the distributed recovery phase.

### 19.9.5.1 Group Replication Basics

The Group Replication distributed recovery procedure can be summarized as the process through which a new server gets missing data from a online server in the group, while listening for events happening in the group. During recovery a server listens to membership events and also to the transactions that are happening while recovery is happening. This is a high level summary. The following sections provide additional detail, by describing the two phases of the procedure.

#### Phase 1

In the first phase, the joiner (joining server), will select one of the online servers on the group to be the *donor* of the state that it is missing. The donor is responsible for handing the joiner all the data it is missing up to the moment it has joined the group. This is achieved by relying on a standard asynchronous replication channel, established between donor and joiner. Through that channel, binary logs flow up until the point that the view change happened when the joiner became part of the group. While the joiner receives binary logs from the donor, it is also applying them.

Furthermore, while the binary logs transfer is ongoing, the joiner is also caching every transaction that is exchanged within the group. I.e., it is listening for transactions that are happening after it joined the group and while it is applying the missing state from the donor. When the first phase ends and the replication channel to the donor is closed, the joiner then starts phase two: the catch up.

#### Phase 2

In this phase, the joiner proceeds to the execution of the cached transactions and when the number of transactions queued for execution finally reaches zero, then the member is declared online.

## Resilience

The recovery procedure withstands donor failures while the joiner is fetching binary logs from it. In such cases, whenever a donor fails during phase 1, the joiner fails over to a new donor and resumes from that one. When that happens the joiner closes the connection to the failed joiner explicitly and opens a connection to a new donor. This happens automatically.

### 19.9.5.2 Recovering From a Point-in-time

To synchronize the joiner with the donor up to a specific point in time, the joiner and donor make use of the MySQL global transaction identifiers (GTIDs) mechanism. However, that is not enough, since that only provides a mean to realize which transactions the joiner is missing. It does not help marking a specific point in time to which the joiner must catch up, nor does it help conveying certification information. This is where the binary log view markers come into play. They mark view changes in the binary log stream, and also contain additional metadata information, provisioning the joiner with missing certification related data.

## View and View Changes

To explain the concept of view change markers, it is important to understand what a view and a view change are.

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are correct and online in the system.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens

At the group communication layer, view changes with their associated view ids are then boundaries between the data exchanged before and after a member joins. This concept is implemented through a new binary log event: the "view change log event". The view id thus becomes a marker as well for transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: (i) one that is randomly generated and (ii) a monotonically increasing integer. The first part is generated when the group is created, and remains unchanged while there is at least one member in the group. The second part is incremented every time a view change happens.

The reason for this heterogeneous pair that makes up the view id is the need to unambiguously mark group changes whenever a member joins or leaves but also whenever all members leave the group and no information remains of what view the group was in. In fact, the sole use of monotonic increasing identifiers could lead to the reuse of the same id after full group shutdowns, destroying the uniqueness of the binary log data markers that recovery depends on. To summarize, the first part identifies whenever the group was started from the beginning and the incremental part when the group changed from that point on.

### 19.9.5.3 View Changes

This section explains the process which controls how the view change identifier is incorporated into a binary log event and written to the log. The following steps are taken:

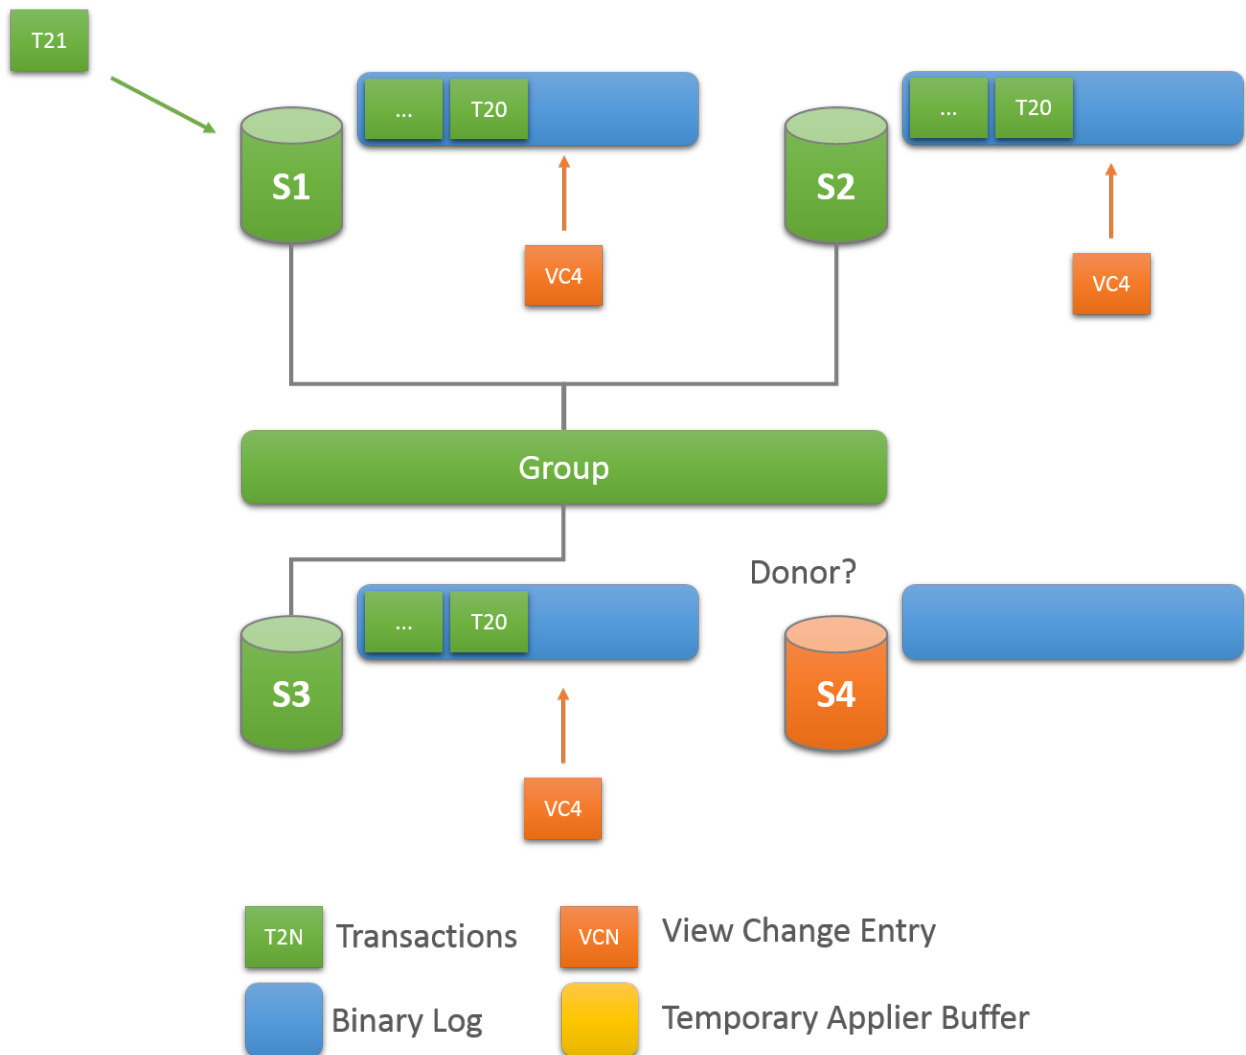

#### Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

**Figure 19.10 Stable Group****View Change: a Member Joins**

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the joiner selects the donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a View change event to the binary log.

**Figure 19.11 A Member Joins****State Transfer: Catching Up**

Once the joiner has chosen which server in the group is to be the donor, a new asynchronous replication connection is established between the two and the state transfer begins (phase 1). This interaction with the donor continues until the joiner's applier thread processes the view change log event that corresponds to the view change triggered when the joiner came into the group. In other words, the joiner replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

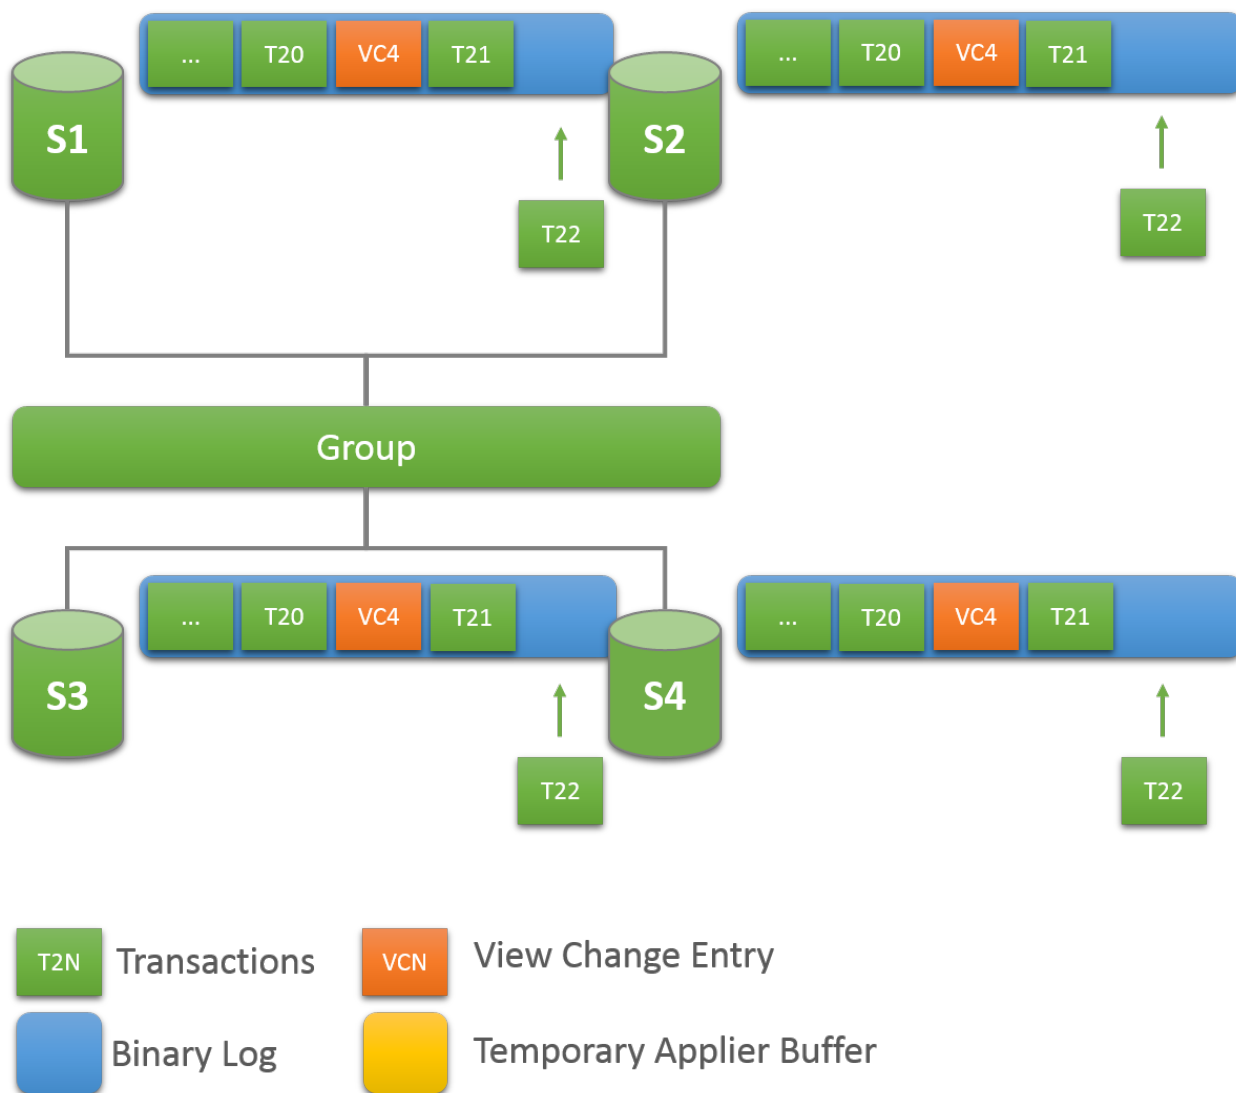

**Figure 19.12 State Transfer: Catching Up**

As view identifiers are transmitted to all members in the group at the same logical time, the joiner knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view id clearly marks which data belongs to each group view.

While the joiner is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

Figure 19.13 Queued Transactions

### Finish: Caught Up

When the joiner recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. An important point to understand is the final recovery procedure. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the joiner entered the group, in other words the last view change. Without it, the joiner would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up (phase 2) is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the joiner does not block any other server in the group while it is catching up. Therefore the number of transactions the joiner is behind when it moves to phase 2 can, for this reason, vary and thus increase or decrease according to the workload.

When the joiner's queued transactions reach zero and its stored data is equal to the other members, its public state changes to online.

Figure 19.14 Instance Online

#### 19.9.5.4 Usage Advice and Limitations of Distributed Recovery

Distributed recovery does have some limitations. It is based on classic asynchronous replication and as such it may be slow if the joiner is not provisioned at all or is provisioned with a very old backup image. This means that if the data to transfer is too big at phase 1, the server may take a very long time to recover. As such, the recommendation is that before adding a server to the group, one should provision it with a fairly recent snapshot of a server already in the group. This minimizes the length of phase 1 and reduces the impact on the donor server, since it has to save and transfer less binary logs.

#### Warning

It is recommended that a server is provisioned before it is added to a group. That way, one minimizes the time spent on the recovery step.

#### 19.9.6 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group

Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through performance\_schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see [Section 19.3, “Monitoring Group Replication”](#).

## 19.9.7 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your group.

### 19.9.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

### 19.9.7.2 Message Compression

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load.

**Table 19.8 LZ4 Compression Ratios for Different Binary Log Formats.**

Workload	Ratio	
	ROW	STMT
mysqlslapd	4,5	4,1
sysbench	3,4	2,9

The TCP peer-to-peer nature of the interconnections between  $N$  participants on the group makes the sender send the same amount of data  $N$  times. Furthermore, binary logs are likely to exhibit a high compression ratio (see table above). This makes compression a compelling feature for workloads that contain large transaction.

**Figure 19.15 Compression Support**

Compression happens at the group communication engine level, before the data is handed over to the group communication thread, so it happens within the context of the mysql user session thread. Transaction payloads may be compressed before being sent out to the group and decompressed when received. Compression is conditional and depends on a configured threshold. By default compression is enabled.

In addition, there is no requirement that all servers in the group have compression enabled to be able to work together. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer.

The compression algorithm used is LZ4. Compression is enabled by default with threshold of 1000000 bytes. The compression threshold, in bytes, may be set to something larger than default. In that case, only transactions that have a payload larger than the threshold are compressed. Below is an example of how to set a compression threshold.

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold= 2097152;
START GROUP_REPLICATION;
```

This sets the compression threshold to 2MB. If a transaction generates a replication message with a payload larger than 2MB, for example a binary log transaction entry larger than 2MB, then it is compressed. To disable compression set threshold to 0.

### 19.9.7.3 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently.

This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: (i) the *certification* queue; (ii) and on the binary log *applier* queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: (i) whether to do flow control at the certifier or at the applier level, or both; and (ii) what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

### Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;

- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

## Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota will be enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

---

## Chapter 20 MySQL NDB Cluster 7.5

### Table of Contents

20.1 NDB Cluster Overview .....	3059
20.1.1 NDB Cluster Core Concepts .....	3060
20.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions .....	3063
20.1.3 NDB Cluster Hardware, Software, and Networking Requirements .....	3066
20.1.4 What is New in MySQL NDB Cluster 7.5 .....	3067
20.1.5 MySQL Server Using InnoDB Compared with NDB Cluster .....	3072
20.1.6 Known Limitations of NDB Cluster .....	3075
20.2 NDB Cluster Installation .....	3086
20.2.1 The NDB Cluster Auto-Installer .....	3089
20.2.2 Installation of NDB Cluster on Linux .....	3104
20.2.3 Installing NDB Cluster on Windows .....	3114
20.2.4 Initial Configuration of NDB Cluster .....	3123
20.2.5 Initial Startup of NDB Cluster .....	3125
20.2.6 NDB Cluster Example with Tables and Data .....	3126
20.2.7 Safe Shutdown and Restart of NDB Cluster .....	3130
20.2.8 Upgrading and Downgrading NDB Cluster .....	3131
20.3 Configuration of NDB Cluster .....	3132
20.3.1 Quick Test Setup of NDB Cluster .....	3133
20.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables .....	3135
20.3.3 NDB Cluster Configuration Files .....	3179
20.3.4 Using High-Speed Interconnects with NDB Cluster .....	3318
20.4 NDB Cluster Programs .....	3319
20.4.1 <code>ndbd</code> — The NDB Cluster Data Node Daemon .....	3319
20.4.2 <code>ndbinfo_select_all</code> — Select From <code>ndbinfo</code> Tables .....	3326
20.4.3 <code>ndbmtd</code> — The NDB Cluster Data Node Daemon (Multi-Threaded) .....	3328
20.4.4 <code>ndb_mgmd</code> — The NDB Cluster Management Server Daemon .....	3329
20.4.5 <code>ndb_mgm</code> — The NDB Cluster Management Client .....	3337
20.4.6 <code>ndb_blob_tool</code> — Check and Repair BLOB and TEXT columns of NDB Cluster Tables .....	3339
20.4.7 <code>ndb_config</code> — Extract NDB Cluster Configuration Information .....	3341
20.4.8 <code>ndb_cpcd</code> — Automate Testing for NDB Development .....	3350
20.4.9 <code>ndb_delete_all</code> — Delete All Rows from an NDB Table .....	3350
20.4.10 <code>ndb_desc</code> — Describe NDB Tables .....	3351
20.4.11 <code>ndb_drop_index</code> — Drop Index from an NDB Table .....	3357
20.4.12 <code>ndb_drop_table</code> — Drop an NDB Table .....	3358
20.4.13 <code>ndb_error_reporter</code> — NDB Error-Reporting Utility .....	3359
20.4.14 <code>ndb_index_stat</code> — NDB Index Statistics Utility .....	3360
20.4.15 <code>ndb_print_backup_file</code> — Print NDB Backup File Contents .....	3366
20.4.16 <code>ndb_print_file</code> — Print NDB Disk Data File Contents .....	3366
20.4.17 <code>ndb_print_schema_file</code> — Print NDB Schema File Contents .....	3367
20.4.18 <code>ndb_print_sys_file</code> — Print NDB System File Contents .....	3367
20.4.19 <code>ndbd_redo_log_reader</code> — Check and Print Content of Cluster Redo Log .....	3368
20.4.20 <code>ndb_restore</code> — Restore an NDB Cluster Backup .....	3369
20.4.21 <code>ndb_select_all</code> — Print Rows from an NDB Table .....	3384
20.4.22 <code>ndb_select_count</code> — Print Row Counts for NDB Tables .....	3388
20.4.23 <code>ndb_setup.py</code> — Start browser-based Auto-Installer for NDB Cluster .....	3388
20.4.24 <code>ndb_show_tables</code> — Display List of NDB Tables .....	3391
20.4.25 <code>ndb_size.pl</code> — NDBCLUSTER Size Requirement Estimator .....	3393
20.4.26 <code>ndb_waiter</code> — Wait for NDB Cluster to Reach a Given Status .....	3396

20.4.27 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs .....	3398
20.5 Management of NDB Cluster .....	3402
20.5.1 Summary of NDB Cluster Start Phases .....	3403
20.5.2 Commands in the NDB Cluster Management Client .....	3405

20.7 NDB Cluster Release Notes .....	3578

This chapter contains information about MySQL *NDB Cluster*, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Recent NDB Cluster release series use version 7 of the [NDB](#) storage engine (also known as [NDBCLUSTER](#)) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 7.5, now available as a General Availability (GA) release beginning with version 7.5.4, incorporates version 7.5 of the [NDB](#) storage engine. Previous GA releases still available for production, NDB 7.3 and NDB Cluster 7.4, incorporate [NDB](#) versions 7.3 and 7.4, respectively.

Support for the [NDB](#) storage engine is not included in standard MySQL Server 5.7 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster users who build from source should use the sources provided for NDB Cluster . (Locations where the sources can be obtained are listed later in this section.)

This chapter contains information about NDB Cluster 7.5 releases through 5.7.16-ndb-7.5.5. NDB Cluster 7.5 is available as a General Availability release, and recommended for new deployments. The NDB Cluster 7.4 and NDB Cluster 7.3 release series are previous GA releases still supported in production. NDB Cluster 7.2 is a previous GA release series which is still supported. We currently recommend that new deployments for production use NDB Cluster 7.5. For more information about NDB Cluster 7.4 and NDB Cluster 7.3, see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#). For information about NDB Cluster 7.2, see [MySQL NDB Cluster 7.2](#).

---

**Supported Platforms.** NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <http://www.mysql.com/support/supportedplatforms/cluster.html>.

**Availability.** NDB Cluster binary and source packages are available for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

**NDB Cluster release numbers.** NDB Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.7 series of releases. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the [NDBCLUSTER](#) storage engine used in the release, and not of the MySQL server version on which the NDB Cluster release is based.

**Version strings used in NDB Cluster software.** The version string displayed by NDB Cluster programs uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

[mysql\\_server\\_version](#) represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 7.5 releases, this is “5.7”. [ndb\\_engine\\_version](#) is the version of the [NDB](#) storage engine used by this release of the NDB Cluster software. You can see this format used in the [mysql](#) client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.7.16-ndb-7.5.5 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 5.7.16-ndb-7.5.5
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the [SHOW](#) command in the [ndb\\_mgm](#) client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=2 @10.0.10.8 (5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)

```

The version string identifies the mainline MySQL version from which the NDB Cluster release was branched and the version of the [NDB](#) storage engine used. For example, the full version string for NDB 7.5.4 (the first NDB 7.5 GA release) was [mysql-5.7.16-ndb-7.5.4](#). From this we can determine the following:

- Since the portion of the version string preceding `-ndb-` is the base MySQL Server version, this means that NDB 7.5.4 derived from MySQL 5.7.16, and contained all feature enhancements and bug fixes from MySQL 5.7 up to and including MySQL 5.7.16.
- Since the portion of the version string following `-ndb-` represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, NDB 7.5.4 used version 7.5.4 of the `NDBCLUSTER` storage engine.

New NDB Cluster releases are numbered according to updates in the `NDB` storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, NDB 7.5.4 (as previously noted) was based on MySQL 5.7.16, while NDB 7.5.3 was based on MySQL 5.7.13 (version string: `mysql-5.7.13-ndb-7.5.3`).

**Compatibility with standard MySQL 5.7 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see [Section 20.1.6, “Known Limitations of NDB Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and NDB Cluster codebases diverge considerably, so that the standard `mysqld` cannot function as a drop-in replacement for the version of `mysqld` supplied with NDB Cluster.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from <https://github.com/mysql/mysql-server>.

The NDB Cluster development sources maintained at <https://github.com/mysql/mysql-server> are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

#### Note

As with MySQL Server 5.7, NDB Cluster 7.5 releases are built using `CMake`.

NDB Cluster 7.5 is available as a General Availability (GA) release, and recommended for new deployments beginning with version 7.5.4. NDB Cluster 7.4 and NDB Cluster 7.3 are previous GA releases which are still supported in production. NDB 7.2 is a previous GA release series which is still supported, although it is no longer recommended for new deployments. We currently recommend that new deployments for production use NDB 7.5. For an overview of major features added in NDB 7.4, see [What is New in NDB Cluster 7.4](#). For similar information about NDB Cluster 7.3, see [What is New in NDB Cluster 7.3](#). For an overview of major features added in previous NDB Cluster releases, see [What is New in NDB Cluster in NDB Cluster 7.2](#). NDB 7.1 and earlier versions of NDB Cluster are no longer being developed or maintained.

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL Web site at <http://www.mysql.com/products/cluster/>.

**Additional Resources.** More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see [Section A.10, “MySQL 5.7 FAQ: MySQL Cluster”](#).
- The NDB Cluster mailing list: <http://lists.mysql.com/cluster>.
- The NDB Cluster Forum: <http://forums.mysql.com/list.php?25>.

- Many NDB Cluster users and developers blog about their experiences with NDB Cluster , and make feeds of these available through [PlanetMySQL](#).

## 20.1 NDB Cluster Overview

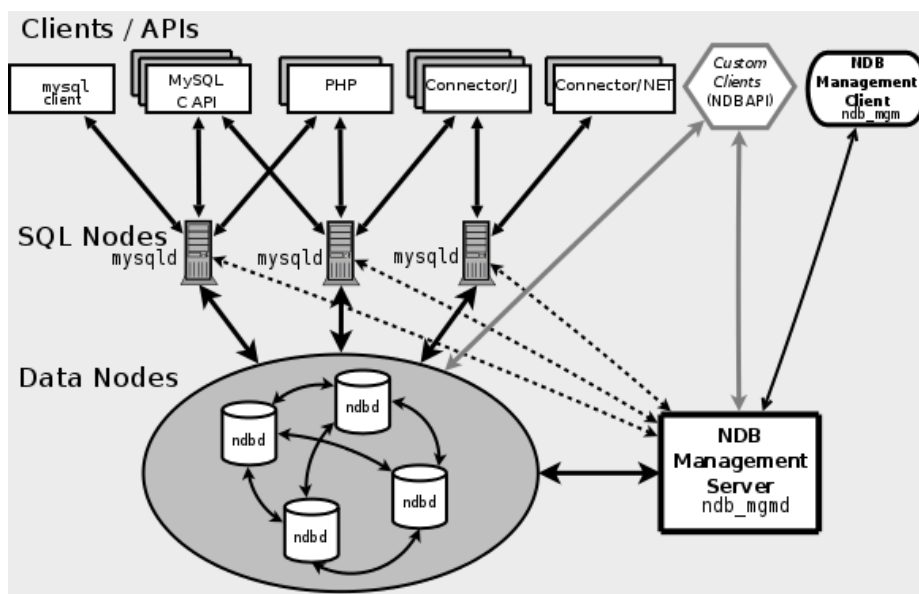

*NDB Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for “*Network DataBase*”). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “NDB Cluster ” refers to the combination of one or more MySQL servers with the **NDB** storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 20.1 NDB Cluster Components**

All these programs work together to form an NDB Cluster (see [Section 20.4, “NDB Cluster Programs”](#)). When data is stored by the **NDB** storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.7 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the **NDB** storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)). Rolling restarts are also used as part of the process of adding new data nodes online (see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Backing up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see [Section 20.5.3, “Online Backup of NDB Cluster”](#), and [Section 20.4.20, “ndb\\_restore — Restore an NDB Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 5.5.4, “mysqldump — A Database Backup Program”](#), for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

## 20.1.1 NDB Cluster Core Concepts

**NDBCLUSTER** (also known as **NDB**) is an in-memory storage engine offering high-availability and data-persistence features.

The **NDBCLUSTER** storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's **NDB** storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node:** The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- **Data node:** This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#)). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 20.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#)) or `ndbmtdd` (see [Section 20.4.3, “ndbmtdd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#)).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#), for more information.

- **SQL node:** This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

### Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in NDB Cluster, see [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see [Using Connector/J with NDB Cluster](#).

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see [The NDB API](#).

NDB-specific Java applications can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to [NDBCLUSTER](#), and so does not require access to a MySQL Server. Support is also provided in NDB Cluster for *ClusterJPA*, an OpenJPA implementation for NDB Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See [Java and NDB Cluster](#), and [The ClusterJ API and Data Object Model](#), for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the [NDB](#) storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see [MySQL NoSQL Connector for JavaScript](#).

The Memcache API for NDB Cluster, implemented as the loadable *ndbmemcache* storage engine for memcached version 1.6 and later, can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard [memcached](#) caching engine is included in the NDB Cluster 7.5 distribution. Each [memcached](#) server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see [ndbmemcache—Memcache API for NDB Cluster](#).

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the [ndb\\_mgm](#) management client supplied with NDB Cluster (see [Section 20.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#)). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see [The MGM API](#).

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as [mysqld](#) server options and variables relating to NDB Cluster. See [MySQL™ Cluster Manager 1.4.1 User Manual](#), for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 20.5.6, “Event Reports Generated in NDB Cluster”](#). Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

**Note**

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the [NDB](#) storage engine, there are two types of checkpoints which work

together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see [NDB Cluster Data Node File System Directory Files](#).

## 20.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**(Data) Node.** An `ndbd` or `ndbmt` process, which stores one or more *replicas*—that is, copies of the *partitions* (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmt` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NoOfReplicas
```

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NoOfReplicas`, see [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#).

### Note

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster ; see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#), for more information.

**Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

**NDB and user-defined partitioning.** NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.
2. The maximum number of partitions that may be defined explicitly for any `NDB` table is  $8 * \text{MaxNoOfExecutionThreads} * [\text{number of node groups}]$ , the number of node groups in an NDB Cluster being determined as discussed previously in this section. When using `ndbd` for data node processes, setting `MaxNoOfExecutionThreads` has no effect; in such a case, it can be treated as though it were equal to 1 for purposes of performing this calculation.

See [Section 20.4.3, “`ndbmt`d — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

For more information relating to NDB Cluster and user-defined partitioning, see [Section 20.1.6, “Known Limitations of NDB Cluster”](#), and [Section 21.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates an NDB Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

**Note**

Only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

**Figure 20.2 NDB Cluster with Two Node Groups**

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

**Figure 20.3 Nodes Required for a 2x2 Cluster**

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an **X**); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

In NDB 7.5.4 and later, the maximum number of node groups supported for a single NDB Cluster instance is 48 (Bug#80845, Bug #22996305).

### 20.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at <http://dev.mysql.com/downloads/cluster/>.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a

protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See [Section 20.5.12.1, “NDB Cluster Security and Networking Issues”](#), for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100  $\mu$ s), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

**SCI support.** It is also possible to use the high-speed Scalable Coherent Interface (SCI) with NDB Cluster, but this is not a requirement. See [Section 20.3.4, “Using High-Speed Interconnects with NDB Cluster”](#), for more about this protocol and its use with NDB Cluster.

## 20.1.4 What is New in MySQL NDB Cluster 7.5

In this section, we describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 7.5 as compared to NDB 7.4 and earlier release series. NDB Cluster 7.5 is available as a General Availability release beginning with NDB 7.5.4, and is recommended for new deployments. NDB Cluster 7.4 a recent General Availability release still supported for new deployments. NDB Cluster 7.3, is a previous GA release, still supported in production for existing deployments. NDB Cluster 7.2 is also a previous GA release series which is still supported in production. NDB 7.1 and earlier releases series are no longer maintained or supported in production. We recommend that new deployments use NDB Cluster 7.4 or NDB Cluster 7.5, which is the latest GA release. For information about features added in NDB 7.4, see [What is New in NDB Cluster 7.4](#); [What is New in NDB Cluster 7.4](#) contains information about features added in NDB 7.3. For information about NDB Cluster 7.2 and previous NDB Cluster releases, see [What is New in NDB Cluster in NDB Cluster 7.2](#).

Major changes and new features in NDB Cluster 7.5 which are likely to be of interest are shown in the following list:

- **ndbinfo Enhancements.** A number of changes are made in the `ndbinfo` database, chief of which is that it now provides detailed information about NDB Cluster node configuration parameters.

The `config_params` table has been made read-only, and has been enhanced with additional columns providing information about each configuration parameter, including the parameter's type, default value, maximum and minimum values (where applicable), a brief description of the parameter, and whether the parameter is required. This table also provides each parameter with a unique `param_number`.

A row in the `config_values` table shows the current value of a given parameter on the node having a specified ID. The parameter is identified by the value of the `config_param` column, which maps to the `config_params` table's `param_number`.

Using this relationship you can write a join on these two tables to obtain the default, maximum, minimum, and current values for one or more NDB Cluster configuration parameters by name. An example SQL statement using such a join is shown here:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name IN ('NodeId', 'HostName', 'DataMemory', 'IndexMemory');
```

For more information about these changes, see [Section 20.5.10.7, “The ndbinfo config\\_params Table”](#). See [Section 20.5.10.8, “The ndbinfo config\\_values Table”](#), for further information and examples.

In addition, the `ndbinfo` database no longer depends on the `MyISAM` storage engine. All `ndbinfo` tables and views now use `NDB` (shown as `NDBINFO`).

Several new `ndbinfo` tables were introduced in NDB 7.5.4. These tables are listed here, with brief descriptions:

- `dict_obj_info` provides the names and types of database objects in `NDB`, as well as information about parent objects where applicable
- `table_distribution_status` provides `NDB` table distribution status information

- `table_fragments` provides information about the distribution of NDB table fragments
- `table_info` provides information about logging, checkpointing, storage, and other options in force for each NDB table
- `table_replicas` provides information about fragment replicas

See the descriptions of the individual tables for more information.

- **Default row and column format changes.** Starting with NDB 7.5.1, the default value for both the `ROW_FORMAT` option and the `COLUMN_FORMAT` option for `CREATE TABLE` can be set to `DYNAMIC` rather than `FIXED`, using a new MySQL server variable `ndb_default_column_format` is added as part of this change; set this to `FIXED` or `DYNAMIC` (or start `mysqld` with the equivalent option `--ndb-default-column-format=FIXED`) to force this value to be used for `COLUMN_FORMAT` and `ROW_FORMAT`. Prior to NDB 7.5.4, the default for this variable was `DYNAMIC`; in this and later versions, the default is `FIXED`, which provides backwards compatibility with prior releases (Bug #24487363).

The row format and column format used by existing table columns are unaffected by this change. New columns added to such tables use the new defaults for these (possibly overridden by `ndb_default_column_format`), and existing columns are changed to use these as well, provided that the `ALTER TABLE` statement performing this operation specifies `ALGORITHM=COPY`.

#### Note

A copying `ALTER TABLE` cannot be done implicitly if `mysqld` is run with `--ndb-allow-copying-alter-table=FALSE`.

- **ndb\_binlog\_index No Longer Dependent On MyISAM.** As of NDB 7.5.2, the `ndb_binlog_index` table employed in NDB Cluster Replication now uses the `InnoDB` storage engine instead of `MyISAM`. When upgrading, you can run `mysql_upgrade` with `--force --upgrade-system-tables` to cause it to execute `ALTER TABLE ... ENGINE=INNODB` on this table. Use of `MyISAM` for this table remains supported for backward compatibility.

A benefit of this change is that it makes it possible to depend on transactional behavior and lock-free reads for this table, which can help alleviate concurrency issues during purge operations and log rotation, and improve the availability of this table.

- **ALTER TABLE Changes.** NDB Cluster formerly supported an alternative syntax for online `ALTER TABLE`. This is no longer supported in NDB Cluster 7.5, which makes exclusive use of `ALGORITHM = DEFAULT | COPY | INPLACE` for table DDL, as in the standard MySQL Server.

Another change affecting the use of this statement is that `ALTER TABLE ... ALGORITHM=INPLACE RENAME` may now contain DDL operations in addition to the renaming.

- **ExecuteOnComputer Parameter Deprecated.** The `ExecuteOnComputer` configuration parameter for `management nodes`, `data nodes`, and `API nodes` has been deprecated and is now subject to removal in a future release of NDB Cluster. You should use the equivalent `HostName` parameter for all three types of nodes.
- **records-per-key Optimization.** The NDB handler now uses the records-per-key interface for index statistics implemented for the optimizer in MySQL 5.7.5. Some of the benefits from this change include those listed here:
  - The optimizer now chooses better execution plans in many cases where a less optimal join index or table join order would previously have been chosen

- Row estimates shown by [EXPLAIN](#) are more accurate
- Cardinality estimates shown by [SHOW INDEX](#) are improved
- **Connection Pool Node IDs.** NDB 7.5.0 adds the `mysql --ndb-cluster-connection-pool-nodeids` option, which allows a set of node IDs to be set for the connection pool. This setting overrides `--ndb-nodeid`, which means that it also overrides both the `--ndb-connectstring` option and the `NDB_CONNECTSTRING` environment variable.

**Note**

You can set the size for the connection pool using the `--ndb-cluster-connection-pool` option for `mysql`.

- **create\_old\_temporals Removed.** The `create_old_temporals` system variable was deprecated in NDB Cluster 7.4, and has now been removed.
- **ndb\_mgm Client PROMPT Command.** NDB Cluster 7.5 adds a new command for setting the client's command-line prompt. The following example illustrates the use of the [PROMPT](#) command:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
-----
[ndbd(NDB)]      4 node(s)
id=5    @10.100.1.1  (mysql-5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=6    @10.100.1.3  (mysql-5.7.16-ndb-7.5.5, Nodegroup: 0)
id=7    @10.100.1.9  (mysql-5.7.16-ndb-7.5.5, Nodegroup: 1)
id=8    @10.100.1.11 (mysql-5.7.16-ndb-7.5.5, Nodegroup: 1)

[ndb_mgmd(MGM)]  1 node(s)
id=50   @10.100.1.8  (mysql-5.7.16-ndb-7.5.5)

[mysqld(API)]   2 node(s)
id=100  @10.100.1.8  (5.7.16-ndb-7.5.5)
id=101  @10.100.1.10 (5.7.16-ndb-7.5.5)

mgm#1: PROMPT
ndb_mgm> EXIT
jon@valhaj:/usr/local/mysql/bin>
```

For additional information and examples, see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#).

- **Increased FIXED column storage per fragment.** NDB Cluster 7.5 and later supports a maximum of 128 TB per fragment of data in [FIXED](#) columns. In NDB Cluster 7.4 and earlier, this was 16 GB per fragment.
- **Deprecated Parameters Removed.** The following NDB Cluster data node configuration parameters were deprecated in previous releases of NDB Cluster, and were removed in NDB 7.5.0:
  - [Id](#): deprecated in NDB 7.1.9; replaced by [NodeId](#).
  - [NoOfDiskPagesToDiskDuringRestartTUP](#), [NoOfDiskPagesToDiskDuringRestartACC](#): both deprecated, had no effect; replaced in MySQL 5.1.6 by [DiskCheckpointSpeedInRestart](#), which itself was later deprecated (in NDB 7.4.1) and is now also removed.

- `NoOfDiskPagesToDiskAfterRestartACC`, `NoOfDiskPagesToDiskAfterRestartTUP`: both deprecated, had no effect; replaced in MySQL 5.1.6 by `DiskCheckpointSpeed`, which itself was later deprecated (in NDB 7.4.1) and is now also removed.
- `ReservedSendBufferMemory`: deprecated in NDB 7.2.5; no longer had any effect.
- `MaxNoOfIndexes`: archaic (pre-MySQL 4.1), had no effect; long since replaced by `MaxNoOfOrderedIndexes` or `MaxNoOfUniqueHashIndexes`.
- `Discless`: archaic (pre-MySQL 4.1) synonym for and long since replaced by `Diskless`.

The archaic and unused (and for this reason also previously undocumented) `ByteOrder` computer configuration parameter was also removed in NDB 7.5.0.

The parameters just described are not supported in NDB 7.5. Attempting to use any of these parameters in an NDB Cluster configuration file now results in an error.

- **DBTC Scan Enhancements.** Scans have been improved by reducing the number of signals used for communication between the `DBTC` and `DBDIH` kernel blocks in `NDB`, enabling higher scalability of data nodes when used for scan operations by decreasing the use of CPU resources for scan operations, in some cases by an estimated five percent.

Also as result of these changes response times should be greatly improved, which could help prevent issues with overload of the main threads. In addition, scans made in the `BACKUP` kernel block have also been improved and made more efficient than in previous releases.

- **JSON column support.** NDB 7.5.2 and later supports the `JSON` column type for `NDB` tables and the JSON functions found in the MySQL Server, subject to the limitation that an `NDB` table can have at most 3 `JSON` columns.
- **Read from any replica; specify number of hashmap partition fragments.** Previously, all reads were directed towards the primary replica except for simple reads. (A simple read is a reads that lock the row while reading it.) Beginning with NDB 7.5.2, it is possible to enabling reads from any replica. This is disabled by default but can be enabled for a given SQL node using the `ndb_read_backup` system variable added in this release.

Previously, it was possible to define tables with only one type of partition mapping, with one primary partition on each LDM in each node, but in NDB 7.5.2 it becomes possible to be more flexible about the assignment of partitions by setting a partition balance (fragment count type). Possible balance schemes are one per node, one per node group, one per LDM per node, and one per LDM per node group.

This setting can be controlled for individual tables by means of a `PARTITION_BALANCE` option (renamed from `FRAGMENT_COUNT_TYPE` in NDB 7.5.4) embedded in `NDB_TABLE` comments in `CREATE TABLE` or `ALTER TABLE` statements. Settings for table-level `READ_BACKUP` are also supported using this syntax. For more information and examples, see [Section 14.1.18.9, “Setting NDB\\_TABLE Options in Table Comments”](#).

In NDB API applications, a table's partition balance can also be get and set using methods supplied for this purpose; see `Table::getPartitionBalance()`, and `Table::setPartitionBalance()`, as well as `Object::PartitionBalance`, for more information about these.

As part of this work, NDB 7.5.2 also introduces the `ndb_data_node_neighbour` system variable. This is intended for use, in transaction hinting, to provide a “nearby” data node to this SQL node.

NDB 7.5.3 adds a further enhancement to `READ_BACKUP`: In this and later versions, it is possible to set `READ_BACKUP` for a given table online as part of `ALTER TABLE ... ALGORITHM=INPLACE ...`.

- **ThreadConfig improvements.** A number of enhancements and feature additions are implemented in NDB 7.5.2 for the `ThreadConfig` multithreaded data node (`ndbmttd`) configuration parameter, including support for an increased number of platforms. These changes are described in the next few paragraphs.

Non-exclusive CPU locking is now supported on FreeBSD and Windows, using `cpubind` and `cpuset`. Exclusive CPU locking is now supported on Solaris (only) using the `cpubind_exclusive` and `cpuset_exclusive` parameters which are introduced in this release.

Thread prioritization is now available, controlled by the new `thread_prio` parameter. `thread_prio` is supported on Linux, FreeBSD, Windows, and Solaris, and varies somewhat by platform. For more information, see the description of `ThreadConfig`.

The `realtime` parameter is now supported on Windows platforms.

- **Partitions larger than 16 GB.** Due to an improvement in the hash index implementation used by NDB Cluster data nodes, partitions of `NDB` tables may now contain more than 16 GB of data for fixed columns, and the maximum partition size for fixed columns is now raised to 128 TB. The previous limitation was due to the fact that the `DBACC` block in the `NDB` kernel used only 32-bit references to the fixed-size part of a row in the `DBTUP` block, although 45-bit references to this data are used in `DBTUP` itself and elsewhere in the kernel outside `DBACC`; all such references in to the data handled in the `DBACC` block now use 45 bits instead.
- **Print SQL statements from `ndb_restore`.** NDB 7.5.4 adds the `--print-sql-log` option for the `ndb_restore` utility provided with the NDB Cluster distribution. This option enables SQL logging to `stdout`. **Important:** Every table to be restored using this option must have an explicitly defined primary key.

See [Section 20.4.20, “`ndb\_restore` — Restore an NDB Cluster Backup](#)”, for more information.

- **Organization of RPM packages.** Beginning with NDB 7.5.4, the naming and organization of RPM packages provided for NDB Cluster align more closely with those released for the MySQL server. The names of all NDB Cluster RPMs are now prefixed with `mysql-cluster`. Data nodes are now installed using the `data-node` package; management nodes are now installed from the `management-server` package; and SQL nodes require the `server` and `common` packages. MySQL and `NDB` client programs, including the `mysql` client and the `ndb_mgm` management client, are now included in the `client` RPM.

For a detailed listing of NDB Cluster RPMs and other information, see [Section 20.2.2.2, “Installing NDB Cluster from RPM”](#).

NDB Cluster 7.5 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See [MySQL™ Cluster Manager 1.4.1 User Manual](#), for more information.

## 20.1.5 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both `NDB` and `InnoDB` can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see `NDB` as a possible alternative or upgrade to the default `InnoDB` storage engine in MySQL 5.7. While `NDB` and `InnoDB` share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the `NDB` storage engine used by NDB 7.5 with `InnoDB` used in MySQL 5.7. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics

for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for [NDB](#) as opposed to [InnoDB](#) backends.

NDB Cluster 7.5 uses a [mysqld](#) based on MySQL 5.7, including support for [InnoDB](#) 1.1. While it is possible to use [InnoDB](#) tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 7.5 distribution with MySQL Server 5.7, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the [InnoDB](#) storage engine), there are some important architectural and implementation differences. [Section 20.1.5.1, “Differences Between the NDB and InnoDB Storage Engines”](#), provides a summary of these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see [Section 20.1.5.2, “NDB and InnoDB Workloads”](#). This in turn has an impact on the types of applications that better suited for use with [NDB](#) or [InnoDB](#). See [Section 20.1.5.3, “NDB and InnoDB Feature Usage Summary”](#), for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the [NDB](#) and [MEMORY](#) storage engines, see [When to Use MEMORY or MySQL Cluster](#).

See [Chapter 16, Alternative Storage Engines](#), for additional information about MySQL storage engines.

### 20.1.5.1 Differences Between the NDB and InnoDB Storage Engines

The NDB Cluster [NDB](#) storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from [InnoDB](#) in a number of ways. For those unaccustomed to working with [NDB](#), unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

Feature	<a href="#">InnoDB</a> 1.1	NDB Cluster <a href="#">NDB</a> 7.5
MySQL Server Version	5.7	5.7
<a href="#">InnoDB</a> Version	<a href="#">InnoDB</a> 5.7.18	<a href="#">InnoDB</a> 5.7.18
NDB Cluster Version	N/A	<a href="#">NDB</a> 7.5.5
Storage Limits	64TB	3TB  (Practical upper limit based on 48 data nodes with 64GB RAM each; can be increased with disk-based data and BLOBs)
Foreign Keys	Yes	Yes.
Transactions	All standard types	<a href="#">READ COMMITTED</a>
MVCC	Yes	No
Data Compression	Yes	No  (NDB Cluster checkpoint and backup files can be compressed)
Large Row Support (> 14K)	Supported for <a href="#">VARBINARY</a> , <a href="#">VARCHAR</a> , <a href="#">BLOB</a> , and <a href="#">TEXT</a> columns	Supported for <a href="#">BLOB</a> and <a href="#">TEXT</a> columns only  (Using these types to store very large amounts of data can lower NDB Cluster performance)

Feature	InnoDB 1.1	NDB Cluster NDB 7.5
<i>Replication Support</i>	Asynchronous and semisynchronous replication using MySQL Replication	Automatic synchronous replication within an NDB Cluster .  Asynchronous replication between NDB Cluster s, using MySQL Replication
<i>Scaleout for Read Operations</i>	Yes (MySQL Replication)	Yes (Automatic partitioning in NDB Cluster ; NDB Cluster Replication)
<i>Scaleout for Write Operations</i>	Requires application-level partitioning (sharding)	Yes (Automatic partitioning in NDB Cluster is transparent to applications)
<i>High Availability (HA)</i>	Requires additional software	Yes (Designed for 99.999% uptime)
<i>Node Failure Recovery and Failover</i>	Requires additional software	Automatic  (Key element in NDB Cluster architecture)
<i>Time for Node Failure Recovery</i>	30 seconds or longer	Typically < 1 second
<i>Real-Time Performance</i>	No	Yes
<i>In-Memory Tables</i>	No	Yes  (Some data can optionally be stored on disk; both in-memory and disk data storage are durable)
<i>NoSQL Access to Storage Engine</i>	Yes	Yes  Multiple APIs, including Memcached, Node.js/JavaScript, Java, JPA, C++, and HTTP/REST
<i>Concurrent and Parallel Writes</i>	Not supported	Up to 48 writers, optimized for concurrent writes
<i>Conflict Detection and Resolution (Multiple Replication Masters)</i>	No	Yes
<i>Hash Indexes</i>	No	Yes
<i>Online Addition of Nodes</i>	Read-only replicas using MySQL Replication	Yes (all node types)
<i>Online Upgrades</i>	No	Yes
<i>Online Schema Modifications</i>	Yes, as part of MySQL 5.6.	Yes.

### 20.1.5.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the [NDB](#) and [InnoDB](#) storage engines with regard to some common types of database-driven application workloads are shown in the following table::

Workload	InnoDB	NDB Cluster (NDB)
High-Volume OLTP Applications	Yes	Yes
DSS Applications (data marts, analytics)	Yes	Limited (Join operations across OLTP datasets not exceeding 3TB in size)
Custom Applications	Yes	Yes
Packaged Applications	Yes	Limited (should be mostly primary key access).  NDB Cluster 7.5 supports foreign keys.
In-Network Telecoms Applications (HLR, HSS, SDP)	No	Yes
Session Management and Caching	Yes	Yes
E-Commerce Applications	Yes	Yes
User Profile Management, AAA Protocol	Yes	Yes

### 20.1.5.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

Preferred application requirements for InnoDB	Preferred application requirements for NDB
<ul style="list-style-type: none"> <li>Foreign keys</li> </ul> <div style="display: flex; align-items: center;">  <div style="margin-left: 10px;"> <p><b>Note</b></p> <p>NDB Cluster 7.5 supports foreign keys.</p> </div> </div> <ul style="list-style-type: none"> <li>Full table scans</li> <li>Very large databases, rows, or transactions</li> <li>Transactions other than <code>READ COMMITTED</code></li> </ul>	<ul style="list-style-type: none"> <li>Write scaling</li> <li>99.999% uptime</li> <li>Online addition of nodes and online schema operations</li> <li>Multiple SQL and NoSQL APIs (see <a href="#">NDB Cluster APIs: Overview and Concepts</a>)</li> <li>Real-time performance</li> <li>Limited use of <code>BLOB</code> columns</li> <li>Foreign keys are supported, although their use may have an impact on performance at high throughput</li> </ul>

### 20.1.6 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the `MyISAM` and `InnoDB` storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following

categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of NDB Cluster :

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in NDB Cluster 7.5, we will add it to the list.

See [Previous NDB Cluster Issues Resolved in NDB Cluster 7.3](#) for a list of issues in earlier releases that have been resolved in NDB Cluster 7.5.

#### Note

Limitations and other issues specific to NDB Cluster Replication are described in [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#).

### 20.1.6.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with [NDB](#) tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the [NDB](#) storage engine or to alter an existing temporary table to use [NDB](#) fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.
- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an [NDB](#) table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on [NDB](#) table columns that use any of the [TEXT](#) or [BLOB](#) data types.
  - **FULLTEXT indexes.** The [NDB](#) storage engine does not support [FULLTEXT](#) indexes, which are possible for [MyISAM](#) and [InnoDB](#) tables only.

However, you can create indexes on [VARCHAR](#) columns of [NDB](#) tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.
- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an [NDB](#) column index is always the same as the width of the column in bytes, up to and including 3072 bytes,

as described earlier in this section. Also see [Section 20.1.6.6, “Unsupported or Missing Features in NDB Cluster”](#), for additional information.)

- **BIT columns.** A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO\_INCREMENT columns.** Like other MySQL storage engines, the `NDB` storage engine can handle a maximum of one `AUTO_INCREMENT` column per table. However, in the case of a Cluster table with no explicit primary key, an `AUTO_INCREMENT` column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit `AUTO_INCREMENT` column unless that column is also declared using the `PRIMARY KEY` option. Attempting to create a table with an `AUTO_INCREMENT` column that is not the table's primary key, and using the `NDB` storage engine, fails with an error.
- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 7.5 is comparable to that provided by `InnoDB`, subject to the following restrictions:
  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.
  - `ON UPDATE CASCADE` is not supported when the reference is to the parent table's primary key.

This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the `NDB` kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

  - `SET DEFAULT` is not supported. (Also not supported by `InnoDB`.)
  - The `NO ACTION` keywords are accepted but treated as `RESCRICT`. (Also the same as with `InnoDB`.)
  - In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

For more information, see [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#), and [Section 1.8.3.2, “FOREIGN KEY Constraints”](#).

- **NDB Cluster and geometry data types.** Geometry data types (`WKT` and `WKB`) are supported for `NDB` tables. However, spatial indexes are not supported.
- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to `[LINEAR] KEY` partitioning. Using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see [User-defined partitioning and the NDB storage engine \(MySQL Cluster\)](#).

**Default partitioning scheme.** All NDB Cluster tables are by default partitioned by [KEY](#) using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the [NDB](#) storage engine is used instead. For additional discussion of these and related issues, see [Section 21.2.5, “KEY Partitioning”](#).

[CREATE TABLE](#) and [ALTER TABLE](#) statements that would cause a user-partitioned [NDBCLUSTER](#) table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned [NDBCLUSTER](#) table is created using an empty column-list (that is, using [PARTITION BY \[LINEAR\] KEY\(\)](#)), then no explicit primary key is required.

**Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can be defined for a [NDBCLUSTER](#) table when employing user-defined partitioning is 8 per node group. (See [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information about NDB Cluster node groups.

**DROP PARTITION not supported.** It is not possible to drop partitions from [NDB](#) tables using [ALTER TABLE ... DROP PARTITION](#). The other partitioning extensions to [ALTER TABLE](#)—[ADD PARTITION](#), [REORGANIZE PARTITION](#), and [COALESCE PARTITION](#)—are supported for Cluster tables, but use copying and so are not optimized. See [Section 21.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 14.1.8, “ALTER TABLE Syntax”](#).

- **Row-based replication.** When using row-based replication with NDB Cluster, binary logging cannot be disabled. That is, the [NDB](#) storage engine ignores the value of [sql\\_log\\_bin](#).
- **JSON data type.** The MySQL [JSON](#) data type is supported for [NDB](#) tables in the [mysqld](#) supplied with NDB 7.5.2 and later.

An [NDB](#) table can have a maximum of 3 [JSON](#) columns.

The NDB API has no special provision for working with [JSON](#) data, which it views simply as [BLOB](#) data. Handling data as [JSON](#) must be performed by the application.

- **CPU and thread info ndbinfo tables.** NDB 7.5.2 adds several new tables to the [ndbinfo](#) information database providing information about CPU and thread activity by node, thread ID, and thread type. The tables are listed here:
  - [cpustat](#): Provides per-second, per-thread CPU statistics
  - [cpustat\\_50ms](#): Raw per-thread CPU statistics data, gathered every 50ms
  - [cpustat\\_1sec](#): Raw per-thread CPU statistics data, gathered each second
  - [cpustat\\_20sec](#): Raw per-thread CPU statistics data, gathered every 20 seconds
  - [threads](#): Names and descriptions of thread types

For more information about these tables, see [Section 20.5.10, “The ndbinfo NDB Cluster Information Database”](#).

- **Lock info ndbinfo tables.** NDB 7.5.3 adds new tables to the `ndbinfo` information database providing information about locks and lock attempts in a running NDB Cluster. These tables are listed here:
  - `cluster_locks`: Current lock requests which are waiting for or holding locks; this information can be useful when investigating stalls and deadlocks. Analogous to `cluster_operations`.
  - `locks_per_fragment`: Counts of lock claim requests, and their outcomes per fragment, as well as total time spent waiting for locks successfully and unsuccessfully. Analogous to `operations_per_fragment` and `memory_per_fragment`.
  - `server_locks`: Subset of cluster transactions—those running on the local `mysqld`, showing a connection id per transaction. Analogous to `server_operations`.

### 20.1.6.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

A rolling restart of the cluster also frees any memory used by deleted rows. See [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#).

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

#### Note

Recall that `TRUNCATE TABLE` drops and re-creates the table. See [Section 14.1.34, “TRUNCATE TABLE Syntax”](#).

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 20.3.3, “NDB Cluster Configuration Files”](#). Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#), for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

**Note**

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
  - The maximum number of data nodes is 48.

A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

- The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
- The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

See [Previous NDB Cluster Issues Resolved in NDB Cluster 7.3](#), for more information.

### 20.1.6.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that `NDB` implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

- Increased frequency of lock wait timeout errors, and reduced concurrency
- Increased transaction processing overhead due to reads requiring a commit phase
- Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

`NDB` uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes

exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; BLOB reads also employ extra locking for consistency.

See [Section 20.5.3.4, “NDB Cluster Backup Troubleshooting”](#), for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- **Transactions and BLOB or TEXT columns.** NDBCLUSTER stores only part of a column value that uses any of MySQL's BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:
  1. For any SELECT from an NDB Cluster table: If the SELECT includes a BLOB or TEXT column, the READ COMMITTED transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
  2. For any SELECT which uses a unique key lookup to retrieve any columns that use any of the BLOB or TEXT data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having BLOB or TEXT columns.

For example, consider the table `t` defined by the following CREATE TABLE statement:

```
CREATE TABLE t (
  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b INT NOT NULL,
  c INT NOT NULL,
  d TEXT,
  INDEX i(b),
  UNIQUE KEY u(c)
) ENGINE = NDB,
```

Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```
SELECT * FROM t WHERE a = 1;

SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;

SELECT * FROM t WHERE d = '1';

SELECT * FROM t;

SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**

As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:

- `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.
- `DELETE FROM` (even with no `WHERE` clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.
- **LOAD DATA statements.** `LOAD DATA INFILE` is not transactional when used on `NDB` tables.

#### Important

When executing a `LOAD DATA INFILE` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine.

### 20.1.6.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 20.1.6.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”](#).

### 20.1.6.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Database and table names.** When using the `NDB` storage engine, the maximum allowed length both for database names and for table names is 63 characters. A statement using a database name or table name longer than this limit fails with an appropriate error.
- **Number of database objects.** The maximum number of *all* `NDB` database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 14000 bytes. Each `BLOB` or `TEXT` column contributes  $256 + 8 = 264$  bytes to this total.
- **BIT column storage per table.** The maximum combined width for all `BIT` columns used in a given `NDB` table is 4096.
- **FIXED column storage.** NDB Cluster 7.5 and later supports a maximum of 128 TB per fragment of data in `FIXED` columns. (Previously, this was 16 GB.)

### 20.1.6.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by `NDB`, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for `NDB` tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is not created by `NDB`.

A statement containing an index prefix, and creating or modifying an `NDB` table, must still be syntactically valid. For example, the following statement always fails with Error 1089 `Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys`, regardless of storage engine:

```
CREATE TABLE t1 (
  c1 INT NOT NULL,
  c2 VARCHAR(100),
  INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.

- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication and binary logging.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 20.6, “NDB Cluster Replication”](#), for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 7.5. Do not enable GTIDs when using the [NDB](#) storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

- **Generated columns.** The [NDB](#) storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that [NDB](#) uses [DataMemory](#) for storage of the generated column as well as [IndexMemory](#) for the index. See [JSON columns and indirect indexing in MySQL Cluster](#), for an example.

NDB Cluster writes changes in stored generated columns to the binary log, but does not log those made to virtual columns. This should not effect NDB Cluster Replication or replication between [NDB](#) and other MySQL storage engines.

#### Note

See [Section 20.1.6.3, “Limits Relating to Transaction Handling in NDB Cluster”](#), for more information relating to limitations on transaction handling in [NDB](#).

### 20.1.6.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster :

- **Range scans.** There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- **Reliability of Records in range.** The [Records in range](#) statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) to alter the execution plan. See [Section 9.9.4, “Index Hints”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.

### 20.1.6.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the [NDB](#) storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running [mysql](#) or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.** NDB Cluster has the following limitations or restrictions with regard to binary logging:
  - [sql\\_log\\_bin](#) has no effect on data operations; however, it is supported for schema operations.

- NDB Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
- Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
  - `CREATE TABLE`
  - `ALTER TABLE`
  - `DROP TABLE`
  - `CREATE DATABASE / CREATE SCHEMA`
  - `DROP DATABASE / DROP SCHEMA`
  - `CREATE TABLESPACE`
  - `ALTER TABLESPACE`
  - `DROP TABLESPACE`
  - `CREATE LOGFILE GROUP`
  - `ALTER LOGFILE GROUP`
  - `DROP LOGFILE GROUP`
- Schema operations (DDL statements) are rejected while any data node restarts.

See also [Section 20.1.6.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 20.1.6.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces:  $2^{32}$  (4294967296)
- Maximum number of data files per tablespace:  $2^{16}$  (65536)
- Maximum data file size: The theoretical limit is 64G; however, the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

Since an NDB Cluster Disk Data table can use at most 1 tablespace, this means that the theoretical upper limit to the amount of data (in bytes) that can be stored on disk by a single `NDB` table is  $32\text{G} * 65536 = 2251799813685248$ , or approximately 2 petabytes.

- The theoretical maximum number of extents per tablespace data file is  $2^{16}$  (65536); however, for practical purposes, the recommended maximum number of extents per data file is  $2^{15}$  (32768).

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 14.1.19, “CREATE TABLESPACE Syntax”](#), for more information.

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.

### 20.1.6.10 Limitations Relating to Multiple NDB Cluster Nodes

#### Multiple SQL nodes.

The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

#### Multiple management nodes.

When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.
- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

#### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#), for more information.

## 20.2 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in [Section 20.3, “Configuration of NDB Cluster”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see [Section 20.2.8, “Upgrading and Downgrading NDB Cluster”](#).

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

NDB Cluster 7.5 also provides an NDB Cluster Auto-Installer, a web-based graphical installer, as part of the NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB Cluster on one (for testing) or more host computers. See [Section 20.2.1, “The NDB Cluster Auto-Installer”](#), for more information.

**Assumptions.** The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

**Cluster nodes and host computers.** The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

Node	IP Address
Management node ( <code>mgmd</code> )	192.168.0.10
SQL node ( <code>mysqld</code> )	192.168.0.20
Data node "A" ( <code>ndbd</code> )	192.168.0.30
Data node "B" ( <code>ndbd</code> )	192.168.0.40

This may be made clearer by the following diagram:

**Figure 20.4 NDB Cluster Multi-Computer Setup**

**Network addressing.** In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host

names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1    ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1    ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1    localhost
127.0.0.2    ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1    localhost
127.0.0.2    ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

#### Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

#### Important

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL Web site (see <http://dev.mysql.com/doc/index-other.html>). We assume that each machine has sufficient memory

for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see [Chapter 2, \*Installing and Upgrading MySQL\*](#). For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see [Section 20.2.2, “Installation of NDB Cluster on Linux”](#). For information about installation of NDB Cluster on Windows operating systems, see [Section 20.2.3, “Installing NDB Cluster on Windows”](#).

For general information about NDB Cluster hardware, software, and networking requirements, see [Section 20.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”](#).

## 20.2.1 The NDB Cluster Auto-Installer

- [Section 20.2.1.1, “NDB Cluster Auto-Installer Requirements”](#)
- [Section 20.2.1.2, “NDB Cluster Auto-Installer Overview”](#)
- [Section 20.2.1.3, “Using the NDB Cluster Auto-Installer”](#)

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

### 20.2.1.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

**Supported platforms.** The NDB Cluster Auto-Installer is available with most NDB 7.5.2 and later NDB Cluster distributions for recent versions of Linux, Windows, Solaris, and MacOS X. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see <http://www.mysql.com/support/supportedplatforms/cluster.html>.

The NDB Cluster Auto-Installer is not supported with NDB 7.5.0 or 7.5.1 (Bug #79853, Bug #22502247).

**Supported Web browsers.** The Web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compatibility with these browsers.

**Required software—setup host.** The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, they can be downloaded from <http://python.org/download/>.
- **Paramiko 1.7.7.1 or higher.** This is required to communicate with remote hosts using SSH. You can download it from <http://www.lag.net/paramiko/>. Paramiko may also be available from your system's package manager.
- **Pycrypto version 2.6 or higher.** This cryptography module is required by Paramiko. If it is not available using your system's package manager, you can download it from <https://www.dlitz.net/software/pycrypto/>.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

The Paramiko and Pycrypto libraries are required only if you intend to deploy NDB Cluster nodes on remote hosts, and are not needed if all nodes are on the same host where the installer is run.

**Required software—remote hosts.** The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_servers](http://en.wikipedia.org/wiki/Comparison_of_SSH_servers).

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

**Authentication and security.** Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

#### Important

You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see [Section 7.1.5, “How to Run MySQL as a Normal User”](#).

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user's SSH password is transmitted in clear text that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https` and `--cert-file` options.
- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file` option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also [Section 20.5.12, “NDB Cluster Security Issues”](#), which discusses security considerations to take into account when deploying NDB Cluster, as well as [Chapter 7, Security](#), for more general MySQL security information.

## 20.2.1.2 NDB Cluster Auto-Installer Overview

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet

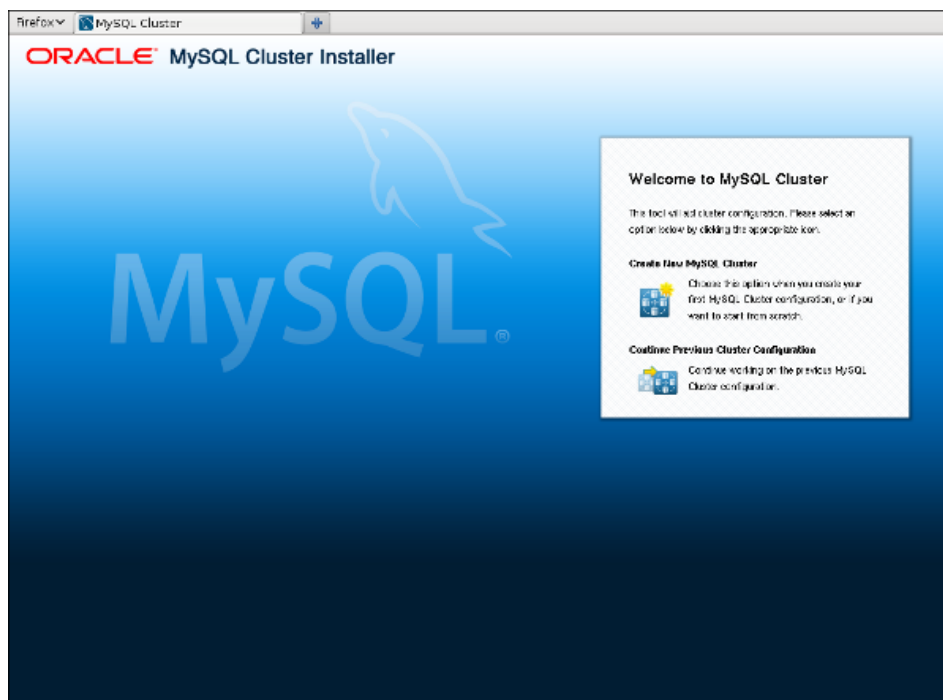

Explorer (see [Section 20.2.1.1, “NDB Cluster Auto-Installer Requirements”](#)). The back end is a server process (`ndb_setup.py`) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access, using the Paramiko library for executing commands remotely (see [Section 20.2.1.1, “NDB Cluster Auto-Installer Requirements”](#)).

The remainder of this section is concerned primarily with the Web client. For more information about using the command-line tool, see [Section 20.4.23, “ndb\\_setup.py — Start browser-based Auto-Installer for NDB Cluster”](#).

**NDB Cluster Auto-Installer Interface.** This section describes the layout and navigation of the NDB Cluster Auto-Installer, whose Welcome screen looks similar to what is shown here when it is first opened in the Web browser:

**Figure 20.5 Welcome Screen For NDB Cluster Auto-Installer**

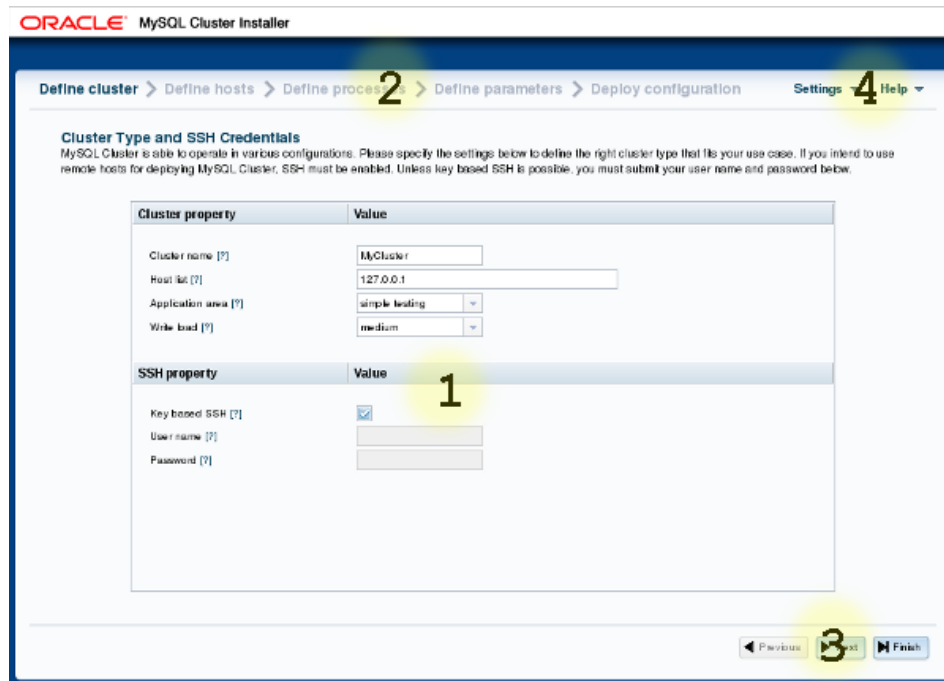

You can access the installer UI by selecting either of the options **Create New NDB Cluster** or **Continue Previous Cluster Configuration**. A typical screen in the Auto-Installer includes the following elements:

1. **Display panel.** The central area where data regarding configuration settings and controls for changing them are displayed.
2. **Breadcrumb navigation.** Located in the top left and top center of the GUI, the breadcrumb navigation bar consists of a series of titles linking to screens that correspond to steps in the configuration of an NDB Cluster. The breadcrumb allows you to jump between these stages in arbitrary order.
3. **Sequential navigation.** This consists of a set of buttons labelled **Previous**, **Next**, and **Finished**, and can be found in the lower right-hand corner of the GUI. The sequential navigation is used to move between steps in the suggested order.

4. **Settings and Help menus.** These menus can be found in the top right corner of the GUI (to the right of the breadcrumb navigation bar). **Settings** provides a way check and possibly alter configuration settings for the Auto-Installer; **Help** can be used to access the installer's built-in help files.

The locations of the elements just described are shown here in a typical page in the Auto-Installer; the numbers superimposed thereupon correspond to those used in the preceding list.

**Figure 20.6 Layout of the NDB Cluster Auto-Installer GUI**

All of these elements except for the display panel are described in greater detail in the remainder of this section. [Section 20.2.1.3, “Using the NDB Cluster Auto-Installer”](#), describes the panels shown in the display area as well as the functionality of each panel and the controls it contains.

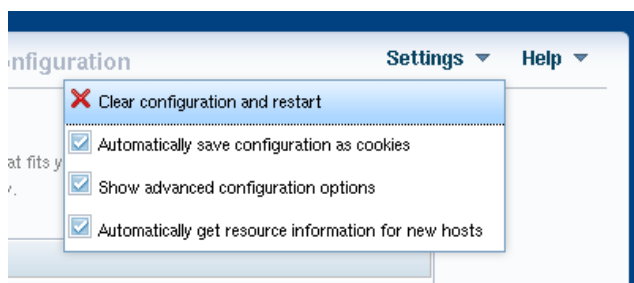

**Arbitrary and sequential navigation.** The Auto-Installer can display any of a number of pages covering different stages in the setup and configuration of an NDB Cluster deployment. You can navigate between pages in either of two ways. The first of these is the breadcrumb trail navigation toolbar displaying the titles of the various pages (in which the title of the current page is highlighted and disabled). From these, any desired page, in any desired order, can be reached by selecting the title of the corresponding page. This toolbar is shown here:

**Figure 20.7 Detail of NDB Cluster Auto-Installer breadcrumb navigation, showing page titles/links**

The second navigation mechanism provided by the Auto-Installer consists of the **Next**, **Previous**, and **Finish** sequential navigation buttons at the bottom right of the page. These can be used to move to the next or previous page in predetermined order, or to go to the very last page. The buttons are enabled and disabled as needed, so that you cannot, for example, advance beyond the last page.

**Settings and Help menus.** These menus are positioned adjacent to one another in the top right corner of the GUI, as shown earlier in this section. The **Settings** menu is shown here in more detail:

**Figure 20.8 NDB Cluster Auto-Installer Settings menu detail**

The entries in the **Settings** menu are described here, in the following list:

- **Clear configuration and restart:** Remove all hosts and processes; reset all parameter values to their defaults; start the installer over at the first page.
- **Automatically save configuration as cookies:** Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session).

Since the SSH password is never saved, you must supply this once again at the beginning of a new session, if one is used.

- **Show advanced configuration options:** Show advanced configuration parameters in the Auto-Installer and make these settable by the user.

Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.

- **Automatically get resource information for new hosts:** Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

As with the installer's navigation elements, one or more of the entries in the **Settings** menu may be disabled due to choices you have made previously.

The **Help** menu is shown here, as it appears when expanded:

**Figure 20.9 The NDB Cluster Auto-Installer Help menu, expanded**

The **Help** menu provides several options, described in the following list:

- **Content:** Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.
- **Current page:** Open the built-in user guide to the section describing the page currently displayed in the installer.
- **About:** This will show a small dialog displaying the installer name and the version number of the NDB Cluster distribution it was supplied with, similar to what is shown here:

**Figure 20.10 The NDB Cluster Auto-Installer About dialog**

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets. One of these tooltips is displayed when the mouse hovers over a widget or the small question mark which can sometimes appear next to a widget label.

In addition, the names of NDB Cluster configuration parameters are linked to their descriptions in the online NDB Cluster documentation, so that if you click on the name of a given parameter, the documentation for that parameter is shown in a separate window.

### 20.2.1.3 Using the NDB Cluster Auto-Installer

- [Starting the NDB Cluster Auto-Installer](#)
- [NDB Cluster Auto-Installer Welcome Screen](#)
- [NDB Cluster Auto-Installer Define Cluster Screen](#)
- [NDB Cluster Auto-Installer Define Hosts Screen](#)
- [NDB Cluster Auto-Installer Define Processes Screen](#)
- [NDB Cluster Auto-Installer Define Attributes Screen](#)
- [NDB Cluster Auto-Installer Deploy Cluster Screen](#)

The NDB Cluster Auto-Installer consists of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster , and listed here:

- **Welcome:** Begin using the Auto-Installer by choosing either to configure a new NDB Cluster , or to continue configuring an existing one.
- **Define Cluster:** Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
- **Define Hosts:** Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes:** Assign one or more processes of a given type or types to each cluster host.

- **Define Attributes:** Set configuration attributes for processes or types of processes.
- **Deploy Cluster:** Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

The following sections describe in greater detail the purpose and function of each of these pages, in the order just listed.

## Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. (See [Section 20.2, “NDB Cluster Installation”](#).) The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable. `ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 5.6\bin` on a Windows system, but this can vary according to where the NDB Cluster software is installed on your system.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, it accepts the same options as does `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```
shell> ndb_setup
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's **Welcome screen** should open in the system's default Web browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying a different port for the Auto-Installer's included Web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) For information about advanced startup options for the NDB Cluster Auto-Installer, see [Section 20.4.23, “ndb\\_setup.py — Start browser-based Auto-Installer for NDB Cluster”](#).

## NDB Cluster Auto-Installer Welcome Screen

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked, as shown here:

Figure 20.11 The NDB Cluster Auto-Installer Welcome screen (Closeup)

This screen provides the following two choices for entering the installer, one of which must be selected to continue:

1. **Create New NDB Cluster** : Start the Auto-Installer with a completely new cluster to be set up and deployed.
2. **Continue Previous Cluster Configuration**: Start the Auto-Installer at the same point where the previous session ended, with all previous settings preserved.

The second option requires that the browser be able to access its cookies from the previous session, as these provide the mechanism by which configuration and other information generated during a session is stored. In other words, to continue the previous session with the Auto-Installer, you must use the same web browser running on the same host as you did for the previous session.

## NDB Cluster Auto-Installer Define Cluster Screen

The **Define Cluster** screen is the first screen to appear following the choice made in the [Welcome screen](#), and is used for setting general properties of the cluster. The layout of the **Define Cluster** screen is shown here:

Figure 20.12 The NDB Cluster Auto-Installer Define Cluster screen

Define cluster > Define hosts > Define processes > Define parameters > Deploy configuration

**Cluster Type and SSH Credentials**  
MySQL Cluster is able to operate in various configurations. Please specify the settings below to define the right cluster type that fits your use case. If you intend to use remote hosts for deploying MySQL Cluster, SSH must be enabled. Unless key-based SSH is possible, you must submit your user name and password below.

Cluster property	Value
Cluster name [?]	MyCluster
Host list [?]	127.0.0.1
Application type [?]	Simple testing
Write load [?]	medium

SSH property	Value
Key-based SSH [?]	<input checked="" type="checkbox"/>
User name [?]	
Password [?]	

Previous Next Finish

The **Define Cluster** screen allows you to set a number of general properties for the cluster, as described in this list:

- **Cluster name:** A name that identifies the cluster. The default is `MyCluster`.
- **Host list:** A comma-delimited list of one or more hosts where cluster processes should run. By default, this is `127.0.0.1`. If you add remote hosts to the list, you must be able to connect to them using the **SSH Credentials** supplied.
- **Application type:** Choose one of the following:
  1. **Simple testing:** Minimal resource usage for small-scale testing. This the default. *Not intended for production environments.*
  2. **Web:** Maximize performance for the given hardware.
  3. **Real-time:** Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.
- **Write load:** Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
  1. **Low:** The expected load includes fewer than 100 write transactions for second.
  2. **Medium:** The expected load includes 100 to 1000 write transactions per second.
  3. **High:** The expected load includes more than 1000 write transactions per second.
- **SSH Credentials:** Choose **Key-Based SSH** or enter **User** and **Password** credentials. The SSH key or a user name with password is required for connecting to any remote hosts specified in the **Host list**. By default, **Key-Based SSH** is selected, and the **User** and **Password** fields are blank.

## NDB Cluster Auto-Installer Define Hosts Screen

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

Figure 20.13 NDB Cluster Define Hosts screen

The hosts currently entered are displayed in the grid with various pieces of information. You can add hosts by clicking the **Add hosts** button and entering a list of one or more comma-separated host names, IP addresses, or both (as when editing the host list on the [Define Cluster screen](#)).

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. When you remove a host in this fashion, any process which was configured for that host is also removed.

If **Automatically get resource information for new hosts** is checked in the [Settings menu](#), the Auto-Installer attempts to retrieve the platform name, amount of memory, and number of CPU cores and to fill these in automatically. The status of this is displayed in the *Resource info* column. Fetching the information from remote hosts is not instantaneous and may take some time, particularly from remote hosts running Windows.

If the SSH user credentials on the [Define Cluster screen](#) are changed, the tool tries to refresh the hardware information from any hosts for which information is missing. However, if a given field has already been edited, the user-supplied information is *not* overwritten by any value fetched from that host.

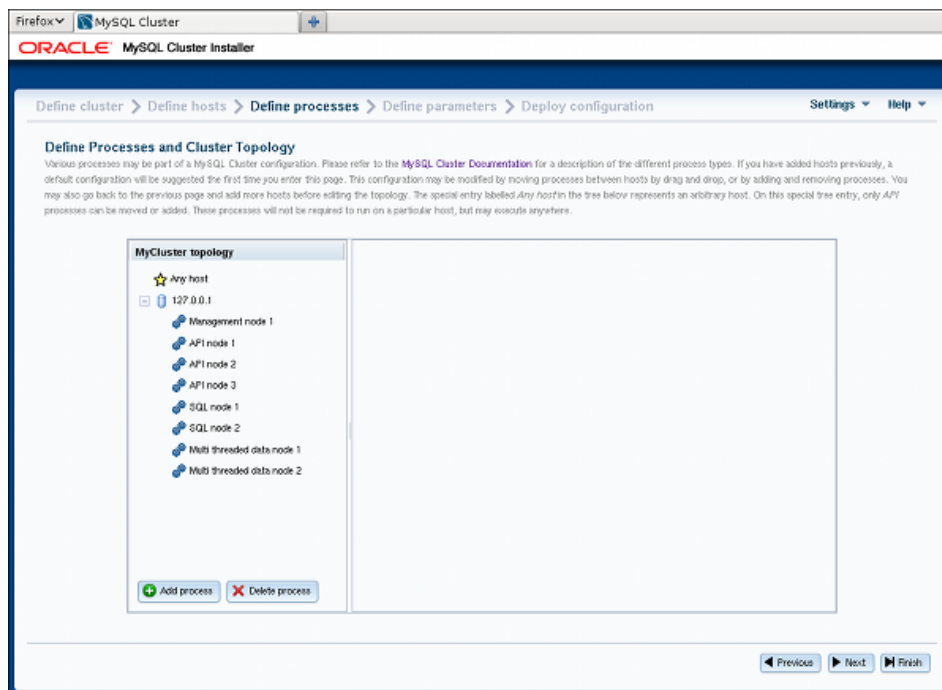

The hardware resource information, platform name, installation directory, and data directory can be edited by the user by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

**Figure 20.14 NDB Cluster Auto-Installer Edit Hosts dialog**

When more than one host is selected, any edited values are applied to all selected hosts.

## NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

**Figure 20.15 NDB Cluster Auto-Installer Define Processes dialog**

The left-hand portion of this screen contains a process tree showing cluster hosts and processes set up to run on each one. On the right is a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the **Define Hosts** screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the following types:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.

- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmt.d`.
- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.
- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See [MySQL NDB Cluster API Developer Guide](#), for more information.

For more information about process (node) types, see [Section 20.1.1, “NDB Cluster Core Concepts”](#).

Processes shown in the tree are numbered sequentially by type, for each host—for example, [SQL node 1](#), [SQL node 2](#), and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node *may* be assigned to a single host, but this is not required. Instead, you can assign it to the special **Any host** entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this Any host entry.*

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

**Figure 20.16 NDB Cluster Auto-Installer Add Process Dialog**

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

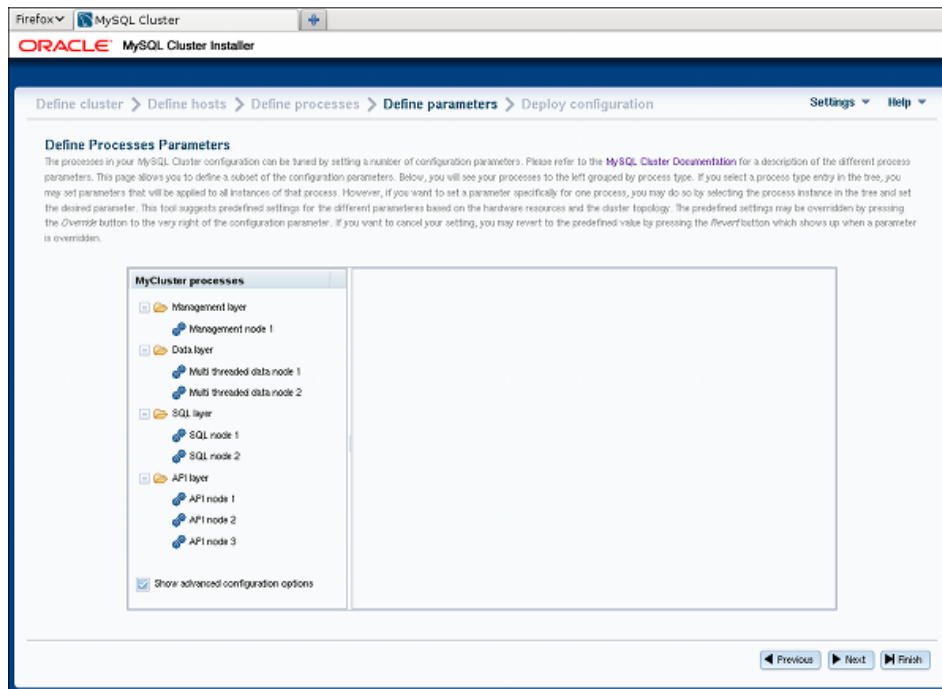

**Removing processes.** To delete a process, right-click on a process in the tree and select **delete process** from the pop up menu that appears, or select a process, then use the **delete process** button below the process tree.

When a process is selected in the process tree, information about that process is displayed in the panel to the right of the tree, where you can change the process name and possibly its type. *Important:* Currently, you can change a single-threaded data node (`ndbd`) to a multi-threaded data node (`ndbmt.d`), or the reverse, only; no other process type changes are allowed. If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.

## NDB Cluster Auto-Installer Define Attributes Screen

This screen has a layout similar to that of the [Define Processes screen](#), with a process tree at the left. Unlike that screen's tree, the **Define Attributes** process tree is organized by process or node type, with single-threaded and multi-threaded data nodes considered to be of the same type for this purpose, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. A panel to the right of this tree displays information regarding the item currently selected. The **Define Attributes** screen is shown here:

**Figure 20.17 NDB Cluster Auto-Installer Define Attributes screen**

A checkbox labelled **Show advanced configuration** is located below the process tree. Checking this box makes advanced options visible in the information pane. These options are set and used whether or not they are visible.

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:

**Figure 20.18 Define Attributes Detail With SQL Process Attributes**

Process property	Value	Override
<b>Node identity and directories</b>		
NodeId [?]	53	
HostName [?]	127.0.0.1	
DataDir [?]	/export/home/tmp/mysql_cluster/53/	+
<b>Communication</b>		
Port [?]	3306	+
Socket [?]	/export/home/tmp/mysql_cluster/53/mysql.socket	+

For some of the attributes shown in the information panel, a button bearing a plus sign is displayed to the right, which means that the value of this attribute can be overridden. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X, as shown here:

**Figure 20.19 Define Attributes Detail, Overriding Attribute Default Value**

Process property	Value	Override
<b>Node identity and directories</b>		
NodeId [?]	53	
HostName [?]	127.0.0.1	
DataDir [?]	/export/home/tmp/a_different_directory/	X
<b>Communication</b>		
Port [?]	3306	+
Socket [?]	/export/home/tmp/mysql_cluster/53/mysql.socket	+

Clicking the X button next to an attribute undoes any changes made to it; it immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

## NDB Cluster Auto-Installer Deploy Cluster Screen

This screen allows you to perform the following tasks:

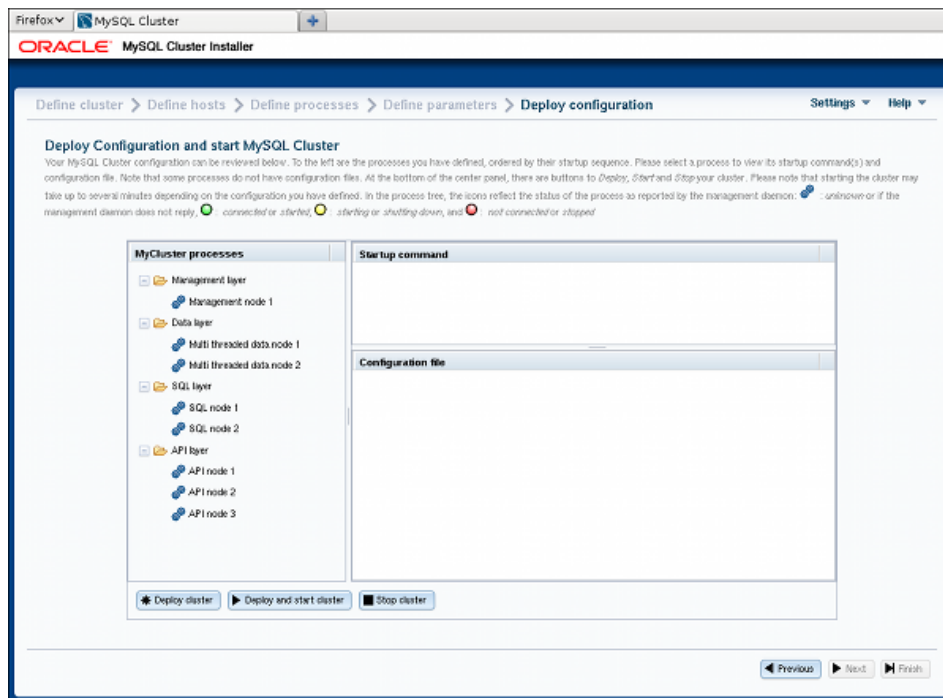

- Review process startup commands and configuration files to be applied

- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Cluster** screen is shown here:

**Figure 20.20 NDB Cluster Auto-Installer Deploy Cluster screen**

Like the **Define Attributes** screen, this screen features a process tree, organized by process type, on the left hand side. Next to each process is a status icon whose color indicates the current status of the process: green if it is running; yellow if it is starting or stopping; red if the process is stopped.

To the right of the process tree are two information panels, the upper panel showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The lower panel shows the contents of the configuration file, if any, for the given process; currently, the management node process is only type of process having a configuration file. Other process types are configured using command-line parameters when starting the process, or by obtaining configuration information from the management nodes as needed in real time.

Three buttons are located immediately below the process tree. These are labelled as and perform the functions described in the following list:

- **Deploy cluster:** Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded.
- **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

**Figure 20.21 Progress Bar With Status of Node Startup Process**

The process status icons adjoining the process tree mentioned previously also update with the status of each process.

- **Stop cluster:** After the cluster has been started, you can stop it using the this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree.

The Auto-Installer generates a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster.

## 20.2.2 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see [Section 20.2.3, “Installing NDB Cluster on Windows”](#).

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmt.d`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a `.tar.gz` archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See [Section 20.2.4, “Initial Configuration of NDB Cluster”](#).

### 20.2.2.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest NDB Cluster 7.5 binary archive (`mysql-cluster-gpl-7.5.5-linux-i686-glibc23.tar.gz`) from the [NDB Cluster downloads area](#). We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).)

**Note**

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see [Section 20.2.4, “Initial Configuration of NDB Cluster”](#)).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql -s /bin/false mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

**Note**

The actual file and directory names vary according to the NDB Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzf mysql-cluster-gpl-7.5.5-linux2.6.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-7.5.5-linux2.6-i686 /usr/local/mysql
```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

```
shell> cd mysql
shell> mysqld --initialize
```

This generates a random password for the MySQL `root` account. If you do *not* want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#), for additional information before performing this step. See also [Section 5.4.4, “mysql\\_secure\\_installation — Improve MySQL Installation Security”](#).

Alternatively, you can change location to the `mysql` directory and run `mysql_install_db` to create the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

However, this method is not recommended, due to the fact that `mysql_install_db` is deprecated, and thus subject to removal in a future release.

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtbd` (multi-threaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtbd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.7.16-ndb-7.5.5-linux-i686-glibc23.tar.gz
shell> cd mysql-5.7.16-ndb-7.5.5-linux-i686-glibc23
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtbd /usr/local/bin/ndbmtbd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtbd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

**Note**

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 20.2.4, “Initial Configuration of NDB Cluster”](#).)

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.7.16-ndb-7.5.5-linux2.6-i686.tar.gz
shell> cd mysql-5.7.16-ndb-7.5.5-linux2.6-i686
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster .

### 20.2.2.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster node using RPM packages supplied by Oracle beginning with NDB 7.5.4. For information about RPMs for previous versions of NDB Cluster , see [Installation using old-style RPMs \(NDB 7.5.3 and earlier\)](#).

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-license-component-ver-rev.distro.arch.rpm

license:= {commercial | community}

component: {management-server | data-node | server | client | other-see text}

ver: major.minor.release

rev: major.minor

distro: {el5 | el6 | el7 | sles12}

arch: {i686 | x86_64}
```

*license* indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for *component*, with descriptions, can be found in the following table:

Component	Description
<code>auto-installer</code>	NDB Cluster Auto Installer program; see <a href="#">Section 20.2.1, “The NDB Cluster Auto-Installer”</a> , for usage
<code>client</code>	MySQL and NDB client programs; includes <code>mysql</code> client, <code>ndb_mgm</code> client, and other client tools
<code>common</code>	Character set and error message information needed by the MySQL server
<code>data-node</code>	<code>ndbd</code> and <code>ndbmt</code> data node binaries
<code>devel</code>	Headers and library files needed for MySQL client development
<code>embedded</code>	Embedded MySQL server
<code>embedded-compat</code>	Backwards-compatible embedded MySQL server
<code>embedded-devel</code>	Header and library files for developing applications for embedded MySQL
<code>java</code>	JAR files needed for support of ClusterJ applications
<code>libs</code>	MySQL client libraries
<code>libs-compat</code>	Backwards-compatible MySQL client libraries
<code>management-server</code>	The NDB Cluster management server ( <code>ndb_mgmd</code> )
<code>memcached</code>	Files needed to support <code>ndbmemcache</code>
<code>ndbclient</code>	NDB client library for running NDB API and MGM API applications ( <code>libndbclient</code> )
<code>ndbclient-devel</code>	Header and other files needed for developing NDB API and MGM API applications
<code>nodejs</code>	Files needed to set up Node.JS support for NDB Cluster
<code>server</code>	The MySQL server ( <code>mysqld</code> ) with NDB storage engine support included, and associated MySQL server programs
<code>test</code>	<code>mysqltest</code> , other MySQL test programs, and support files

A single bundle (`.tar` file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- *Management node:* `management-server`
- *Data node:* `data-node`
- *SQL node:* `server` and `common`

In addition, the `client` RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part NDB storage engine version number in 7.5.x format, shown as 7.5.5 in the examples. `rev` provides the RPM revision number in `major.minor` format. In the examples shown in this section, we use 1.1 for this value.

The `distro` (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `e16` (Oracle Linux 6, Red Hat Enterprise Linux 6), `e17` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (`e17`).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as 7.5.5) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

**Data nodes.** On a computer that is to host an NDB Cluster data node it is necessary to install only the `data-node` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv mysql-cluster-community-data-node-7.5.5-1.1.e17.x86_64.rpm
```

This installs the `ndbd` and `ndbmtd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

**SQL nodes.** Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv mysql-cluster-community-server-7.5.5-1.1.e17.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with NDB storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`,

respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

### Important

You must use the versions of these RPMs released for NDB Cluster ; those released for the standard MySQL server do not provide support for the [NDB](#) storage engine.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv mysql-cluster-community-client-7.5.5-1.1.el7.x86_64.rpm
```

This installs the `mysql` client and other MySQL client programs, such as `mysqladmin` and `mysqldump`, to `/usr/bin`.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `management-server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `management-server` RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv mysql-cluster-commercial-management-server-7.5.5-1.1.el7.x86_64.rpm
```

This RPM installs the management server binary `ndb_mgmd` in the `/usr/sbin` directory. While this is the only program actually required for running a management node, it is also a good idea to have the `ndb_mgm` NDB Cluster management client available as well. You can obtain this program, as well as other [NDB](#) client programs such as `ndb_desc` and `ndb_config`, by installing the `client` RPM as described previously.

### Note

Previously, `ndb_mgm` was installed by the same RPM used to install the management server. In NDB 7.5.4 and later, all [NDB](#) client programs are obtained from the same `client` RPM that installs `mysql` and other MySQL clients.

See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), for the relevant information.

**Installation using old-style RPMs (NDB 7.5.3 and earlier).** *The information in the remainder of this section applies only to NDB 7.5.3 and earlier, and provides the steps necessary to install the correct executables for each type of NDB Cluster node using “old-style” RPM packages as supplied by Oracle prior to NDB 7.5.4. The filenames for these “old-style” RPMs use the following pattern:*

```
MySQL-Cluster-component-producttype-ndbversion-revision.distribution.architecture.rpm

component:= {server | client [| other]}

producttype:= {gpl | advanced}

ndbversion:= major.minor.release

distribution:= {sles11 | rhel5 | el6}

architecture:= {i386 | x86_64}
```

The *component* can be *server* or *client*. (Other values are possible, but since only the *server* and *client* components are required for a working NDB Cluster installation, we do not discuss them here.) The *producttype* for Community RPMs downloaded from <http://dev.mysql.com/downloads/cluster/> is always *gpl*; *advanced* is used to indicate commercial releases. *ndbversion* represents the three-part NDB storage engine version number in 7.5.x format; we use 7.5.3 throughout the rest of this section. The RPM *revision* is shown as 1 in the examples following. The *distribution* can be one of *sles11* (SUSE Enterprise Linux 11), *rhel5* (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), or *el6* (Oracle Linux 6, Red Hat Enterprise Linux 6). The *architecture* is *i386* for 32-bit RPMs and *x86\_64* for 64-bit versions.

For an NDB Cluster, one and possibly two RPMs are required:

- The *server* RPM (for example, `MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm`), which supplies the core files needed to run a MySQL Server with NDBCLUSTER storage engine support (that is, as an NDB Cluster SQL node) as well as all NDB Cluster executables, including the management node, data node, and `ndb_mgm` client binaries. This RPM is always required for installing NDB Cluster.
- If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the *client* RPM (for example, `MySQL-Cluster-client-gpl-7.5.3-1.sles11.i386.rpm`), which supplies the `mysql` client

*It is very important that all of the Cluster RPMs to be installed have the same version number. The *architecture* designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.*

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the *server* RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program `ndbd` or `ndbmtd` (both in `/usr/sbin`) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the *server* RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm
```

This installs the MySQL server binary (`mysqld`) with NDB storage engine support in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the *client* RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-client-gpl-7.5.3-1.sles11.i386.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `server` RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The `server` RPM also installs `ndb_mgm`, the NDB management client.

See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle. See [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), for information about required post-installation configuration.

### 20.2.2.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such as Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle provides `.deb` installer files for NDB Cluster 7.5 for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, `ndbver` is the 3-part NDB engine version number, `debianver` is the major version of Debian (6.0 or 7), and `arch` is one of `i686` or `x86_64`. In the examples that follow, we assume you wish to install NDB 7.5.5 on a 64-bit Debian 7 system; in this case, the installer file is named `mysql-cluster-gpl-7.5.5-debian7-x86_64.deb`.

Once you have downloaded the appropriate `.deb` file, you can install it from the command line using `dpkg`, like this:

```
shell> dpkg -i mysql-cluster-gpl-7.5.5-debian7-i686.deb
```

You can also remove it using `dpkg` as shown here:

```
shell> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as `GDebi` for the Gnome desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where `version` is the 2-part release series version for the included MySQL server. For NDB 7.5, this is always 5.7. The directory layout is the same as that for the generic Linux binary distribution (see [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

### 20.2.2.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs

in a few key respects discussed here. For general information about building MySQL from source, see [Section 2.9, “Installing MySQL from Source”](#). For information about compiling NDB Cluster on Windows platforms, see [Section 20.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at <http://dev.mysql.com/downloads/cluster/>. The archived source file should have a name similar to `mysql-cluster-gpl-7.5.5.tar.gz`. You can also obtain MySQL development sources from [launchpad.net](http://launchpad.net). *Building NDB Cluster from standard MySQL Server 5.7 sources is not supported.*

The `WITH_NDBCLUSTER_STORAGE_ENGINE` option for `CMake` causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option (or its alias `WITH_NDBCLUSTER`) is required when building NDB Cluster.

### Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

After you have run `make` && `make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.** When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.** The only executable required on a data node host is the data node binary `ndbd` or `ndbmtbd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multi-threaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmtbd` to be built automatically; `make install` places the `ndbmtbd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.9, “Installing MySQL from Source”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.9, “Installing MySQL from Source”](#) on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster .

## 20.2.3 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 7.5 binaries for Windows can be obtained from <http://dev.mysql.com/downloads/cluster/>. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see [Section 20.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see [Section 20.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

### 20.2.3.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary `no-install` NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see [Section 20.2, “NDB Cluster Installation”](#)), as shown in the following table:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmt.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmt.exe`, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

#### Note

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows binary archive from <http://dev.mysql.com/downloads/cluster/>. This archive has a filename of the form `mysql-cluster-gpl-noinstall-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as 7.5.5), and `arch` is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the NDB Cluster 7.5.5 `no-install` archive for 32-bit Windows systems is named `mysql-cluster-gpl-noinstall-7.5.5-win32.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the `no-install` archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address 192.168.0.20, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-noinstall-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.7`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.7\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see [Section 2.3.5, "Installing MySQL on Microsoft Windows Using a noinstall Zip Archive"](#).

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see [Section 2.3.5.2, "Creating an Option File"](#)), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

**Data nodes.** An NDB Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmttd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmttd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=192.168.0.10 # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
# Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:
  - The IP address or hostname of any SQL nodes
  - The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
  - The number of replicas, using the `NoOfReplicas` configuration parameter (see [Section 20.1.2, "NDB Cluster Nodes, Node Groups, Replicas, and Partitions"](#))
  - The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2           # Number of replicas
DataDir=C:/mysql/cluster-data # Directory for each data node's data files
                           # Forward slashes used in directory path,
                           # rather than backslashes. This is correct;
                           # see Important note in text
DataMemory=80M           # Memory allocated to data storage
```

```

IndexMemory=18M  # Memory allocated to index storage
                  # For DataMemory and IndexMemory, we have used the
                  # default values. Since the "world" database takes up
                  # only about 500KB, this should be more than enough for
                  # this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=192.168.0.10          # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs  # Directory for management node log files

[ndbd]
# Options for data node "A":
                                 # (one [ndbd] section per data node)
HostName=192.168.0.30          # Hostname or IP address

[ndbd]
# Options for data node "B":
                                 # Hostname or IP address
HostName=192.168.0.40

[mysqld]
# SQL node options:
HostName=192.168.0.20          # Hostname or IP address

```

Save this file as the text file `C:\mysql\bin\config.ini`.

### Important

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the `[ndb_mgmd]` section of an NDB Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs      # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

## 20.2.3.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build NDB Cluster, you must use the NDB Cluster sources, which you can obtain from <http://dev.mysql.com/downloads/cluster/>.

Attempting to build NDB Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` or `WITH_NDBCLUSTER` option in addition to any other build options you wish to use with `CMake`. (`WITH_NDBCLUSTER` is supported as an alias for `WITH_NDBCLUSTER_STORAGE_ENGINE`, and works in exactly the same way.)

**Important**

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

Once the build process is complete, you can create a Zip archive containing the compiled binaries; [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#) provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see [Section 20.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

### 20.2.3.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.7.16-ndb-7.5.5
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See [Section 20.2.3.4, “Installing NDB Cluster Processes as Windows Services”](#), where we show how to install and run NDB Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

**Important**

An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have

corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

For additional information about options which can be used with `ndb_mgmd`, see [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), as well as [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see [Section 20.2.3.4, “Installing NDB Cluster Processes as Windows Services”](#).)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.7.16-ndb-7.5.5)
Node 3: starting (Last completed phase 3) (mysql-5.7.16-ndb-7.5.5)

Node 2: starting (Last completed phase 4) (mysql-5.7.16-ndb-7.5.5)
Node 3: starting (Last completed phase 4) (mysql-5.7.16-ndb-7.5.5)

Node 2: Started (version 7.5.5)
Node 3: Started (version 7.5.5)

ndb_mgm>
```

#### Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#).

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2      @192.168.0.30  (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=3      @192.168.0.40  (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)]  1 node(s)
id=1      @192.168.0.10  (Version: 5.7.16-ndb-7.5.5)

[mysqld(API)]    1 node(s)
id=4      @192.168.0.20  (Version: 5.7.16-ndb-7.5.5)
```

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster's `NDBCLUSTER` storage engine. See [Section 20.2.6, "NDB Cluster Example with Tables and Data"](#), for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtl.exe` as Windows services. For information on how to do this, see [Section 20.2.3.4, "Installing NDB Cluster Processes as Windows Services"](#).

#### 20.2.3.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical `Services` utility.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
  as 'C:\mysql\bin\ndbd.exe' "--service=ndb_mgmd"
Service successfully installed.
```

### Important

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> NET START ndb_mgmd
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP ndb_mgmd
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'NDB Cluster Management Server'
  as 'C:\mysql\bin\ndb_mgmd.exe' "--service=mgmd1"
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> NET START mgmd1
```

```
The NDB Cluster Management Server service is starting.  
The NDB Cluster Management Server service was started successfully.
```

```
C:\> NET STOP mgmdl  
The NDB Cluster Management Server service is stopping..  
The NDB Cluster Management Server service was stopped successfully.
```

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove  
Removing service 'NDB Cluster Management Server'  
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the `--remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmdl  
Removing service 'mgmdl'  
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install  
Installing service 'NDB Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'  
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd  
The NDB Cluster Data Node Daemon service is starting.  
The NDB Cluster Data Node Daemon service was started successfully.  
  
C:\> NET STOP ndbd  
The NDB Cluster Data Node Daemon service is stopping..  
The NDB Cluster Data Node Daemon service was stopped successfully.  
  
C:\> NET START 'NDB Cluster Data Node Daemon'  
The NDB Cluster Data Node Daemon service is starting.  
The NDB Cluster Data Node Daemon service was started successfully.  
  
C:\> NET STOP 'NDB Cluster Data Node Daemon'  
The NDB Cluster Data Node Daemon service is stopping..  
The NDB Cluster Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove  
Removing service 'NDB Cluster Data Node Daemon'  
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> NET START dnode1
The NDB Cluster Data Node Daemon service is starting.
The NDB Cluster Data Node Daemon service was started successfully.

C:\> NET STOP dnode1
The NDB Cluster Data Node Daemon service is stopping..
The NDB Cluster Data Node Daemon service was stopped successfully.
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove`. For additional information, see [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

## 20.2.4 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see [Section 20.2.1, “The NDB Cluster Auto-Installer”](#).

For our four-node, four-host NDB Cluster (see [Cluster nodes and host computers](#)), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connection strings, see [Section 20.3.3.3, “NDB Cluster Connection Strings”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

**Configuring the data nodes and SQL nodes.** The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

### Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

### Important

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2      # Number of replicas
DataMemory=80M      # How much memory to allocate for data storage
IndexMemory=18M     # How much memory to allocate for index storage
                    # For DataMemory and IndexMemory, we have used the
                    # default values. Since the "world" database takes up
                    # only about 500KB, this should be more than enough for
                    # this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202     # This the default; however, you can use any
                    # port that is free for all the hosts in the cluster
                    # Note: It is recommended that you do not specify the port
                    # number at all and simply allow the default value to be used
                    # instead

[ndb_mgmd]
# Management process options:
hostname=192.168.0.10 # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node log files

[ndbd]
# Options for data node "A":
                    # (one [ndbd] section per data node)
hostname=192.168.0.30 # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files
```

```
[ndbd]
# Options for data node "B":
hostname=192.168.0.40      # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20      # Hostname or IP address
                           # (additional mysqld connections can be
                           # specified for this node for various
                           # purposes such as running ndb_restore)
```

**Note**

The `world` database can be downloaded from <http://dev.mysql.com/doc/index-other.html>.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 20.2.5, “Initial Startup of NDB Cluster”](#).

For more detailed information about the available NDB Cluster configuration parameters and their uses, see [Section 20.3.3, “NDB Cluster Configuration Files”](#), and [Section 20.3, “Configuration of NDB Cluster”](#). For configuration of NDB Cluster as relates to making backups, see [Section 20.5.3.3, “Configuration for NDB Cluster Backups”](#).

**Note**

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

## 20.2.5 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), for details.)

For additional options which can be used with `ndb_mgmd`, see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=3 @192.168.0.40 (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.7.16-ndb-7.5.5)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.7.16-ndb-7.5.5)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

#### Note

The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See [Section 20.2.6, “NDB Cluster Example with Tables and Data”](#), for a brief discussion.

## 20.2.6 NDB Cluster Example with Tables and Data

#### Note

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.7.16-ndb-7.5.5

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 20.5.12.2, “NDB Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access [NDB](#) tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the [SELECT](#) statement just shown by using the PHP 5.X [mysqli](#) extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
  </tbody>
<?
  # then display the results...
  while($row = $result->fetch_object())
    printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
          $row->Name, $row->Population);
?>
  </tbody>
</table>
<?
  # ...and verify the number of rows that were retrieved
  printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

## 20.2.7 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See [Section 20.4.27](#), “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtdd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MYSQL`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (192.168.0.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.
- On the SQL host (192.168.0.20):

```
shell> mysqld_safe &
```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see [Section 20.2.3.4](#), “Installing NDB Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (192.168.0.10 in our example setup), execute the following command:

```
C:\> NET START ndb_mgmd
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40), execute the following command:

```
C:\> NET START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see [Section 20.2.3.3](#), “Initial Startup of NDB Cluster on Windows”).
- On the SQL node host (192.168.0.20), execute the following command:

```
C:\> NET START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the

cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#).

### 20.2.8 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 7.5 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring an NDB Cluster prior to attempting an upgrade or downgrade. See [Section 20.3, “Configuration of NDB Cluster”](#).

#### Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software.* See [Section 2.11.1, “Upgrading MySQL”](#).

The table shown here provides information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB 7.5. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 7.5 release series can be found following the table.

### Upgrades and Downgrades, NDB Cluster 7.5

Figure 20.22 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 7.5

**Version support.** The following versions of NDB Cluster are supported for upgrades to GA releases of NDB Cluster 7.5 (7.5.4 and later):

- NDB Cluster 7.4 GA releases (7.4.4 and later)
- NDB Cluster 7.3 GA releases (7.3.2 and later)

- NDB Cluster 7.2 GA releases (7.2.4 and later)

**Known Issues.** The following issues are known to occur when upgrading to or between the stated releases:

- When upgrading from NDB 7.5.2 or 7.5.3 to a later version, the use of `mysqld` with the `--initialize` and `--ndbcluster` options together caused problems later running `mysql_upgrade`.

When run with `--initialize`, the server does not require NDB support; having NDB enabled at this time can cause problems with `ndbinfo` tables. To keep this from happening, the `--initialize` option now causes `mysqld` to ignore the `--ndbcluster` option if the latter is also specified.

A workaround for an upgrade that has failed for these reasons can be accomplished as follows:

1. Perform a rolling restart of the entire cluster
2. Delete all `.frm` files in the `data/ndbinfo` directory
3. Run `mysql_upgrade`.

(Bug #81689, Bug #82724, Bug #24521927, Bug #23518923)

- During an online upgrade from an NDB Cluster 7.3 release to an NDB 7.4 (or later) release, the failures of several data nodes running the lower version during local checkpoints (LCPs), and just prior to upgrading these nodes, led to additional node failures following the upgrade. This was due to lingering elements of the `EMPTY_LCP` protocol initiated by the older nodes as part of an LCP-plus-restart sequence, and which is no longer used in NDB 7.4 and later due to LCP optimizations implemented in those versions. This issue was fixed in NDB 7.5.4. (Bug #23129433)
- Beginning with NDB 7.5.2, the `ndb_binlog_index` table uses the InnoDB storage engine. (Use of the MyISAM storage engine for this table continues to be supported for backward compatibility.)

When upgrading a previous release to NDB 7.5.2 or later, you can use the `--force --upgrade-system-tables` options with `mysql_upgrade` so that it performs `ALTER TABLE ... ENGINE=INNODB` on the `ndb_binlog_index` table.

For more information, see [Section 20.6.4, “NDB Cluster Replication Schema and Tables”](#).

- Online upgrades from previous versions of NDB Cluster to NDB 7.5.1 were not possible due to missing entries in the matrix used to test upgrade compatibility between versions. (Bug #22024947)

Also in NDB 7.5.1, `mysql_upgrade` failed to upgrade the `sys` schema if a `sys` database directory existed but was empty. (Bug #81352, Bug #23249846, Bug #22875519)

## 20.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as NDBCLUSTER, although NDB is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in

`my.cnf`, or with the `mysql` client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see [MySQL Server Options for NDB Cluster](#).

You can use also the NDB Cluster Auto-Installer to set up and deploy an NDB Cluster on one or more hosts using a browser-based GUI. For more information, see [Section 20.2.1, “The NDB Cluster Auto-Installer”](#).

For general information about installing NDB Cluster, see [Section 20.2, “NDB Cluster Installation”](#).

### 20.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

By default, `ndbd` looks for the management server at `localhost` on port 1186.

#### Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.7.18

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      1 node(s)
id=2      @127.0.0.1  (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0, *)

[ndb_mgmd(MGM)]  1 node(s)
id=1      @127.0.0.1  (Version: 5.7.16-ndb-7.5.5)

[mysqld(API)]    3 node(s)
id=3      @127.0.0.1  (Version: 5.7.16-ndb-7.5.5)
id=4      (not connected, accepting connect from any host)
id=5      (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster . You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

## 20.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, `shm`, or `sci`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

**Considerations when restarting nodes.** For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

### Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space. In addition, it is generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

### Note

4294967039 often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RN1L` and is equal to `0xFFFFFFFF`, or  $2^{32} - 2^8 - 1$ .

## 20.3.2.1 NDB Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#).

These parameters also apply to `ndbmt_d`, the multi-threaded version of `ndbd`. For more information, see [Section 20.4.3, “ndbmt\\_d — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

NDB Cluster also supports the addition of new data node groups online, to a running cluster. For more information, see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#).

**Table 20.1 Data Node Configuration Parameters**

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/Maximum or Permitted Values		
Arbitration	enumeration	N	NDB 7.5.0
	Default		
	Default, Disabled, WaitExternal		
ArbitrationTimeout	milliseconds	N	NDB 7.5.0
	7500		
	10 / 4294967039 (0xFFFFFFFF)		
BackupDataBufferSize	bytes	N	NDB 7.5.1
	16M		
	512K / 4294967039 (0xFFFFFFFF)		
BackupDataDir	path	IN	NDB 7.5.0
	FileSystemPath		
	...		
BackupDiskWriteSpeedPct	percent	N	NDB 7.5.0
	50		
	0 / 90		
BackupLogBufferSize	bytes	N	NDB 7.5.0
	16M		
	2M / 4294967039 (0xFFFFFFFF)		
BackupMaxWriteSize	bytes	N	NDB 7.5.0
	1M		
	256K / 4294967039 (0xFFFFFFFF)		
BackupMemory	bytes	N	NDB 7.5.0
	32M		
	0 / 4294967039 (0xFFFFFFFF)		
BackupReportFrequency	seconds	N	NDB 7.5.0

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/Maximum or Permitted Values		
	0		
	0 / 4294967039 (0xFFFFFFFF)		
BackupWriteSize	bytes	N	NDB 7.5.0
	256K		
	32K / 4294967039 (0xFFFFFFFF)

### 20.3.2.2 NDB Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#).

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

**Table 20.3 Management Node Configuration Parameters**

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/Maximum or Permitted Values		
<code>ArbitrationDelay</code>	milliseconds	N	NDB 7.5.0
	0		

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/Maximum or Permitted Values		
	0 / 4294967039 (0xFFFFFFFF)		
ArbitrationRank	0-2	N	NDB 7.5.0
	1		
	0 / 2		
DataDir	path	N	NDB 7.5.0
	.		
	...		
ExecuteOnComputer	name	S	NDB 7.5.0
	[none]		
	...		
HeartbeatIntervalMgmdMgmd	milliseconds	N	NDB 7.5.0
	1500		
	100 / 4294967039 (0xFFFFFFFF)		
HeartbeatThreadPriority	string	S	NDB 7.5.0
	[none]		
	...		
HostName	name or IP address	N	NDB 7.5.0
	[none]		
	...		
Id	unsigned	IS	NDB 7.5.0
	[none]		
	1 / 255		
LogDestination	{CONSOLE SYSLOG FILE}	N	NDB 7.5.0
	[see text]		
	...		
NodeId	unsigned	IS	NDB 7.5.0
	[none]		
	1 / 255		
PortNumber	unsigned	S	NDB 7.5.0
	1186		

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/Maximum or Permitted Values		
<code>PortNumberStats</code>	0 / 64K	N	NDB 7.5.0
	unsigned		
	[none]		
<code>TotalSendBufferMemory</code>	0 / 64K	N	NDB 7.5.0
	bytes		
	0		
<code>wan</code>	256K / 4294967039 (0xFFFFFFFF)	N	NDB 7.5.0
	boolean		
	false		
	true, false		

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#), for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 20.1.6.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 20.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

**Note**

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#); for information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

**Table 20.4 SQL Node / API Node Configuration Parameters**

Parameter Name	Type or Units	Restart Type	In Version ... (and later)
	Default Value		
	Minimum/Maximum or Permitted Values		
<code>ApiVerbose</code>	bytes	N	NDB 7.5.2

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 20.3.2.4 Other NDB Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#), [Section 20.3.3.11, “NDB Cluster Shared-Memory Connections”](#), or [Section 20.3.3.12, “SCI Transport Connections in NDB Cluster”](#), as appropriate.

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

### 20.3.2.5 NDB Cluster mysqld Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 6.1.3, “Server Option and Variable Reference”](#).

**Table 20.9 MySQL Server Options and Variables for MySQL Cluster: MySQL Cluster NDB 7.5**

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">Com_show_ndb_status</a>		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW NDB STATUS statements		
<a href="#">Handler_discover</a>		
No	No	Yes
No	Both	No
DESCRIPTION: Number of times that tables have been discovered		
<a href="#">ndb-batch-size</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Size (in bytes) to use for NDB transaction batches		
<a href="#">ndb-blob-read-batch-bytes</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.		
<a href="#">ndb-blob-write-batch-bytes</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.		
<a href="#">ndb-cluster-connection-pool</a>		
Yes	Yes	Yes
Yes	Global	No
DESCRIPTION: Number of connections to the cluster used by MySQL		
<a href="#">ndb-cluster-connection-pool-nodeids</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for --ndb-cluster-connection-pool		
<a href="#">ndb-connectstring</a>		
Yes	No	No
Yes		No
DESCRIPTION: Point to the management server that distributes the cluster configuration		
<a href="#">ndb-default-column-format</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table. <a href="#">ndb-deferred-constraints</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only. <a href="#">ndb-distribution</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH) <a href="#">ndb-log-apply-status</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option. <a href="#">ndb-log-empty-epochs</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled. <a href="#">ndb-log-empty-update</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled. <a href="#">ndb-log-exclusive-reads</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts. <a href="#">ndb-log-orig</a>		
Yes	Yes	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Global	No
DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table. <a href="#">ndb-log-transaction-id</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF. <a href="#">ndb-mgmd-host</a>		
Yes	No	No
Yes		No
DESCRIPTION: Set the host (and port, if desired) for connecting to management server <a href="#">ndb-nodeid</a>		
Yes	No	Yes
Yes	Global	No
DESCRIPTION: MySQL Cluster node ID for this MySQL server <a href="#">ndb-recv-thread-activation-threshold</a>		
Yes	No	No
Yes		No
DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads) <a href="#">ndb-recv-thread-cpu-mask</a>		
Yes	No	No
Yes		No
DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details. <a href="#">ndb-transid-mysql-connection-map</a>		
Yes	No	No
No		No
DESCRIPTION: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name. <a href="#">ndb-wait-connected</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections. <a href="#">ndb-wait-setup</a>		
Yes	Yes	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Global	No
DESCRIPTION: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete. <a href="#">ndb-allow-copying-alter-table</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables <a href="#">Ndb_api_bytes_received_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node). <a href="#">Ndb_api_bytes_received_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Amount of data (in bytes) received from the data nodes in this client session. <a href="#">Ndb_api_bytes_received_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) received from the data nodes by this slave. <a href="#">Ndb_api_bytes_sent_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node). <a href="#">Ndb_api_bytes_sent_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Amount of data (in bytes) sent to the data nodes by this slave. <a href="#">Ndb_api_event_bytes_count_injector</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of bytes of events received by the NDB binary log injector thread. <a href="#">Ndb_api_event_data_count_injector</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of row change events received by the NDB binary log injector thread.		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">Ndb_api_event_nondata_count_injector</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of events received, other than row change events, by the NDB binary log injector thread.		
<a href="#">Ndb_api_pk_op_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of operations based on or using primary keys by this MySQL Server (SQL node).		
<a href="#">Ndb_api_pk_op_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of operations based on or using primary keys in this client session.		
<a href="#">Ndb_api_pk_op_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of operations based on or using primary keys by this slave.		
<a href="#">Ndb_api_pruned_scan_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of scans that have been pruned to a single partition by this MySQL Server (SQL node).		
<a href="#">Ndb_api_pruned_scan_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of scans that have been pruned to a single partition in this client session.		
<a href="#">Ndb_api_range_scan_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of range scans that have been started by this slave.		
<a href="#">Ndb_api_read_row_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows that have been read by this MySQL Server (SQL node).		
<a href="#">Ndb_api_read_row_count_session</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
No	No	Yes
No	Session	No
DESCRIPTION: Total number of rows that have been read in this client session. <a href="#">Ndb_api_scan_batch_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of batches of rows received by this slave. <a href="#">Ndb_api_table_scan_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node). <a href="#">Ndb_api_table_scan_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of table scans that have been started, including scans of internal tables, in this client session. <a href="#">Ndb_api_trans_abort_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted by this MySQL Server (SQL node). <a href="#">Ndb_api_trans_abort_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of transactions aborted in this client session. <a href="#">Ndb_api_trans_abort_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted by this slave. <a href="#">Ndb_api_trans_close_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node). <a href="#">Ndb_api_trans_close_count_session</a>		
No	No	Yes

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
No	Session	No
DESCRIPTION: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session.		
<a href="#">Ndb_api_trans_close_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this slave.		
<a href="#">Ndb_api_trans_commit_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions committed by this MySQL Server (SQL node).		
<a href="#">Ndb_api_trans_commit_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of transactions committed in this client session.		
<a href="#">Ndb_api_trans_commit_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions committed by this slave.		
<a href="#">Ndb_api_trans_local_read_row_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows that have been read by this slave.		
<a href="#">Ndb_api_trans_start_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions started by this MySQL Server (SQL node).		
<a href="#">Ndb_api_trans_start_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of transactions started in this client session.		
<a href="#">Ndb_api_trans_start_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions started by this slave.		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
<a href="#">Ndb_api_uk_op_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of operations based on or using unique keys by this MySQL Server (SQL node).		
<a href="#">Ndb_api_uk_op_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of operations based on or using unique keys by this slave.		
<a href="#">Ndb_api_wait_exec_complete_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node).		
<a href="#">Ndb_api_wait_exec_complete_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of times thread has been blocked while waiting for execution of an operation to complete in this client session.		
<a href="#">Ndb_api_wait_exec_complete_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for execution of an operation to complete by this slave.		
<a href="#">Ndb_api_wait_meta_request_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node).		
<a href="#">Ndb_api_wait_meta_request_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of times thread has been blocked waiting for a metadata-based signal in this client session.		
<a href="#">Ndb_api_wait_nanos_count</a>		
No	No	Yes
No	Global	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
DESCRIPTION: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node).		
<a href="#">Ndb_api_wait_nanos_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session.		
<a href="#">Ndb_api_wait_nanos_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave.		
<a href="#">Ndb_api_wait_scan_result_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node).		
<a href="#">Ndb_api_wait_scan_result_count_session</a>		
No	No	Yes
No	Session	No
DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal in this client session.		
<a href="#">Ndb_api_wait_scan_result_count_slave</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal by this slave.		
<a href="#">ndb_autoincrement_prefetch_sz</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: NDB auto-increment prefetch size		
<a href="#">ndb_cache_check_time</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache		
<a href="#">ndb_clear_apply_status</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Yes	No
No	Global	Yes
DESCRIPTION: Causes RESET SLAVE to clear all rows from the ndb_apply_status table. ON by default.		
<a href="#">Ndb_cluster_node_id</a>		
No	No	Yes
No	Both	No
DESCRIPTION: If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster		
<a href="#">Ndb_config_from_host</a>		
No	No	Yes
No	Both	No
DESCRIPTION: The host name or IP address of the Cluster management server. Formerly Ndb_connected_host		
<a href="#">Ndb_config_from_port</a>		
No	No	Yes
No	Both	No
DESCRIPTION: The port for connecting to Cluster management server. Formerly Ndb_connected_port		
<a href="#">Ndb_conflict_fn_epoch_trans</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of rows that have been found in conflict by the NDB\$EPOCH_TRANS() conflict detection function		
<a href="#">Ndb_conflict_fn_max</a>		
No	No	Yes
No	Global	No
DESCRIPTION: If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied		
<a href="#">Ndb_conflict_fn_old</a>		
No	No	Yes
No	Global	No
DESCRIPTION: If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied		
<a href="#">Ndb_conflict_trans_detect_iter_count</a>		
No	No	Yes
No	Global	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
DESCRIPTION: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.		
<a href="#">Ndb_conflict_trans_row_reject_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.		
<a href="#">ndb_data_node_neighbour</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables		
<a href="#">ndb_default_column_format</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.		
<a href="#">ndb_deferred_constraints</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.		
<a href="#">ndb_distribution</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)		
<a href="#">ndb_eventbuffer_free_percent</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc.		
<a href="#">ndb_eventbuffer_max_alloc</a>		
Yes	Yes	No
Yes	Global	Yes

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).		
<a href="#">ndb_extra_logging</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Controls logging of MySQL Cluster schema, connection, and data distribution events in the MySQL error log		
<a href="#">ndb_force_send</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Forces sending of buffers to NDB immediately, without waiting for other threads		
<a href="#">ndb_fully_replicated</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Whether new NDB tables are fully replicated		
<a href="#">ndb_index_stat_enable</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Use NDB index statistics in query optimization		
<a href="#">ndb_index_stat_option</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces		
<a href="#">ndb_join_pushdown</a>		
No	Yes	No
No	Both	Yes
DESCRIPTION: Enables pushing down of joins to data nodes		
<a href="#">ndb_log_apply_status</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID.		
<a href="#">ndb_log_bin</a>		
Yes	Yes	No
No	Both	Yes

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.		
<a href="#">ndb_log_binlog_index</a>		
Yes	Yes	No
No	Global	Yes
DESCRIPTION: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.		
<a href="#">ndb_log_empty_epochs</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.		
<a href="#">ndb_log_empty_update</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.		
<a href="#">ndb_log_exclusive_reads</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.		
<a href="#">ndb_log_orig</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.		
<a href="#">ndb_log_transaction_id</a>		
No	Yes	No
No	Global	No
DESCRIPTION: Whether NDB transaction IDs are written into the binary log. (Read-only.)		
<a href="#">ndb_log_updated_only</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Log complete rows (ON) or updates only (OFF)		
<a href="#">Ndb_number_of_data_nodes</a>		
No	No	Yes

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
No	Global	No
DESCRIPTION: If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster		
<a href="#">ndb_optimization_delay</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.		
<a href="#">ndb_optimized_node_selection</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator		
<a href="#">Ndb_pushed_queries_defined</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of joins that API nodes have attempted to push down to the data nodes		
<a href="#">Ndb_pushed_queries_executed</a>		
No	No	Yes
No	Global	No
DESCRIPTION: Number of joins successfully pushed down and executed on the data nodes		
<a href="#">ndb_read_backup</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Enable read from any replica		
<a href="#">ndb_rcv_thread_activation_threshold</a>		
No	No	No
No		No
DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)		
<a href="#">ndb_rcv_thread_cpu_mask</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.		
<a href="#">ndb_report_thresh_binlog_epoch_slip</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status <a href="#">ndb_report_thresh_binlog_mem_usage</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status <a href="#">Ndb_scan_count</a>		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of scans executed by NDB since the cluster was last started <a href="#">ndb_show_foreign_key_mock_tables</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Show the mock tables used to support foreign_key_checks=0. <a href="#">ndb_slave_conflict_role</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information. <a href="#">Ndb_slave_max_replicated_epoch</a>		
No	Yes	No
No	Global	No
DESCRIPTION: The most recently committed NDB epoch on this slave. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected. <a href="#">ndb_table_no_logging</a>		
No	Yes	No
No	Session	Yes
DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table. <a href="#">ndb_table_temporary</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
No	Yes	No
No	Session	Yes
DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged		
<a href="#">ndb_use_exact_count</a>		
No	Yes	No
No	Both	Yes
DESCRIPTION: Use exact row count when planning queries		
<a href="#">ndb_use_transactions</a>		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query		
<a href="#">ndb_version</a>		
No	Yes	No
No	Global	No
DESCRIPTION: Shows build and NDB engine version as an integer.		
<a href="#">ndb_version_string</a>		
No	Yes	No
No	Global	No
DESCRIPTION: Shows build information including NDB engine version in ndb-x.y.z format.		
<a href="#">ndbcluster</a>		
Yes	No	No
Yes		No
DESCRIPTION: Enable NDB Cluster (if this version of MySQL supports it)		
Disabled by <code>--skip-ndbcluster</code>		
<a href="#">ndbinfo_database</a>		
No	Yes	No
No	Global	No
DESCRIPTION: The name used for the NDB information database; read only.		
<a href="#">ndbinfo_max_bytes</a>		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: Used for debugging only.		
<a href="#">ndbinfo_max_rows</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
<b>Notes</b>		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: Used for debugging only. <a href="#">ndbinfo_offline</a>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views. <a href="#">ndbinfo_show_hidden</a>		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF. <a href="#">ndbinfo_table_prefix</a>		
Yes	Yes	No
No	Both	Yes
DESCRIPTION: The prefix to use for naming ndbinfo internal base tables <a href="#">ndbinfo_version</a>		
No	Yes	No
No	Global	No
DESCRIPTION: The version of the ndbinfo engine; read only. <a href="#">server-id-bits</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value. <a href="#">server_id_bits</a>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value. <a href="#">slave_allow_batching</a>		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Turns update batching on and off for a replication slave <a href="#">transaction_allow_batching</a>		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
No	Yes	No
No	Session	Yes
DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.		

### 20.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- **my.cnf:** Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- **config.ini:** This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. **config.ini** contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

**Caching of configuration data.** NDB uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.** When **--initial** is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the --reload option.** The **--reload** option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using --config-cache=FALSE.** This disables **--config-cache** (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the **config.ini** file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named **mysql-cluster** in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is **/usr/local/mysql-cluster**.) This can be overridden at runtime by starting the management server with the **--configdir** option. Configuration cache files are binary files named according to the pattern **ndb\_node\_id\_config.bin.seq\_id**, where **node\_id** is the management server's node ID in the cluster, and **seq\_id** is a cache identifier. Cache files are numbered sequentially using **seq\_id**, in the order in which they are created. The management server uses the latest cache file as determined by the **seq\_id**.

**Note**

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#).

### 20.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

**Note**

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 5.7)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see [Section 20.3.3.3, “NDB Cluster Connection Strings”](#).)

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
```

```
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see [NDB Cluster System Variables](#).

The `NDB` Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for `NDB` Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (`:`) as well as the equal sign (`=`); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

### Note

In some older releases of `NDB` Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
```

```

NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com

```

**Note**

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster , and is almost certain not to be sufficient for production settings. See [Section 20.3.3.2, “Recommended Starting Configuration for NDB Cluster”](#), which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

## Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster , but be may used as a convenience when setting up a large cluster. See [Section 20.3.3.4, “Defining Computers in an NDB Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster , as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 20.3.3.10, “NDB Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)

- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.7, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 20.3.3.11, “NDB Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 7.2 or later.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

### 20.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

**Starting `config.ini` file.** The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 7.5:

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid
```

```
# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb\_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1

# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtdd; in particular, you should not set
# RealTimeScheduler for ndbmtdd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1

# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.
```

```

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

```

**Recommended my.cnf options for SQL nodes.** MySQL Servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`

- `--ndb-force-send=1`
- `--engine-condition-pushdown=1`

### 20.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long):      "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):     "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If `port_num` is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
    [bind-address=host-definition, ]
    host-definition[:bind-address=host-definition]
    host-definition[:bind-address=host-definition]
    [, ...]]

host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `192.168.178.242` regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `192.168.178.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `192.168.178.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

### 20.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	string	[none]	...	IS

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

#### Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	name or IP address	[none]	...	N

This is the computer's hostname or IP address.

### 20.3.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

#### Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	[none]	1 - 255	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster .

- `NodeId`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	[none]	1 - 255	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- `ExecuteOnComputer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	name	[none]	...	S

This refers to the `id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `PortNumber`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	1186	0 - 64K	S

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	name or IP address	[none]	...	N

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LogDestination`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	{CONSOLE  SYSLOG FILE}	[see text]	...	N

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

### Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- **filename**: The name of the log file.

The default log file name used in such cases is `ndb_nodeid_cluster.log`.

- **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- **maxfiles**: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the **FILE** parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	0-2	1	0 - 2	N

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. **ArbitrationRank** can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its **ArbitrationRank** to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting **ArbitrationRank** to 0 on all management and SQL nodes, or by setting the **Arbitration** parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting **Arbitration** causes any settings for **ArbitrationRank** to be disregarded.

- **ArbitrationDelay**

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	0	0 - 4294967039 (0xFFFFFFFF)	N

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- [DataDir](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	path	.	...	N

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the [FILE](#) parameter for [LogDestination](#) as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- [PortNumberStats](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	[none]	0 - 64K	N

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- [Wan](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	boolean	false	true, false	N

Use WAN TCP setting as default.

- [HeartbeatThreadPriority](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	string	[none]	...	S

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]  
  
policy:  
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first out) or [RR](#) (round robin). The policy value is followed optionally by the priority (an integer).

- [TotalSendBufferMemory](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	03191	256K - 4294967039 (0xFFFFFFFF)	N

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

- `HeartbeatIntervalMgmdMgmd`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	1500	100 - 4294967039 (0xFFFFFFFF)	N

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

#### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 20.1.6.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 20.3.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means  $100 \times 1024 = 102400$ .) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see [Disk Data Configuration Parameters](#)).

All of these parameters also apply to `ndbmt` (the multi-threaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmt` only; these have no effect when used with `ndbd`. For more information, see [Multi-Threading Configuration Parameters \(ndbmt\)](#). See also [Section 20.4.3, “ndbmt — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- [NodeId](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	[none]	1 - 48	IS

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the only supported parameter name to use when identifying data nodes. (`Id` was removed in NDB 7.5.0.)

- [ExecuteOnComputer](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	name	[none]	...	S

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

#### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the `HostName` parameter instead.

- [HostName](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	name or IP address	localhost	...	N

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- [ServerPort](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	[none]	1 - 64K	S

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd`

`default`] section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

#### Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- `NodeGroup`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0		[none]	0 - 65536	IS

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 20.5.14.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

- `NoOfReplicas`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	2	1 - 4	IS

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2, which is the recommended setting in most common usage scenarios.

The maximum possible value is 4; *currently, only the values 1 and 2 are actually supported.*

### Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	path	.	...	IN

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	path	<code>DataDir</code>	...	IN

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

### Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	path	[see text]	...	IN

This parameter specifies the directory in which backups are placed.

### Important

The string `'/BACKUP'` is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

## Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	80M	1M - 1024G	N

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory`. This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force NDB to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient. You can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts. (Bug #13436216)

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	18M	1M - 1T	N

This parameter controls the amount of storage used for hash indexes in NDB Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

You can estimate the size of a hash index using this formula:

```
size = ( (fragments * 32K) + (rows * 18) )
      * replicas
```

`fragments` is the number of fragments, `replicas` is the number of replicas (normally 2), and `rows` is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)
sample_rows = IndexStatSaveSize
```

```
* ((0.01 * IndexStatSaveScale * log2(rows * sample_size)) + 1)
/ sample_size
```

In the preceding formula, *key\_size* is the size of the ordered index key in bytes, *key\_attributes* is the number of attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table *t1* has 1 million rows and an ordered index named *ix1* on two four-byte integers. Assume in addition that *IndexStatSaveSize* and *IndexStatSaveScale* are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8 + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
              * ((0.01 * 100 * log2(1000000*20)) + 1)
              / 20
              = 32768 * ((1 * ~16.811) + 1) / 20
              = 32768 * ~17.811 / 20
              = ~29182 rows
```

The expected index memory usage is thus  $2 * 18 * 29182 = \sim 1050550$  bytes.

The default value for *IndexMemory* is 18MB. The minimum is 1MB.

- *StringMemory*

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	% or bytes	25	0 - 4294967039 (0xFFFFFFFF)	S

This parameter determines how much memory is allocated for strings such as table names, and is specified in an *[ndbd]* or *[ndbd default]* section of the *config.ini* file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of *.FRM* files, *MaxNoOfTriggers*, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify *StringMemory* config parameter: Permanent error: Schema error, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns *a* and *b* consuming roughly 10

bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

**MinFreePct.** A proportion (5% by default) of data node resources including `DataMemory` and `IndexMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	5	0 - 100	N

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	4096	32 - 4294967039 (0xFFFFFFFF)	N

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

```
MinTotalNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then  $10 * 11 = 110$  transaction records are required for this transaction, per MySQL server, or  $110 * 10 = 1100$  transaction records total. Each data node can be expected to handle  $\text{MinTotalNoOfConcurrentTransactions} / \text{number of data nodes}$ . For an NDB Cluster having 4 data nodes, this would mean setting [MaxNoOfConcurrentTransactions](#) on each data node to  $1100 / 4 = 275$ . In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's [MaxNoOfConcurrentTransactions](#) is sufficient to cover a number of transactions equal to  $\text{MinTotalNoOfConcurrentTransactions} / \text{number of node groups}$ . If this cluster has a single node group, then [MaxNoOfConcurrentTransactions](#) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for [MaxNoOfConcurrentTransactions](#) should always be no more than the value of [MaxNoOfConcurrentOperations](#).

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- [MaxNoOfConcurrentOperations](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	32K	32 - 4294967039 (0xFFFFFFFF)	N

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ . To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	UNDEFINED	32 - 4294967039 (0xFFFFFFFF)	N

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- `MaxDMLOperationsPerTransaction`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	operations (DML)	4294967295	32 - 4294967295	N

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set [MaxDMLOperationsPerTransaction](#) to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of [\[ndbd\]](#) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	8K	0 - 4294967039 (0xFFFFFFFF)	N

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- [MaxNoOfFiredTriggers](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	4000	0 - 4294967039 (0xFFFFFFFF)	N

The default value of [MaxNoOfFiredTriggers](#) is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- [TransactionBufferMemory](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	1M	1K - 4294967039 (0xFFFFFFFF)	N

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains  $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.** There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to  $10000 \times 128$  bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to  $10000 \times 16$  bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `MaxNoOfConcurrentScans`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	256	2 - 500	N

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- `MaxNoOfLocalScans`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	[see text]	32 - 4294967039 (0xFFFFFFFF)	N

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

---

```
4 * MaxNoOfConcurrentScans * [# data nodes] + 2
```

The minimum value is 32.

- `BatchSizePerLocalScan`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	256	1 - 992	N

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

`BatchSizePerLocalScan` has a strong connection to the `BatchSize` defined in the SQL nodes.

- `LongMessageBuffer`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	64M	512K - 4294967039 (0xFFFFFFFF)	N

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- `MaxParallelCopyInstances`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	0	0 - 64	S

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, `MaxParallelCopyInstances` provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- `MaxParallelScansPerFragment`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	256	1 - 4294967039 (0xFFFFFFFF)	N

It is possible to configure the maximum number of parallel scans (`TUP` scans and `TUX` scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

The default value for this parameter is 256.

## Memory Allocation

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	32M	1M - 1G	N

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives *Out of memory* errors, but it is evident by examining the cluster logs or the output of `DUMP 1000` that all available memory has not yet been used, you can increase the value of this parameter (or `MaxNoOfTables`, or both) to cause NDB to make sufficient memory available.

## Hash Map Size

`DefaultHashMapSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	LDM threads	3840	0 - 3840	N

The size of the table hash maps used by NDB is configurable using this parameter. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

Value	Description / Effect
0	Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.
240	Original hash map size (used by default in all NDB Cluster releases prior to NDB 7.2.7)
3840	Larger hash map size (used by default beginning with NDB 7.2.7)

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.4 to NDB Cluster 7.5.

**Logging and checkpointing.** The following `[ndbd]` parameters control log and checkpoint behavior.

- `NoOfFragmentLogFiles`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	16	3 - 4294967039 (0xFFFFFFFF)	IN

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (*Out of log file space temporarily*). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

### Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- [FragmentLogFileSize](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	16M	4M - 1G	IN

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for [NoOfFragmentLogFiles](#).

- [InitFragmentLogFiles](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	[see values]	SPARSE	SPARSE, FULL	IN

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. [InitFragmentLogFiles](#) takes either of two values:

- [SPARSE](#). Fragment log files are created sparsely. This is the default value.
- [FULL](#). Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting [InitFragmentLogFiles=FULL](#) may help eliminate I/O errors on writes to the REDO log.

- [MaxNoOfOpenFiles](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	0	20 - 4294967039 (0xFFFFFFFF)	N

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- [InitialNoOfOpenFiles](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	files	27	20 - 4294967039 (0xFFFFFFFF)	N

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [MaxNoOfSavedMessages](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	25	0 - 4294967039 (0xFFFFFFFF)	N

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- [MaxLCPStartDelay](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	seconds	0	0 - 600	N

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- [LcpScanProgressTimeout](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	second	60	0 - 4294967039 (0xFFFFFFFF)	N

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the [LcpScanProgressTimeout](#) data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

**Metadata objects.** The next set of `[ndbnd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

#### Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	1000	32 - 4294967039 (0xFFFFFFFF)	N

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be  $6 * \text{greatest\_number\_of\_attributes} = 600$ .

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	128	8 - 20320	N

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

#### Note

The sum of `MaxNoOfTables` and `MaxNoOfOrderedIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- `MaxNoOfOrderedIndexes`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	128	0 - 4294967039 (0xFFFFFFFF)	N

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

#### Note

The sum of `MaxNoOfTables` and `MaxNoOfOrderedIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- `MaxNoOfTriggers`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	768	0 - 4294967039 (0xFFFFFFFF)	N

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfSubscriptions`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	0	0 - 4294967039 (0xFFFFFFFF)	N

Each [NDB](#) table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for [MaxNoOfSubscriptions](#) is 0, which is treated as equal to [MaxNoOfTables](#). Each subscription consumes 108 bytes.

- [MaxNoOfSubscribers](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	0	0 - 4294967039 (0xFFFFFFFF)	N

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as  $2 * \text{MaxNoOfTables}$ ; that is, there is one subscription per [NDB](#) table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of [mysqld](#) processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Cluster s, with one [mysqld](#) attached to each cluster, and each of these [mysqld](#) processes acts as a master and as a slave, you should set [MaxNoOfSubscribers](#) equal to  $3 * \text{MaxNoOfTables}$ .

For more information, see [Section 20.6, “NDB Cluster Replication”](#).

- [MaxNoOfConcurrentSubOperations](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	256	0 - 4294967039 (0xFFFFFFFF)	N

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of [\[ndbdl\]](#) parameters taking on boolean values. These parameters can each be specified as [TRUE](#) by setting them equal to [1](#) or [Y](#), and as [FALSE](#) by setting them equal to [0](#) or [N](#).

- [LateAlloc](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	numeric	1	0 - 1	N

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- [LockPagesInMainMemory](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	numeric	0	0 - 2	N

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values [0](#), [1](#), or [2](#), which act as shown in the following list:

- [0](#): Disables locking. This is the default value.
- [1](#): Performs the lock after allocating memory for the process.
- [2](#): Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. ([LockPagesInMainMemory](#) uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and <http://linux.die.net/man/2/mlock>).

#### Note

In older NDB Cluster releases, this parameter was a Boolean. [0](#) or `false` was the default setting, and disabled locking. [1](#) or `true` enabled locking of the process after its memory was allocated. NDB Cluster 7.5 treats `true` or `false` for the value of this parameter as an error.

#### Important

Beginning with [glibc](#) 2.10, [glibc](#) uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The [glibc](#) behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to [glibc](#) 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also [http://sourceware.org/bugzilla/show\\_bug.cgi?id=13137](http://sourceware.org/bugzilla/show_bug.cgi?id=13137) for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with [glibc](#).

- [StopOnError](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	boolean	1	0, 1	N

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

### Important

If the data node process exits in an uncontrolled fashion (due, for example, to performing `kill -9` on the data node process while performing a query, or to a segmentation fault), and `StopOnError` is set to 0, the angel process attempts to restart it in exactly the same way as it was started previously—that is, using the same startup options that were employed the last time the node was started. Thus, if the data node process was originally started using the `--initial` option, it is also restarted with `--initial`. This means that, in such cases, if the failure occurs on a sufficient number of data nodes in a very short interval, the effect is the same as if you had performed an initial restart of the entire cluster, leading to loss of all data. (Bug #24945638)

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- `CrashOnCorruptedTuple`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	boolean	true	true, false	S

When this parameter is enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. In NDB 7.5, it is enabled by default.

- `Diskless`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	true false (1 0)	false	true, false	IS

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

### Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `ODirect`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	boolean	false	true, false	N

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `RestartOnErrorInsert`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	error code	2	0 - 4	N

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `CompressedBackup`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	boolean	false	true, false	N

Setting this parameter to `1` causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

#### Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- `CompressedLCP`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	boolean	false	true, false	N

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

#### Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

## Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	6000	70 - 4294967039 (0xFFFFFFFF)	N

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	6000	70 - 4294967039 (0xFFFFFFFF)	N

This is similar to the `TimeBetweenWatchDogCheck` parameter, except that `TimeBetweenWatchDogCheckInitial` controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- `StartPartialTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	30000	0 - 4294967039 (0xFFFFFFFF)	N

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- `StartPartitionedTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	60000	0 - 4294967039	N
		3214	(0xFFFFFFFF)	

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	0	0 - 4294967039 (0xFFFFFFFF)	N

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- `StartNoNodeGroupTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	15000	0 - 4294967039 (0xFFFFFFFF)	N

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodeGroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#), for more information.

- `HeartbeatIntervalDbDb`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	5000	10 - 4294967039 (0xFFFFFFFF)	N

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also [Network communication and latency](#), as well as the description of the [ConnectCheckIntervalDelay](#) configuration parameter.

- [HeartbeatIntervalDbApi](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	1500	100 - 4294967039 (0xFFFFFFFF)	N

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see [Network communication and latency](#).

- [HeartbeatOrder](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	numeric	0	0 - 65535	S

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers [host1](#) and [host2](#), and that these data nodes make up 2 node groups, as shown in the following table:

Node Group	Nodes Running on <a href="#">host1</a>	Nodes Running on <a href="#">host2</a>
<i>Node Group 0:</i>	Node A	Node B
<i>Node Group 1:</i>	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Node	HeartbeatOrder
A	10
B	20
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	0	0 - 4294967039 (0xFFFFFFFF)	N

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- `TimeBetweenLocalCheckpoints`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	number of 4-byte words, as a base-2 logarithm	20	0 - 31	N

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	2000	20 - 32000	N

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenGlobalCheckpointsTimeout`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	120000	10 - 4294967039 (0xFFFFFFFF)	N

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- `TimeBetweenEpochs`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	100	0 - 32000	N

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- [TimeBetweenEpochsTimeout](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	0	0 - 256000	N

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP save takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- [MaxBufferedEpochs](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	epochs	100	0 - 100000	N

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the [NDB](#) client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- [MaxBufferedEpochBytes](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	26214400	26214400 (0x01900000) - 4294967039 (0xFFFFFFFF)	N

The total number of bytes allocated for buffering epochs by this node.

- [TimeBetweenInactiveTransactionAbortCheck](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	1000	1000 - 4294967039 (0xFFFFFFFF)	N

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	[see text]	0 - 4294967039 (0xFFFFFFFF)	N

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	1200	50 - 4294967039 (0xFFFFFFFF)	N

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- [DiskSyncSize](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	4M	32K - 4294967039 (0xFFFFFFFF)	N

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

#### Note

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- [MaxDiskWriteSpeed](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	numeric	20M	1M - 1024G	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster .

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOtherNodeRestart](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	numeric	50M	1M - 1024G	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOwnRestart](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	numeric	200M	1M - 1024G	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MinDiskWriteSpeed](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	numeric	10M	1M - 1024G	S

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- [ArbitrationTimeout](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	milliseconds	7500	10 - 4294967039 (0xFFFFFFFF)	N

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- [Arbitration](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	enumeration	Default	Default, Disabled, WaitExternal	N

The [Arbitration](#) parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the [ArbitrationRank](#) settings for the management and API nodes. This is the default value.
- **Disabled.** Setting [Arbitration](#) = `Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplish the same task as setting [ArbitrationRank](#) to 0 on all management and API nodes. When [Arbitration](#) is set in this way, any [ArbitrationRank](#) settings are ignored.
- **WaitExternal.** The [Arbitration](#) parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by [ArbitrationTimeout](#) has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting [Arbitration](#) = `WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that [ArbitrationTimeout](#) be 2 times as long as the interval required by the external cluster manager to perform arbitration.

#### Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when [Arbitration](#) is set to different values for individual data nodes.

- [RestartSubscriberConnectTimeout](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	ms	12000	0 - 4294967039 (0xFFFFFFFF)	S

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set [RestartSubscriberConnectTimeout](#) to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

**Buffering and logging.** Several [\[ndbd\]](#) configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the [NDB](#) storage engine's file system abstraction layer.

- [UndoIndexBuffer](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	2M	1M - 4294967039 (0xFFFFFFFF)	N

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The [NDB](#) storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 ([Index UNDO buffers overloaded](#)).

#### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [UndoDataBuffer](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	16M	1M - 4294967039 (0xFFFFFFFF)	N

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`Data UNDO buffers overloaded`).

#### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [RedoBuffer](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	32M	1M - 4294967039 (0xFFFFFFFF)	N

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO log buffers overloaded`). For this reason, you should exercise care if you attempt to decrease the value of [RedoBuffer](#) as part of an online change in the cluster's configuration.

[ndbmt](#) allocates a separate buffer for each LDM thread (see [ThreadConfig](#)). For example, with 4 LDM threads, an [ndbmt](#) data node actually has 4 buffers and allocates [RedoBuffer](#) bytes to each one, for a total of  $4 * \text{RedoBuffer}$  bytes.

- [EventLogBufferSize](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	8192	0 - 64K	S

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- [LogLevelStartup](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	1	0 - 15	N

The reporting level for events generated during startup of the process.

The default level is 1.

- [LogLevelShutdown](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	0	0 - 15	N

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- [LogLevelStatistic](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	0	0 - 15	N

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- [LogLevelCheckpoint](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	log level	0	0 - 15	N

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	0	0 - 15	N

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	0	0 - 15	N

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	0	0 - 15	N

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	levelr	0	0 - 15	N

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	0	0 - 15	N

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	unsigned	0	0 - 4294967039 (0xFFFFFFFF)	N

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 20.5.6.2, “NDB Cluster Log Events”](#).

- `StartupStatusReportFrequency`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	seconds	0	0 - 4294967039 (0xFFFFFFFF)	N

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see [Section 20.5.1, “Summary of NDB Cluster Start Phases”](#)). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Data Node Debugging Parameters.** It is also possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 (default - no logging) and 1 (logging enabled) are the only supported values prior to NDB 7.5.2. In NDB 7.5.2 and later, setting this parameter to 2 enables logging of additional `DBDICT` debugging output (Bug #20368450).

**Backup parameters.** The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	16M	512K - 4294967039 (0xFFFFFFFF)	N

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	16M	2M - 4294967039 (0xFFFFFFFF)	N
NDB 7.5.1	bytes	16M	512K - 4294967039 (0xFFFFFFFF)	N

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as [BackupWriteSize](#), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum was changed from 2M to 512K in NDB 7.5.1. (Bug #22749509)

- [BackupDiskWriteSpeedPct](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	percent	50	0 - 90	N

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by [MinDiskWriteSpeed](#) and [MaxDiskWriteSpeed](#). Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the [BackupDiskWriteSpeedPct](#) configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints. (This makes the disk write rate budget behave similarly to how it was handled in NDB Cluster 7.3 and earlier.)

The default value for this parameter is 50 (interpreted as 50%).

- [BackupLogBufferSize](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	16M	2M - 4294967039 (0xFFFFFFFF)	N

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 20.5.3.3, "Configuration for NDB Cluster Backups"](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to

become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- [BackupMemory](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	32M	0 - 4294967039 (0xFFFFFFFF)	N

This parameter is deprecated, and subject to removal in a future version of NDB Cluster . Any setting made for it is ignored.

- [BackupReportFrequency](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	seconds	0	0 - 4294967039 (0xFFFFFFFF)	N

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

- [BackupWriteSize](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	256K	32K - 4294967039 (0xFFFFFFFF)	N

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- [BackupMaxWriteSize](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	bytes	1M	256K - 4294967039 (0xFFFFFFFF)	N

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

## NDB Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

**Note**

To make use of these parameters, the data node process must be run as system root.

- `LockExecuteThreadToCPU`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	CPU ID	64K	0 - 64K	N

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	CPU ID	[none]	0 - 64K	N

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). *There is no default value.*

- `RealtimeScheduler`

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	boolean	false	true, false	N

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- [SchedulerExecutionTimer](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	µs	50	0 - 11000	N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- [SchedulerResponsiveness](#)

Effective Version	Type/Units	Default	Range/Values	Restart Type
NDB 7.5.0	integer	5	0 - 10	S

Set the balance in the [NDB](#) scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- [SchedulerSpinTimer](#)
