If an internal in-memory temporary table becomes too large, MySQL handles this automatically by changing the table from in-memory to on-disk format, handled by the storage engine defined by `internal_tmp_disk_storage_engine`. You can increase the permissible temporary table size as described in [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

For `MEMORY` tables explicitly created with `CREATE TABLE`, only the `max_heap_table_size` system variable determines how large the table is permitted to grow and there is no conversion to on-disk format.

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).
- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, so the normal slow memory allocation and freeing is avoided. Memory is allocated only for unexpectedly large strings.
- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, a buffer as large as the largest `BLOB` value is allocated.
- MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The initial table cache size is defined by the `table_open_cache` system variable; see [Section 9.4.3.1, “How MySQL Opens and Closes Tables”](#).

MySQL also requires memory for the table definition cache. The `table_definition_cache` system variable defines the number of table definitions (from `.frm` files) that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.
- The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

## Monitoring MySQL Memory Usage

The following example demonstrates how to use `Performance Schema` and `sys schema` to monitor MySQL memory usage.

Most Performance Schema memory instrumentation is disabled by default. Instruments can be enabled by updating the `ENABLED` column of the Performance Schema `setup_instruments` table. Memory instruments have names in the form of `memory/code_area/instrument_name`, where `code_area` is a value such as `sql` or `innodb`, and `instrument_name` is the instrument detail.

1. To view available MySQL memory instruments, query the Performance Schema `setup_instruments` table. The following query returns hundreds of memory instruments for all code areas.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%memory%';
```

You can narrow results by specifying a code area. For example, you can limit results to `InnoDB` memory instruments by specifying `innodb` as the code area.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%memory/innodb%';
```

| NAME                                      | ENABLED | TIMED |
|---|---------|-------|
| memory/innodb/adaptive hash index         | NO      | NO    |
| memory/innodb/buf_buf_pool                | NO      | NO    |
| memory/innodb/dict_stats_bg_recalc_pool_t | NO      | NO    |
| memory/innodb/dict_stats_index_map_t      | NO      | NO    |
| memory/innodb/dict_stats_n_diff_on_level  | NO      | NO    |
| memory/innodb/other                       | NO      | NO    |
| memory/innodb/row_log_buf                 | NO      | NO    |
| memory/innodb/row_merge_sort              | NO      | NO    |
| memory/innodb/std                         | NO      | NO    |
| memory/innodb/trx_sys_t:rw_trx_ids        | NO      | NO    |
| ...                                       |         |       |

Depending on your MySQL installation, code areas may include `performance_schema`, `sql`, `client`, `innodb`, `myisam`, `csv`, `memory`, `blackhole`, `archive`, `partition`, and others.

- To enable memory instruments, add a `performance-schema-instrument` rule to your MySQL configuration file. For example, to enable all memory instruments, add this rule to your configuration file and restart the server:

```
performance-schema-instrument='memory/%=COUNTED'
```

#### Note

Enabling memory instruments at startup ensures that memory allocations that occur at startup are counted.

After restarting the server, the `ENABLED` column of the Performance Schema `setup_instruments` table should report `YES` for memory instruments that you enabled. The `TIMED` column in the `setup_instruments` table is ignored for memory instruments because memory operations are not timed.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%memory/innodb%';
```

| NAME                                      | ENABLED | TIMED |
|---|---------|-------|
| memory/innodb/adaptive hash index         | NO      | NO    |
| memory/innodb/buf_buf_pool                | NO      | NO    |
| memory/innodb/dict_stats_bg_recalc_pool_t | NO      | NO    |
| memory/innodb/dict_stats_index_map_t      | NO      | NO    |
| memory/innodb/dict_stats_n_diff_on_level  | NO      | NO    |
| memory/innodb/other                       | NO      | NO    |
| memory/innodb/row_log_buf                 | NO      | NO    |
| memory/innodb/row_merge_sort              | NO      | NO    |
| memory/innodb/std                         | NO      | NO    |
| memory/innodb/trx_sys_t::rw_trx_ids       | NO      | NO    |

- Query memory instrument data. In this example, memory instrument data is queried in the Performance Schema `memory_summary_global_by_event_name` table, which summarizes data by `EVENT_NAME`. The `EVENT_NAME` is the name of the instrument.

The following query returns memory data for the `InnoDB` buffer pool. For column descriptions, see [Section 24.10.15.9, “Memory Summary Tables”](#).

```
mysql> SELECT * FROM performance_schema.memory_summary_global_by_event_name
-> WHERE EVENT_NAME LIKE 'memory/innodb/buf_buf_pool'\G
EVENT_NAME: memory/innodb/buf_buf_pool
COUNT_ALLOC: 1
COUNT_FREE: 0
SUM_NUMBER_OF_BYTES_ALLOC: 137428992
SUM_NUMBER_OF_BYTES_FREE: 0
LOW_COUNT_USED: 0
CURRENT_COUNT_USED: 1
HIGH_COUNT_USED: 1
LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 137428992
HIGH_NUMBER_OF_BYTES_USED: 137428992
```

The same underlying data can be queried using the `sys` schema `memory_global_by_current_bytes` table, which shows current memory usage within the server globally, broken down by allocation type.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes
-> WHERE event_name LIKE 'memory/innodb/buf_buf_pool'\G
***** 1. row *****
event_name: memory/innodb/buf_buf_pool
current_count: 1
current_alloc: 131.06 MiB
current_avg_alloc: 131.06 MiB
high_count: 1
high_alloc: 131.06 MiB
```

```
high_avg_alloc: 131.06 MiB
```

This `sys` schema query aggregates currently allocated memory (`current_alloc`) by code area:

```
mysql> SELECT SUBSTRING_INDEX(event_name,'/',2) AS
-> code_area, sys.format_bytes(SUM(current_alloc))
-> AS current_alloc
-> FROM sys.x$memory_global_by_current_bytes
-> GROUP BY SUBSTRING_INDEX(event_name,'/',2)
-> ORDER BY SUM(current_alloc) DESC;
```

| code_area                 | current_alloc |
|---------------------------|---------------|
| memory/innodb             | 843.24 MiB    |
| memory/performance_schema | 81.29 MiB     |
| memory/mysys              | 8.20 MiB      |
| memory/sql                | 2.47 MiB      |
| memory/memory             | 174.01 KiB    |
| memory/myisam             | 46.53 KiB     |
| memory/blackhole          | 512 bytes     |
| memory/federated          | 512 bytes     |
| memory/csv                | 512 bytes     |
| memory/vio                | 496 bytes     |

For more information about `sys` schema, see [Chapter 25, MySQL sys Schema](#).

### 9.12.4.2 Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

The kernel for some recent systems such as Red Hat Enterprise Linux appear to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      0
HugePages_Free:       0
HugePages_Rsvd:       0
HugePages_Surp:       0
Hugepagesize:         4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much
# memory must be available.
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is permitted to access this
# memory (102 in this case). The mysql user must be a
# member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem permitted per segment
# (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax

# Increase total amount of shared memory. The value
# is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:       0
HugePages_Surp:       0
Hugepagesize:         4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an “unlimited” value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages` option. For example, you can use the following lines in your server's `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, `InnoDB` uses large pages automatically for its buffer pool and additional memory pool. If `InnoDB` cannot do this, it falls back to use of traditional memory and writes a warning to the error log: `Warning: Using conventional memory pool`

To verify that large pages are being used, check `/proc/meminfo` again:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:       2
```

```
HugePages_Surp:      0
Hugepagesize:       4096 kB
```

## 9.12.5 Optimizing Network Use

### 9.12.5.1 How MySQL Uses Threads for Client Connections

Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See [Section 6.1.5, “Server System Variables”](#), and [Section 6.1.7, “Server Status Variables”](#).)

The thread cache has a size determined by the `thread_cache_size` system variable. The default value is 0 (no caching), which causes a thread to be set up for each new connection and disposed of when the connection terminates. Set `thread_cache_size` to *N* to enable *N* inactive connection threads to be cached. `thread_cache_size` can be set at server startup or changed while the server runs. A connection thread becomes inactive when the client connection with which it was associated terminates.

To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, monitor the `Threads_cached` and `Threads_created` status variables.

You can set `max_connections` at server startup or at runtime to control the maximum number of clients that can connect simultaneously.

When the thread stack is too small, this limits the complexity of the SQL statements which the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of *N* bytes for each thread, start the server with `--thread_stack=N`.

### 9.12.5.2 DNS Lookup Optimization and the Host Cache

The MySQL server maintains a host cache in memory that contains information about clients: IP address, host name, and error information. The server uses this cache for nonlocal TCP connections. It does not use the cache for TCP connections established using a loopback interface address (`127.0.0.1` or `:::1`), or for connections established using a Unix socket file, named pipe, or shared memory.

For each new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If not, the server attempts to resolve the host name. First, it resolves the

IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The `host_cache` Performance Schema table exposes the contents of the host cache so that it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. See [Section 24.10.16.1, “The host\\_cache Table”](#).

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to `NULL` and the flag is false. This entry is also used for subsequent client connections from the same originating IP.
2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains `NULL` and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (Another DNS resolution attempt occurs the next time a client connects from this IP.)
3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see [Section 24.10.16.1, “The host\\_cache Table”](#).

The server performs host name resolution using the thread-safe `gethostbyaddr_r()` and `gethostbyname_r()` calls if the operating system supports them. Otherwise, the thread performing the lookup locks a mutex and calls `gethostbyaddr()` and `gethostbyname()` instead. In this case, no other thread can resolve host names that are not in the host cache until the thread holding the mutex lock releases it.

The server uses the host cache for several purposes:

- By caching the results of IP-to-host name lookups, the server avoids doing a DNS lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.
- The cache contains information about errors that occur during the connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` system variable determines the number of permitted errors before blocking occurs. See [Section B.5.2.6, “Host ‘host\\_name’ is blocked”](#).

To unblock blocked hosts, flush the host cache by issuing a `FLUSH HOSTS` statement or executing a `mysqladmin flush-hosts` command.

It is possible for a blocked host to become unblocked even without `FLUSH HOSTS` if activity from other hosts has occurred since the last connection attempt from the blocked host. This can occur because the server discards the least recently used cache entry to make room for a new entry if the cache is full when a connection arrives from a client IP not in the cache. If the discarded entry is for a blocked host, that host becomes unblocked.

The host cache is enabled by default. To disable it, set the `host_cache_size` system variable to 0, either at server startup or at runtime.

To disable DNS host name lookups, start the server with the `--skip-name-resolve` option. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by disabling DNS lookups with `--skip-name-resolve` or by increasing the value of `host_cache_size` to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the `--skip-networking` option.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the `Connection_errors_xxx` status variables (see [Section 6.1.7, “Server Status Variables”](#)).

## 9.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a “workload”) works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.
- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.
- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.
- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The two most important features to try with each workload are the [MySQL query cache](#), and the [adaptive hash index](#) for [InnoDB](#) tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

### 9.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expression)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+-----+
| BENCHMARK(1000000,1+1) |
+-----+
| 0 |
+-----+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

### 9.13.2 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

A free benchmark suite is the Open Source Database Benchmark, available at <http://osdb.sourceforge.net/>.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See [Section 5.5.9, “mysqlslap — Load Emulation Client”](#).
- You can also try benchmarking packages such as SysBench and DBT2, available at <https://launchpad.net/sysbench>, and <http://osdlbdt.sourceforge.net/#dbt2>.

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

### 9.13.3 Measuring Performance with performance\_schema

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See [Chapter 24, MySQL Performance Schema](#) for details.

## 9.14 Examining Thread Information

When you are attempting to ascertain what your MySQL server is doing, it can be helpful to examine the process list, which is the set of threads currently executing within the server. Process list information is available from these sources:

- The `SHOW [FULL] PROCESSLIST` statement: [Section 14.7.5.29, “SHOW PROCESSLIST Syntax”](#)
- The `SHOW PROFILE` statement: [Section 14.7.5.31, “SHOW PROFILES Syntax”](#)
- The `INFORMATION_SCHEMA.PROCESSLIST` table: [Section 23.17, “The INFORMATION\\_SCHEMA PROCESSLIST Table”](#)
- The `mysqladmin processlist` command: [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)
- The Performance Schema `threads` table, stage tables, and lock tables: [Section 24.10.16, “Performance Schema Miscellaneous Tables”](#), [Section 24.10.5, “Performance Schema Stage Event Tables”](#), [Section 24.10.12, “Performance Schema Lock Tables”](#).
- The `sys` schema `processlist` view, which presents information from the Performance Schema `threads` table in a more accessible format: [Section 25.4.3.22, “The processlist and x\\$processlist Views”](#)
- The `sys` schema `session` view, which presents information about user sessions (like the `sys` schema `processlist` view, but with background processes filtered out): [Section 25.4.3.33, “The session and x\\$session Views”](#)

Access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance

consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

You can always view information about your own threads. To view information about threads being executed for other accounts, you must have the `PROCESS` privilege.

Each process list entry contains several pieces of information:

- `Id` is the connection identifier for the client associated with the thread.
- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none is selected.
- `Command` and `State` indicate what the thread is doing.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a thread running on a slave that is processing events from the master, the thread time is set to the time found in the events and thus reflects current time on the master and not the slave.
- `Info` contains the text of the statement being executed by the thread, or `NULL` if it is not executing one. By default, this value contains only the first 100 characters of the statement. To see the complete statements, use `SHOW FULL PROCESSLIST`.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

### 9.14.1 Thread Command Values

A thread can have any of the following `Command` values:

- `Binlog Dump`

This is a thread on a master server for sending binary log contents to a slave server.

- `Change user`

The thread is executing a change-user operation.

- `Close stmt`

The thread is closing a prepared statement.

- `Connect`

A replication slave is connected to its master.

- `Connect Out`

A replication slave is connecting to its master.

- `Create DB`

The thread is executing a create-database operation.

- `Daemon`

This thread is internal to the server, not a thread that services a client connection.

- `Debug`

The thread is generating debugging information.

- `Delayed insert`

The thread is a delayed-insert handler.

- `Drop DB`

The thread is executing a drop-database operation.

- `Error`

- `Execute`

The thread is executing a prepared statement.

- `Fetch`

The thread is fetching the results from executing a prepared statement.

- `Field List`

The thread is retrieving information for table columns.

- `Init DB`

The thread is selecting a default database.

- `Kill`

The thread is killing another thread.

- `Long Data`

The thread is retrieving long data in the result of executing a prepared statement.

- `Ping`

The thread is handling a server-ping request.

- `Prepare`

The thread is preparing a prepared statement.

- `Processlist`

The thread is producing information about server threads.

- `Query`

The thread is executing a statement.

- `Quit`

The thread is terminating.

- `Refresh`

The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

- `Register Slave`

The thread is registering a slave server.

- `Reset stmt`

The thread is resetting a prepared statement.

- `Set option`

The thread is setting or resetting a client statement-execution option.

- `Shutdown`

The thread is shutting down the server.

- `Sleep`

The thread is waiting for the client to send a new statement to it.

- `Statistics`

The thread is producing server-status information.

- `Table Dump`

The thread is sending table contents to a slave server.

- `Time`

Unused.

## 9.14.2 General Thread States

The following list describes thread `State` values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- `After create`

This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- `Analyzing`

The thread is calculating a `MyISAM` table key distributions (for example, for `ANALYZE TABLE`).

- `checking permissions`

The thread is checking whether the server has the required privileges to execute the statement.

- `Checking table`

The thread is performing a table check operation.

- `cleaning up`

The thread has processed one command and is preparing to free memory and reset certain state variables.

- `closing tables`

The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- `converting HEAP to MyISAM`

The thread is converting an internal temporary table from a `MEMORY` table to an on-disk `MyISAM` table.

- `copy to tmp table`

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

For a thread in this state, the Performance Schema can be used to obtain about the progress of the copy operation. See [Section 24.10.5, “Performance Schema Stage Event Tables”](#).

- `Copying to group table`

If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

The server is copying to a temporary table in memory.

- `altering table`

The server is in the process of executing an in-place `ALTER TABLE`.

- `Copying to tmp table on disk`

The server is copying to a temporary table on disk. The temporary result set has become too large (see [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#)). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating index`

The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- `Creating sort index`

The thread is processing a `SELECT` that is resolved using an internal temporary table.

- `creating table`

The thread is creating a table. This includes creation of temporary tables.

- `Creating tmp table`

The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be `Copying to tmp table on disk`.

- `committing alter table to storage engine`

The server has finished an in-place `ALTER TABLE` and is committing the result.

- `deleting from main table`

The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `discard_or_import_tablespace`

The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- `end`

This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- `executing`

The thread has begun executing a statement.

- `Execution of init_command`

The thread is executing statements in the value of the `init_command` system variable.

- `freeing items`

The thread has executed a command. Some freeing of items done during this state involves the query cache. This state is usually followed by `cleaning up`.

- `FULLTEXT initialization`

The server is preparing to perform a natural-language full-text search.

- `init`

This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log, the `InnoDB` log, and some query cache cleanup operations.

For the `end` state, the following operations could be happening:

- Removing query cache entries after data in a table is changed
- Writing an event to the binary log
- Freeing memory buffers, including for blobs
- `Killed`

Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `logging slow query`

The thread is writing a statement to the slow-query log.

- `login`

The initial state for a connection thread until the client has been authenticated successfully.

- `manage keys`

The server is enabling or disabling a table index.

- `NULL`

This state is used for the `SHOW PROCESSLIST` state.

- `Opening tables`

The thread is trying to open a table. This should be a very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

- `optimizing`

The server is performing initial optimizations for a query.

- `preparing`

This state occurs during query optimization.

- `Purging old relay logs`

The thread is removing unneeded relay log files.

- `query end`

This state occurs after processing a query but before the `freeing items` state.

- `Reading from net`

The server is reading a packet from the network. This state is called `Receiving from client` as of MySQL 5.7.8.

- `Receiving from client`

The server is reading a packet from the client. This state is called `Reading from net` prior to MySQL 5.7.8.

- `Removing duplicates`

The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `removing tmp table`

The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- `rename`

The thread is renaming a table.

- `rename result table`

The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- `Reopen tables`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

The repair code is using a sort to create indexes.

- `preparing for alter table`

The server is preparing to execute an in-place `ALTER TABLE`.

- `Repair done`

The thread has completed a multi-threaded repair for a `MyISAM` table.

- `Repair with keycache`

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Rolling back`

The thread is rolling back a transaction.

- `Saving state`

For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- `Searching rows for update`

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sending data`

The thread is reading and processing rows for a `SELECT` statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.

- `Sending to client`

The server is writing a packet to the client. This state is called `Writing to net` prior to MySQL 5.7.8.

- `setup`

The thread is beginning an `ALTER TABLE` operation.

- `Sorting for group`

The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

The thread is doing a sort to satisfy an `ORDER BY`.

- `Sorting index`

The thread is sorting index pages for more efficient access during a `MyISAM` table optimization operation.

- `Sorting result`

For a `SELECT` statement, this is similar to `Creating sort index`, but for nontemporary tables.

- `statistics`

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- `System lock`

The thread has called `mysql_lock_tables()` and the thread state has not been updated since. This is a very general state that can occur for many reasons.

For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when `InnoDB` waits for a table-level lock during execution of `LOCK TABLES`. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same `MyISAM` tables, you can disable external system locks with the `--skip-external-locking` option. However, external locking is disabled by default, so it is likely that this option will have no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `update`

The thread is getting ready to start updating the table.

- `Updating`

The thread is searching for rows to update and is updating them.

- `updating main table`

The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- `updating reference tables`

The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- `User lock`

The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `User sleep`

The thread has invoked a `SLEEP()` call.

- `Waiting for commit lock`

`FLUSH TABLES WITH READ LOCK` is waiting for a commit lock.

- `Waiting for global read lock`

`FLUSH TABLES WITH READ LOCK` is waiting for a global read lock or the global `read_only` system variable is being set.

- `Waiting for tables`

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for table flush`

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen

the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for lock_type lock`

The server is waiting to acquire a `THR_LOCK` lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

This state indicates a wait for a `THR_LOCK`:

- `Waiting for table level lock`

These states indicate a wait for a metadata lock:

- `Waiting for event metadata lock`
- `Waiting for global read lock`
- `Waiting for schema metadata lock`
- `Waiting for stored function metadata lock`
- `Waiting for stored procedure metadata lock`
- `Waiting for table metadata lock`
- `Waiting for trigger metadata lock`

For information about table lock indicators, see [Section 9.11.1, “Internal Locking Methods”](#). For information about metadata locking, see [Section 9.11.4, “Metadata Locking”](#). To see which locks are blocking lock requests, use the Performance Schema lock tables described at [Section 24.10.12, “Performance Schema Lock Tables”](#).

- `Waiting on cond`

A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- `Writing to net`

The server is writing a packet to the network. This state is called `Sending to client` as of MySQL 5.7.8.

### 9.14.3 Query Cache Thread States

These thread states are associated with the query cache (see [Section 9.10.3, “The MySQL Query Cache”](#)).

- `checking privileges on cached query`

The server is checking whether the user has privileges to access a cached query result.

- `checking query cache for query`

The server is checking whether the current query is present in the query cache.

- `invalidating query cache entries`

Query cache entries are being marked invalid because the underlying tables have changed.

- `sending cached result to client`

The server is taking the result of a query from the query cache and sending it to the client.

- `storing result in query cache`

The server is storing the result of a query in the query cache.

- `Waiting for query cache lock`

This state occurs while a session is waiting to take the query cache lock. This can happen for any statement that needs to perform some query cache operation, such as an `INSERT` or `DELETE` that invalidates the query cache, a `SELECT` that looks for a cached entry, `RESET QUERY CACHE`, and so forth.

### 9.14.4 Replication Master Thread States

The following list shows the most common states you may see in the `State` column for the master's `Binlog Dump` thread. If you see no `Binlog Dump` threads on a master server, this means that replication is not running—that is, that no slaves are currently connected.

- `Finished reading one binlog; switching to next binlog`

The thread has finished reading a binary log file and is opening the next one to send to the slave.

- `Master has sent all binlog to slave; waiting for more updates`

The thread has read all remaining updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

- `Sending binlog event to slave`

Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

- `Waiting to finalize termination`

A very brief state that occurs as the thread is stopping.

### 9.14.5 Replication Slave I/O Thread States

The following list shows the most common states you see in the `State` column for a slave server I/O thread. This state also appears in the `Slave_IO_State` column displayed by `SHOW SLAVE STATUS`, so you can get a good view of what is happening by using that statement.

- `Checking master version`

A state that occurs very briefly, after the connection to the master is established.

- `Connecting to master`

The thread is attempting to connect to the master.

- `Queueing master event to the relay log`

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Reconnecting after a failed binlog dump request`

The thread is trying to reconnect to the master.

- `Reconnecting after a failed master event read`

The thread is trying to reconnect to the master. When connection is established again, the state becomes `Waiting for master to send event`.

- `Registering slave on master`

A state that occurs very briefly after the connection to the master is established.

- `Requesting binlog dump`

A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log file name and position.

- `Waiting for its turn to commit`

A state that occurs when the slave thread is waiting for older worker threads to commit if `slave_preserve_commit_order` is enabled.

- `Waiting for master to send event`

The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Waiting for master update`

The initial state before `Connecting to master`.

- `Waiting for slave mutex on exit`

A state that occurs briefly as the thread is stopping.

- `Waiting for the slave SQL thread to free enough relay log space`

You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting to reconnect after a failed binlog dump request`

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

- `Waiting to reconnect after a failed master event read`

An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

## 9.14.6 Replication Slave SQL Thread States

The following list shows the most common states you may see in the `State` column for a slave server SQL thread:

- `Killing slave`

The thread is processing a `STOP SLAVE` statement.

- `Making temporary file (append) before replaying LOAD DATA INFILE`

The thread is executing a `LOAD DATA INFILE` statement and is appending the data to a temporary file containing the data from which the slave will read rows.

- `Making temporary file (create) before replaying LOAD DATA INFILE`

The thread is executing a `LOAD DATA INFILE` statement and is creating a temporary file containing the data from which the slave will read rows. This state can only be encountered if the original `LOAD DATA INFILE` statement was logged by a master running a version of MySQL earlier than version 5.0.3.

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Slave has read all relay log; waiting for more updates`

The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- `Waiting for an event from Coordinator`

Using the multi-threaded slave (`slave_parallel_workers` is greater than 1), one of the slave worker threads is waiting for an event from the coordinator thread.

- `Waiting for slave mutex on exit`

A very brief state that occurs as the thread is stopping.

- `Waiting for Slave Workers to free pending events`

This waiting action occurs when the total size of events being processed by Workers exceeds the size of the `slave_pending_jobs_size_max` system variable. The Coordinator resumes scheduling when the size drops below this limit. This state occurs only when `slave_parallel_workers` is set greater than 0.

- `Waiting for the next event in relay log`

The initial state before `Reading event from the relay log`.

- `Waiting until MASTER_DELAY seconds after master executed event`

The SQL thread has read an event but is waiting for the slave delay to lapse. This delay is set with the `MASTER_DELAY` option of `CHANGE MASTER TO`.

The `Info` column for the SQL thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and may be executing it.

### 9.14.7 Replication Slave Connection Thread States

These thread states occur on a replication slave but are associated with connection threads, not with the I/O or SQL threads.

- `Changing master`

The thread is processing a `CHANGE MASTER TO` statement.

- `Killing slave`

The thread is processing a `STOP SLAVE` statement.

- `Opening master dump table`

This state occurs after `Creating table from master dump`.

- `Reading master dump table data`

This state occurs after `Opening master dump table`.

- `Rebuilding the index on master dump table`

This state occurs after `Reading master dump table data`.

### 9.14.8 MySQL Cluster Thread States

- `Committing events to binlog`
- `Opening mysql.ndb_apply_status`
- `Processing events`

The thread is processing events for binary logging.

- `Processing events from schema table`

The thread is doing the work of schema replication.

- `Shutting down`
- `Syncing ndb table schema operation and binlog`

This is used to have a correct binary log of schema operations for NDB.

- `Waiting for allowed to take ndbcluster global schema lock`

The thread is waiting for permission to take a global schema lock.

- `Waiting for event from ndbcluster`

The server is acting as an SQL node in a MySQL Cluster, and is connected to a cluster management node.

- `Waiting for first event from ndbcluster`
- `Waiting for ndbcluster binlog update to reach current position`
- `Waiting for ndbcluster global schema lock`

The thread is waiting for a global schema lock held by another thread to be released.

- `Waiting for ndbcluster to start`
- `Waiting for schema epoch`

The thread is waiting for a schema epoch (that is, a global checkpoint).

### 9.14.9 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- `Clearing`

The scheduler thread or a thread that was executing an event is terminating and is about to end.

- `Initialized`

The scheduler thread or a thread that will execute an event has been initialized.

- `Waiting for next activation`

The scheduler has a nonempty event queue but the next activation is in the future.

- `Waiting for scheduler to stop`

The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- `Waiting on empty queue`

The scheduler's event queue is empty and it is sleeping.

---

| 10.6 Comment Syntax .....                         | 1385 |

This chapter discusses the rules for writing the following elements of [SQL](#) statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Comments

## 10.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and [NULL](#). The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

### 10.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote ( `'` ) or double quote ( `"` ) characters. Examples:

```
'a string'
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```

If the [ANSI\\_QUOTES](#) SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A *binary string* is a string of bytes. Every binary string has a character set and collation named `binary`. A *nonbinary string* is a string of characters. It has a character set other than `binary` and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see [Section 11.1.8.5, “The binary Collation Compared to `\_bin` Collations”](#).)

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _binary'string';
SELECT _utf8'string' COLLATE utf8_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see [Section 11.1.3.7, “The National Character Set”](#), and [Section 11.1.3.8, “Character Set Introducers”](#).

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in [Table 10.1, “Special Character Escape Sequences”](#). For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`. Escape processing is done according to the character set indicated by the `character_set_connection` system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in [Section 11.1.3.6, “Character String Literal Character Set and Collation”](#).

**Table 10.1 Special Character Escape Sequences**

| Escape Sequence | Character Represented by Sequence                        |
|-----------------|--|
| <code>\0</code> | An ASCII NUL ( <code>x'00'</code> ) character            |
| <code>\'</code> | A single quote ( <code>'</code> ) character              |
| <code>\"</code> | A double quote ( <code>"</code> ) character              |
| <code>\b</code> | A backspace character                                    |
| <code>\n</code> | A newline (linefeed) character                           |
| <code>\r</code> | A carriage return character                              |
| <code>\t</code> | A tab character  |
| <code>\z</code> | ASCII 26 (Control+Z); see note following the table       |
| <code>\\</code> | A backslash ( <code>\</code> ) character                 |
| <code>\%</code> | A <code>%</code> character; see note following the table |
| <code>\_</code> | A <code>_</code> character; see note following the table |

The ASCII 26 character can be encoded as `\Z` to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The `\%` and `\_` sequences are used to search for literal instances of `%` and `_` in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the `LIKE` operator in [Section 13.5.1, “String Comparison Functions”](#). If you use `\%` or `\_` outside of pattern-matching contexts, they evaluate to the strings `\%` and `\_`, not to `%` and `_`.

There are several ways to include quote characters within a string:

- A `'` inside a string quoted with `'` may be written as `''`.
- A `"` inside a string quoted with `"` may be written as `""`.
- Precede the quote character by an escape character (`\`).
- A `'` inside a string quoted with `"` needs no special treatment and need not be doubled or escaped. In the same way, `"` inside a string quoted with `'` needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', "hello", ""hello"", 'hel'lo', \'hello';
+-----+-----+-----+-----+-----+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-----+-----+-----+-----+-----+

mysql> SELECT "hello", 'hello', "'hello'", "hel"lo", \'hello';
+-----+-----+-----+-----+-----+
| hello | 'hello' | "'hello'" | hel"lo | "hello |
+-----+-----+-----+-----+-----+

mysql> SELECT 'This\nIs\nFour\nLines';
+-----+
| This
Is
Four
Lines |
+-----+

mysql> SELECT 'disappearing\ backslash';
+-----+
| disappearing backslash |
+-----+
```

To insert binary data into a string column (such as a `BLOB` column), you should represent certain characters by escape sequences. Backslash (`\`) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape `NUL` or Control+Z. The `mysql` client truncates quoted strings containing `NUL` characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see [Table 10.1, “Special Character Escape Sequences”](#).

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string_quote()` C API function to escape characters. See [Section 26.8.7.56, “mysql\\_real\\_escape\\_string\\_quote\(\)”](#). Within SQL statements that construct other SQL statements, you can use the `QUOTE()` function. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See [Section 26.10, “MySQL Perl API”](#). Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data

values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

## 10.1.2 Number Literals

Number literals include exact-value (integer and [DECIMAL](#)) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include `.` as a decimal separator. Numbers may be preceded by `-` or `+` to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The [DECIMAL](#) data type is a fixed-point type and calculations are exact. In MySQL, the [DECIMAL](#) type has several synonyms: [NUMERIC](#), [DEC](#), [FIXED](#). The integer types also are exact-value types. For more information about exact-value calculations, see [Section 13.21, “Precision Math”](#).

The [FLOAT](#) and [DOUBLE](#) data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with [FLOAT](#) or [DOUBLE](#) are [DOUBLE PRECISION](#) and [REAL](#).

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

## 10.1.3 Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of `'2015-07-21'`, `'20150721'`, and `20150721` as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, consult these sections:

- [Section 12.1.2, “Date and Time Type Overview”](#)
- [Section 12.3, “Date and Time Types”](#)

**Standard SQL and ODBC Date and Time Literals.** Standard SQL permits temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes those constructions and also the corresponding ODBC syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

MySQL uses the type keyword and these constructions produce [DATE](#), [TIME](#), and [DATETIME](#) values, respectively, including a trailing fractional seconds part if specified. The [TIMESTAMP](#) syntax produces a [DATETIME](#) value in MySQL because [DATETIME](#) has a range that more closely corresponds to the standard SQL [TIMESTAMP](#) type, which has a year range from `0001` to `9999`. (The MySQL [TIMESTAMP](#) year range is `1970` to `2038`.)

**String and Numeric Literals in Date and Time Context.** MySQL recognizes [DATE](#) values in these formats:

- As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A “relaxed” syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, '2012-12-31', '2012/12/31', '2012^12^31', and '2012@12@31' are equivalent.
- As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '20070523' and '070523' are interpreted as '2007-05-23', but '071332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.
- As a number in either [YYYYMMDD](#) or [YYMMDD](#) format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.

MySQL recognizes [DATETIME](#) and [TIMESTAMP](#) values in these formats:

- As a string in either 'YYYY-MM-DD HH:MM:SS' or 'YY-MM-DD HH:MM:SS' format. A “relaxed” syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, '2012-12-31 11:30:45', '2012^12^31 11+30+45', '2012/12/31 11\*30\*45', and '2012@12@31 11^30^45' are equivalent.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

The date and time parts can be separated by [T](#) rather than a space. For example, '2012-12-31 11:30:45' '2012-12-31T11:30:45' are equivalent.

- As a string with no delimiters in either 'YYYYMMDDHHMMSS' or 'YYMMDDHHMMSS' format, provided that the string makes sense as a date. For example, '20070523091528' and '070523091528' are interpreted as '2007-05-23 09:15:28', but '071122129015' is illegal (it has a nonsensical minute part) and becomes '0000-00-00 00:00:00'.
- As a number in either [YYYYMMDDHHMMSS](#) or [YYMMDDHHMMSS](#) format, provided that the number makes sense as a date. For example, 19830905132800 and 830905132800 are interpreted as '1983-09-05 13:28:00'.

A [DATETIME](#) or [TIMESTAMP](#) value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 12.3.6, “Fractional Seconds in Time Values”](#).

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range 70–99 are converted to 1970–1999.
- Year values in the range 00–69 are converted to 2000–2069.

See also [Section 12.3.8, “Two-Digit Years in Dates”](#).

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. '2015-6-9' is the same as '2015-06-09'. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. '2015-10-30 1:2:3' is the same as '2015-10-30 01:02:03'.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in [YYYYMMDD](#) or [YYYYMMDDHHMMSS](#) format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in [YYMMDD](#) or [YYMMDDHHMMSS](#) format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according to their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are `99` and `03`, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value `'1999-03-00'`, use `'990300'`.

MySQL recognizes `TIME` values in these formats:

- As a string in `'D HH:MM:SS'` format. You can also use one of the following “relaxed” syntaxes: `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM'`, `'D HH'`, or `'SS'`. Here `D` represents days and can have a value from 0 to 34.
- As a string with no delimiters in `'HHMMSS'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.
- As a number in `HHMMSS` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `SS`, `MMSS`, or `HHMMSS`.

A trailing fractional seconds part is recognized in the `'D HH:MM:SS.fraction'`, `'HH:MM:SS.fraction'`, `'HHMMSS.fraction'`, and `HHMMSS.fraction` time formats, where `fraction` is the fractional part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 12.3.6](#), “Fractional Seconds in Time Values”.

For `TIME` values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. `'8:3:2'` is the same as `'08:03:02'`.

## 10.1.4 Hexadecimal Literals

Hexadecimal literal values are written using `X'val'` or `0xval` notation, where `val` contains hexadecimal digits (`0..9, A..F`). Lettercase of the digits and of any leading `x` does not matter. A leading `0x` is case sensitive and cannot be written as `0X`.

Legal hexadecimal literals:

```
X'01AF'
X'01af'
x'01AF'
x'01af'
0x01AF
0x01af
```

Illegal hexadecimal literals:

```
X'0G'    (G is not a hexadecimal digit)
0X01AF   (0X must be written as 0x)
```

Values written using `X'val'` notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax;
check the manual that corresponds to your MySQL server
```

version for the right syntax to use near 'X'FFF''

```
mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using `0xval` notation that contain an odd number of digits are treated as having an extra leading 0. For example, `0xaaa` is interpreted as `0x0aaa`.

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+-----+-----+
| X'4D7953514C' | CHARSET(X'4D7953514C') |
+-----+-----+
| MySQL         | binary                  |
+-----+-----+
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+-----+-----+
| 0x5461626c65 | CHARSET(0x5461626c65) |
+-----+-----+
| Table        | binary                  |
+-----+-----+
```

A hexadecimal literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] X'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;
```

The examples use `X'val'` notation, but `0xval` notation permits introducers as well. For information about introducers, see [Section 11.1.3.8, “Character Set Introducers”](#).

In numeric contexts, MySQL treats a hexadecimal literal like a `BIGINT` (64-bit integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+
| A   | 65  | 65  |
+-----+-----+
```

An empty hexadecimal value (`X''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(X''), LENGTH(X'');
+-----+-----+
| CHARSET(X'') | LENGTH(X'') |
+-----+-----+
| binary      | 0           |
+-----+-----+
mysql> SELECT X''+0;
+-----+
| X''+0 |
+-----+
```

```
+-----+
|      0      |
+-----+
```

The `X'val'` notation is based on standard SQL. The `0x` notation is based on ODBC, for which hexadecimal strings are often used to supply values for `BLOB` columns.

To convert a string or a number to a string in hexadecimal format, use the `HEX()` function:

```
mysql> SELECT HEX('cat');
+-----+
| HEX('cat') |
+-----+
| 636174      |
+-----+
mysql> SELECT X'636174';
+-----+
| X'636174'   |
+-----+
| cat         |
+-----+
```

## 10.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case sensitive and cannot be written as `0B`.

Legal bit-value literals:

```
b'01'
B'01'
0b01
```

Illegal bit-value literals:

```
b'2'      (2 is not a binary digit)
0B01      (0B must be written as 0b)
```

By default, a bit-value literal is a binary string:

```
mysql> SELECT b'1000001', CHARSET(b'1000001');
+-----+-----+
| b'1000001' | CHARSET(b'1000001') |
+-----+-----+
| A          | binary              |
+-----+-----+
mysql> SELECT 0b1100001, CHARSET(0b1100001);
+-----+-----+
| 0b1100001 | CHARSET(0b1100001) |
+-----+-----+
| a          | binary              |
+-----+-----+
```

A bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] b'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 b'1000001';
SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;
```

The examples use `b'val'` notation, but `0bval` notation permits introducers as well. For information about introducers, see [Section 11.1.3.8, “Character Set Introducers”](#).

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a bit literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = b'1100001';
mysql> SET @v2 = b'1100001'+0;
mysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| a   | 97  | 97  |
+-----+-----+-----+
```

An empty bit value (`b''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(b''), LENGTH(b'');
+-----+-----+
| CHARSET(b'') | LENGTH(b'') |
+-----+-----+
| binary       | 0           |
+-----+-----+
mysql> SELECT b''+0;
+-----+
| b''+0 |
+-----+
| 0      |
+-----+
```

Bit-value notation is convenient for specifying values to be assigned to `BIT` columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as `BIN()` or `HEX()`. High-order 0 digits are not displayed in the converted value.

```
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;
+-----+-----+-----+-----+
| b+0 | BIN(b) | OCT(b) | HEX(b) |
+-----+-----+-----+-----+
| 255 | 11111111 | 377    | FF     |
| 10  | 1010    | 12     | A      |
| 5   | 101     | 5      | 5      |
+-----+-----+-----+-----+
```

## 10.1.6 Boolean Literals

The constants `TRUE` and `FALSE` evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
-> 1, 1, 0, 0
```

## 10.1.7 NULL Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase. A synonym is `\N` (case sensitive). Treatment of `\N` as a synonym for `NULL` in SQL statements is deprecated as of MySQL 5.7.18 and is removed in MySQL 8.0; use `NULL` instead.

Be aware that the `NULL` value is different from values such as `0` for numeric types or the empty string for string types. For more information, see [Section B.5.4.3, “Problems with NULL Values”](#).

For text file import or export operations performed with `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See [Section 14.2.6, “LOAD DATA INFILE Syntax”](#). Use of `\N` in text files is unaffected by the deprecation of `\N` in SQL statements.

## 10.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. [Section 10.2.2, “Identifier Case Sensitivity”](#), describes which types of identifiers are case sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you *must* quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at [Section 10.3, “Keywords and Reserved Words”](#).

Identifiers are converted to Unicode internally. They may contain these characters:

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z\$\_] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF
- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
  - ASCII: U+0001 .. U+007F
  - Extended: U+0080 .. U+FFFF
- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.
- Identifiers may begin with a digit but unless quoted may not consist solely of digits.
- Database, table, and column names cannot end with space characters.

The identifier quote character is the backtick (```):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The `ANSI_QUOTES` mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in [Section 6.1.8, “Server SQL Modes”](#).

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b` that contains a column named `c"d`:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
+-----+-----+
| 1   | 2   |
+-----+-----+
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with `Me` or `MeN`, where `M` and `N` are integers. For example, avoid using `1e` as an identifier, because an expression such as `1e+3` is ambiguous. Depending on context, it might be interpreted as the expression `1e + 3` or as the number `1e+3`.

Be careful when using `MD5()` to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See [Section 10.4, "User-Defined Variables"](#), for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in [Section 10.2.3, "Mapping of Identifiers to File Names"](#). If you have databases or tables from an older version of MySQL that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#`. For information about referring to such names or converting them to the newer encoding, see that section.

The following table describes the maximum length for each type of identifier.

| Identifier               | Maximum Length (characters)                |
|--------------------------|--|
| Database                 | 64 (NDB storage engine: 63)                |
| Table                    | 64 (NDB storage engine: 63)                |
| Column                   | 64   |
| Index                    | 64   |
| Constraint               | 64   |
| Stored Program           | 64   |
| View                     | 64   |
| Tablespace               | 64   |
| Server                   | 64   |
| Log File Group           | 64   |
| Alias                    | 256 (see exception following table)        |
| Compound Statement Label | 16   |
| User-Defined Variable    | 64 as of MySQL 5.7.5, no limit before that |

Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns. As indicated earlier, the permissible Unicode characters are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted.

MySQL Cluster imposes a maximum length of 63 characters for names of databases and tables. See [Section 20.1.6.5, “Limits Associated with Database Objects in NDB Cluster”](#).

## 10.2.1 Identifier Qualifiers

MySQL permits names that consist of a single identifier or multiple identifiers. The components of a multiple-part name must be separated by period (.) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which the final identifier is interpreted.

In MySQL, you can refer to a table column using any of the following forms.

| Column Reference                       | Meaning   |
|--|---|
| <code>col_name</code>                  | The column <code>col_name</code> from whichever table used in the statement contains a column of that name. |
| <code>tbl_name.col_name</code>         | The column <code>col_name</code> from table <code>tbl_name</code> of the default database.                  |
| <code>db_name.tbl_name.col_name</code> | The column <code>col_name</code> from table <code>tbl_name</code> of the database <code>db_name</code> .    |

The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.

If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write ``my-table`.`my-column``, not ``my-table.my-column``.

A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference in a statement unless the reference would be ambiguous. Suppose that tables `t1` and `t2` each contain a column `c`, and you retrieve `c` in a `SELECT` statement that uses both `t1` and `t2`. In this case, `c` is ambiguous because it is not unique among the tables used in the statement. You must qualify it with a table name as `t1.c` or `t2.c` to indicate which table you mean. Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must refer to columns in those tables as `db1.t.col_name` and `db2.t.col_name`.

The syntax `.tbl_name` means the table `tbl_name` in the default database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a `.` character.

## 10.2.2 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case sensitive in Windows, but are case sensitive in most varieties of Unix. One notable exception is OS X, which is Unix-based but uses a default file system type (HFS+) that is not case sensitive. However, OS X also supports UFS volumes, which are case sensitive just as on any Unix. See [Section 1.8.1, “MySQL Extensions to Standard SQL”](#). The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

**Note**

Although database, table, and trigger names are not case sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and event names are not case sensitive on any platform, nor are column aliases.

However, names of logfile groups are case sensitive. This differs from standard SQL.

By default, table aliases are case sensitive on Unix, but not so on Windows or OS X. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
-> WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable, which you can set when starting `mysqld`. `lower_case_table_names` can take the values shown in the following table. This variable does *not* affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` is 0. On Windows, the default value is 1. On OS X, the default value is 2.

| Value | Meaning   |
|-------|---|
| 0     | Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case sensitive. You should <i>not</i> set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or OS X). If you force this variable to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive file system and access <code>MyISAM</code> table names using different lettercases, index corruption may result. |
| 1     | Table names are stored in lowercase on disk and name comparisons are not case sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.   |
| 2     | Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. This works <i>only</i> on file systems that are not case sensitive! <code>InnoDB</code> table names are stored in lowercase, as for <code>lower_case_table_names=1</code> .   |

If you are using MySQL on only one platform, you do not normally have to change the `lower_case_table_names` variable from its default value. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.
- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you

must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

**Exception:** If you are using [InnoDB](#) tables and you are trying to avoid these data transfer problems, you should set `lower_case_table_names` to 1 on all platforms to force names to be converted to lowercase.

If you plan to set the `lower_case_table_names` system variable to 1 on Unix, you must first convert your old database and table names to lowercase before stopping `mysqld` and restarting it with the new variable setting. To do this for an individual table, use `RENAME TABLE`:

```
RENAME TABLE T1 TO t1;
```

To convert one or more entire databases, dump them before setting `lower_case_table_names`, then drop the databases, and reload them after setting `lower_case_table_names`:

1. Use `mysqldump` to dump each database:

```
mysqldump --databases db1 > db1.sql
mysqldump --databases db2 > db2.sql
...
```

Do this for each database that must be recreated.

2. Use `DROP DATABASE` to drop each database.
3. Stop the server, set `lower_case_table_names`, and restart the server.
4. Reload the dump file for each database. Because `lower_case_table_names` is set, each database and table name will be converted to lowercase as it is recreated:

```
mysql < db1.sql
mysql < db2.sql
...
```

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see [Section 11.1.8.7, “Using Collation in INFORMATION\\_SCHEMA Searches”](#).

## 10.2.3 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and each table by one or more files in the appropriate database directory. For the table format files (`.FRM`), the data is always stored in this structure and location.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the same location as the `FRM` files, or the information may be stored in a separate file. [InnoDB](#) data is stored in the InnoDB data files. If you are using tablespaces with [InnoDB](#), then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (`x'00'`). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters ([a..zA..Z](#)), digits ([0..9](#)) and underscore ([\\_](#)) are encoded as is. Consequently, their case sensitivity directly depends on file system features.
- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

| Code Range | Pattern         | Number    | Used | Unused | Blocks                                |
|------------|-----------------|-----------|------|--------|---------------------------------------|
| 00C0..017F | [@][0..4][g..z] | 5*20= 100 | 97   | 3      | Latin-1 Supplement + Latin Extended-A |
| 0370..03FF | [@][5..9][g..z] | 5*20= 100 | 88   | 12     | Greek and Coptic                      |
| 0400..052F | [@][g..z][0..6] | 20*7= 140 | 137  | 3      | Cyrillic + Cyrillic Supplement        |
| 0530..058F | [@][g..z][7..8] | 20*2= 40  | 38   | 2      | Armenian                              |
| 2160..217F | [@][g..z][9]    | 20*1= 20  | 16   | 4      | Number Forms                          |
| 0180..02AF | [@][g..z][a..k] | 20*11=220 | 203  | 17     | Latin Extended-B + IPA Extensions     |
| 1E00..1EFF | [@][g..z][l..r] | 20*7= 140 | 136  | 4      | Latin Extended Additional             |
| 1F00..1FFF | [@][g..z][s..z] | 20*8= 160 | 144  | 16     | Greek Extended                        |
| .... ....  | [@][a..f][g..z] | 6*20= 120 | 0    | 120    | RESERVED                              |
| 24B6..24E9 | [@][@][a..z]    | 26        | 26   | 0      | Enclosed Alphanumerics                |
| FF21..FF5A | [@][a..z][@]    | 26        | 26   | 0      | Halfwidth and Fullwidth forms         |

One of the bytes in the sequence encodes lettercase. For example: [LATIN CAPITAL LETTER A WITH GRAVE](#) is encoded as [@0G](#), whereas [LATIN SMALL LETTER A WITH GRAVE](#) is encoded as [@0g](#). Here the third byte ([G](#) or [g](#)) indicates lettercase. (On a case-insensitive file system, both letters will be treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore ([\\_](#)), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits [a..f](#):

```
0x003F -> @03f
0xFFFF -> @ffff
```

The hexadecimal values correspond to character values in the [ucs2](#) double-byte character set.

On Windows, some names such as [nul](#), [prn](#), and [aux](#) are encoded by appending [@@@](#) to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

If you have databases or tables from a version of MySQL older than 5.1.6 that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of [#mysql50#](#) in the output from [INFORMATION\\_SCHEMA](#) tables or [SHOW](#) statements. For example, if you have a table named [a@b](#) and its name encoding has not been updated, [SHOW TABLES](#) displays it like this:

```
mysql> SHOW TABLES;
```

```
+-----+
| Tables_in_test |
+-----+
| #mysql50#a@b   |
+-----+
```

To refer to such a name for which the encoding has not been updated, you must supply the `#mysql50#` prefix:

```
mysql> SHOW COLUMNS FROM `a@b`;
ERROR 1146 (42S02): Table 'test.a@b' doesn't exist

mysql> SHOW COLUMNS FROM `#mysql50#a@b`;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| i     | int(11)| YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

To update old names to eliminate the need to use the special prefix to refer to them, re-encode them with `mysqlcheck`. The following commands update all names to the new encoding:

```
shell> mysqlcheck --check-upgrade --all-databases
shell> mysqlcheck --fix-db-names --fix-table-names --all-databases
```

To check only specific databases or tables, omit `--all-databases` and provide the appropriate database or table arguments. For information about `mysqlcheck` invocation syntax, see [Section 5.5.3](#), “`mysqlcheck` — A Table Maintenance Program”.

#### Note

The `#mysql50#` prefix is intended only to be used internally by the server. You should not create databases or tables with names that use this prefix.

Also, `mysqlcheck` cannot fix names that contain literal instances of the `@` character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 5.1.6 or later, and then reload the dump file after upgrading.

#### Note

Conversion of pre-MySQL 5.1 database names containing special characters to 5.1 format with the addition of a `#mysql50#` prefix is deprecated as of MySQL 5.7.6 and will be removed in a future version of MySQL. Because such conversions are deprecated, the `--fix-db-names` and `--fix-table-names` options for `mysqlcheck` and the `UPGRADE DATA DIRECTORY NAME` clause for the `ALTER DATABASE` statement are also deprecated.

Upgrades are supported only from one release series to another (for example, 5.0 to 5.1, or 5.1 to 5.5), so there should be little remaining need for conversion of older 5.0 database names to current versions of MySQL. As a workaround, upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

## 10.2.4 Function Name Parsing and Resolution

MySQL 5.7 supports built-in (native) functions, user-defined functions (UDFs), and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

## Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following `(` parenthesis character.
- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The `sql/lex.h` source file lists the names of these special functions for which following whitespace determines their interpretation:

- MySQL 5.7.7 and up: Names defined by the `SYM_FN()` macro in the `symbols[]` array
- Before MySQL 5.7.7: Names listed in the `sql_functions[]` array

In MySQL 5.7, there are about 30 such function names. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

The following table names the functions that are affected by the `IGNORE_SPACE` setting and listed as special in the `sql/lex.h` source file.

|            |              |         |              |
|------------|--------------|---------|--------------|
| ADDDATE    | BIT_AND      | BIT_OR  | BIT_XOR      |
| CAST       | COUNT        | CURDATE | CURTIME      |
| DATE_ADD   | DATE_SUB     | EXTRACT | GROUP_CONCAT |
| MAX        | MID          | MIN     | NOW          |
| POSITION   | SESSION_USER | STD     | STDDEV       |
| STDDEV_POP | STDDEV_SAMP  | SUBDATE | SUBSTR       |
| SUBSTRING  | SUM          | SYSDATE | SYSTEM_USER  |
| TRIM       | VARIANCE     | VAR_POP | VAR_SAMP     |

For functions not listed as special in `sql/lex.h`, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. `ASCII` is one such name. However, for these nonaffected function names, interpretation may vary in expression context: `func_name ()` is interpreted as a built-in function if there is one with the given name; if not, `func_name ()` is interpreted as a user-defined function or stored function if one exists with that name.

The `IGNORE_SPACE` SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With `IGNORE_SPACE` disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count (i INT);
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

- With `IGNORE_SPACE` enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT (*) FROM mytable;
```

However, enabling `IGNORE_SPACE` also has the side effect that the parser treats the affected function names as reserved words (see [Section 10.3, “Keywords and Reserved Words”](#)). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

To use the function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

To enable the `IGNORE_SPACE` SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

`IGNORE_SPACE` is also enabled by certain other composite modes such as `ANSI` that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check [Section 6.1.8, “Server SQL Modes”](#), to see which composite modes enable `IGNORE_SPACE`.

To minimize the dependency of SQL code on the `IGNORE_SPACE` setting, use these guidelines:

- Avoid creating UDFs or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use `count` (one of the affected function names affected by `IGNORE_SPACE`), so they fail with or without whitespace following the name if `IGNORE_SPACE` is enabled:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

### Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:

- Built-in functions and user-defined functions

An error occurs if you try to create a UDF with the same name as a built-in function.

- Built-in functions and stored functions

It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, invoke it as `test.PI()` because the server resolves `PI()` without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.

- User-defined functions and stored functions

User-defined functions and stored functions share the same namespace, so you cannot create a UDF and a stored function with the same name.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

- If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF and `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. Then modify any affected code to use the new name.
- If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use `schema_name.func_name()` syntax). In either case, modify any affected code accordingly.

## 10.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as `SELECT`, `DELETE`, or `BIGINT`, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if you quote them as described in [Section 10.2, “Schema Object Names”](#):

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
```

`BEGIN` and `END` are keywords but not reserved, so their use as identifiers does not require quoting. `INTERVAL` is a reserved keyword and must be quoted to be used as an identifier:

```
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following `(` character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see [Section 10.2.4, “Function Name Parsing and Resolution”](#).

The following table shows the keywords and reserved words in MySQL 5.7, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, `_FILENAME` is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the table are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and uses a `yacc` parser.

**Table 10.2 Keywords and Reserved Words in MySQL 5.7**

|                             |                                       |                              |
|-----------------------------|---------------------------------------|------------------------------|
| <code>ACCESSIBLE</code> (R) | <code>ACCOUNT</code> <sup>a</sup>     | <code>ACTION</code>          |

## 10.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, `.`, `_`, and `$`. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var``).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. (Exception: A user with access to the Performance Schema `user_variables_by_thread` table can see all user variables for all sessions.) All variables for a given client session are automatically freed when that client exits.

User variable names are not case sensitive. Names have a maximum length of 64 characters as of MySQL 5.7.5. (Length is not constrained before that.)

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator.

You can also assign a value to a user variable in statements other than `SET`. In this case, the assignment operator must be `:=` and not `=` because the latter is treated as the comparison operator `=` in non-`SET` statements:

```
mysql> SET @t1=1, @t2=2, @t3:=4;
mysql> SELECT @t1, @t2, @t3, @t4 := @t1+@t2+@t3;
+-----+
| @t1 | @t2 | @t3 | @t4 := @t1+@t2+@t3 |
+-----+
| 1 | 2 | 4 | 7 |
+-----+
```

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string. A value having the `JSON` data type is converted to a string with a character set of `utf8mb4` and a collation of `utf8mb4_bin`.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(... AS UNSIGNED)`:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A   | 65  | 65  |
+-----+-----+-----+
mysql> SET @v1 = b'1000001';
mysql> SET @v2 = b'1000001'+0;
mysql> SET @v3 = CAST(b'1000001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A   | 65  | 65  |
+-----+-----+-----+
```

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

As a general rule, other than in `SET` statements, you should never assign a value to a user variable and read the value within the same statement. For example, to increment a variable, this is okay:

```
SET @a = @a + 1;
```

For other statements, such as `SELECT`, you might get the results you expect, but this is not guaranteed. In the following statement, you might think that MySQL will evaluate `@a` first and then do an assignment second:

```
SELECT @a, @a:=@a+1, ...;
```

However, the order of evaluation for expressions involving user variables is undefined.

Another issue with assigning a value to a variable and reading the value within the same non-`SET` statement is that the default result type of a variable is based on its type at the start of the statement. The following example illustrates this:

```
mysql> SET @a='test';
mysql> SELECT @a, (@a:=20) FROM tbl_name;
```

For this `SELECT` statement, MySQL reports to the client that column one is a string and converts all accesses of `@a` to strings, even though `@a` is set to a number for the second row. After the `SELECT` statement executes, `@a` is regarded as a number for the next statement.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to `0`, `0.0`, or `' '` to define its type before you use it.

In a `SELECT` statement, each select expression is evaluated only when sent to the client. This means that in a `HAVING`, `GROUP BY`, or `ORDER BY` clause, referring to a variable that is assigned a value in the select expression list does *not* work as expected:

```
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to `b` in the `HAVING` clause refers to an alias for an expression in the select list that uses `@aa`. This does not work as expected: `@aa` contains the value of `id` from the previous selected row, not from the current row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as `SELECT`. This is true even if the variable is quoted, as shown in the following example:

```
mysql> SELECT c1 FROM t;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| c1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "`c1`";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| `c1` |
+-----+
1 row in set (0.00 sec)
```

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```
mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)
```

See [Section 14.5, “Prepared SQL Statement Syntax”](#), for more information.

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");

    if( mysqli_connect_errno() )
        die("Connection failed: %s\n", mysqli_connect_error());

    $col = "c1";

    $query = "SELECT $col FROM t";

    $result = $mysqli->query($query);

    while($row = $result->fetch_assoc())
    {
        echo "<p>" . $row["$col"] . "</p>\n";
    }

    $result->close();

    $mysqli->close();
?>
```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

## 10.5 Expression Syntax

The following rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. See the notes after the grammar for additional information about some of the terms.

```
expr:
    expr OR expr
  | expr || expr
  | expr XOR expr
  | expr AND expr
  | expr && expr
  | NOT expr
  | ! expr
  | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
  | boolean_primary

boolean_primary:
    boolean_primary IS [NOT] NULL
```

```

| boolean_primary <=> predicate
| boolean_primary comparison_operator predicate
| boolean_primary comparison_operator {ALL | ANY} (subquery)
| predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
| bit_expr [NOT] IN (subquery)
| bit_expr [NOT] IN (expr [, expr] ...)
| bit_expr [NOT] BETWEEN bit_expr AND predicate
| bit_expr SOUNDS LIKE bit_expr
| bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]
| bit_expr [NOT] REGEXP bit_expr
| bit_expr

bit_expr:
| bit_expr | bit_expr
| bit_expr & bit_expr
| bit_expr << bit_expr
| bit_expr >> bit_expr
| bit_expr + bit_expr
| bit_expr - bit_expr
| bit_expr * bit_expr
| bit_expr / bit_expr
| bit_expr DIV bit_expr
| bit_expr MOD bit_expr
| bit_expr % bit_expr
| bit_expr ^ bit_expr
| bit_expr + interval_expr
| bit_expr - interval_expr
| simple_expr

simple_expr:
| literal
| identifier
| function_call
| simple_expr COLLATE collation_name
| param_marker
| variable
| simple_expr || simple_expr
| + simple_expr
| - simple_expr
| ~ simple_expr
| ! simple_expr
| BINARY simple_expr
| (expr [, expr] ...)
| ROW (expr, expr [, expr] ...)
| (subquery)
| EXISTS (subquery)
| {identifier expr}
| match_expr
| case_expr
| interval_expr

```

#### Notes:

For operator precedence, see in [Section 13.3.1, “Operator Precedence”](#).

For literal value syntax, see [Section 10.1, “Literal Values”](#).

For identifier syntax, see [Section 10.2, “Schema Object Names”](#).

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: [Section 10.4, “User-Defined Variables”](#)
- System variables: [Section 6.1.6, “Using System Variables”](#)
- Local variables: [Section 14.6.4.1, “Local Variable DECLARE Syntax”](#)

- Parameters: [Section 14.1.16, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#)

*param\_marker* is `?` as used in prepared statements for placeholders. See [Section 14.5.1, “PREPARE Syntax”](#).

*(subquery)* indicates a subquery that returns a single value; that is, a scalar subquery. See [Section 14.2.10.1, “The Subquery as Scalar Operand”](#).

*{identifier expr}* is ODBC escape syntax and is accepted for ODBC compatibility. The value is *expr*. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

*match\_expr* indicates a `MATCH` expression. See [Section 13.9, “Full-Text Search Functions”](#).

*case\_expr* indicates a `CASE` expression. See [Section 13.4, “Control Flow Functions”](#).

*interval\_expr* represents a time interval. The syntax is `INTERVAL expr unit`, where *unit* is a specifier such as `HOUR`, `DAY`, or `WEEK`. For the full list of *unit* specifiers, see the description of the `DATE_ADD()` function in [Section 13.7, “Date and Time Functions”](#).

The meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See [Section 6.1.8, “Server SQL Modes”](#).

## 10.6 Comment Syntax

MySQL Server supports three comment styles:

- From a `#` character to the end of the line.
- From a `--` sequence to the end of the line. In MySQL, the `--` (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in [Section 1.8.2.4, “‘--’ as the Start of a Comment”](#).
- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```
mysql> SELECT 1+1;      # This comment continues to the end of line
mysql> SELECT 1+1;      -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

Nested comments are not supported. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.)

Comments in this format, `/*!12345 ... */`, are not stored on the server. If this format is used to comment stored routines, the comments will not be retained on the server.

Another variant of C-style comment syntax is used to specify optimizer hints. Hint comments include a `+` character following the `/*` comment opening sequence. Example:

```
SELECT /*+ BKA(t1) */ FROM ... ;
```

For more information, see [Section 9.9.3, “Optimizer Hints”](#).

The use of short-form `mysql` commands such as `\C` within multiple-line `/* ... */` comments is not supported.

---

| 11.7 MySQL Server Locale Support .....                               | 1460 |

This chapter covers issues of globalization, which includes internationalization (MySQL's capabilities for adapting to local use) and localization (selecting particular local conventions):

- MySQL support for character sets in SQL statements.
- How to configure the server to support different character sets.
- Selecting the language for error messages.
- How to set the server's time zone and enable per-connection time zone support.
- Selecting the locale for day and month names.

## 11.1 Character Set Support

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level. MySQL supports the use of character sets for the [MyISAM](#), [MEMORY](#), and [InnoDB](#) storage engines.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.

- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see [Section 11.1.5, “Configuring Application Character Set and Collation”](#), and [Section 11.1.4, “Connection Character Sets and Collations”](#).

### 11.1.1 Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: `A`, `B`, `a`, `b`. We give each letter a number: `A` = 0, `B` = 1, `a` = 2, `b` = 3. The letter `A` is a symbol, the number 0 is the *encoding* for `A`, and the combination of all four letters and their encodings is a *character set*.

Suppose that we want to compare two string values, `A` and `B`. The simplest way to do this is to look at the encodings: 0 for `A` and 1 for `B`. Because 0 is less than 1, we say `A` is less than `B`. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a *binary* collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters `a` and `b` as equivalent to `A` and `B`; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just `A` and `B` but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German `ö`), and for multiple-character mappings (such as the rule that `ö` = `oe` in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

### 11.1.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets. To display the available character sets, use the `INFORMATION_SCHEMA.CHARACTER_SETS` table or the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see [Section 11.1.10, “Supported Character Sets and Collations”](#).

```
mysql> SHOW CHARACTER SET;
```

| Charset | Description                 | Default collation  | Maxlen |
|---------|-----------------------------|--------------------|--------|
| big5    | Big5 Traditional Chinese    | big5_chinese_ci    | 2      |
| ...     |                             |                    |        |
| latin1  | cp1252 West European        | latin1_swedish_ci  | 1      |
| latin2  | ISO 8859-2 Central European | latin2_general_ci  | 1      |
| ...     |                             |                    |        |
| utf8    | UTF-8 Unicode               | utf8_general_ci    | 3      |
| ucs2    | UCS-2 Unicode               | ucs2_general_ci    | 2      |
| ...     |                             |                    |        |
| utf8mb4 | UTF-8 Unicode               | utf8mb4_general_ci | 4      |
| ...     |                             |                    |        |
| binary  | Binary pseudo charset       | binary             | 1      |
| ...     |                             |                    |        |

By default, the `SHOW CHARACTER SET` statement displays all available character sets. It takes an optional `LIKE` or `WHERE` clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

| Charset | Description                 | Default collation | Maxlen |
|---------|-----------------------------|-------------------|--------|
| latin1  | cp1252 West European        | latin1_swedish_ci | 1      |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1      |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci | 1      |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci | 1      |

A given character set always has at least one collation, and most character sets have several. To list the display collations for a character set, use the `INFORMATION_SCHEMA.COLLATIONS` table or the `SHOW COLLATION` statement.

By default, the `SHOW COLLATION` statement displays all available collations. It takes an optional `LIKE` or `WHERE` clause that indicates which collation names to display. For example, to see the collations for the `latin1` (cp1252 West European) character set, use this statement:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

| Collation         | Charset | Id | Default | Compiled | Sortlen |
|-------------------|---------|----|---------|----------|---------|
| latin1_german1_ci | latin1  | 5  | Yes     | Yes      | 1       |
| latin1_swedish_ci | latin1  | 8  |         | Yes      | 1       |
| latin1_danish_ci  | latin1  | 15 |         | Yes      | 1       |
| latin1_german2_ci | latin1  | 31 |         | Yes      | 2       |
| latin1_bin        | latin1  | 47 |         | Yes      | 1       |
| latin1_general_ci | latin1  | 48 |         | Yes      | 1       |
| latin1_general_cs | latin1  | 49 |         | Yes      | 1       |
| latin1_spanish_ci | latin1  | 94 |         | Yes      | 1       |

The `latin1` collations have the following meanings.

| Collation                      | Meaning   |
|--------------------------------|---|
| <code>latin1_bin</code>        | Binary according to <code>latin1</code> encoding    |
| <code>latin1_danish_ci</code>  | Danish/Norwegian                                    |
| <code>latin1_general_ci</code> | Multilingual (Western European)                     |
| <code>latin1_general_cs</code> | Multilingual (ISO Western European), case sensitive |
| <code>latin1_german1_ci</code> | German DIN-1 (dictionary order)                     |
| <code>latin1_german2_ci</code> | German DIN-2 (phone book order)                     |
| <code>latin1_spanish_ci</code> | Modern Spanish                                      |

| Collation                      | Meaning         |
|--------------------------------|-----------------|
| <code>latin1_swedish_ci</code> | Swedish/Finnish |

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has a *default collation*. For example, the default collations for `latin1` and `utf8` are `latin1_swedish_ci` and `utf8_general_ci`, respectively. The `INFORMATION_SCHEMA.CHARACTER_SETS` table and the `SHOW CHARACTER SET` statement indicate the default collation for each character set. The `INFORMATION_SCHEMA.COLLATIONS` table and the `SHOW COLLATION` statement have a column that indicates for each collation whether it is the default for its character set (`Yes` if so, empty if not).
- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see [Section 11.1.3.1, “Collation Naming Conventions”](#).

When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 11.1.2.1 String Repertoire

The *repertoire* of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only characters in the Unicode range `U+0000` to `U+007F`.
- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+10FFFF`. This includes characters in the Basic Multilingual Plane (BMP) range (`U+0000` to `U+FFFF`) and supplementary characters outside the BMP range (`U+01000` to `U+10FFFF`).

The **ASCII** range is a subset of **UNICODE** range, so a string with **ASCII** repertoire can be converted safely without loss of information to the character set of any string with **UNICODE** repertoire or to a character set that is a superset of **ASCII**. (All MySQL character sets are supersets of **ASCII** with the exception of `swe7`, which reuses some punctuation characters for Swedish accented characters.) The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error.

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for string constants depends on string content:

```
SET NAMES utf8; SELECT 'abc';
SELECT _utf8'def';
SELECT N'MySQL';
```

Although the character set is `utf8` in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is **ASCII** rather than **UNICODE**.

- Columns having the `ascii` character set have **ASCII** repertoire because of their character set. In the following table, `c1` has **ASCII** repertoire:

```
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```
CREATE TABLE t1 (
  c1 CHAR(1) CHARACTER SET latin1,
  c2 CHAR(1) CHARACTER SET ascii
);
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset ([ascii](#) to [latin1](#)) conversion can occur and a result is returned:

```
+-----+
| CONCAT(c1,c2) |
+-----+
| ab           |
+-----+
```

- Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8'abc')` has [ASCII](#) repertoire because its argument has [ASCII](#) repertoire.
- For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is [ASCII](#) if `character_set_connection` is [ascii](#), and [UNICODE](#) otherwise:

```
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-----+
| CONCAT(FORMAT(a, 4), b) |
+-----+
| 1.0000b                |
+-----+
```

- Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire ([UNICODE](#) is wider than [ASCII](#)). Consider the following `CONCAT()` calls:

```
CONCAT(_ucs2 X'0041', _ucs2 X'0042')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
```

For the first call, the repertoire is [ASCII](#) because both arguments are within the range of the [ascii](#) character set. For the second call, the repertoire is [UNICODE](#) because the second argument is outside the [ascii](#) character set range.

- The repertoire for function return values is determined based only on the repertoire of the arguments that affect the result's character set and collation.

```
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is `ASCII` because the two string arguments (the second argument and the third argument) both have `ASCII` repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

### 11.1.2.2 UTF-8 for Metadata

*Metadata* is “the data about the data.” Anything that *describes* the database—as opposed to being the *contents* of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from `SHOW` are metadata. This is also true of the contents of tables in `INFORMATION_SCHEMA` because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the `SHOW` statements nor `SELECT` statements for tables in `INFORMATION_SCHEMA` would work properly because different rows in the same column of the results of these operations would be in different character sets.
- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()`, `CURRENT_USER()`, `SESSION_USER()`, `SYSTEM_USER()`, `DATABASE()`, and `VERSION()` functions have the UTF-8 character set by default.

The server sets the `character_set_system` system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_system | utf8 |
+-----+-----+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `latin1`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See [Section 11.1.4, “Connection Character Sets and Collations”](#).) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see [Section 11.1.8.4, “Collation of Expressions”](#).

### 11.1.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see [Section 11.1.4, “Connection Character Sets and Collations”](#).

#### 11.1.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, `utf8_general_ci` and `latin1_swedish_ci` are collations for the `utf8` and `latin1` character sets, respectively. The `binary` character set has a single collation, also named `binary`, with no suffixes.
- A language-specific collation includes a language name. For example, `utf8_turkish_ci` and `utf8_hungarian_ci` sort characters for the `utf8` character set using the rules of Turkish and Hungarian, respectively.
- Collation suffixes indicate whether a collation is case and accent sensitive, or binary. The following table shows the suffixes used to indicate these characteristics.

**Table 11.1 Collation Case Sensitivity Suffixes**

| Suffix           | Meaning            |
|------------------|--------------------|
| <code>_ai</code> | Accent insensitive |
| <code>_as</code> | Accent sensitive   |

| Suffix            | Meaning          |
|-------------------|------------------|
| <code>_ci</code>  | Case insensitive |
| <code>_cs</code>  | Case sensitive   |
| <code>_bin</code> | Binary           |

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain `_ai` or `_as`, `_ci` in the name implies `_ai` and `_cs` in the name implies `_as`. For example, `latin1_general_ci` is explicitly case insensitive and implicitly accent insensitive, and `latin1_general_cs` is explicitly case sensitive and implicitly accent sensitive.

For the `binary` collation of the `binary` character set, comparisons are based on numeric byte values. For the `_bin` collation of a nonbinary character set, comparisons are based on numeric character code values, which differ from byte values for multibyte characters. For more information, see [Section 11.1.8.5, “The binary Collation Compared to `\_bin` Collations”](#).

- For Unicode character sets, collation names may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys. For example:
  - `utf8_unicode_520_ci` is based on UCA 5.2.0 weight keys (<http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>).
  - `utf8_unicode_ci` (with no version named) is based on UCA 4.0.0 weight keys (<http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>).
- For Unicode character sets, the `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24. For more information, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), and [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

### 11.1.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=latin1`. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--character-set-server=latin1 --collation-server=latin1_swedish_ci` because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```
shell> mysqld
shell> mysqld --character-set-server=latin1
shell> mysqld --character-set-server=latin1 \
           --collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` options for `CMake`. For example:

```
shell> cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```
shell> cmake . -DDEFAULT_CHARSET=latin1 \
           -DDEFAULT_COLLATION=latin1_german1_ci
```

Both `mysqld` and `CMake` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

### 11.1.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set *charset\_name* and collation *collation\_name* are used.
- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set *charset\_name* and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement.
- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with *collation\_name* and collation *collation\_name* are used.
- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```
USE db_name;
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

- For `CREATE TABLE` statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit `CHARACTER SET` and `COLLATE` table options.
- For `LOAD DATA` statements that include no `CHARACTER SET` clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit `CHARACTER SET` clause.
- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no `CHARACTER SET` or `COLLATE` attribute. To override this, provide explicit `CHARACTER SET` and `COLLATE` attributes.

### 11.1.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]]

ALTER TABLE tbl_name
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.
- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement.
- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.
- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

### 11.1.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, or `TEXT`) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
```

```
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

These clauses can also be used for [ENUM](#) and [SET](#) columns:

```
col_name {ENUM | SET} (val_list)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
    coll VARCHAR(5)
        CHARACTER SET latin1
        COLLATE latin1_german1_ci
);

ALTER TABLE t1 MODIFY
    coll VARCHAR(5)
        CHARACTER SET latin1
        COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both [CHARACTER SET \*charset\\_name\*](#) and [COLLATE \*collation\\_name\*](#) are specified, character set *charset\_name* and collation *collation\_name* are used.

```
CREATE TABLE t1
(
    coll CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set [utf8](#) and collation [utf8\\_unicode\\_ci](#).

- If [CHARACTER SET \*charset\\_name\*](#) is specified without [COLLATE](#), character set *charset\_name* and its default collation are used.

```
CREATE TABLE t1
(
    coll CHAR(10) CHARACTER SET utf8
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set [utf8](#) and the default collation for [utf8](#), which is [utf8\\_general\\_ci](#). To see the default collation for each character set, use the [SHOW CHARACTER SET](#) statement.

- If [COLLATE \*collation\\_name\*](#) is specified without [CHARACTER SET](#), the character set associated with *collation\_name* and collation *collation\_name* are used.

```
CREATE TABLE t1
(
    coll CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation [utf8\\_polish\\_ci](#) and the character set is the one associated with the collation, which is [utf8](#).

- Otherwise (neither [CHARACTER SET](#) nor [COLLATE](#) is specified), the table character set and collation are used.

```
CREATE TABLE t1
(
  col1 CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

### 11.1.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string'`, the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8'abc' COLLATE utf8_danish_ci;
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charset_name`.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

MySQL determines the character set and collation of a character string literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.
- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified), the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:

- A nonbinary string with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
```

- A nonbinary string with `utf8` character set and its default collation (that is, `utf8_general_ci`):

```
SELECT _utf8'Müller';
```

- A binary string with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';
```

- A nonbinary string with the connection default character set and `utf8_general_ci` collation (fails if the connection character set is not `utf8`):

```
SELECT 'Müller' COLLATE utf8_general_ci;
```

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in [Section 11.1.4, “Connection Character Sets and Collations”](#)), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

Example 1:

```
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+-----+-----+
| HEX('à\n') | HEX(_sjis'à\n') |
+-----+-----+
| E00A      | E00A              |
+-----+-----+
```

Here, `à` (hexadecimal value `E0`) is followed by `\n`, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of `latin1` to produce a literal newline (hexadecimal value `0A`). This happens even for the second string. That is, the `_sjis` introducer does not affect the parser's escape processing.

Example 2:

```
mysql> SET NAMES sjis;
mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+-----+-----+
| HEX('à\n') | HEX(_latin1'à\n') |
+-----+-----+
| E05C6E     | E05C6E             |
+-----+-----+
```

Here, `character_set_connection` is `sjis`, a character set in which the sequence of `à` followed by `\` (hexadecimal values `05` and `5C`) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the `\` is not interpreted as an escape character. The following `n` (hexadecimal value `6E`) is not interpreted as part of an escape sequence. This is true even for the second string; the `_latin1` introducer does not affect escape processing.

### 11.1.3.7 The National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NVARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N 'literal'` (or `n 'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

### 11.1.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] literal [COLLATE collation_name]
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8'abc' COLLATE utf8_danish_ci;

SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;

SELECT _latin1 b'1000001';
SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charset_name`.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

Character string literals can be designated as binary strings by using the `_binary` introducer. Hexadecimal literals and bit-value literals are binary strings by default, so `_binary` is permitted, but unnecessary.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.
- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified:
  - For a character string literal, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
  - For a hexadecimal literal or bit-value literal, the only permitted collation is `binary` because these types of literals are binary strings by default.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified):
  - For a character string literal, the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.
  - For a hexadecimal literal or bit-value literal, the character set and collation are `binary`.

Examples:

- Nonbinary strings with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;  
SELECT _latin1 X'0A0D' COLLATE latin1_german1_ci;  
SELECT _latin1 b'0110' COLLATE latin1_german1_ci;
```

- Nonbinary strings with `utf8` character set and its default collation (that is, `utf8_general_ci`):

```
SELECT _utf8'Müller';  
SELECT _utf8 X'0A0D';  
SELECT _utf8 b'0110';
```

- Binary strings with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';  
SELECT X'0A0D';  
SELECT b'0110';
```

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.

- A nonbinary string with the connection default character set and `utf8_general_ci` collation (fails if the connection character set is not `utf8`):

```
SELECT 'Müller' COLLATE utf8_general_ci;
```

This construction (`COLLATE` only) does not work for hexadecimal literals or bit literals because their character set is `binary` no matter the connection character set, and `binary` is not compatible with the `utf8_general_ci` collation. The only permitted `COLLATE` clause in the absence of an introducer is `COLLATE binary`.

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by [character\\_set\\_connection](#). For additional discussion and examples, see [Section 11.1.3.6, “Character String Literal Character Set and Collation”](#).

### 11.1.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

#### Example 1: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a [latin1](#) character set and a [latin1\\_german1\\_ci](#) collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a [latin1](#) column in a [latin2](#) table.

#### Example 2: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a [latin1](#) character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for [latin1](#) is always [latin1\\_swedish\\_ci](#), column [c1](#) has a collation of [latin1\\_swedish\\_ci](#) (not [latin1\\_danish\\_ci](#)).

#### Example 3: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column [c1](#) is [latin1](#) and its collation is [latin1\\_danish\\_ci](#).

#### Example 4: Database, Table, and Column Definition

```
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
  c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column [c1](#) is [latin2](#) and its collation is [latin2\\_czech\\_ci](#).

### 11.1.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

## 11.1.4 Connection Character Sets and Collations

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The server character set and collation are the values of the `character_set_server` and `collation_server` system variables.
- The character set and collation of the default database are the values of the `character_set_database` and `collation_database` system variables.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has connection-related character set and collation system variables.

A “connection” is what you make when you connect to the server. The client sends SQL statements, such as queries, over the connection to the server. The server sends responses, such as result sets or error messages, over the connection back to the client. This leads to several questions about character set and collation handling for client connections, each of which can be answered in terms of system variables:

- What character set is the statement in when it leaves the client?

The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

- What character set should the server translate a statement to after receiving it?

For this, the server uses the `character_set_connection` and `collation_connection` system variables. It converts statements sent by the client from `character_set_client` to `character_set_connection` (except for string literals that have an introducer such as `_latin1` or `_utf8`). `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence.

- What character set should the server translate to before shipping result sets or error messages back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, and result metadata such as column names and error messages.

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings *for each connection to the server*.

Two statements affect the connection-related character set variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement.)

A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection = charset_name;
```

Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation, use the optional `COLLATE` clause:

```
SET NAMES 'charset_name' COLLATE 'collation_name'
```

- `SET CHARACTER SET charset_name`

`SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database`. A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET collation_connection = @@collation_database;
```

Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.

#### Note

`ucs2`, `utf16`, `utf16le`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES` or `SET CHARACTER SET`.

The MySQL client programs `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` determine the default character set to use as follows:

- In the absence of other information, the programs use the compiled-in default character set, usually `latin1`.
- The programs can autodetect which character set to use based on the operating system setting, such as the value of the `LANG` or `LC_ALL` locale environment variable on Unix systems or the code page setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting `LANG` to `ru_RU.KOI8-R` causes the `koi8r` character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, `ucs2` is not supported as a connection character set.

C applications can use character set autodetection based on the OS setting by invoking `mysql_options()` as follows before connecting to the server:

```
mysql_options(mysql,
              MYSQL_SET_CHARSET_NAME,
              MYSQL_AUTODETECT_CHARSET_NAME);
```

- The programs support a `--default-character-set` option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

When a client connects to the server, it sends the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

With the `mysql` client, to use a character set different from the default, you could explicitly execute `SET NAMES` every time you start up. To accomplish the same result more easily, add the `--default-character-set` option setting to your `mysql` command line or in your option file. For example, the following option file setting changes the three connection-related character set variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset utf8
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that `mysql` uses when it reconnects after the connection has dropped.

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET latin1` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy if there are characters that are not in both character sets.

If you want the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```
SET character_set_results = NULL;
```

To see the values of the character set and collation system variables that apply to your connection, use these statements:

```
SHOW VARIABLES LIKE 'character_set%';
SHOW VARIABLES LIKE 'collation%';
```

You must also consider the environment within which your MySQL applications execute. See [Section 11.1.5, “Configuring Application Character Set and Collation”](#).

For more information about character sets and error messages, see [Section 11.1.6, “Error Message Character Set”](#).

## 11.1.5 Configuring Application Character Set and Collation

For applications that store data using the default MySQL character set and collation (`latin1`, `latin1_swedish_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might require `utf8`, whereas applications that use another database might require `sjis`.
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the `utf8` character set and `utf8_general_ci` collation.

**Specify character settings per database.** To create a database such that its tables will use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
  DEFAULT CHARACTER SET utf8
  DEFAULT COLLATE utf8_general_ci;
```

Tables created in the database will use `utf8` and `utf8_general_ci` by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'utf8'` statement after connecting. The statement can be used regardless of connection method: The `mysql` client, PHP scripts, and so forth.

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, for connections made using `mysql`, you can specify the `--default-character-set=utf8` command-line option to achieve the same effect as `SET NAMES 'utf8'`.

For more information about configuring client connections, see [Section 11.1.4, “Connection Character Sets and Collations”](#).

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 14.1.16, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)

**Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

```
[mysqld]
character-set-server=utf8
collation-server=utf8_general_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'utf8'"` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this will yield inconsistent results because the `init_connect` value is not executed for users who have the `SUPER` privilege.

**Specify character settings at MySQL configuration time.** To select a character set and collation when you configure and build MySQL from source, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` options for `CMake`:

```
shell> cmake . -DDEFAULT_CHARSET=utf8 \
          -DDEFAULT_COLLATION=utf8_general_ci
```

The resulting server uses `utf8` and `utf8_general_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` and `--collation-server` to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. If you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

## 11.1.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages and returning them to clients. For information about the language of error messages (rather than the character set), see [Section 11.2, “Setting the Error Message Language”](#).

The server constructs error messages using UTF-8 and returns them to clients in the character set specified by the `character_set_results` system variable.

The server constructs error messages as follows:

- The message template uses UTF-8.
- Parameters in the message template are replaced with values that apply to a specific error occurrence:
  - Identifiers such as table or column names use UTF-8 internally so they are copied as is.
  - Character (nonbinary) string values are converted from their character set to UTF-8.
  - Binary string values are copied as is for bytes in the range `0x20` to `0x7E`, and using `\x` hexadecimal encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert `0x41CF9F` into a `VARBINARY` unique column, the resulting error message uses UTF-8 with some bytes hexadecimal encoded:

```
Duplicate entry 'A\xC3\x9F' for key 1
```

To return a message to the client after it has been constructed, the server converts it from UTF-8 to the character set specified by the `character_set_results` system variable. If `character_set_results` has a value of `NULL` or `binary`, no conversion occurs. No conversion occurs if the variable value is `utf8`, either, because that matches the original error message character set.

For characters that cannot be represented in `character_set_results`, some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (`0x0000` to `0xFFFF`) are written using `\nnnn` notation.
- Characters outside the BMP range (`0x01000` to `0x10FFFF`) are written using `\+nnnnnnn` notation.

Clients can set `character_set_results` to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results`, see [Section 11.1.4, “Connection Character Sets and Collations”](#).

The encoding that occurs during the conversion to `character_set_results` before returning error messages to clients can result in different message content compared to earlier versions (before MySQL 5.5). For example, if an error occurs for an attempt to drop a table named `㇏` (KATAKANA

LETTER PE) and `character_set_results` is a character set such as `latin1` that does not contain that character, the resulting message sent to the client has an encoded table name:

```
ERROR 1051 (42S02): Unknown table '\30DA'
```

Before MySQL 5.5, the name is not encoded:

```
ERROR 1051 (42S02): Unknown table ' '
```

## 11.1.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.
- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `coll` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `coll` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```
ALTER TABLE t MODIFY coll VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values will be padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` function:

```
UPDATE t SET coll = TRIM(TRAILING 0x00 FROM coll);
```

Suppose that table `t` has a nonbinary column named `coll` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET utf8;
```

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored `sjis` values in a column, even though MySQL's default character set was `latin1`. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was `latin1` and `coll` is defined as `CHAR(50)` but its contents are `sjis` values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY coll BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as [INSERT](#) or [UPDATE](#) after an upgrade to MySQL 4.1 or later. In that case, MySQL would store new values in the column using [latin1](#), and the column will contain a mix of [sjis](#) and [latin1](#) values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with [ALTER TABLE](#). For example, if you specified [NOT NULL](#) and an explicit [DEFAULT](#) value, you should also provide them in the [ALTER TABLE](#) statement. Otherwise, the resulting column definition will not include those attributes.

To convert all character columns in a table, the [ALTER TABLE ... CONVERT TO CHARACTER SET charset](#) statement may be useful. See [Section 14.1.8, “ALTER TABLE Syntax”](#).

## 11.1.8 Collation Issues

The following sections discuss various aspects of character set collations.

### 11.1.8.1 Using COLLATE in SQL Statements

With the [COLLATE](#) clause, you can override whatever the default collation is for a comparison. [COLLATE](#) may be used in various parts of SQL statements. Here are some examples:

- With [ORDER BY](#):

```
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With [AS](#):

```
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With [GROUP BY](#):

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With [DISTINCT](#):

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With [WHERE](#):

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
SELECT *
FROM t1
```

```
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With **HAVING**:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

### 11.1.8.2 COLLATE Clause Precedence

The **COLLATE** clause has high precedence (higher than `| |`), so the following two expressions are equivalent:

```
x | | y COLLATE z
x | | (y COLLATE z)
```

### 11.1.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

### 11.1.8.4 Collation of Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `charset_name`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should the comparison use the collation of the column `x`, or of the string literal `'Y'`? Both `x` and `'Y'` have collations, so which collation takes precedence?

Standard SQL resolves such questions using what used to be called “coercibility” rules. MySQL assigns coercibility values as follows:

- An explicit **COLLATE** clause has a coercibility of 0. (Not coercible at all.)
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- **NULL** or an expression that is derived from **NULL** has a coercibility of 5.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.

- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

```
SELECT CONCAT(utf8_column, latin1_column) FROM t1;
```

It returns a result that has a character set of `utf8` and the same collation as `utf8_column`. Values of `latin1_column` are automatically converted to `utf8` before concatenating.

- For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, except that it is for collations rather than data types.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

Examples:

| Comparison                                     | Collation Used                              |
|--|---|
| <code>column1 = 'A'</code>                     | Use collation of <code>column1</code>       |
| <code>column1 = 'A' COLLATE x</code>           | Use collation of <code>'A' COLLATE x</code> |
| <code>column1 COLLATE x = 'A' COLLATE y</code> | Error                                       |

The `COERCIBILITY()` function can be used to determine the coercibility of a string expression:

```
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
```

See [Section 13.14, “Information Functions”](#).

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument `1` in the expression `CONCAT(1, 'abc')`, the result is a character (nonbinary) string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. See [Section 13.2, “Type Conversion in Expression Evaluation”](#).

### 11.1.8.5 The binary Collation Compared to `_bin` Collations

This section describes how the `binary` collation for binary strings compares to the `_bin` collations for nonbinary strings.

Binary strings (as stored using the `BINARY`, `VARBINARY`, and `BLOB` data types) have a character set and collation named `binary`. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order.

Nonbinary strings (as stored using the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation other than `binary`. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. One of these is the binary collation for the character set, indicated by a `_bin` suffix in the collation name. For example, the binary collations for `latin1` and `utf8` are named `latin1_bin` and `utf8_bin`, respectively.

The `binary` collation differs from the `_bin` collations in several respects.

**The unit for comparison and sorting.** Binary strings are sequences of bytes. For the `binary` collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For the `_bin` collation, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

**Character set conversion.** A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values from another column that has a different character set:

```
UPDATE t1 SET utf8_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
```

- When assigning column values for `INSERT` or `UPDATE` using a string literal:

```
SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```
SET NAMES latin1;
SELECT utf8_bin_column FROM t2;
```

For binary string columns, no conversion occurs. For the preceding cases, the string value is copied byte-wise.

**Lettercase conversion.** Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for `_bin` collations that ignore lettercase for ordering:

```
mysql> SET NAMES latin1 COLLATE latin1_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-----+-----+
| LOWER('aA') | UPPER('zZ') |
+-----+-----+
| aa          | ZZ          |
+-----+-----+
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must be converted to a nonbinary string:

```
mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING latin1));
+-----+-----+
| LOWER('aA') | LOWER(CONVERT('aA' USING latin1)) |
+-----+-----+
| aA          | aa          |
+-----+-----+
```

**Trailing space handling in comparisons.** Nonbinary strings have `PADSPACE` behavior for all collations, including `_bin` collations. Trailing spaces are insignificant in comparisons:

```
mysql> SET NAMES utf8 COLLATE utf8_bin;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
| 1          |
+-----+
```

```
+-----+
```

For binary strings, all characters are significant in comparisons, including trailing spaces:

```
mysql> SET NAMES binary;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|          0 |
+-----+
```

**Trailing space handling for inserts and retrievals.** `CHAR(N)` columns store nonbinary strings. Values shorter than `N` characters are extended with spaces on insertion. For retrieval, trailing spaces are removed.

`BINARY(N)` columns store binary strings. Values shorter than `N` bytes are extended with `0x00` bytes on insertion. For retrieval, nothing is removed; a value of the declared length is always returned.

```
mysql> CREATE TABLE t1 (
      a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,
      b BINARY(10)
);
mysql> INSERT INTO t1 VALUES ('a','a');
mysql> SELECT HEX(a), HEX(b) FROM t1;
+-----+
| HEX(a) | HEX(b) |
+-----+
| 61     | 61000000000000000000 |
+-----+
```

### 11.1.8.6 Examples of the Effect of Collation

#### Example 1: Sorting German Umlauts

Suppose that column `X` in table `T` has these `latin1` column values:

```
Muffler
Müller
MX Systems
MySQL
```

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations.

| <code>latin1_swedish_ci</code> | <code>latin1_german1_ci</code> | <code>latin1_german2_ci</code> |
|--------------------------------|--------------------------------|--------------------------------|
| Muffler                        | Muffler                        | Müller                         |
| MX Systems                     | Müller                         | Muffler                        |
| Müller                         | MX Systems                     | MX Systems                     |
| MySQL                          | MySQL                          | MySQL                          |

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.

- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

### Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (
    c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (
    c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (
    c CHAR(10)
) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, you'll get these results in comparisons:

```
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bar    |
| Bär    |
+-----+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bär    |
+-----+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bar    |
| Bär    |
+-----+
```

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

### 11.1.8.7 Using Collation in `INFORMATION_SCHEMA` Searches

String columns in `INFORMATION_SCHEMA` tables have a collation of `utf8_general_ci`, which is case insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in `INFORMATION_SCHEMA` string columns can be case sensitive or insensitive, depending on the characteristics of the underlying file system and the value of the `lower_case_table_names` system variable. For example, searches may be case sensitive if the file system is case sensitive. This section describes this behavior and how to modify it if necessary; see also Bug #34921.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with `'test'` match, but comparisons with `'TEST'` do not:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

These results occur with the `lower_case_table_names` system variable set to 0. Changing the value of `lower_case_table_names` to 1 or 2 causes the second query to return the same (nonempty) result as the first query.

On Windows or OS X, file systems are not case sensitive, so comparisons match both `'test'` and `'TEST'`:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME = 'TEST';
+-----+
| SCHEMA_NAME |
+-----+
| TEST        |
+-----+
```

The value of `lower_case_table_names` makes no difference in this context.

The preceding behavior occurs because the `utf8_general_ci` collation is not used for `INFORMATION_SCHEMA` queries when searching for values that correspond to objects represented in the file system. It is a result of file system-scanning optimizations implemented for `INFORMATION_SCHEMA` searches. For information about these optimizations, see [Section 9.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#).

If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (see [Section 11.1.8.1, “Using COLLATE in SQL Statements”](#)). For example, to perform a case-insensitive search, use `COLLATE` with the `INFORMATION_SCHEMA` column name:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
        WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'TEST';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+
```

In the preceding queries, it is important to apply the `COLLATE` clause to the `INFORMATION_SCHEMA` column name. Applying `COLLATE` to the comparison value has no effect.

You can also use the `UPPER()` or `LOWER()` function:

```
WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'
```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with `utf8_bin`) is case sensitive; the others are not:

```
WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8_general_ci` collation because `INFORMATION_SCHEMA` is a “virtual” database not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match `'information_schema'` or `'INFORMATION_SCHEMA'` regardless of platform:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      WHERE SCHEMA_NAME = 'information_schema';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+
```

## 11.1.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the [Unicode Consortium Web site](http://unicode.org/).

BMP characters have these characteristics:

- Their code point values are between 0 and 65535 (or `U+0000` and `U+FFFF`).
- They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).
- They can be encoded in a fixed-length encoding using 16 bits (2 bytes).
- They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP. Their code point values are between `U+10000` and `U+10FFFF`. Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters.

MySQL supports these Unicode character sets:

- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character.
- `ucs2`, the UCS-2 encoding of the Unicode character set using two bytes per character.

- `utf8mb4`, a UTF-8 encoding of the Unicode character set using one to four bytes per character.
- `utf16`, the UTF-16 encoding for the Unicode character set using two or four bytes per character. Like `ucs2` but with an extension for supplementary characters.
- `utf16le`, the UTF-16LE encoding for the Unicode character set. Like `utf16` but little-endian rather than big-endian.
- `utf32`, the UTF-32 encoding for the Unicode character set using four bytes per character.

[Table 11.2, “Unicode Character Set General Characteristics”](#), summarizes the general characteristics of Unicode character sets supported by MySQL.

**Table 11.2 Unicode Character Set General Characteristics**

| Character Set        | Supported Characters  | Required Storage Per Character |
|----------------------|-----------------------|--------------------------------|
| <code>utf8</code>    | BMP only              | 1, 2, or 3 bytes               |
| <code>ucs2</code>    | BMP only              | 2 bytes                        |
| <code>utf8mb4</code> | BMP and supplementary | 1, 2, 3, or 4 bytes            |
| <code>utf16</code>   | BMP and supplementary | 2 or 4 bytes                   |
| <code>utf16le</code> | BMP and supplementary | 2 or 4 bytes                   |
| <code>utf32</code>   | BMP and supplementary | 4 bytes                        |

Characters outside the BMP compare as REPLACEMENT CHARACTER and convert to '?' when converted to a Unicode character set that supports only BMP characters (`utf8` or `ucs2`).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only `utf8` and `ucs2` character sets, there are potential incompatibility issues for your applications; see [Section 11.1.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”](#). That section also describes how to convert tables from `utf8` to the (4-byte) `utf8mb4` character set, and what constraints may apply in doing so.

A similar set of collations is available for most Unicode character sets. For example, each has a Danish collation, the names of which are `ucs2_danish_ci`, `utf16_danish_ci`, `utf32_danish_ci`, `utf8_danish_ci`, and `utf8mb4_danish_ci`. The exception is `utf16le`, which has only two collations. For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see [Section 11.1.10.1, “Unicode Character Sets”](#).

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values will need to be performed when transferring data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set accordingly; for example, by issuing a `SET NAMES 'utf8'` statement. `ucs2`, `utf16`, `utf16le`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES` or `SET CHARACTER SET`. (See [Section 11.1.4, “Connection Character Sets and Collations”](#).)

The following sections provide additional detail on the Unicode character sets in MySQL.

### 11.1.9.1 The utf8 Character Set (3-Byte UTF-8 Unicode Encoding)

UTF-8 (Unicode Transformation Format with 8-bit units) is an alternative way to store Unicode data. It is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. (An older standard for UTF-8 encoding, RFC 2279, describes UTF-8 sequences that take

from one to six bytes. RFC 3629 renders RFC 2279 obsolete; for this reason, sequences with five and six bytes are no longer used.)

The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

The `utf8` character set in MySQL has these characteristics:

- No support for supplementary characters (BMP characters only).
- A maximum of three bytes per multibyte character.

Exactly the same set of characters is available in `utf8` and `ucs2`. That is, they have the same repertoire.

#### Tip

To save space with UTF-8, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL must reserve three bytes for each character in a `CHAR CHARACTER SET utf8` column because that is the maximum possible character length. For example, MySQL must reserve 30 bytes for a `CHAR(10) CHARACTER SET utf8` column.

For additional information about data type storage, see [Section 12.8, “Data Type Storage Requirements”](#). For information about `InnoDB` physical row storage, including how `InnoDB` tables that use `COMPACT` row format handle UTF-8 `CHAR(N)` columns internally, see [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#).

### 11.1.9.2 The utf8mb3 Character Set (Alias for utf8)

The `utf8` character set uses a maximum of three bytes per character. To make this character limit explicit (much as the limit of four bytes per character is explicit in the `utf8mb4` character set name, use the character set name `utf8mb3`, which is an alias for `utf8`. `utf8mb3` can be used in `CHARACTER SET` clauses, and `utf8mb3_collation_substring` in `COLLATE` clauses, where `collation_substring` is `bin`, `czech_ci`, `danish_ci`, `esperanto_ci`, `estonian_ci`, and so forth. For example:

```
CREATE TABLE t (s1 CHAR(1) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8) COLLATE utf8_czech_ci;
```

MySQL immediately converts instances of `utf8mb3` in an alias to `utf8`, so in statements such as `SHOW CREATE TABLE` or `SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS` or `SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS`, users will see the true name, `utf8` or `utf8_collation_substring`.

The `utf8mb3` alias is also valid in certain places other than `CHARACTER SET` clauses. For example, these are legal:

```
mysqld --character-set-server=utf8mb3
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
```

```
SELECT _utf8mb3 'a';
```

There is no `utf8mb3` alias for the corresponding `utf8` collation for collation names that include a version number to indicate the Unicode Collation Algorithm version on which the collation is based (for example, `utf8_unicode_520_ci`).

### 11.1.9.3 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The character set named `utf8` uses a maximum of three bytes per character and contains only BMP characters. The `utf8mb4` character set uses a maximum of four bytes per character supports supplementary characters:

- For a BMP character, `utf8` and `utf8mb4` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8` cannot store the character at all, whereas `utf8mb4` requires four bytes to store it. Because `utf8` cannot store the character at all, you have no supplementary characters in `utf8` columns and need not worry about converting characters or losing data when upgrading `utf8` data from older versions of MySQL.

`utf8mb4` is a superset of `utf8`, so for an operation such as the following concatenation, the result has character set `utf8mb4` and the collation of `utf8mb4_col`:

```
SELECT CONCAT(utf8_col, utf8mb4_col);
```

Similarly, the following comparison in the `WHERE` clause works according to the collation of `utf8mb4_col`:

```
SELECT * FROM utf8_tbl, utf8mb4_tbl
WHERE utf8_tbl.utf8_col = utf8mb4_tbl.utf8mb4_col;
```

**Tip:** To save space with `utf8mb4`, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL must reserve four bytes for each character in a `CHAR CHARACTER SET utf8mb4` column because that is the maximum possible length. For example, MySQL must reserve 40 bytes for a `CHAR(10) CHARACTER SET utf8mb4` column.

### 11.1.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a 2-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a 2-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the [Unicode Consortium Web site](#).

In MySQL, the `ucs2` character set is a fixed-length 16-bit encoding for Unicode BMP characters.

### 11.1.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The `utf16` character set is the `ucs2` character set with an extension that enables encoding of supplementary characters:

- For a BMP character, `utf16` and `ucs2` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf16` has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than `0xffff`, take 10 bits and add them to `0xd800` and put them in the first 16-bit word, take 10 more bits and add them to `0xdc00` and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between `0xd800` and `0xdbff`, and the last 16 bits are a number between `0xdc00` and `0xdfff`. Examples are in Section [15.5 Surrogates Area](#) of the Unicode 4.0 document.

Because `utf16` supports surrogates and `ucs2` does not, there is a validity check that applies only in `utf16`: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column) VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like `0xffff`). For example, since `U+F8FF` is the Apple Logo, this is legal:

```
INSERT INTO t (utf16_column) VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a `utf16` column or index is only half of the maximum length for a `ucs2` column or index. For example, the maximum length of a `MEMORY` table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for `ucs2` and `utf16` columns:

```
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

#### 11.1.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)

This is the same as `utf16` but is little-endian rather than big-endian.

#### 11.1.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)

The `utf32` character set is fixed length (like `ucs2` and unlike `utf16`). `utf32` uses 32 bits for every character, unlike `ucs2` (which uses 16 bits for every character), and unlike `utf16` (which uses 16 bits for some characters and 32 bits for others).

`utf32` takes twice as much space as `ucs2` and more space than `utf16`, but `utf32` has the same advantage as `ucs2` that it is predictable for storage: The required number of bytes for `utf32` equals the number of characters times 4. Also, unlike `utf16`, there are no tricks for encoding in `utf32`, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a `utf8mb4` value given the `utf32` code value:

```
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32,
                  utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for `utf32`: No code value may be greater than `0x10ffff`. For example, this is illegal:

```
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

#### 11.1.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting from the `utf8` character set to the `utf8mb4` character set, or vice versa.

**Note**

The discussion here focuses primarily on converting between `utf8` and `utf8mb4`, but similar principles apply to converting between the `ucs2` character set and character sets such as `utf16` or `utf32`.

The `utf8` and `utf8mb4` character sets differ as follows:

- `utf8` supports only characters in the Basic Multilingual Plane (BMP). `utf8mb4` additionally supports supplementary characters that lie outside the BMP.
- `utf8` uses a maximum of three bytes per character. `utf8mb4` uses a maximum of four bytes per character.

One advantage of converting from `utf8` to `utf8mb4` is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In most respects, converting from `utf8` to `utf8mb4` should present few problems. These are the primary potential areas of incompatibility:

- For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum permitted length in characters is less for `utf8mb4` columns than for `utf8` columns.
- For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8` columns.

Consequently, to convert tables from `utf8` to `utf8mb4`, it may be necessary to change some column or index definitions.

Tables can be converted from `utf8` to `utf8mb4` by using `ALTER TABLE`. Suppose that a table was originally defined as follows:

```
CREATE TABLE t1 (
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci NOT NULL,
  col2 CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL
) CHARACTER SET utf8;
```

The following statement converts `t1` to use `utf8mb4`:

```
ALTER TABLE t1
  DEFAULT CHARACTER SET utf8mb4,
  MODIFY col1 CHAR(10)
    CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
  MODIFY col2 CHAR(10)
    CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

In terms of table content, conversion from `utf8` to `utf8mb4` presents no problems:

- For a BMP character, `utf8` and `utf8mb4` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8` cannot store the character at all, whereas `utf8mb4` requires four bytes. Because `utf8` cannot store the character at all, `utf8` columns have no supplementary characters and you need not worry about converting characters or losing data when converting to `utf8mb4`.

In terms of table structure, the catch when converting from `utf8` to `utf8mb4` is that the maximum length of a column or index key is unchanged in terms of *bytes*. Therefore, it is smaller in terms of *characters* because the maximum length of a character is four bytes instead of three. For the `CHAR`, `VARCHAR`, and `TEXT` data types, watch for these issues when converting your MySQL tables:

- Check all definitions of `utf8` columns and make sure they will not exceed the maximum length for the storage engine.

- Check all indexes on `utf8` columns and make sure they will not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use `utf8` rather than `utf8mb4`.

Here are some examples where structural changes may be needed:

- A `TINYTEXT` column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a `TINYTEXT` column that uses `utf8` but must be able to contain more than 63 characters. You cannot convert it to `utf8mb4` unless you also change the data type to a longer type such as `TEXT`.

Similarly, a very long `VARCHAR` column may need to be changed to one of the longer `TEXT` types if you want to convert it from `utf8` to `utf8mb4`.

- `InnoDB` has a maximum index length of 767 bytes for tables that use `COMPACT` or `REDUNDANT` row format, so for `utf8` or `utf8mb4` columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have `utf8` columns with indexes longer than 191 characters, you must index a smaller number of characters.

In an `InnoDB` table that uses `COMPACT` or `REDUNDANT` row format, these column and index definitions are legal:

```
coll VARCHAR(500) CHARACTER SET utf8, INDEX (coll(255))
```

To use `utf8mb4` instead, the index must be smaller:

```
coll VARCHAR(500) CHARACTER SET utf8mb4, INDEX (coll(191))
```

#### Note

For `InnoDB` tables that use `COMPRESSED` or `DYNAMIC` row format, you can enable the `innodb_large_prefix` option to permit **index key prefixes** longer than 767 bytes (up to 3072 bytes). Creating such tables also requires the option values `innodb_file_format=barracuda` and `innodb_file_per_table=true`.) In this case, enabling the `innodb_large_prefix` option enables you to index a maximum of 1024 or 768 characters for `utf8` or `utf8mb4` columns, respectively. For related information, see [Section 15.8.8, “Limits on InnoDB Tables”](#).

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from `utf8` to `utf8mb4` without problems, using `ALTER TABLE` as described previously.

The following items summarize other potential areas of incompatibility:

- Performance of 4-byte UTF-8 (`utf8mb4`) is slower than for 3-byte UTF-8 (`utf8`). To avoid this penalty, continue to use `utf8`.
- `SET NAMES 'utf8mb4'` causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them. More generally, applications cannot send `utf8mb4`, `utf16`, `utf16le`, or `utf32` data to an older server that does not understand it:
  - `utf8mb4`, `utf16`, and `utf32` are not recognized before MySQL 5.5.3.
  - `utf16le` is not recognized before MySQL 5.6.1.

- For replication, if character sets that support supplementary characters are to be used on the master, all slaves must understand them as well. If you attempt to replicate from a newer master to an older slave, `utf8` data will be seen as `utf8` by the slave and should replicate correctly. But you cannot send `utf8mb4`, `utf16`, `utf16le`, or `utf32` data to an older slave that does not understand it:
- `utf8mb4`, `utf16`, and `utf32` are not recognized before MySQL 5.5.3.
- `utf16le` is not recognized before MySQL 5.6.1.

Also, keep in mind the general principle that if a table has different definitions on the master and slave, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use `utf8` on the master and `utf8mb4` on the slave.

If you have converted to `utf8mb4`, `utf16`, `utf16le`, or `utf32`, and then decide to convert back to `utf8` or `ucs2` (for example, to downgrade to an older version of MySQL), these considerations apply:

- `utf8` and `ucs2` data should present no problems.
- The server must be recent enough to recognize definitions referring to the character set from which you are converting.
- For object definitions that refer to the `utf8mb4` character set, you can dump them with `mysqldump` prior to downgrading, edit the dump file to change instances of `utf8mb4` to `utf8`, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server will see `utf8` in the dump file object definitions and create new objects that use the (3-byte) `utf8` character set.

### 11.1.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table. For example:

```
mysql> SHOW CHARACTER SET;
```

| Charset  | Description                 | Default collation   | Maxlen |
|----------|-----------------------------|---------------------|--------|
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     | 2      |
| dec8     | DEC West European           | dec8_swedish_ci     | 1      |
| cp850    | DOS West European           | cp850_general_ci    | 1      |
| hp8      | HP West European            | hp8_english_ci      | 1      |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    | 1      |
| latin1   | cp1252 West European        | latin1_swedish_ci   | 1      |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   | 1      |
| swe7     | 7bit Swedish                | swe7_swedish_ci     | 1      |
| ascii    | US ASCII                    | ascii_general_ci    | 1      |
| ujis     | EUC-JP Japanese             | ujis_japanese_ci    | 3      |
| sjis     | Shift-JIS Japanese          | sjis_japanese_ci    | 2      |
| hebrew   | ISO 8859-8 Hebrew           | hebrew_general_ci   | 1      |
| tis620   | TIS620 Thai                 | tis620_thai_ci      | 1      |
| euckr    | EUC-KR Korean               | euckr_korean_ci     | 2      |
| koi8u    | KOI8-U Ukrainian            | koi8u_general_ci    | 1      |
| gb2312   | GB2312 Simplified Chinese   | gb2312_chinese_ci   | 2      |
| greek    | ISO 8859-7 Greek            | greek_general_ci    | 1      |
| cp1250   | Windows Central European    | cp1250_general_ci   | 1      |
| gbk      | GBK Simplified Chinese      | gbk_chinese_ci      | 2      |
| latin5   | ISO 8859-9 Turkish          | latin5_turkish_ci   | 1      |
| armscii8 | ARMSCII-8 Armenian          | armscii8_general_ci | 1      |
| utf8     | UTF-8 Unicode               | utf8_general_ci     | 3      |
| ucs2     | UCS-2 Unicode               | ucs2_general_ci     | 2      |
| cp866    | DOS Russian                 | cp866_general_ci    | 1      |
| keybcs2  | DOS Kamenicky Czech-Slovak  | keybcs2_general_ci  | 1      |
| macce    | Mac Central European        | macce_general_ci    | 1      |

|          |                                 |                     |   |
|----------|---------------------------------|---------------------|---|
| macroman | Mac West European               | macroman_general_ci | 1 |
| cp852    | DOS Central European            | cp852_general_ci    | 1 |
| latin7   | ISO 8859-13 Baltic              | latin7_general_ci   | 1 |
| utf8mb4  | UTF-8 Unicode                   | utf8mb4_general_ci  | 4 |
| cp1251   | Windows Cyrillic                | cp1251_general_ci   | 1 |
| utf16    | UTF-16 Unicode                  | utf16_general_ci    | 4 |
| utf16le  | UTF-16LE Unicode                | utf16le_general_ci  | 4 |
| cp1256   | Windows Arabic                  | cp1256_general_ci   | 1 |
| cp1257   | Windows Baltic                  | cp1257_general_ci   | 1 |
| utf32    | UTF-32 Unicode                  | utf32_general_ci    | 4 |
| binary   | Binary pseudo charset           | binary              | 1 |
| geostd8  | GEOSTD8 Georgian                | geostd8_general_ci  | 1 |
| cp932    | SJIS for Windows Japanese       | cp932_japanese_ci   | 2 |
| eucjpms  | UJIS for Windows Japanese       | eucjpms_japanese_ci | 3 |
| gb18030  | China National Standard GB18030 | gb18030_chinese_ci  | 4 |

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 11.1.10.1 Unicode Character Sets

MySQL supports multiple Unicode character sets:

- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character.
- `ucs2`, the UCS-2 encoding of the Unicode character set using two bytes per character.
- `utf8mb4`, a UTF-8 encoding of the Unicode character set using one to four bytes per character.
- `utf16`, the UTF-16 encoding for the Unicode character set using two or four bytes per character. Like `ucs2` but with an extension for supplementary characters.
- `utf16le`, the UTF-16LE encoding for the Unicode character set. Like `utf16` but little-endian rather than big-endian.
- `utf32`, the UTF-32 encoding for the Unicode character set using four bytes per character.

`utf8` and `ucs2` support Basic Multilingual Plane (BMP) characters. `utf8mb4`, `utf16`, `utf16le`, and `utf32` support BMP and supplementary characters.

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see [Section 11.1.9, “Unicode Support”](#).

Most Unicode character sets have a general collection (indicated by `_general` in the name or by the absence of a language specifier), a binary collation (indicated by `_bin` in the name), and several language-specific collations (indicated by language specifiers). For example, for `utf8`, `utf8_general_ci` and `utf8_bin` are its general and binary collations, and `utf8_danish_ci` is one of its language-specific collations.

Collation support for `utf16le` is limited. The only collations available are `utf16le_general_ci` and `utf16le_bin`. These are similar to `utf16_general_ci` and `utf16_bin`.

A language name shown in the following table indicates a language-specific collation. Unicode character sets may include collations for one or more of these languages.

**Table 11.3 Unicode Collation Language Specifiers**

| Language        | Language Specifier    |
|-----------------|-----------------------|
| Classical Latin | <code>roman</code>    |
| Croatian        | <code>croatian</code> |

| Language                | Language Specifier      |
|-------------------------|-------------------------|
| Czech                   | <code>czech</code>      |
| Danish                  | <code>danish</code>     |
| Esperanto               | <code>esperanto</code>  |
| Estonian                | <code>estonian</code>   |
| German phone book order | <code>german2</code>    |
| Hungarian               | <code>hungarian</code>  |
| Icelandic               | <code>icelandic</code>  |
| Latvian                 | <code>latvian</code>    |
| Lithuanian              | <code>lithuanian</code> |
| Persian                 | <code>persian</code>    |
| Polish                  | <code>polish</code>     |
| Romanian                | <code>romanian</code>   |
| Sinhala                 | <code>sinhala</code>    |
| Slovak                  | <code>slovak</code>     |
| Slovenian               | <code>slovenian</code>  |
| Modern Spanish          | <code>spanish</code>    |
| Traditional Spanish     | <code>spanish2</code>   |
| Swedish                 | <code>swedish</code>    |
| Turkish                 | <code>turkish</code>    |
| Vietnamese              | <code>vietnamese</code> |

Croatian collations are tailored for these Croatian letters: Č, Ć, DŽ, Đ, Lj, Nj, Š, Ž.

Danish collations may also be used for Norwegian.

For Classical Latin collations, I and J compare as equal, and U and V compare as equal.

Spanish collations are available for modern and traditional Spanish. For both, ñ (n-tilde) is a separate letter between n and o. In addition, for traditional Spanish, ch is a separate letter between c and d, and ll is a separate letter between l and m.

Traditional Spanish collations may also be used for Asturian and Galician.

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

```
Ü = Y < Ö
```

For questions about particular language orderings, [unicode.org](http://www.unicode.org) provides Common Locale Data Repository (CLDR) collation charts at <http://www.unicode.org/cldr/charts/30/collation/index.html>.

The `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24. For more information, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), and [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

MySQL implements the `xxx_unicode_ci` collations according to the Unicode Collation Algorithm (UCA) described at <http://www.unicode.org/reports/tr10/>. The collation uses the version-4.0.0 UCA weight keys: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. The `xxx_unicode_ci` collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects primarily Vietnamese, Yoruba,

and some smaller languages such as Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the `CHAR_LENGTH()` function or in result set metadata).

Unicode collations based on UCA versions later than 4.0.0 include the version in the collation name. Thus, `utf8_unicode_520_ci` is based on UCA 5.2.0 weight keys (<http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>). For collations of `utf8` that include a UCA version, there is no `utf8mb3` alias; see [Section 11.1.9.2, “The utf8mb3 Character Set \(Alias for utf8\)”](#).

MySQL implements language-specific Unicode collations if the ordering based only on UCA does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules.

`LOWER()` and `UPPER()` perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version more recent than 4.0.0 is converted by these functions only if the argument has a collation that uses a recent enough UCA version.

For any Unicode character set, operations performed using the `xxx_general_ci` collation are faster than those for the `xxx_unicode_ci` collation. For example, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. The reason for this is that `utf8_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, in German and some other languages ß is equal to ss. `utf8_unicode_ci` also supports contractions and ignorable characters. `utf8_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci` (for the effect of this in comparisons or searches, see [Section 11.1.8.6, “Examples of the Effect of Collation”](#)):

```
Ä = A
Ö = O
Ü = U
```

A difference between the collations is that this is true for `utf8_general_ci`:

```
ß = s
```

Whereas this is true for `utf8_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

```
ß = ss
```

MySQL implements `utf8` language-specific collations if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8` collations.

`utf8_general_ci` also is satisfactory for both German and French, except that ß is equal to s, and not to ss. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the `utf8_german2_ci` collation, which compares the following sets of characters equal:

```
Ä = Æ = AE
Ö = Œ = OE
```

```

Ü = UE
ß = ss

```

`utf8_german2_ci` is similar to `latin1_german2_ci`, but the latter does not compare `Æ` equal to `AE` or `Œ` equal to `OE`. There is no `utf8_german_ci` corresponding to `latin1_german_ci` for German dictionary order because `utf8_general_ci` suffices.

For all Unicode collations except the binary (`_bin`) collations, MySQL performs a table lookup to find a character's collating weight. This weight can be displayed using the `WEIGHT_STRING()` function. (See [Section 13.5, “String Functions”](#).) If a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (`xxx_general_ci`), weight = code point.
- For BMP characters in UCA collations (for example, `xxx_unicode_ci` and language-specific collations), the following algorithm applies:

```

if (code >= 0x3400 && code <= 0x4DB5)
    base= 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
    base= 0xFB40; /* CJK Ideograph */
else
    base= 0xFBC0; /* All other characters */
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;

```

The result is a sequence of two collating elements, `aaaa` followed by `bbbb`. For example:

```

mysql> SELECT HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci));
+-----+
| HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci)) |
+-----+
| FBC084CF                                                    |
+-----+

```

Thus, `U+04cf CYRILLIC SMALL LETTER PALOCHKA` is, with all UCA 4.0.0 collations, greater than `U+04c0 CYRILLIC LETTER PALOCHKA`. With UCA 5.2.0 collations, all palochkas sort together.

- For supplementary characters in general collations, the weight is the weight for `0xffff REPLACEMENT CHARACTER`. For supplementary characters in UCA 4.0.0 collations, their collating weight is `0xffffd`. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and `COUNT(DISTINCT)`:

```

CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xffffd); /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;

```

The result is 2 because in the MySQL `xxx_unicode_ci` collations, the replacement character has a weight of `0x0dc6`, whereas Deseret Bee and Deseret Tee both have a weight of `0xffffd`. (Were the `utf32_general_ci` collation used instead, the result is 1 because all three characters have a weight of `0xffffd` in that collation.)

An example with cuneiform characters and `WEIGHT_STRING()`:

```

/*
The four characters in the INSERT string are
00000041 # LATIN CAPITAL LETTER A

```

```

0001218F # CUNEIFORM SIGN KAB
000121A7 # CUNEIFORM SIGN KISH
00000042 # LATIN CAPITAL LETTER B
*/
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT_STRING(s1)) FROM t;

```

The result is:

```
0E33 FFFD FFFD 0E4A
```

[0E33](#) and [0E4A](#) are primary weights as in [UCA 4.0.0](#). [FFFD](#) is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it is very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by the MySQL rule and secondarily by code point value, it is easy:

```
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

- For supplementary characters based on UCA versions higher than 4.0.0 (for example, [xxx\\_unicode\\_520\\_ci](#)), supplementary characters do not necessarily all have the same collation weight. Some have explicit weights from the UCA [allkeys.txt](#) file. Others have weights calculated from this algorithm:

```

aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;

```

There is a difference between “ordering by the character's code value” and “ordering by the character's binary representation,” a difference that appears only with [utf16\\_bin](#), because of surrogates.

Suppose that [utf16\\_bin](#) (the binary collation for [utf16](#)) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in [utf16\\_bin](#) would differ from the order in [utf8\\_bin](#). For example, the following chart shows two rare characters. The first character is in the range [E000-FFFF](#), so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

| Code point | Character                   | utf8        | utf16       |
|------------|-----------------------------|-------------|-------------|
| -----      | -----                       | ----        | -----       |
| 0FF9D      | HALFWIDTH KATAKANA LETTER N | EF BE 9D    | FF 9D       |
| 10384      | UGARITIC LETTER DELTA       | F0 90 8E 84 | D8 00 DF 84 |

The two characters in the chart are in order by code point value because [0xff9d](#) < [0x10384](#). And they are in order by [utf8](#) value because [0xef](#) < [0xf0](#). But they are not in order by [utf16](#) value, if we use byte-by-byte comparison, because [0xff](#) > [0xd8](#).

So MySQL's [utf16\\_bin](#) collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in [utf16](#), it converts to the character's code-point value, and then compares. Therefore, [utf8\\_bin](#) and [utf16\\_bin](#) are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS\_BASIC collation: “UCS\_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS\_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is [ucs2](#), comparison is byte-by-byte, but [ucs2](#) strings should not contain surrogates, anyway.

### 11.1.10.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
  - `ascii_bin`
  - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
  - `cp850_bin`
  - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
  - `dec8_bin`
  - `dec8_swedish_ci` (default)
- `hp8` (HP Western European) collations:
  - `hp8_bin`
  - `hp8_english_ci` (default)
- `latin1` (cp1252 West European) collations:
  - `latin1_bin`
  - `latin1_danish_ci`
  - `latin1_general_ci`
  - `latin1_general_cs`
  - `latin1_german1_ci`
  - `latin1_german2_ci`
  - `latin1_spanish_ci`
  - `latin1_swedish_ci` (default)

`latin1` is the default character set. MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between `0x80` and `0x9f` as “undefined,” whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, `0x80` is the Euro sign. For the “undefined” entries in `cp1252`, MySQL translates `0x81` to Unicode `0x0081`, `0x8d` to `0x008d`, `0x8f` to `0x008f`, `0x90` to `0x0090`, and `0x9d` to `0x009d`.

The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For

an example of the effect this has in comparisons or when doing searches, see [Section 11.1.8.6, “Examples of the Effect of Collation”](#).

- `latin1_german1_ci` (dictionary) rules:

```
Ä = A
Ö = O
Ü = U
ß = s
```

- `latin1_german2_ci` (phone-book) rules:

```
Ä = AE
Ö = OE
Ü = UE
ß = ss
```

In the `latin1_spanish_ci` collation, `ñ` (n-tilde) is a separate letter between `n` and `o`.

- `macroman` (Mac West European) collations:
  - `macroman_bin`
  - `macroman_general_ci` (default)
- `swe7` (7bit Swedish) collations:
  - `swe7_bin`
  - `swe7_swedish_ci` (default)

### 11.1.10.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- `cp1250` (Windows Central European) collations:
  - `cp1250_bin`
  - `cp1250_croatian_ci`
  - `cp1250_czech_cs`
  - `cp1250_general_ci` (default)
  - `cp1250_polish_ci`
- `cp852` (DOS Central European) collations:
  - `cp852_bin`
  - `cp852_general_ci` (default)
- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:
  - `keybcs2_bin`
  - `keybcs2_general_ci` (default)
- `latin2` (ISO 8859-2 Central European) collations:
  - `latin2_bin`

- `latin2_croatian_ci`
- `latin2_czech_cs`
- `latin2_general_ci` (default)
- `latin2_hungarian_ci`
- `macce` (Mac Central European) collations:
  - `macce_bin`
  - `macce_general_ci` (default)

#### 11.1.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMSCII-8 Armenian) collations:
  - `armscii8_bin`
  - `armscii8_general_ci` (default)
- `cp1256` (Windows Arabic) collations:
  - `cp1256_bin`
  - `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
  - `geostd8_bin`
  - `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
  - `greek_bin`
  - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
  - `hebrew_bin`
  - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
  - `latin5_bin`
  - `latin5_turkish_ci` (default)

#### 11.1.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
  - `cp1257_bin`

- `cp1257_general_ci` (default)
- `cp1257_lithuanian_ci`
- `latin7` (ISO 8859-13 Baltic) collations:
  - `latin7_bin`
  - `latin7_estonian_cs`
  - `latin7_general_ci` (default)
  - `latin7_general_cs`

#### 11.1.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- `cp1251` (Windows Cyrillic) collations:
  - `cp1251_bin`
  - `cp1251_bulgarian_ci`
  - `cp1251_general_ci` (default)
  - `cp1251_general_cs`
  - `cp1251_ukrainian_ci`
- `cp866` (DOS Russian) collations:
  - `cp866_bin`
  - `cp866_general_ci` (default)
- `koi8r` (KOI8-R Relcom Russian) collations:
  - `koi8r_bin`
  - `koi8r_general_ci` (default)
- `koi8u` (KOI8-U Ukrainian) collations:
  - `koi8u_bin`
  - `koi8u_general_ci` (default)

#### 11.1.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See [The cp932 Character Set](#), for additional information about the `cp932` and `sjis` character sets. See [The gb18030 Character Set](#), for additional information about character set support for the Chinese National Standard GB 18030.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see [Section A.11, “MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#).

- `big5` (Big5 Traditional Chinese) collations:
  - `big5_bin`

- `big5_chinese_ci` (default)
- `cp932` (SJIS for Windows Japanese) collations:
  - `cp932_bin`
  - `cp932_japanese_ci` (default)
- `eucjpms` (UJIS for Windows Japanese) collations:
  - `eucjpms_bin`
  - `eucjpms_japanese_ci` (default)
- `euckr` (EUC-KR Korean) collations:
  - `euckr_bin`
  - `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:
  - `gb2312_bin`
  - `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
  - `gbk_bin`
  - `gbk_chinese_ci` (default)
- `gb18030` (China National Standard GB18030) collations:
  - `gb18030_bin`
  - `gb18030_chinese_ci` (default)
  - `gb18030_unicode_520_ci`
- `sjis` (Shift-JIS Japanese) collations:
  - `sjis_bin`
  - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
  - `tis620_bin`
  - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
  - `ujis_bin`
  - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

## The `cp932` Character Set

Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See <http://www.iana.org/assignments/character-sets>.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

#### How does `cp932` differ from `sjis`?

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
- Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See <http://support.microsoft.com/kb/170559/EN-US/>.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at <https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx> provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (`ucs2`) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte 0x87):

<https://msdn.microsoft.com/en-us/global/gg674964>

- NEC selected—IBM extended characters (lead byte 0xED and 0xEE):

<https://msdn.microsoft.com/en-us/global/gg671837>  
<https://msdn.microsoft.com/en-us/global/gg671838>

- IBM selected characters (lead byte 0xFA, 0xFB, 0xFC):

<https://msdn.microsoft.com/en-us/global/gg671839>  
<https://msdn.microsoft.com/en-us/global/gg671840>  
<https://msdn.microsoft.com/en-us/global/gg671841>

- cp932 supports conversion of user-defined characters in combination with `ucjpm`, and solves the problems with `sjis/ujis` conversion. For details, please refer to <http://www.sjfaq.org/afaq/encodings.html>.

For some characters, conversion to and from `ucs2` is different for `sjis` and `cp932`. The following tables illustrate these differences.

Conversion to `ucs2`:

| <code>sjis/cp932</code> Value | <code>sjis -&gt; ucs2</code> Conversion | <code>cp932 -&gt; ucs2</code> Conversion |
|-------------------------------|---|--|
| 5C                            | 005C                                    | 005C                                     |
| 7E                            | 007E                                    | 007E                                     |
| 815C                          | 2015                                    | 2015                                     |
| 815F                          | 005C                                    | FF3C                                     |
| 8160                          | 301C                                    | FF5E                                     |
| 8161                          | 2016                                    | 2225                                     |
| 817C                          | 2212                                    | FF0D                                     |
| 8191                          | 00A2                                    | FFE0                                     |
| 8192                          | 00A3                                    | FFE1                                     |
| 81CA                          | 00AC                                    | FFE2                                     |

Conversion from `ucs2`:

| <code>ucs2</code> value | <code>ucs2 -&gt; sjis</code> Conversion | <code>ucs2 -&gt; cp932</code> Conversion |
|-------------------------|---|--|
| 005C                    | 815F                                    | 5C                                       |
| 007E                    | 7E                                      | 7E                                       |
| 00A2                    | 8191                                    | 3F                                       |
| 00A3                    | 8192                                    | 3F                                       |
| 00AC                    | 81CA                                    | 3F                                       |
| 2015                    | 815C                                    | 815C                                     |
| 2016                    | 8161                                    | 3F                                       |
| 2212                    | 817C                                    | 3F                                       |
| 2225                    | 3F                                      | 8161                                     |
| 301C                    | 8160                                    | 3F                                       |
| FF0D                    | 3F                                      | 817C                                     |

| ucs2 value | ucs2 -> sjis Conversion | ucs2 -> cp932 Conversion |
|------------|-------------------------|--------------------------|
| FF3C       | 3F                      | 815F                     |
| FF5E       | 3F                      | 8160                     |
| FFE0       | 3F                      | 8191                     |
| FFE1       | 3F                      | 8192                     |
| FFE2       | 3F                      | 81CA                     |

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` (or `--skip-character-set-client-handshake`) has an important effect. See [Section 6.1.4, “Server Command Options”](#).

## The gb18030 Character Set

In MySQL, the `gb18030` character set, introduced in MySQL 5.7.4, corresponds to the “Chinese National Standard GB 18030-2005: Information technology—Chinese coded character set”, which is the official character set of the People's Republic of China (PRC).

### Characteristics of the MySQL gb18030 Character Set

- Supports all code points defined by the GB 18030-2005 standard. Unassigned code points in the ranges (GB+8431A439, GB+90308130) and (GB+E3329A36, GB+EF39EF39) are treated as '?' (0x3F). Conversion of unassigned code points return '?'.
- Supports UPPER and LOWER conversion for all GB18030 code points. Case folding defined by Unicode is also supported (based on `CaseFolding-6.3.0.txt`).
- Supports Conversion of data to and from other character sets.
- Supports SQL statements such as `SET NAMES`.
- Supports comparison between `gb18030` strings, and between `gb18030` strings and strings of other character sets. There is a conversion if strings have different character sets. Comparisons that include or ignore trailing spaces are also supported.
- The private use area (U+E000, U+F8FF) in Unicode is mapped to `gb18030`.
- There is no mapping between (U+D800, U+DFFF) and GB18030. Attempted conversion of code points in this range returns '?'.
- If an incoming sequence is illegal, an error or warning is returned. If an illegal sequence is used in `CONVERT()`, an error is returned. Otherwise, a warning is returned.
- For consistency with `utf8` and `utf8mb4`, UPPER is not supported for ligatures.
- Searches for ligatures also match uppercase ligatures when using the `gb18030_unicode_520_ci` collation.
- If a character has more than one uppercase character, the chosen uppercase character is the one whose lowercase is the character itself.
- The minimum multibyte length is 1 and the maximum is 4. The character set determines the length of a sequence using the first 1 or 2 bytes.

### Supported Collations

- `gb18030_bin`: A binary collation.
- `gb18030_chinese_ci`: The default collation, which supports Pinyin. Sorting of non-Chinese characters is based on the order of the original sort key. The original sort key is `GB(UPPER(ch))`

if `UPPER(ch)` exists. Otherwise, the original sort key is `GB(ch)`. Chinese characters are sorted according to the Pinyin collation defined in the Unicode Common Locale Data Repository (CLDR 24). Non-Chinese characters are sorted before Chinese characters with the exception of `GB+FE39FE39`, which is the code point maximum.

- `gb18030_unicode_520_ci`: A Unicode collation. Use this collation if you need to ensure that ligatures are sorted correctly.

### 11.1.10.8 The Binary Character Set

The `binary` character set is the character set of binary strings, which are sequences of bytes. The `binary` character set has one collation, also named `binary`. Comparison and sorting are based on numeric byte values. The effect is that lettercase and accent differences are significant in comparisons. That is, the `binary` collation is case sensitive and accent sensitive.

```
mysql> SET NAMES 'binary';
mysql> SELECT CHARSET('abc'), COLLATION('abc');
+-----+-----+
| CHARSET('abc') | COLLATION('abc') |
+-----+-----+
| binary        | binary          |
+-----+-----+
mysql> SELECT 'abc' = 'ABC', 'a' = 'ä';
+-----+-----+
| 'abc' = 'ABC' | 'a' = 'ä'       |
+-----+-----+
| 0             | 0               |
+-----+-----+
```

For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 11.1.8.5, “The binary Collation Compared to \\_bin Collations”](#).

To convert a string expression to a binary string, any of these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If *expr* is a character string literal, the `_binary` introducer may be used to designate it as a binary string. For example:

```
_binary 'a'
```

The `_binary` introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see [Section 11.1.3.8, “Character Set Introducers”](#).

## 11.2 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can also be displayed in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish.

You can select which language the server uses for error messages using the instructions in this section.

The server searches for the error message file in two locations:

- It tries to find the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

```
shell> mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
```

In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

- If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.

The `lc_messages_dir` system variable has only a global value and is read only. `lc_messages` has global and session values and can be modified at runtime, so the error message language can be changed while the server is running, and individual clients each can have a different error message language by changing their session `lc_messages` value to a different locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```
mysql> SET lc_messages = 'en_US';
```

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

For information about changing the character set for error messages (rather than the language), see [Section 11.1.6, “Error Message Character Set”](#).

You can change the content of the error messages produced by the server using the instructions in the MySQL Internals manual, available at [MySQL Internals: Error Messages](#). If you do change the content of error messages, remember to repeat your changes after each upgrade to a newer version of MySQL.

## 11.3 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

```
<charset name="latin1">
  <family>Western</family>
  <description>cp1252 West European</description>
  ...
  <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
    <flag>primary</flag>
    <flag>compiled</flag>
```

```
</collation>
<collation name="latin1_danish_ci" id="15" order="Danish"/>
...
<collation name="latin1_bin" id="47" order="Binary">
  <flag>binary</flag>
  <flag>compiled</flag>
</collation>
...
</charset>
```

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of `general_ci` (general, case insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See [Section 11.3.1, “Character Definition Arrays”](#).
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See [Section 11.3.1, “Character Definition Arrays”](#).
  - For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
  - If the character set requires string collating functions, see [Section 11.3.2, “String Collating Support for Complex Character Sets”](#).
  - If the character set requires multibyte character support, see [Section 11.3.3, “Multi-Byte Character Support for Complex Character Sets”](#).
3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

- a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```
#ifdef HAVE_CHARSET_MYSET
    add_compiled_collation(&my_charset_MYSET_general_ci);
    add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

- b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.
  - c. Edit `cmake/character_sets.cmake`:
    - i. Add `MYSET` to the value of with `CHARSETS_AVAILABLE` in alphabetic order.
    - ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, or CMake will not recognize `-DDEFAULT_CHARSET=MYSET`.
4. Reconfigure, recompile, and test.

### 11.3.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSET`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[ ]`, `to_lower_MYSET[ ]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling EOF.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```
#define _MY_U    01    /* Upper case */
#define _MY_L    02    /* Lower case */
#define _MY_NMR  04    /* Numeral (digit) */
#define _MY_SPC  010   /* Spacing character */
#define _MY_PNT  020   /* Punctuation */
#define _MY_CTR  040   /* Control character */
#define _MY_B    0100  /* Blank */
```

```
#define _MY_X    0200    /* hexadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in [Section 11.3.2, “String Collating Support for Complex Character Sets”](#).

### 11.3.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 11.3.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

## 11.4 Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The `WEIGHT_STRING()` function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use

`HEX(WEIGHT_STRING(str))` to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in 'AaBb' if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

```
mysql> SELECT HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci));
+-----+
| HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci)) |
+-----+
| 41414242                                             |
+-----+
mysql> SELECT HEX(WEIGHT_STRING(BINARY 'AaBb'));
+-----+
| HEX(WEIGHT_STRING(BINARY 'AaBb')) |
+-----+
| 41614262                             |
+-----+
```

MySQL supports several collation implementations, as discussed in [Section 11.4.1, “Collation Implementation Types”](#). Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (`xxx_bin`) collations.

The following sections describe how to add collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the collation is present.

The instructions here cover only collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in [Section 11.3, “Adding a Character Set”](#). However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

#### Note

If you modify an existing collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. For further information, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).

- The Locale Data Markup Language (LDML) specification: <http://www.unicode.org/reports/tr35/>

### 11.4.1 Collation Implementation Types

MySQL implements several types of collations:

### Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX(WEIGHT_STRING('a')), HEX(WEIGHT_STRING('A'));
+-----+-----+
| HEX(WEIGHT_STRING('a')) | HEX(WEIGHT_STRING('A')) |
+-----+-----+
| 41                      | 41                      |
+-----+-----+
1 row in set (0.01 sec)

mysql> SELECT 'a' = 'A';
+-----+
| 'a' = 'A' |
+-----+
|          1 |
+-----+
1 row in set (0.12 sec)
```

For implementation instructions, see [Section 11.4.3, “Adding a Simple Collation to an 8-Bit Character Set”](#).

### Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in [Section 11.3, “Adding a Character Set”](#).

### Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multibyte character 'ㇿ' has a character code of 0x82C0, and the weight is also 0x82C0.

```
mysql> CREATE TABLE t1
  (c1 VARCHAR(2) CHARACTER SET sjis COLLATE sjis_japanese_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x82C0);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1    | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a     | 61      | 41                     |
| A     | 41      | 41                     |
| ㇿ    | 82C0    | 82C0                   |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multibyte character '臙' has a character code of 0x81B0 but a weight of 0xC286.

```
mysql> CREATE TABLE t1
      (c1 VARCHAR(2) CHARACTER SET gbk COLLATE gbk_chinese_ci);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),('0x81B0');
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1    | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a     | 61      | 41                     |
| A     | 41      | 41                     |
| 0x81B0 | 81B0    | C286                   |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

For implementation instructions, see [Section 11.3, “Adding a Character Set”](#).

### Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case insensitive and accent insensitive. `utf8_general_ci` is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of `0x0041` and compare as equal.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1
      (c1 CHAR(1) CHARACTER SET UTF8 COLLATE utf8_general_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),('À'),('á');
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1    | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a     | 61      | 0041                   |
| A     | 41      | 0041                   |
| À     | C380    | 0041                   |
| á     | C3A1    | 0041                   |
+-----+-----+-----+
4 rows in set (0.00 sec)
```

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits).
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: 'a' has a weight of `0x0E33`.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.05 sec)

mysql> SELECT HEX('a'), HEX(WEIGHT_STRING('a'));
+-----+-----+
| HEX('a') | HEX(WEIGHT_STRING('a')) |
+-----+-----+
```

```
| HEX('a') | HEX(WEIGHT_STRING('a')) |
+-----+-----+
| 61      | 0E33      |
+-----+-----+
1 row in set (0.02 sec)
```

- A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.11 sec)

mysql> SELECT HEX('ß'), HEX(WEIGHT_STRING('ß'));
+-----+-----+
| HEX('ß') | HEX(WEIGHT_STRING('ß')) |
+-----+-----+
| C39F     | 0FEA0FEA                |
+-----+-----+
1 row in set (0.00 sec)
```

- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_czech_ci';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT HEX('ch'), HEX(WEIGHT_STRING('ch'));
+-----+-----+
| HEX('ch') | HEX(WEIGHT_STRING('ch')) |
+-----+-----+
| 6368      | 0EE2                      |
+-----+-----+
1 row in set (0.00 sec)
```

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see [Section 11.3, “Adding a Character Set”](#). For a UCA collation, see [Section 11.4.4, “Adding a UCA Collation to a Unicode Character Set”](#).

### Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

## 11.4.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. MySQL supports two-byte collation IDs. The range of IDs from 1024 to 2047 is reserved for user-defined collations. The collation ID that you choose will appear in these contexts:

- The `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table.
- The `Id` column of `SHOW COLLATION` output.
- The `charsetnr` member of the `MYSQL_FIELD` C API data structure.
- The `number` member of the `MY_CHARSET_INFO` data structure returned by the `mysql_get_character_set_info()` C API function.

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
+-----+
```

```
| MAX ( ID ) |
+-----+
|      210 |
+-----+
```

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
+-----+
| ID |
+-----+
| 1 |
| 2 |
| ... |
| 52 |
| 53 |
| 57 |
| 58 |
| ... |
| 98 |
| 99 |
| 128 |
| 129 |
| ... |
| 210 |
+-----+
```

### Warning

Before MySQL 5.5, which provides for a range of user-defined collation IDs, you must choose an ID in the range from 1 to 254. In this case, if you upgrade MySQL, you may find that the collation ID you choose has been assigned to a collation included in the new MySQL distribution. In this case, you will need to choose a new value for your own collation.

In addition, before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

## 11.4.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the `<collation>` elements associated with a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in [Section 11.4.2, “Choosing a Collation ID”](#). The following steps use an ID of 1024.
2. Modify the `Index.xml` and `latin1.xml` configuration files. These files are located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. For example:

```
<charset name="latin1">
...
<collation name="latin1_test_ci" id="1024"/>
...
</charset>
```

- In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the `<map>` element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C D7 5C 55 55 55 59 59 DE DF
41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C F7 5C 55 55 55 59 59 DE FF
</map>
</collation>
```

- Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'latin1_test_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_test_ci | latin1 | 1024 | | | 1 |
+-----+-----+-----+-----+-----+-----+
```

#### 11.4.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at <http://www.unicode.org/reports/tr35/>. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined. It is not possible to create user-defined UCA collations for `utf16le`; there is no `utf16le_unicode_ci` collation that would serve as the basis for such collations.

**Table 11.4 MySQL Character Sets Available for User-Defined UCA Collations**

| Character Set      | Base Collation                |
|--------------------|-------------------------------|
| <code>utf8</code>  | <code>utf8_unicode_ci</code>  |
| <code>ucs2</code>  | <code>ucs2_unicode_ci</code>  |
| <code>utf16</code> | <code>utf16_unicode_ci</code> |
| <code>utf32</code> | <code>utf32_unicode_ci</code> |

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

### 11.4.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see [Section 11.4.4.2, "LDML Syntax Supported in MySQL"](#).

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```
+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567
```

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in [Section 11.4.2, "Choosing a Collation ID"](#). The following steps use an ID of 1029.
2. To modify the `Index.xml` configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value                                     |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```
<charset name="utf8">
...
  <collation name="utf8_phone_ci" id="1029">
    <rules>
      <reset>\u0000</reset>
      <i>\u0020</i> <!-- space -->
      <i>\u0028</i> <!-- left parenthesis -->
      <i>\u0029</i> <!-- right parenthesis -->
      <i>\u002B</i> <!-- plus -->
      <i>\u002D</i> <!-- hyphen -->
    </rules>
  </collation>
...
</charset>
```

4. If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.
5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'utf8_phone_ci';
```

| Collation     | Charset | Id   | Default | Compiled | Sortlen |
|---------------|---------|------|---------|----------|---------|
| utf8_phone_ci | utf8    | 1029 |         |          | 8       |

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```
mysql> CREATE TABLE phonebook (
    name VARCHAR(64),
    phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci
);
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)
```

Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```
mysql> SELECT * FROM phonebook ORDER BY phone;
+-----+-----+
| name | phone |
+-----+-----+
| Sanja | +380 (912) 8008005 |
| Bar | +7-912-800-80-01 |
| Svoj | +7 912 800 80 02 |
| Ramil | (7912) 800 80 03 |
| Hf | +7 (912) 800 80 04 |
+-----+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)
```

### 11.4.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at <http://www.unicode.org/reports/tr35/>, which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL `Index.xml` file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file. See [Section 11.4.4.3, “Diagnostics During Index.xml Parsing”](#).

#### Character Representation

Characters named in LDML rules can be written literally or in `\unnnn` format, where `nnnn` is the hexadecimal Unicode code point value. For example, `A` and `á` can be written literally or as `\u0041` and `\u00E1`. Within hexadecimal values, the digits `A` through `F` are not case sensitive; `\u00E1` and `\u00e1` are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of `0000` to `FFFF`. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.

The `Index.xml` file itself should be written using UTF-8 encoding.

#### Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter `'A'`:

```
<reset>A</reset>
<reset>\u0041</reset>
```

- The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
  - Use primary differences to distinguish separate letters.
  - Use secondary differences to distinguish accent variations.
  - Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the `'G'` character:

```
<p>G</p>
<p>\u0047</p>
```

- The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause `'b'` to sort the same as `'a'`:

```
<reset>a</reset>
<i>b</i>
```

- Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

**Table 11.5 Abbreviated Shift Syntax**

| Abbreviated Syntax                    | Nonabbreviated Syntax   |
|---------------------------------------|---|
| <code>&lt;pc&gt;xyz&lt;/pc&gt;</code> | <code>&lt;p&gt;x&lt;/p&gt;&lt;p&gt;y&lt;/p&gt;&lt;p&gt;z&lt;/p&gt;</code> |
| <code>&lt;sc&gt;xyz&lt;/sc&gt;</code> | <code>&lt;s&gt;x&lt;/s&gt;&lt;s&gt;y&lt;/s&gt;&lt;s&gt;z&lt;/s&gt;</code> |
| <code>&lt;tc&gt;xyz&lt;/tc&gt;</code> | <code>&lt;t&gt;x&lt;/t&gt;&lt;t&gt;y&lt;/t&gt;&lt;t&gt;z&lt;/t&gt;</code> |
| <code>&lt;ic&gt;xyz&lt;/ic&gt;</code> | <code>&lt;i&gt;x&lt;/i&gt;&lt;i&gt;y&lt;/i&gt;&lt;i&gt;z&lt;/i&gt;</code> |

- An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put 'z' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>z</p>
```

- A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters 'xyz' greater at the primary level than 'a':

```
<reset>a</reset>
<p>xyz</p>
```

- Long expansions and long contractions can be used together. These rules put the sequence of three characters 'xyz' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>xyz</p>
```

- Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```
<reset>c</reset>
<x><s>k</s><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```
<reset>cs</reset>
<x><t>ccs</t><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

- Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '-' greater at the secondary level than 'a', but only when '-' occurs after 'b':

```
<reset>a</reset>
<x><context>b</context><s>-</s></x>
```

- Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```
<reset>a</reset>
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

- Reset rules permit a `before` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `before` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `before` attribute values specify the sort level by name or the equivalent numeric value:

```
<reset before="primary">
<reset before="1">

<reset before="secondary">
<reset before="2">

<reset before="tertiary">
<reset before="3">
```

- A reset rule can name a logical reset position rather than a literal character:

```
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
<first_primary_ignorable/>
<last_primary_ignorable/>
<first_variable/>
<last_variable/>
<first_non_ignorable/>
<last_non_ignorable/>
<first_trailing/>
<last_trailing/>
```

These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:

```
<reset><last_non_ignorable/></reset>
<p>z</p>
```

Logical positions have the code points shown in the following table.

**Table 11.6 Logical Reset Position Code Points**

| Logical Position                                | Unicode 4.0.0 Code Point | Unicode 5.2.0 Code Point |
|---|--------------------------|--------------------------|
| <code>&lt;first_non_ignorable/&gt;</code>       | U+02D0                   | U+02D0                   |
| <code>&lt;last_non_ignorable/&gt;</code>        | U+A48C                   | U+1342E                  |
| <code>&lt;first_primary_ignorable/&gt;</code>   | U+0332                   | U+0332                   |
| <code>&lt;last_primary_ignorable/&gt;</code>    | U+20EA                   | U+101FD                  |
| <code>&lt;first_secondary_ignorable/&gt;</code> | U+0000                   | U+0000                   |
| <code>&lt;last_secondary_ignorable/&gt;</code>  | U+FE73                   | U+FE73                   |
| <code>&lt;first_tertiary_ignorable/&gt;</code>  | U+0000                   | U+0000                   |
| <code>&lt;last_tertiary_ignorable/&gt;</code>   | U+FE73                   | U+FE73                   |
| <code>&lt;first_trailing/&gt;</code>            | U+0000                   | U+0000                   |

| Logical Position                     | Unicode 4.0.0 Code Point | Unicode 5.2.0 Code Point |
|--------------------------------------|--------------------------|--------------------------|
| <code>&lt;last_trailing/&gt;</code>  | U+0000                   | U+0000                   |
| <code>&lt;first_variable/&gt;</code> | U+0009                   | U+0009                   |
| <code>&lt;last_variable/&gt;</code>  | U+2183                   | U+1D371                  |

- The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:
  - `simple`: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
  - `expand`: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of 0E29 and 0E2A and we want to put all basic Latin letters between '0' and '1':

```
<reset>0</reset>
<pc>abcdefghijklmnopqrstuvwxyz</pc>
```

For simple shift mode, weights are calculated as follows:

```
'a' has weight 0E29+1
'b' has weight 0E29+2
'c' has weight 0E29+3
...
```

However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

```
'a' has weight [0E29][233D+1]
'b' has weight [0E29][233D+2]
'c' has weight [0E29][233D+3]
...
```

233D is the UCA 4.0.0 weight for character 0xA48C, which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses 3ACA, for character 0x1342E.

### MySQL-Specific LDML Extensions

An extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is 4.0.0. For example, this specification indicates a collation that is based on UCA 5.2.0:

```
<collation id="nnn" name="utf8_xxx_ci" version="5.2.0">
...
</collation>
```

#### 11.4.4.3 Diagnostics During Index.xml Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- Unknown tags are written to the error log. For example, the following message results if a collation definition contains a `<aaa>` tag:

```
[Warning] Buffered warning: Unknown LDML tag:
'charsets/charset/collation/rules/aaa'
```

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.
- Problems with collations generate warnings that clients can display with `SHOW WARNINGS`. Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

```
<reset>abcdefghi</reset>
<i>x</i>
```

An attempt to use the collation produces warnings:

```
mysql> SELECT _utf8'test' COLLATE utf8_test_ci;
ERROR 1273 (HY000): Unknown collation: 'utf8_test_ci'
mysql> SHOW WARNINGS;
```

| Level   | Code | Message                                |
|---------|------|--|
| Error   | 1273 | Unknown collation: 'utf8_test_ci'      |
| Warning | 1273 | Expansion is too long at 'abcdefghi=x' |

## 11.5 Character Set Configuration

You can change the default server character set and collation with the `--character-set-server` and `--collation-server` options when you start the server. The collation must be a legal collation for the default character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.) See [Section 6.1.4, “Server Command Options”](#).

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- Your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory). This can be fixed by using the `--character-sets-dir` option when you run the program in question. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 5.7/share/charsets"
```

- The character set is a complex character set that cannot be loaded dynamically. In this case, you must recompile the program with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See [Section 11.4.4, “Adding a UCA Collation to a Unicode Character Set”](#).

- The character set is a dynamic character set, but you do not have a configuration file for it. In this case, you should install the configuration file for the character set from a new MySQL distribution.
- If your character set index file does not contain the name for the character set, your program displays an error message. The file is named `Index.xml` and the message is:

Character set '*charset\_name*' is not a compiled character set and is not specified in the '/usr/share/mysql/charsets/Index.xml' file

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set`—that is, setting the client character set to match the system character set—should fix the problem.

For `MyISAM` tables, you can check the character set name and number for a table with `myisamchk -dvv tbl_name`.

## 11.6 MySQL Server Time Zone Support

MySQL Server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` system variable. The value does not change thereafter.

You can set the system time zone for MySQL Server at startup with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`. The permissible values for `--timezone` or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server's current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial value for `time_zone` is '`SYSTEM`', which indicates that the server time zone is the same as the system time zone.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone=timezone` option on the command line, or you can use the following line in an option file:

```
default-time-zone='timezone'
```

If you have the `SUPER` privilege, you can set the global server time zone value at runtime with this statement:

```
mysql> SET GLOBAL time_zone = timezone;
```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
mysql> SET time_zone = timezone;
```

The current session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values

stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the current time zone to UTC for storage, and from UTC to the current time zone for retrieval.

The current time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current values of the global and client-specific time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

`timezone` values can be given in several formats, none of which are case sensitive:

- The value `'SYSTEM'` indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as `'+10:00'` or `'-6:00'`.
- The value can be given as a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`. Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated.

## Populating the Time Zone Tables

Several tables in the `mysql` system database exist to maintain time zone information (see [Section 6.3, “The mysql System Database”](#)). The MySQL installation procedure creates the time zone tables, but does not load them. You must do so manually using the following instructions.

### Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See the notes at the end of this section.

If your system has its own `zoneinfo` database (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Solaris, and OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a `zoneinfo` database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or to generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone needs to account for leap seconds, initialize the leap second information like this, where `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

- After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

If your system is one that has no zoneinfo database (for example, Windows), you can use a package that is available for download at the MySQL Developer Zone:

```
http://dev.mysql.com/downloads/timezones.html
```

Download a time zone package that contains SQL statements and unpack it, then load the package file contents into the time zone tables:

```
shell> mysql -u root mysql < file_name
```

Then restart the server.

#### Warning

Do *not* use a downloadable package that contains `MyISAM` tables. MySQL 5.7.5 and up uses `InnoDB` for the time zone tables. Trying to replace them with `MyISAM` tables will cause problems.

#### Warning

Do not use a downloadable package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

For information about time zone settings in replication setup, please see [Section 18.4.1, “Replication Features and Issues”](#).

## 11.6.1 Staying Current with Time Zone Changes

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are two factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the Web site for your operating system vendor for an update that addresses the time changes.
- If you replace the system's `/etc/localtime` timezone file with a version that uses rules differing from those in effect at `mysqld` startup, you should restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.
- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date. If your system has its own zoneinfo database, you should reload the MySQL time zone tables whenever the zoneinfo database is updated. For systems that do not

have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables. For instructions for both methods, see [Populating the Time Zone Tables](#). `mysqld` caches time zone information that it looks up, so after updating the time zone tables, you should restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+-----+
| COUNT(*) |
+-----+
|          0 |
+-----+
```

A count of zero indicates that the table is empty. In this case, no one can be using named time zones, and you don't need to update the tables. A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, you should be sure to reload your time zone tables so that anyone who uses named time zones will get correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses these two queries:

```
SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you would see an incorrect result like this:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 02:00:00 |
+-----+
```

After updating the tables, you should see the correct result:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----+
| 2007-03-11 01:00:00 |
+-----+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+
```

```
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----+-----+
| 2007-03-11 01:00:00 |
+-----+-----+
```

## 11.6.2 Time Zone Leap Second Support

Leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values. The following example demonstrates this. It changes the local time zone to UTC so there is no difference between internal values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (
      a INT,
      ts TIMESTAMP DEFAULT NOW(),
      PRIMARY KEY (ts)
);
Query OK, 0 rows affected (0.01 sec)

mysql> -- change to UTC
mysql> SET time_zone = '+00:00';
Query OK, 0 rows affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:59'
mysql> SET timestamp = 1230767999;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:60'
mysql> SET timestamp = 1230768000;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.00 sec)

mysql> -- values differ internally but display the same
mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
+-----+-----+-----+
| a    | ts                | UNIX_TIMESTAMP(ts) |
+-----+-----+-----+
| 1    | 2008-12-31 23:59:59 | 1230767999         |
| 2    | 2008-12-31 23:59:59 | 1230768000         |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> -- only the non-leap value matches
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
+-----+-----+
| a    | ts                |
+-----+-----+
| 1    | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)

mysql> -- the leap value with seconds=60 is invalid
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
Empty set, 2 warnings (0.00 sec)
```

To work around this, you can use a comparison based on the UTC value actually stored in column, which has the leap second correction applied:

```
mysql> -- selecting using UNIX_TIMESTAMP value return leap value
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
+-----+-----+
| a      | ts      |
+-----+-----+
| 2      | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)
```

## 11.7 MySQL Server Locale Support

The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

The `lc_time_names` value does not affect the result from `FORMAT()`, but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable.

Locale names have language and region subtags listed by IANA (<http://www.iana.org/assignments/language-subtag-registry>) such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting, but you can set the value at server startup or set the `GLOBAL` value if you have the `SUPER` privilege. Any client can examine the value of `lc_time_names` or set its `SESSION` value to affect the locale for its own connection.

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| en_US           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| Friday                | January                  |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| Friday Fri January Jan                  |
+-----+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| es_MX           |
+-----+
1 row in set (0.00 sec)
```

```
mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| viernes                | enero                    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| viernes vie enero ene                    |
+-----+
1 row in set (0.00 sec)
```

The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

| 12.9 Choosing the Right Type for a Column .....   | 1528 |
| 12.10 Using Data Types from Other Database Engines .....                                      | 1528 |

MySQL supports a number of [SQL](#) data types in several categories: numeric types, date and time types, string (character and byte) types, spatial types, and the [JSON](#) data type. This chapter provides an overview of these data types, a more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overview is intentionally brief. The more detailed descriptions later in the chapter should be consulted for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- [M](#) indicates the maximum display width for integer types. For floating-point and fixed-point types, [M](#) is the total number of digits that can be stored (the precision). For string types, [M](#) is the maximum length. The maximum permissible value of [M](#) depends on the data type.
- [D](#) applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than [M](#)–2.

- *fsp* applies to the `TIME`, `DATETIME`, and `TIMESTAMP` types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The *fsp* value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)
- Square brackets (`[` and `]`) indicate optional parts of type definitions.

## 12.1 Data Type Overview

### 12.1.1 Numeric Type Overview

A summary of the numeric data types follows. For additional information about properties and storage requirements of the numeric types, see [Section 12.2, “Numeric Types”](#), and [Section 12.8, “Data Type Storage Requirements”](#).

*M* indicates the maximum display width for integer types. The maximum display width is 255. Display width is unrelated to the range of values a type can contain, as described in [Section 12.2, “Numeric Types”](#). For floating-point and fixed-point types, *M* is the total number of digits that can be stored.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

#### Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled. See [Section 13.10, “Cast Functions and Operators”](#).

- `BIT[(M)]`

A bit-value type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

- `TINYINT[(M)] [UNSIGNED] [ZEROFILL]`

A very small integer. The signed range is `-128` to `127`. The unsigned range is `0` to `255`.

- `BOOL`, `BOOLEAN`

These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false                  |
+-----+

mysql> SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
| true                   |
+-----+
```

```
+-----+
mysql> SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
| true                    |
+-----+
```

However, the values `TRUE` and `FALSE` are merely aliases for `1` and `0`, respectively, as shown here:

```
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
| true                            |
+-----+

mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false') |
+-----+
| true                          |
+-----+

mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false') |
+-----+
| false                         |
+-----+

mysql> SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false                         |
+-----+
```

The last two statements display the results shown because `2` is equal to neither `1` nor `0`.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is `-32768` to `32767`. The unsigned range is `0` to `65535`.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-sized integer. The signed range is `-8388608` to `8388607`. The unsigned range is `0` to `16777215`.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is `-2147483648` to `2147483647`. The unsigned range is `0` to `4294967295`.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This type is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you should not use unsigned big integers larger than `9223372036854775807` (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.
- In `MIN(col_name)` or `MAX(col_name)`, where `col_name` refers to a `BIGINT` column.
- When using operators (+, -, \*, and so on) where both operands are integers.
- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The -, +, and \* operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than `9223372036854775807`.
- `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`

A packed “exact” fixed-point number. *M* is the total number of digits (the precision) and *D* is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the - sign are not counted in *M*. If *D* is 0, values have no decimal point or fractional part. The maximum number of digits (*M*) for `DECIMAL` is 65. The maximum number of supported decimals (*D*) is 30. If *D* is omitted, the default is 0. If *M* is omitted, the default is 10.

`UNSIGNED`, if specified, disallows negative values.

All basic calculations (+, -, \*, /) with `DECIMAL` columns are done with a precision of 65 digits.

- `DEC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DECIMAL`. The `FIXED` synonym is available for compatibility with other database systems.

- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`

A small (single-precision) floating-point number. Permissible values are `-3.402823466E+38` to `-1.175494351E-38`, 0, and `1.175494351E-38` to `3.402823466E+38`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

*M* is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

`UNSIGNED`, if specified, disallows negative values.

Using `FLOAT` might give you some unexpected problems because all calculations in MySQL are done with double precision. See [Section B.5.4.7, “Solving Problems with No Matching Rows”](#).

- `DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]`

A normal-size (double-precision) floating-point number. Permissible values are `-1.7976931348623157E+308` to `-2.2250738585072014E-308`, 0, and `2.2250738585072014E-308` to `1.7976931348623157E+308`. These are the theoretical limits,

based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

*M* is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

**UNSIGNED**, if specified, disallows negative values.

- `DOUBLE PRECISION[(M,D)] [UNSIGNED] [ZEROFILL], REAL[(M,D)] [UNSIGNED] [ZEROFILL]`

These types are synonyms for **DOUBLE**. Exception: If the **REAL\_AS\_FLOAT** SQL mode is enabled, **REAL** is a synonym for **FLOAT** rather than **DOUBLE**.

- `FLOAT(p) [UNSIGNED] [ZEROFILL]`

A floating-point number. *p* represents the precision in bits, but MySQL uses this value only to determine whether to use **FLOAT** or **DOUBLE** for the resulting data type. If *p* is from 0 to 24, the data type becomes **FLOAT** with no *M* or *D* values. If *p* is from 25 to 53, the data type becomes **DOUBLE** with no *M* or *D* values. The range of the resulting column is the same as for the single-precision **FLOAT** or double-precision **DOUBLE** data types described earlier in this section.

`FLOAT(p)` syntax is provided for ODBC compatibility.

## 12.1.2 Date and Time Type Overview

A summary of the temporal data types follows. For additional information about properties and storage requirements of the temporal types, see [Section 12.3, “Date and Time Types”](#), and [Section 12.8, “Data Type Storage Requirements”](#). For descriptions of functions that operate on temporal values, see [Section 13.7, “Date and Time Functions”](#).

For the **DATE** and **DATETIME** range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL permits fractional seconds for **TIME**, **DATETIME**, and **TIMESTAMP** values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where *type\_name* is **TIME**, **DATETIME**, or **TIMESTAMP**, and *fsp* is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The *fsp* value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

Any **TIMESTAMP** or **DATETIME** column in a table can have automatic initialization and updating properties.

- DATE**

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays **DATE** values in 'YYYY-MM-DD' format, but permits assignment of values to **DATE** columns using either strings or numbers.

- `DATETIME[(fsp)]`

A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. MySQL displays **DATETIME** values in 'YYYY-MM-DD HH:MM:SS[.fraction]' format, but permits assignment of values to **DATETIME** columns using either strings or numbers.

An optional *fsp* value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

Automatic initialization and updating to the current date and time for `DATETIME` columns can be specified using `DEFAULT` and `ON UPDATE` column definition clauses, as described in [Section 12.3.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#).

- `TIMESTAMP[ ( fsp ) ]`

A timestamp. The range is '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC. `TIMESTAMP` values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A `TIMESTAMP` cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the “zero” `TIMESTAMP` value.

An optional *fsp* value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

The way the server handles `TIMESTAMP` definitions depends on the value of the `explicit_defaults_for_timestamp` system variable (see [Section 6.1.5, “Server System Variables”](#)). By default, `explicit_defaults_for_timestamp` is disabled and the server handles `TIMESTAMP` as follows:

Unless specified otherwise, the first `TIMESTAMP` column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes `TIMESTAMP` useful for recording the timestamp of an `INSERT` or `UPDATE` operation. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default, the first `TIMESTAMP` column has these properties, as previously noted. However, any `TIMESTAMP` column in a table can be defined to have these properties.

If `explicit_defaults_for_timestamp` is enabled, there is no automatic assignment of the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes to any `TIMESTAMP` column. They must be included explicitly in the column definition. Also, any `TIMESTAMP` not explicitly declared as `NOT NULL` permits `NULL` values.

- `TIME[ ( fsp ) ]`

A time. The range is '-838:59:59.000000' to '838:59:59.000000'. MySQL displays `TIME` values in 'HH:MM:SS[.fraction]' format, but permits assignment of values to `TIME` columns using either strings or numbers.

An optional *fsp* value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- `YEAR[ ( 4 ) ]`

A year in four-digit format. MySQL displays `YEAR` values in `YYYY` format, but permits assignment of values to `YEAR` columns using either strings or numbers. Values display as 1901 to 2155, and 0000.

**Note**

The `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. To convert `YEAR(2)` columns to `YEAR(4)`, see [Section 12.3.4, “`YEAR\(2\)` Limitations and Migrating to `YEAR\(4\)`”](#).

For additional information about [YEAR](#) display format and interpretation of input values, see [Section 12.3.3, “The YEAR Type”](#).

The [SUM\(\)](#) and [AVG\(\)](#) aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

#### Note

The MySQL server can be run with the [MAXDB](#) SQL mode enabled. In this case, [TIMESTAMP](#) is identical with [DATETIME](#). If this mode is enabled at the time that a table is created, [TIMESTAMP](#) columns are created as [DATETIME](#) columns. As a result, such columns use [DATETIME](#) display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See [Section 6.1.8, “Server SQL Modes”](#).

### 12.1.3 String Type Overview

A summary of the string data types follows. For additional information about properties and storage requirements of the string types, see [Section 12.4, “String Types”](#), and [Section 12.8, “Data Type Storage Requirements”](#).

In some cases, MySQL may change a string column to a type different from that given in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. See [Section 14.1.18.6, “Silent Column Specification Changes”](#).

MySQL interprets length specifications in character column definitions in character units. This applies to [CHAR](#), [VARCHAR](#), and the [TEXT](#) types.

Column definitions for many string data types can include attributes that specify the character set or collation of the column. These attributes apply to the [CHAR](#), [VARCHAR](#), the [TEXT](#) types, [ENUM](#), and [SET](#) data types:

- The [CHARACTER SET](#) attribute specifies the character set, and the [COLLATE](#) attribute specifies a collation for the character set. For example:

```
CREATE TABLE t
(
  c1 VARCHAR(20) CHARACTER SET utf8,
  c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named [c1](#) that has a character set of [utf8](#) with the default collation for that character set, and a column named [c2](#) that has a character set of [latin1](#) and a case-sensitive collation.

The rules for assigning the character set and collation when either or both of the [CHARACTER SET](#) and [COLLATE](#) attributes are missing are described in [Section 11.1.3.5, “Column Character Set and Collation”](#).

[CHARSET](#) is a synonym for [CHARACTER SET](#).

- Specifying the [CHARACTER SET binary](#) attribute for a character string data type causes the column to be created as the corresponding binary string data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- The `BINARY` attribute is shorthand for specifying the table default character set and the binary (`_bin`) collation of that character set. In this case, comparison and sorting are based on numeric character code values.
- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`.
- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`.

Character column comparison and sorting are based on the collation assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary (`_bin`) collation or the `BINARY` attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see [Section 11.1, “Character Set Support”](#).

- `[NATIONAL] CHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A fixed-length string that is always right-padded with spaces to the specified length when stored. *M* represents the column length in characters. The range of *M* is 0 to 255. If *M* is omitted, the length is 1.

#### Note

Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

`CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. [Section 11.1.3.7, “The National Character Set”](#).

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you have to be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `''` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A variable-length string. *M* represents the maximum column length in characters. The range of *M* is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8`

characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

MySQL stores `VARCHAR` values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

#### Note

MySQL follows the standard SQL specification, and does *not* remove trailing spaces from `VARCHAR` values.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. [Section 11.1.3.7, “The National Character Set”](#). `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY(M)`

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. `M` represents the column length in bytes.

- `VARBINARY(M)`

The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. `M` represents the maximum column length in bytes.

- `TINYBLOB`

A `BLOB` column with a maximum length of 255 ( $2^8 - 1$ ) bytes. Each `TINYBLOB` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 255 ( $2^8 - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. Each `TINYTEXT` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `BLOB(M)`

A `BLOB` column with a maximum length of 65,535 ( $2^{16} - 1$ ) bytes. Each `BLOB` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length `M` can be given for this type. If this is done, MySQL creates the column as the smallest `BLOB` type large enough to hold values `M` bytes long.

- `TEXT(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 65,535 ( $2^{16} - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. Each `TEXT` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length `M` can be given for this type. If this is done, MySQL creates the column as the smallest `TEXT` type large enough to hold values `M` characters long.

- `MEDIUMBLOB`

A `BLOB` column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) bytes. Each `MEDIUMBLOB` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- `MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A **TEXT** column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. Each **MEDIUMTEXT** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **LONGBLOB**

A **BLOB** column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) bytes. The effective maximum length of **LONGBLOB** columns depends on the configured maximum packet size in the client/server protocol and available memory. Each **LONGBLOB** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **LONGTEXT** [**CHARACTER SET** *charset\_name*] [**COLLATE** *collation\_name*]

A **TEXT** column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of **LONGTEXT** columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each **LONGTEXT** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **ENUM**('value1', 'value2', ...) [**CHARACTER SET** *charset\_name*] [**COLLATE** *collation\_name*]

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., **NULL** or the special '' error value. **ENUM** values are represented internally as integers.

An **ENUM** column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its **ENUM** and **SET** columns considered as a group. For more information on these limits, see [Section C.10.5, “Limits Imposed by .frm File Structure”](#).

- **SET**('value1', 'value2', ...) [**CHARACTER SET** *charset\_name*] [**COLLATE** *collation\_name*]

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... **SET** values are represented internally as integers.

A **SET** column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its **ENUM** and **SET** columns considered as a group. For more information on this limit, see [Section C.10.5, “Limits Imposed by .frm File Structure”](#).

## 12.2 Numeric Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (**INTEGER**, **SMALLINT**, **DECIMAL**, and **NUMERIC**), as well as the approximate numeric data types (**FLOAT**, **REAL**, and **DOUBLE PRECISION**). The keyword **INT** is a synonym for **INTEGER**, and the keywords **DEC** and **FIXED** are synonyms for **DECIMAL**. MySQL treats **DOUBLE** as a synonym for **DOUBLE PRECISION** (a nonstandard extension). MySQL also treats **REAL** as a synonym for **DOUBLE PRECISION** (a nonstandard variation), unless the **REAL\_AS\_FLOAT** SQL mode is enabled.

The **BIT** data type stores bit values and is supported for **MyISAM**, **MEMORY**, **InnoDB**, and **NDB** tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see [Section 12.2.6, “Out-of-Range and Overflow Handling”](#).

For information about numeric type storage requirements, see [Section 12.8, “Data Type Storage Requirements”](#).

The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see [Section 13.6.1, “Arithmetic Operators”](#).

### 12.2.1 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types [INTEGER](#) (or [INT](#)) and [SMALLINT](#). As an extension to the standard, MySQL also supports the integer types [TINYINT](#), [MEDIUMINT](#), and [BIGINT](#). The following table shows the required storage and range for each integer type.

| Type                      | Storage<br>(Bytes) | Minimum Value<br>(Signed/Unsigned) | Maximum Value<br>(Signed/Unsigned)          |
|---------------------------|--------------------|------------------------------------|---|
| <a href="#">TINYINT</a>   | 1                  | -128<br>0                          | 127<br>255                                  |
| <a href="#">SMALLINT</a>  | 2                  | -32768<br>0                        | 32767<br>65535                              |
| <a href="#">MEDIUMINT</a> | 3                  | -8388608<br>0                      | 8388607<br>16777215                         |
| <a href="#">INT</a>       | 4                  | -2147483648<br>0                   | 2147483647<br>4294967295                    |
| <a href="#">BIGINT</a>    | 8                  | -9223372036854775808<br>0          | 9223372036854775807<br>18446744073709551615 |

### 12.2.2 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The [DECIMAL](#) and [NUMERIC](#) types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, [NUMERIC](#) is implemented as [DECIMAL](#), so the following remarks about [DECIMAL](#) apply equally to [NUMERIC](#).

MySQL stores [DECIMAL](#) values in binary format. See [Section 13.21](#), “Precision Math”.

In a [DECIMAL](#) column declaration, the precision and scale can be (and usually is) specified; for example:

```
salary DECIMAL(5,2)
```

In this example, [5](#) is the precision and [2](#) is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that [DECIMAL\(5,2\)](#) be able to store any value with five digits and two decimals, so values that can be stored in the [salary](#) column range from [-999.99](#) to [999.99](#).

In standard SQL, the syntax [DECIMAL\(M\)](#) is equivalent to [DECIMAL\(M,0\)](#). Similarly, the syntax [DECIMAL](#) is equivalent to [DECIMAL\(M,0\)](#), where the implementation is permitted to decide the value of [M](#). MySQL supports both of these variant forms of [DECIMAL](#) syntax. The default value of [M](#) is 10.

If the scale is 0, [DECIMAL](#) values contain no decimal point or fractional part.

The maximum number of digits for [DECIMAL](#) is 65, but the actual range for a given [DECIMAL](#) column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

### 12.2.3 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The [FLOAT](#) and [DOUBLE](#) types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For `FLOAT`, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses. MySQL also supports this optional precision specification, but the precision value is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an 8-byte double-precision `DOUBLE` column.

MySQL permits a nonstandard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here,  $(M,D)$  means that values can be stored with up to  $M$  digits in total, of which  $D$  digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see [Section B.5.4.8, “Problems with Floating-Point Values”](#)

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

## 12.2.4 Bit-Value Type - BIT

The `BIT` data type is used to store bit values. A type of `BIT(M)` enables storage of  $M$ -bit values.  $M$  can range from 1 to 64.

To specify bit values, `b'value'` notation can be used. `value` is a binary value written using zeros and ones. For example, `b'111'` and `b'1000000'` represent 7 and 128, respectively. See [Section 10.1.5, “Bit-Value Literals”](#).

If you assign a value to a `BIT(M)` column that is less than  $M$  bits long, the value is padded on the left with zeros. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

**MySQL Cluster.** The maximum combined size of all `BIT` columns used in a given `NDB` table must not exceed 4096 bits.

## 12.2.5 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, `INT(4)` specifies an `INT` with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used or not is up to the application.)

The display width does *not* constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of `-32768` to `32767`, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) attribute `ZEROFILL`, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(4) ZEROFILL`, a value of 5 is retrieved as `0005`.

### Note

The `ZEROFILL` attribute is ignored when a column is involved in expressions or `UNION` queries.

If you store values larger than the display width in an integer column that has the `ZEROFILL` attribute, you may experience problems when MySQL generates

temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

All integer types can have an optional (nonstandard) attribute `UNSIGNED`. Unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift from `-2147483648` and `2147483647` up to `0` and `4294967295`.

Floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Integer or floating-point data types can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. (`AUTO_INCREMENT` sequences begin with `1`.)

Storing `0` into an `AUTO_INCREMENT` column has the same effect as storing `NULL`, unless the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled.

Inserting `NULL` to generate `AUTO_INCREMENT` values requires that the column be declared `NOT NULL`. If the column is declared `NULL`, inserting `NULL` stores a `NULL`. When you insert any other value into an `AUTO_INCREMENT` column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

In MySQL 5.7, negative values for `AUTO_INCREMENT` columns are not supported.

## 12.2.6 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range. If you store `256` into a `TINYINT` or `TINYINT UNSIGNED` column, MySQL stores `127` or `255`, respectively.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Column-assignment conversions that occur due to clipping when MySQL is not operating in strict mode are reported as warnings for `ALTER TABLE`, `LOAD DATA INFILE`, `UPDATE`, and multiple-row `INSERT` statements. In strict mode, these statements fail, and some or all the values will not be inserted or changed, depending on whether the table is a transactional table and other factors. For details, see [Section 6.1.8, "Server SQL Modes"](#).

Overflow during numeric expression evaluation results in an error. For example, the largest signed `BIGINT` value is `9223372036854775807`, so the following expression produces an error:

```
mysql> SELECT 9223372036854775807 + 1;
```

```
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned;

```
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-----+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-----+
| 9223372036854775808 |
+-----+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```
mysql> SELECT 9223372036854775807.0 + 1;
+-----+
| 9223372036854775807.0 + 1 |
+-----+
| 9223372036854775808.0 |
+-----+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

## 12.3 Date and Time Types

The date and time types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The `TIMESTAMP` type has special automatic updating behavior, described later. For temporal type storage requirements, see [Section 12.8, “Data Type Storage Requirements”](#).

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see [Section 10.1.3, “Date and Time Literals”](#). It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.

- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, '98-09-04'), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, '09-04-98', '04-09-98').
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  - Year values in the range 70-99 are converted to 1970-1999.
  - Year values in the range 00-69 are converted to 2000-2069.

See also [Section 12.3.8, “Two-Digit Years in Dates”](#).

- Conversion of values from one temporal type to another occurs according to the rules in [Section 12.3.7, “Conversion Between Date and Time Types”](#).
- MySQL automatically converts a date or time value to a number if the value is used in a numeric context and vice versa.
- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range [TIME](#) values are clipped to the appropriate endpoint of the [TIME](#) range.
- By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See [Section 6.1.8, “Server SQL Modes”](#).) You can get MySQL to accept certain dates, such as '2009-11-31', by enabling the [ALLOW\\_INVALID\\_DATES](#) SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.
- MySQL permits you to store dates where the day or month and day are zero in a [DATE](#) or [DATETIME](#) column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as '2009-00-00' or '2009-01-00'. If you store dates such as these, you should not expect to get correct results for functions such as [DATE\\_SUB\(\)](#) or [DATE\\_ADD\(\)](#) that require complete dates. To disallow zero month or day parts in dates, enable the [NO\\_ZERO\\_IN\\_DATE](#) mode.
- MySQL permits you to store a “zero” value of '0000-00-00' as a “dummy date.” This is in some cases more convenient than using [NULL](#) values, and uses less data and index space. To disallow '0000-00-00', enable the [NO\\_ZERO\\_DATE](#) mode.
- “Zero” date or time values used through Connector/ODBC are converted automatically to [NULL](#) because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values '0' or 0, which are easier to write. For temporal types that include a date part ([DATE](#), [DATETIME](#), and [TIMESTAMP](#)), use of these values produces warnings if the [NO\\_ZERO\\_DATE](#) SQL mode is enabled.

| Data Type                 | “Zero” Value          |
|---------------------------|-----------------------|
| <a href="#">DATE</a>      | '0000-00-00'          |
| <a href="#">TIME</a>      | '00:00:00'            |
| <a href="#">DATETIME</a>  | '0000-00-00 00:00:00' |
| <a href="#">TIMESTAMP</a> | '0000-00-00 00:00:00' |
| <a href="#">YEAR</a>      | 0000                  |

## 12.3.1 The DATE, DATETIME, and TIMESTAMP Types

The [DATE](#), [DATETIME](#), and [TIMESTAMP](#) types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes [DATE](#), [DATETIME](#), and [TIMESTAMP](#) values in several formats, described in [Section 10.1.3, “Date and Time Literals”](#). For the [DATE](#) and [DATETIME](#) range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The [DATE](#) type is used for values with a date part but no time part. MySQL retrieves and displays [DATE](#) values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

The [DATETIME](#) type is used for values that contain both date and time parts. MySQL retrieves and displays [DATETIME](#) values in 'YYYY-MM-DD HH:MM:SS' format. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.

The [TIMESTAMP](#) data type is used for values that contain both date and time parts. [TIMESTAMP](#) has a range of '1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC.

A [DATETIME](#) or [TIMESTAMP](#) value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. In particular, any fractional part in a value inserted into a [DATETIME](#) or [TIMESTAMP](#) column is stored rather than discarded. With the fractional part included, the format for these values is 'YYYY-MM-DD HH:MM:SS[.fraction]', the range for [DATETIME](#) values is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999', and the range for [TIMESTAMP](#) values is '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.999999'. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 12.3.6, “Fractional Seconds in Time Values”](#).

The [TIMESTAMP](#) and [DATETIME](#) data types offer automatic initialization and updating to the current date and time. For more information, see [Section 12.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

MySQL converts [TIMESTAMP](#) values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as [DATETIME](#).) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a [TIMESTAMP](#) value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable. For more information, see [Section 11.6, “MySQL Server Time Zone Support”](#).

Invalid [DATE](#), [DATETIME](#), or [TIMESTAMP](#) values are converted to the “zero” value of the appropriate type ('0000-00-00' or '0000-00-00 00:00:00').

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as '10:11:12' might look like a time value because of the :, but is interpreted as the year '2010-11-12' if used in a date context. The value '10:45:15' is converted to '0000-00-00' because '45' is not a valid month.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`. See [Section 6.1.8, “Server SQL Modes”](#), for more information.

- MySQL does not accept `TIMEESTAMP` values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value `'0000-00-00 00:00:00'`.
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  - Year values in the range `00-69` are converted to `2000-2069`.
  - Year values in the range `70-99` are converted to `1970-1999`.

See also [Section 12.3.8, “Two-Digit Years in Dates”](#).

#### Note

The MySQL server can be run with the `MAXDB` SQL mode enabled. In this case, `TIMEESTAMP` is identical with `DATETIME`. If this mode is enabled at the time that a table is created, `TIMEESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See [Section 6.1.8, “Server SQL Modes”](#).

## 12.3.2 The TIME Type

MySQL retrieves and displays `TIME` values in `'HH:MM:SS'` format (or `'HHH:MM:SS'` format for large hours values). `TIME` values may range from `'-838:59:59'` to `'838:59:59'`. The hours part may be so large because the `TIME` type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes `TIME` values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See [Section 10.1.3, “Date and Time Literals”](#). For information about fractional seconds support in MySQL, see [Section 12.3.6, “Fractional Seconds in Time Values”](#). In particular, any fractional part in a value inserted into a `TIME` column is stored rather than discarded. With the fractional part included, the range for `TIME` values is `'-838:59:59.000000'` to `'838:59:59.000000'`.

Be careful about assigning abbreviated values to a `TIME` column. MySQL interprets abbreviated `TIME` values with colons as time of the day. That is, `'11:12'` means `'11:12:00'`, not `'00:11:12'`. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`.

The only delimiter recognized between a time part and a fractional seconds part is the decimal point.

By default, values that lie outside the `TIME` range but are otherwise valid are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to `'-838:59:59'` and `'838:59:59'`. Invalid `TIME` values are converted to `'00:00:00'`. Note that because `'00:00:00'` is itself a valid `TIME` value, there is no way to tell, from a value of `'00:00:00'` stored in a table, whether the original value was specified as `'00:00:00'` or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See [Section 6.1.8, “Server SQL Modes”](#).

## 12.3.3 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR` or `YEAR(4)` and has a display width of four characters.

**Note**

The `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. To convert `YEAR(2)` columns to `YEAR(4)`, see [Section 12.3.4, “YEAR\(2\) Limitations and Migrating to YEAR\(4\)”](#).

MySQL displays `YEAR` values in `YYYY` format, with a range of 1901 to 2155, or 0000.

You can specify input `YEAR` values in a variety of formats:

- As a 4-digit number in the range 1901 to 2155.
- As a 4-digit string in the range '1901' to '2155'.
- As a 1- or 2-digit number in the range 1 to 99. MySQL converts values in the ranges 1 to 69 and 70 to 99 to `YEAR` values in the ranges 2001 to 2069 and 1970 to 1999.
- As a 1- or 2-digit string in the range '0' to '99'. MySQL converts values in the ranges '0' to '69' and '70' to '99' to `YEAR` values in the ranges 2000 to 2069 and 1970 to 1999.
- The result of inserting a numeric 0 has a display value of 0000 and an internal value of 0000. To insert zero and have it be interpreted as 2000, specify it as a string '0' or '00'.
- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()`.

MySQL converts invalid `YEAR` values to 0000.

See also [Section 12.3.8, “Two-Digit Years in Dates”](#).

## 12.3.4 YEAR(2) Limitations and Migrating to YEAR(4)

This section describes problems that can occur when using `YEAR(2)` and provides information about converting existing `YEAR(2)` columns to `YEAR(4)`.

Although the internal range of values for `YEAR(4)` and the deprecated `YEAR(2)` type is the same (1901 to 2155, and 0000), the display width for `YEAR(2)` makes that type inherently ambiguous because displayed values indicate only the last two digits of the internal values and omit the century digits. The result can be a loss of information under certain circumstances. For this reason, before MySQL 5.7.5, avoid using `YEAR(2)` in your applications and use `YEAR(4)` wherever you need a `YEAR` data type. As of MySQL 5.7.5, support for `YEAR(2)` is removed and existing `YEAR(2)` columns must be converted to `YEAR(4)` to become usable again.

### YEAR(2) Limitations

Issues with the `YEAR(2)` data type include ambiguity of displayed values, and possible loss of information when values are dumped and reloaded or converted to strings.

- Displayed `YEAR(2)` values can be ambiguous. It is possible for up to three `YEAR(2)` values that have different internal values to have the same displayed value, as the following example demonstrates:

```
mysql> CREATE TABLE t (y2 YEAR(2), y4 YEAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t (y2) VALUES(1912),(2012),(2112);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> UPDATE t SET y4 = y2;
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0

mysql> SELECT * FROM t;
+-----+-----+
```

```

+----+----+
| y2 | y4 |
+----+----+
| 12 | 1912 |
| 12 | 2012 |
| 12 | 2112 |
+----+----+
3 rows in set (0.00 sec)

```

- If you use `mysqldump` to dump the table created in the preceding item, the dump file represents all `y2` values using the same 2-digit representation (12). If you reload the table from the dump file, all resulting rows have internal value 2012 and display value 12, thus losing the distinctions among them.
- Conversion of a `YEAR(2)` or `YEAR(4)` data value to string form uses the display width of the `YEAR` type. Suppose that `YEAR(2)` and `YEAR(4)` columns both contain the value 1970. Assigning each column to a string results in a value of '70' or '1970', respectively. That is, loss of information occurs for conversion from `YEAR(2)` to string.
- Values outside the range from 1970 to 2069 are stored incorrectly when inserted into a `YEAR(2)` column in a `CSV` table. For example, inserting 2111 results in a display value of 11 but an internal value of 2011.

To avoid these problems, use `YEAR(4)` rather than `YEAR(2)`. Suggestions regarding migration strategies appear later in this section.

## Reduced/Removed YEAR(2) Support in MySQL 5.7

Before MySQL 5.7.5, support for `YEAR(2)` is diminished. As of MySQL 5.7.5, support for `YEAR(2)` is removed.

- `YEAR(2)` column definitions for new tables produce warnings or errors:
- Before MySQL 5.7.5, `YEAR(2)` column definitions for new tables are converted (with an `ER_INVALID_YEAR_COLUMN_LENGTH` warning) to `YEAR(4)`:

```

mysql> CREATE TABLE t1 (y YEAR(2));
Query OK, 0 rows affected, 1 warning (0.04 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Warning
      Code: 1818
      Message: YEAR(2) column type is deprecated. Creating YEAR(4) column instead.
1 row in set (0.00 sec)

mysql> SHOW CREATE TABLE t1\G
***** 1. row *****
      Table: t1
      Create Table: CREATE TABLE `t1` (
        `y` year(4) DEFAULT NULL
      ) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

```

- As of MySQL 5.7.5, `YEAR(2)` column definitions for new tables produce an `ER_INVALID_YEAR_COLUMN_LENGTH` error:

```

mysql> CREATE TABLE t1 (y YEAR(2));
ERROR 1818 (HY000): Supports only YEAR or YEAR(4) column.

```

- `YEAR(2)` column in existing tables remain as `YEAR(2)`:
- Before MySQL 5.7.5, `YEAR(2)` is processed in queries as in older versions of MySQL.
- As of MySQL 5.7.5, `YEAR(2)` columns in queries produce warnings or errors.

- Several programs or statements convert `YEAR(2)` to `YEAR(4)` automatically:
  - `ALTER TABLE` statements that result in a table rebuild.
  - `REPAIR TABLE` (which `CHECK TABLE` recommends you use if it finds that a table contains `YEAR(2)` columns).
  - `mysql_upgrade` (which uses `REPAIR TABLE`).
- Dumping with `mysqldump` and reloading the dump file. Unlike the conversions performed by the preceding three items, a dump and reload has the potential to change values.

A MySQL upgrade usually involves at least one of the last two items. However, with respect to `YEAR(2)`, `mysql_upgrade` is preferable. You should avoid using `mysqldump` because, as noted, that can change values.

## Migrating from YEAR(2) to YEAR(4)

To convert `YEAR(2)` columns to `YEAR(4)`, you can do so manually at any time without upgrading. Alternatively, you can upgrade to a version of MySQL with reduced or removed support for `YEAR(2)` (MySQL 5.6.6 or later), then have MySQL convert `YEAR(2)` columns automatically. In the latter case, avoid upgrading by dumping and reloading your data because that can change data values. In addition, if you use replication, there are upgrade considerations you must take into account.

To convert `YEAR(2)` columns to `YEAR(4)` manually, use `ALTER TABLE` or `REPAIR TABLE`. Suppose that a table `t1` has this definition:

```
CREATE TABLE t1 (ycol YEAR(2) NOT NULL DEFAULT '70');
```

Modify the column using `ALTER TABLE` as follows:

```
ALTER TABLE t1 FORCE;
```

The `ALTER TABLE` statement converts the table without changing `YEAR(2)` values. If the server is a replication master, the `ALTER TABLE` statement replicates to slaves and makes the corresponding table change on each one.

Another migration method is to perform a binary upgrade: Install MySQL without dumping and reloading your data. Then run `mysql_upgrade`, which uses `REPAIR TABLE` to convert `YEAR(2)` columns to `YEAR(4)` without changing data values. If the server is a replication master, the `REPAIR TABLE` statements replicate to slaves and make the corresponding table changes on each one, unless you invoke `mysql_upgrade` with the `--skip-write-binlog` option.

Upgrades to replication servers usually involve upgrading slaves to a newer version of MySQL, then upgrading the master. For example, if a master and slave both run MySQL 5.5, a typical upgrade sequence involves upgrading the slave to 5.6, then upgrading the master to 5.6. With regard to the different treatment of `YEAR(2)` as of MySQL 5.6.6, that upgrade sequence results in a problem: Suppose that the slave has been upgraded but not yet the master. Then creating a table containing a `YEAR(2)` column on the master results in a table containing a `YEAR(4)` column on the slave. Consequently, these operations will have a different result on the master and slave, if you use statement-based replication:

- Inserting numeric 0. The resulting value has an internal value of 2000 on the master but 0000 on the slave.
- Converting `YEAR(2)` to string. This operation uses the display value of `YEAR(2)` on the master but `YEAR(4)` on the slave.

To avoid such problems, modify all `YEAR(2)` columns on the master to `YEAR(4)` before upgrading. (Use `ALTER TABLE`, as described previously.) Then you can upgrade normally (slave first, then master) without introducing any `YEAR(2)` to `YEAR(4)` differences between the master and slave.

One migration method should be avoided: Do not dump your data with `mysqldump` and reload the dump file after upgrading. This has the potential to change `YEAR(2)` values, as described previously.

A migration from `YEAR(2)` to `YEAR(4)` should also involve examining application code for the possibility of changed behavior under conditions such as these:

- Code that expects selecting a `YEAR` column to produce exactly two digits.
- Code that does not account for different handling for inserts of numeric 0: Inserting 0 into `YEAR(2)` or `YEAR(4)` results in an internal value of 2000 or 0000, respectively.

### 12.3.5 Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`

`TIMESTAMP` and `DATETIME` columns can be automatically initialized and updated to the current date and time (that is, the current timestamp).

For any `TIMESTAMP` or `DATETIME` column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.
- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to `CURRENT_TIMESTAMP`).

In addition, you can initialize or update any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

To specify automatic properties, use the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for `CURRENT_TIMESTAMP` have the same meaning as `CURRENT_TIMESTAMP`. These are `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.

Use of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` is specific to `TIMESTAMP` and `DATETIME`. The `DEFAULT` clause also can be used to specify a constant (nonautomatic) default value; for example, `DEFAULT 0` or `DEFAULT '2000-01-01 00:00:00'`.

#### Note

The following examples use `DEFAULT 0`, a default that can produce warnings or errors depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See [Section 6.1.8, “Server SQL Modes”](#).

`TIMESTAMP` or `DATETIME` column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

- With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);
```

- With a `DEFAULT` clause but no `ON UPDATE CURRENT_TIMESTAMP` clause, the column has the given default value and is not automatically updated to the current timestamp.

The default depends on whether the `DEFAULT` clause specifies `CURRENT_TIMESTAMP` or a constant value. With `CURRENT_TIMESTAMP`, the default is the current timestamp.

```
CREATE TABLE t1 (  
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,  
  dt DATETIME DEFAULT CURRENT_TIMESTAMP  
);
```

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```
CREATE TABLE t1 (  
  ts TIMESTAMP DEFAULT 0,  
  dt DATETIME DEFAULT 0  
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause and a constant `DEFAULT` clause, the column is automatically updated to the current timestamp and has the given constant default value.

```
CREATE TABLE t1 (  
  ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP,  
  dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP  
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause but no `DEFAULT` clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.

The default in this case is type dependent. `TIMESTAMP` has a default of 0 unless defined with the `NULL` attribute, in which case the default is `NULL`.

```
CREATE TABLE t1 (  
  ts1 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,      -- default 0  
  ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL  
);
```

`DATETIME` has a default of `NULL` unless defined with the `NOT NULL` attribute, in which case the default is 0.

```
CREATE TABLE t1 (  
  dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP,      -- default NULL  
  dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0  
);
```

`TIMESTAMP` and `DATETIME` columns have no automatic properties unless they are specified explicitly, with this exception: By default, the *first* `TIMESTAMP` column has both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` if neither is specified explicitly. To suppress automatic properties for the first `TIMESTAMP` column, use one of these strategies:

- Enable the `explicit_defaults_for_timestamp` system variable. If this variable is enabled, the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses that specify automatic initialization and updating are available, but are not assigned to any `TIMESTAMP` column unless explicitly included in the column definition.
- Alternatively, if `explicit_defaults_for_timestamp` is disabled (the default), do either of the following:
  - Define the column with a `DEFAULT` clause that specifies a constant default value.

- Specify the `NULL` attribute. This also causes the column to permit `NULL` values, which means that you cannot assign the current timestamp by setting the column to `NULL`. Assigning `NULL` sets the column to `NULL`.

Consider these table definitions:

```
CREATE TABLE t1 (
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
    ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t2 (
  ts1 TIMESTAMP NULL,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
    ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t3 (
  ts1 TIMESTAMP NULL DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
    ON UPDATE CURRENT_TIMESTAMP);
```

The tables have these properties:

- In each table definition, the first `TIMESTAMP` column has no automatic initialization or updating.
- The tables differ in how the `ts1` column handles `NULL` values. For `t1`, `ts1` is `NOT NULL` and assigning it a value of `NULL` sets it to the current timestamp. For `t2` and `t3`, `ts1` permits `NULL` and assigning it a value of `NULL` sets it to `NULL`.
- `t2` and `t3` differ in the default value for `ts1`. For `t2`, `ts1` is defined to permit `NULL`, so the default is also `NULL` in the absence of an explicit `DEFAULT` clause. For `t3`, `ts1` permits `NULL` but has an explicit default of 0.

If a `TIMESTAMP` or `DATETIME` column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:

```
CREATE TABLE t1 (
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)
);
```

This is not permitted:

```
CREATE TABLE t1 (
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP(3)
);
```

## TIMESTAMP Initialization and the NULL Attribute

By default, `TIMESTAMP` columns are `NOT NULL`, cannot contain `NULL` values, and assigning `NULL` assigns the current timestamp. To permit a `TIMESTAMP` column to contain `NULL`, explicitly declare it with the `NULL` attribute. In this case, the default value also becomes `NULL` unless overridden with a `DEFAULT` clause that specifies a different default value. `DEFAULT NULL` can be used to explicitly specify `NULL` as the default value. (For a `TIMESTAMP` column not declared with the `NULL` attribute, `DEFAULT NULL` is invalid.) If a `TIMESTAMP` column permits `NULL` values, assigning `NULL` sets it to `NULL`, not to the current timestamp.

The following table contains several `TIMESTAMP` columns that permit `NULL` values:

```
CREATE TABLE t
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

A `TIMESTAMP` column that permits `NULL` values does *not* take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP` and no value is specified for the column
- `CURRENT_TIMESTAMP` or any of its synonyms such as `NOW()` is explicitly inserted into the column

In other words, a `TIMESTAMP` column defined to permit `NULL` values auto-initializes only if its definition includes `DEFAULT CURRENT_TIMESTAMP`:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the `TIMESTAMP` column permits `NULL` values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the `TIMESTAMP` column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```
INSERT INTO t1 VALUES (NOW());
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
```

## 12.3.6 Fractional Seconds in Time Values

MySQL 5.7 has fractional seconds support for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Inserting a `TIME`, `DATE`, or `TIMESTAMP` value with a fractional seconds part into a column of the same type but having fewer fractional digits results in rounding, as shown in this example:

```
mysql> CREATE TABLE fractest( c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP(2) );
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO fractest VALUES
  > ('17:51:04.777', '2014-09-08 17:51:04.777', '2014-09-08 17:51:04.777');
Query OK, 1 row affected (0.03 sec)

mysql> SELECT * FROM fractest;
+-----+-----+-----+
| c1          | c2          | c3          |
+-----+-----+-----+
| 17:51:04.78 | 2014-09-08 17:51:04.78 | 2014-09-08 17:51:04.78 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

No warning or error is given when such rounding occurs. This behavior follows the SQL standard, and is not affected by the server's `sql_mode` setting.

- Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, `NOW()` with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.
- Syntax for temporal literals produces temporal values: `DATE 'str'`, `TIME 'str'`, and `TIMESTAMP 'str'`, and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See [Standard SQL and ODBC Date and Time Literals](#)

### 12.3.7 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although `DATE`, `DATETIME`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. `TIMESTAMP` values cannot be earlier than 1970 UTC or later than '2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Conversion of `DATE` values:

- Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of '00:00:00' because the `DATE` value contains no time information.
- Conversion to a `TIME` value is not useful; the result is '00:00:00'.

Conversion of `DATETIME` and `TIMESTAMP` values:

- Conversion to a `DATE` value takes fractional seconds into account and rounds the time part. For example, '1999-12-31 23:59:59.499' becomes '1999-12-31', whereas '1999-12-31 23:59:59.500' becomes '2000-01-01'.
- Conversion to a `TIME` value discards the date part because the `TIME` type contains no date information.

For conversion of `TIME` values to other temporal types, the value of `CURRENT_DATE()` is used for the date part. The `TIME` is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from '00:00:00' to '23:59:59'.

Suppose that the current date is '2012-01-01'. `TIME` values of '12:00:00', '24:00:00', and '-12:00:00', when converted to `DATETIME` or `TIMESTAMP` values, result in '2012-01-01 12:00:00', '2012-01-02 00:00:00', and '2011-12-31 12:00:00', respectively.

Conversion of `TIME` to `DATE` is similar but discards the time part from the result: '2012-01-01', '2012-01-02', and '2011-12-31', respectively.

Explicit conversion can be used to override implicit conversion. For example, in comparison of `DATE` and `DATETIME` values, the `DATE` value is coerced to the `DATETIME` type by adding a time part of '00:00:00'. To perform the comparison by ignoring the time part of the `DATETIME` value instead, use the `CAST()` function in the following way:

```
date_col = CAST(datetime_col AS DATE)
```

Conversion of `TIME` and `DATETIME` values to numeric form (for example, by adding +0) depends on whether the value contains a fractional seconds part. `TIME(N)` or `DATETIME(N)` is converted to integer when `N` is 0 (or omitted) and to a `DECIMAL` value with `N` decimal digits when `N` is greater than 0:

```
mysql> SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;
+-----+-----+-----+
| CURTIME() | CURTIME()+0 | CURTIME(3)+0 |
+-----+-----+-----+
| 09:28:00 | 92800 | 92800.887 |
+-----+-----+-----+
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+-----+-----+-----+
| NOW() | NOW()+0 | NOW(3)+0 |
+-----+-----+-----+
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
+-----+-----+-----+
```

## 12.3.8 Two-Digit Years in Dates

Date values with two-digit years are ambiguous because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For `DATETIME`, `DATE`, and `TIMESTAMP` types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range `00–69` are converted to `2000–2069`.
- Year values in the range `70–99` are converted to `1970–1999`.

For `YEAR`, the rules are the same, with this exception: A numeric `00` inserted into `YEAR(4)` results in `0000` rather than `2000`. To specify zero for `YEAR(4)` and have it be interpreted as `2000`, specify it as a string `'0'` or `'00'`.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing four-digit year values.

`ORDER BY` properly sorts `YEAR` values that have two-digit years.

Some functions like `MIN()` and `MAX()` convert a `YEAR` to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the `YEAR` to four-digit year format.

## 12.4 String Types

The string types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`. This section describes how these types work and how to use them in your queries. For string type storage requirements, see [Section 12.8, “Data Type Storage Requirements”](#).

### 12.4.1 The CHAR and VARCHAR Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The `CHAR` and `VARCHAR` types are declared with a length that indicates the maximum number of characters you want to store. For example, `CHAR(30)` can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

In contrast to [CHAR](#), [VARCHAR](#) values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a [CHAR](#) or [VARCHAR](#) column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 6.1.8, “Server SQL Modes”](#).

For [VARCHAR](#) columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For [CHAR](#) columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

[VARCHAR](#) values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between [CHAR](#) and [VARCHAR](#) by showing the result of storing various string values into [CHAR\(4\)](#) and [VARCHAR\(4\)](#) columns (assuming that the column uses a single-byte character set such as [latin1](#)).

| Value      | <a href="#">CHAR(4)</a> | Storage Required | <a href="#">VARCHAR(4)</a> | Storage Required |
|------------|-------------------------|------------------|----------------------------|------------------|
| ' '        | ' '                     | 4 bytes          | ' '                        | 1 byte           |
| 'ab'       | 'ab '                   | 4 bytes          | 'ab'                       | 3 bytes          |
| 'abcd'     | 'abcd'                  | 4 bytes          | 'abcd'                     | 5 bytes          |
| 'abcdefgh' | 'abcd'                  | 4 bytes          | 'abcd'                     | 5 bytes          |

The values shown as stored in the last row of the table apply *only when not using strict mode*; if MySQL is running in strict mode, values that exceed the column length are *not stored*, and an error results.

[InnoDB](#) encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a [CHAR\(255\)](#) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with [utf8mb4](#).

If a given value is stored into the [CHAR\(4\)](#) and [VARCHAR\(4\)](#) columns, the values retrieved from the columns are not always the same because trailing spaces are removed from [CHAR](#) columns upon retrieval. The following example illustrates this difference:

```
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab ', 'ab ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+-----+-----+
| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
+-----+-----+
| (ab )              | (ab)                |
+-----+-----+
1 row in set (0.06 sec)
```

Values in [CHAR](#) and [VARCHAR](#) columns are sorted and compared according to the character set collation assigned to the column.

All MySQL collations are of type [PADSPACE](#). This means that all [CHAR](#), [VARCHAR](#), and [TEXT](#) values in MySQL are compared without regard to any trailing spaces. “Comparison” in this context does not include the [LIKE](#) pattern-matching operator, for which trailing spaces are significant. For example:

```
mysql> CREATE TABLE names (myname CHAR(10));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO names VALUES ('Monty');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT myname = 'Monty', myname = 'Monty ' FROM names;
+-----+-----+
| myname = 'Monty' | myname = 'Monty ' |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT myname LIKE 'Monty', myname LIKE 'Monty ' FROM names;
+-----+-----+
| myname LIKE 'Monty' | myname LIKE 'Monty ' |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

This is true for all MySQL versions, and is not affected by the server SQL mode.

#### Note

For more information about MySQL character sets and collations, see [Section 11.1, “Character Set Support”](#). For additional information about storage requirements, see [Section 12.8, “Data Type Storage Requirements”](#).

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

## 12.4.2 The BINARY and VARBINARY Types

The **BINARY** and **VARBINARY** types are similar to **CHAR** and **VARCHAR**, except that they contain binary strings rather than nonbinary strings. That is, they contain byte strings rather than character strings. This means they have the **binary** character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for **BINARY** and **VARBINARY** as it is for **CHAR** and **VARCHAR**, except that the length for **BINARY** and **VARBINARY** is a length in bytes rather than in characters.

The **BINARY** and **VARBINARY** data types are distinct from the **CHAR BINARY** and **VARCHAR BINARY** data types. For the latter types, the **BINARY** attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary (**\_bin**) collation for the column character set to be used, and the column itself contains nonbinary character strings rather than binary byte strings. For example, **CHAR(5) BINARY** is treated as **CHAR(5) CHARACTER SET latin1 COLLATE latin1\_bin**, assuming that the default character set is **latin1**. This differs from **BINARY(5)**, which stores 5-bytes binary strings that have the **binary** character set and collation. For information about differences between binary strings and binary collations for nonbinary strings, see [Section 11.1.8.5, “The binary Collation Compared to \\_bin Collations”](#).

If strict SQL mode is not enabled and you assign a value to a **BINARY** or **VARBINARY** column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 6.1.8, “Server SQL Modes”](#).

When **BINARY** values are stored, they are right-padded with the pad value to the specified length. The pad value is **0x00** (the zero byte). Values are right-padded with **0x00** on insert, and no trailing bytes

are removed on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

Example: For a `BINARY(3)` column, `'a '` becomes `'a \0'` when inserted. `'a\0'` becomes `'a \0\0'` when inserted. Both inserted values remain unchanged when selected.

For `VARBINARY`, there is no padding on insert and no bytes are stripped on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad bytes will result in a duplicate-key error. For example, if a table contains `'a '`, an attempt to store `'a\0'` causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how `0x00`-padding of `BINARY` values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+-----+-----+-----+
| HEX(c) | c = 'a' | c = 'a\0\0' |
+-----+-----+-----+
| 610000 | 0 | 1 |
+-----+-----+-----+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use `VARBINARY` or one of the `BLOB` data types instead.

### 12.4.3 The BLOB and TEXT Types

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`. These differ only in the maximum length of the values they can hold. The four `TEXT` types are `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. These correspond to the four `BLOB` types and have the same maximum lengths and storage requirements. See [Section 12.8, “Data Type Storage Requirements”](#).

`BLOB` values are treated as binary strings (byte strings). They have the `binary` character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. `TEXT` values are treated as nonbinary strings (character strings). They have a character set other than `binary`, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a `BLOB` or `TEXT` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 6.1.8, “Server SQL Modes”](#).

Truncation of excess trailing spaces from values to be inserted into `TEXT` columns always generates a warning, regardless of the SQL mode.

For `TEXT` and `BLOB` columns, there is no padding on insert and no bytes are stripped on select.

If a `TEXT` column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number

of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for `BLOB` columns.

In most respects, you can regard a `BLOB` column as a `VARBINARY` column that can be as large as you like. Similarly, you can regard a `TEXT` column as a `VARCHAR` column. `BLOB` and `TEXT` differ from `VARBINARY` and `VARCHAR` in the following ways:

- For indexes on `BLOB` and `TEXT` columns, you must specify an index prefix length. For `CHAR` and `VARCHAR`, a prefix length is optional. See [Section 9.3.4, “Column Indexes”](#).
- `BLOB` and `TEXT` columns cannot have `DEFAULT` values.

If you use the `BINARY` attribute with a `TEXT` data type, the column is assigned the binary (`_bin`) collation of the column character set.

`LONG` and `LONG VARCHAR` map to the `MEDIUMTEXT` data type. This is a compatibility feature.

MySQL Connector/ODBC defines `BLOB` values as `LONGVARBINARY` and `TEXT` values as `LONGVARCHAR`.

Because `BLOB` and `TEXT` values can be extremely long, you might encounter some constraints in using them:

- Only the first `max_sort_length` bytes of the column are used when sorting. The default value of `max_sort_length` is 1024. You can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` at server startup or runtime. Any client can change the value of its session `max_sort_length` variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
      -> ORDER BY comment;
```

- Instances of `BLOB` or `TEXT` columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the `MEMORY` storage engine does not support those data types (see [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#)). Use of disk incurs a performance penalty, so include `BLOB` or `TEXT` columns in the query result only if they are really needed. For example, avoid using `SELECT *`, which selects all columns.
- The maximum size of a `BLOB` or `TEXT` object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the `max_allowed_packet` variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` enable you to change the client-side `max_allowed_packet` value. See [Section 6.1.1, “Configuring the Server”](#), [Section 5.5.1, “mysql — The MySQL Command-Line Tool”](#), and [Section 5.5.4, “mysqldump — A Database Backup Program”](#). You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see [Section 12.8, “Data Type Storage Requirements”](#)

Each `BLOB` or `TEXT` value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in `BLOB` or `TEXT` columns. You may find MySQL's string handling functions useful for working with such data. See [Section 13.5, “String Functions”](#). For security and other reasons, it is usually preferable to do so using application code rather than giving application users the `FILE` privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (<http://forums.mysql.com/>).

## 12.4.4 The ENUM Type

An `ENUM` is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time. It has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See [Section 12.8, “Data Type Storage Requirements”](#) for the storage requirements for `ENUM` types.
- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in [Enumeration Limitations](#).
- Using `ENUM` columns in `ORDER BY` clauses requires extra care, as explained in [Enumeration Sorting](#).

## Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an `ENUM` column like this:

```
CREATE TABLE shirts (
  name VARCHAR(40),
  size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'),
('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+-----+-----+
| name   | size   |
+-----+-----+
| t-shirt | medium |
+-----+-----+
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of `'medium'` would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string `'medium'` in a `VARCHAR` column.

## Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following `SELECT` statement to find rows into which invalid `ENUM` values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the `NULL` value is `NULL`.
- The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as `ENUM('Mercury', 'Venus', 'Earth')` can have any of the values shown here. The index of each value is also shown.

| Value                  | Index             |
|------------------------|-------------------|
| <code>NULL</code>      | <code>NULL</code> |
| <code>''</code>        | 0                 |
| <code>'Mercury'</code> | 1                 |
| <code>'Venus'</code>   | 2                 |

| Value   | Index |
|---------|-------|
| 'Earth' | 3     |

An [ENUM](#) column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its [ENUM](#) and [SET](#) columns considered as a group. For more information on these limits, see [Section C.10.5, “Limits Imposed by .frm File Structure”](#).

If you retrieve an [ENUM](#) value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an [ENUM](#) column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

Functions such as [SUM\(\)](#) or [AVG\(\)](#) that expect a numeric argument cast the argument to a number if necessary. For [ENUM](#) values, the index number is used in the calculation.

## Handling of Enumeration Literals

Trailing spaces are automatically deleted from [ENUM](#) member values in the table definition when a table is created.

When retrieved, values stored into an [ENUM](#) column are displayed using the lettercase that was used in the column definition. Note that [ENUM](#) columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an [ENUM](#) column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does *not* work with [LOAD DATA](#), which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an [ENUM](#) column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).

```
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
+-----+
| numbers |
+-----+
| 1       |
| 2       |
| 2       |
+-----+
```

To determine all possible values for an [ENUM](#) column, use [SHOW COLUMNS FROM tbl\\_name LIKE 'enum\\_col'](#) and parse the [ENUM](#) definition in the [Type](#) column of the output.

In the C API, [ENUM](#) values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [Section 26.8.5, “C API Data Structures”](#).

## Empty or NULL Enumeration Values

An enumeration value can also be the empty string (' ') or [NULL](#) under certain circumstances:

- If you insert an invalid value into an `ENUM` (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numeric value 0. See [Index Values for Enumeration Literals](#) for details about the numeric indexes for the enumeration values.

If strict SQL mode is enabled, attempts to insert invalid `ENUM` values result in an error.

- If an `ENUM` column is declared to permit `NULL`, the `NULL` value is a valid value for the column, and the default value is `NULL`. If an `ENUM` column is declared `NOT NULL`, its default value is the first element of the list of permitted values.

## Enumeration Sorting

`ENUM` values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, `'b'` sorts before `'a'` for `ENUM('b', 'a')`. The empty string sorts before nonempty strings, and `NULL` values sort before all other enumeration values.

To prevent unexpected results when using the `ORDER BY` clause on an `ENUM` column, use one of these techniques:

- Specify the `ENUM` list in alphabetic order.
- Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

## Enumeration Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does *not* work because the `CONCAT` function cannot be used to construct an enumeration value:

```
CREATE TABLE sizes (
    size ENUM('small', CONCAT('med','ium'), 'large')
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do *not* work:

```
SET @mysize = 'medium';

CREATE TABLE sizes (
    size ENUM('small', @mysize, 'large')
);
```

We strongly recommend that you do *not* use numbers as enumeration values, because it does not save on storage over the appropriate `TINYINT` or `SMALLINT` type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See [Handling of Enumeration Literals](#) to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

## 12.4.5 The SET Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. `SET` column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that `SET` member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
' '
'one'
'two'
'one,two'
```

A `SET` column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on this limit, see [Section C.10.5, “Limits Imposed by .frm File Structure”](#).

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from `SET` member values in the table definition when a table is created.

When retrieved, values stored in a `SET` column are displayed using the lettercase that was used in the column definition. Note that `SET` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores `SET` values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a `SET` value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a `SET` column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a `SET` column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as `SET('a','b','c','d')`, the members have the following decimal and binary values.

| SET Member | Decimal Value | Binary Value |
|------------|---------------|--------------|
| 'a'        | 1             | 0001         |
| 'b'        | 2             | 0010         |
| 'c'        | 4             | 0100         |
| 'd'        | 8             | 1000         |

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth `SET` value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one `SET` element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose that a column is specified as `SET('a','b','c','d')`:

```
mysql> CREATE TABLE myset (col SET('a','b','c','d'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
```

```
+-----+
| col |
+-----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+-----+
5 rows in set (0.04 sec)
```

If you set a [SET](#) column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+-----+-----+-----+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+-----+
| col |
+-----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+-----+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid [SET](#) values result in an error.

[SET](#) values are sorted numerically. [NULL](#) values sort before non-[NULL](#) [SET](#) values.

Functions such as [SUM\(\)](#) or [AVG\(\)](#) that expect a numeric argument cast the argument to a number if necessary. For [SET](#) values, the cast operation causes the numeric value to be used.

Normally, you search for [SET](#) values using the [FIND\\_IN\\_SET\(\)](#) function or the [LIKE](#) operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where [set\\_col](#) contains the [value](#) set member. The second is similar, but not the same: It finds rows where [set\\_col](#) contains [value](#) anywhere, even as a substring of another set member.

The following statements also are permitted:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to ['val1,val2'](#) returns different results than comparing values to ['val2,val1'](#). You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a [SET](#) column, use [SHOW COLUMNS FROM tbl\\_name LIKE set\\_col](#) and parse the [SET](#) definition in the [Type](#) column of the output.

In the C API, [SET](#) values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [Section 26.8.5, “C API Data Structures”](#).

## 12.5 Extensions for Spatial Data

The Open Geospatial Consortium (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the *OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengeospatial.org/standards/sfs>.

Following the OGC specification, MySQL implements spatial extensions as a subset of the **SQL with Geometry Types** environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The data types and functions are available for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. For indexing spatial columns, [MyISAM](#) and [InnoDB](#) support both [SPATIAL](#) and non-[SPATIAL](#) indexes. The other storage engines support non-[SPATIAL](#) indexes, as described in [Section 14.1.14, “CREATE INDEX Syntax”](#).

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

**Geometry** is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. The term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

The following material covers these topics:

- The spatial data types implemented in MySQL model
- The basis of the spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data

- MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see [Section 13.15, “Spatial Analysis Functions”](#).

## MySQL GIS Conformance and Compatibility

MySQL does not implement the following GIS features:

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` should be called in MySQL as `ST_Length()`

The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context.

## Additional Resources

- The Open Geospatial Consortium publishes the *OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. The Open Geospatial Consortium (OGC) maintains a Web site at <http://www.opengeospatial.org/>. The specification is available there at <http://www.opengeospatial.org/standards/sfs>. It contains additional information relevant to the material here.
- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <http://forums.mysql.com/list.php?23>.

### 12.5.1 Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINESTRING`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINESTRING`, and `POLYGON`) restrict their values to a particular geometry type.

The other data types hold collections of values:

- `MULTIPOINT`
- `MULTILINESTRING`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, and `GEOMETRYCOLLECTION`) restrict collection members to those having a particular geometry type.

MySQL spatial data types have their basis in the OpenGIS geometry model, described in [Section 12.5.2, “The OpenGIS Geometry Model”](#). For examples showing how to use spatial data types in MySQL, see [Section 12.5.3, “Using Spatial Data”](#).

## 12.5.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

### 12.5.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (noninstantiable)
  - `Point` (instantiable)
  - `Curve` (noninstantiable)
    - `LineString` (instantiable)
      - `Line`
      - `LinearRing`
  - `Surface` (noninstantiable)
    - `Polygon` (instantiable)
  - `GeometryCollection` (instantiable)
    - `MultiPoint` (instantiable)
    - `MultiCurve` (noninstantiable)
      - `MultiLineString` (instantiable)
    - `MultiSurface` (noninstantiable)
      - `MultiPolygon` (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.

- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

### 12.5.2.2 Geometry Class

`Geometry` is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the `Geometry` subclasses. Particular subclasses have their own specific properties, described later.

#### Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is  $2^{32}-1$ . If a larger value is given, only the lower 32 bits are used. All computations are done assuming SRID 0, regardless of the actual SRID value. SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes.

- Its **coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geodetic** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **nonsimple**. Geometry values of types (`LineString`, `MultiPoint`, `MultiLineString`) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.
- Whether the value is **closed** or **not closed**. Geometry values of types (`LineString`, `MultiString`) are either closed or not closed. Each type determines its own assertions for being closed or not closed.

- Whether the value is **empty** or **nonempty** A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a `NULL` value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of  $-1$ ,  $0$ ,  $1$ , or  $2$ :
  - $-1$  for an empty geometry.
  - $0$  for a geometry with no length and no area.
  - $1$  for a geometry with nonzero length and zero area.
  - $2$  for a geometry with nonzero area.

`Point` objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

### 12.5.2.3 Point Class

A `Point` is a geometry that represents a single location in coordinate space.

#### `Point` Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

#### `Point` Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

### 12.5.2.4 Curve Class

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a noninstantiable class.

#### `Curve` Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
- A `Curve` is closed if its start point is equal to its endpoint.
- The boundary of a closed `Curve` is empty.
- The boundary of a nonclosed `Curve` consists of its two endpoints.
- A `Curve` that is simple and closed is a `LinearRing`.

### 12.5.2.5 LineString Class

A `LineString` is a `Curve` with linear interpolation between points.

### LineString Examples

- On a world map, [LineString](#) objects could represent rivers.
- In a city map, [LineString](#) objects could represent streets.

### LineString Properties

- A [LineString](#) has coordinates of segments, defined by each consecutive pair of points.
- A [LineString](#) is a [Line](#) if it consists of exactly two points.
- A [LineString](#) is a [LinearRing](#) if it is both closed and simple.

## 12.5.2.6 Surface Class

A [Surface](#) is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is [Polygon](#).

### Surface Properties

- A [Surface](#) is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple [Surface](#) as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple [Surface](#) is the set of closed curves corresponding to its exterior and interior boundaries.

## 12.5.2.7 Polygon Class

A [Polygon](#) is a planar [Surface](#) representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the [Polygon](#).

### Polygon Examples

- On a region map, [Polygon](#) objects could represent forests, districts, and so on.

### Polygon Assertions

- The boundary of a [Polygon](#) consists of a set of [LinearRing](#) objects (that is, [LineString](#) objects that are both simple and closed) that make up its exterior and interior boundaries.
- A [Polygon](#) has no rings that cross. The rings in the boundary of a [Polygon](#) may intersect at a [Point](#), but only as a tangent.
- A [Polygon](#) has no lines, spikes, or punctures.
- A [Polygon](#) has an interior that is a connected point set.
- A [Polygon](#) may have holes. The exterior of a [Polygon](#) with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a [Polygon](#) a simple geometry.

## 12.5.2.8 GeometryCollection Class

A [GeometryCollection](#) is a geometry that is a collection of one or more geometries of any class.

All the elements in a [GeometryCollection](#) must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a [GeometryCollection](#), although the subclasses of [GeometryCollection](#) described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

#### 12.5.2.9 MultiPoint Class

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

##### `MultiPoint` Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

##### `MultiPoint` Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

#### 12.5.2.10 MultiCurve Class

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a noninstantiable class.

##### `MultiCurve` Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `Curve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

#### 12.5.2.11 MultiLineString Class

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

##### `MultiLineString` Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

#### 12.5.2.12 MultiSurface Class

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a noninstantiable class. Its only instantiable subclass is `MultiPolygon`.

##### `MultiSurface` Assertions

- Surfaces within a `MultiSurface` have no interiors that intersect.
- Surfaces within a `MultiSurface` have boundaries that intersect at most at a finite number of points.

### 12.5.2.13 MultiPolygon Class

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

#### `MultiPolygon` Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

#### `MultiPolygon` Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

#### `MultiPolygon` Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

## 12.5.3 Using Spatial Data

This section describes how to create tables that include spatial data type columns, and how to manipulate spatial information.

### 12.5.3.1 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

There are functions available to convert between different data formats; see [Section 13.15.6, “Geometry Format Conversion Functions”](#).

#### Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see [Section 12.5, “Extensions for Spatial Data”](#)).

Examples of WKT representations of geometry objects:

- A `Point`:

```
POINT(15 20)
```

The point coordinates are specified with no separating comma. This differs from the syntax for the SQL `Point()` function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both extract the X-coordinate from a `Point` object. The first produces the object directly using the `Point()` function. The second uses a WKT representation converted to a `Point` with `GeomFromText()`.

```
mysql> SELECT ST_X(Point(15, 20));
+-----+
| ST_X(POINT(15, 20)) |
+-----+
| 15 |
+-----+

mysql> SELECT ST_X(ST_GeomFromText('POINT(15 20)'));
+-----+
| ST_X(ST_GeomFromText('POINT(15 20)')) |
+-----+
| 15 |
+-----+
```

- A `LineString` with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

The point coordinate pairs are separated by commas.

- A `Polygon` with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A `MultiPoint` with three `Point` values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

As of MySQL 5.7.9, spatial functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid, whereas before MySQL 5.7.9 the second one produces an error:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

As of MySQL 5.7.9, output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----+
| ST_AsText(ST_GeomFromText(@mp)) |
+-----+
| MULTIPOINT((1 1),(2 2),(3 3)) |
+-----+
```

Before MySQL 5.7.9, output for the same value does not include parentheses around each point:

```
mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----+
| ST_AsText(ST_GeomFromText(@mp)) |
```

```
+-----+
| MULTIPPOINT(1 1,2 2,3 3) |
+-----+
```

- A `MultiLineString` with two `LineString` values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A `MultiPolygon` with two `Polygon` values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

## Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by `BLOB` values containing geometric WKB information. This format is defined by the OpenGIS specification (see [Section 12.5, “Extensions for Spatial Data”](#)). It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes, each represented by two hexadecimal digits:

```
010100000000000000000000F03F000000000000F03F
```

The sequence consists of these components:

```
Byte order:    01
WKB type:      01000000
X coordinate:  00000000000000F03F
Y coordinate:  00000000000000F03F
```

Component representation is as follows:

- The byte order is either 1 or 0 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.
- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

### 12.5.3.2 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. See also the notes about spatial indexes under [Section 12.5.3.6, “Creating Spatial Indexes”](#).

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the [ALTER TABLE](#) statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

### 12.5.3.3 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the [INSERT](#) statement:

```
INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

- Perform the conversion prior to the [INSERT](#):

```
SET @g = ST_GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use [ST\\_GeomFromText\(\)](#) to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a [POINT\(1 1\)](#) value with hex literal syntax:

```
mysql> INSERT INTO geom VALUES
-> (ST_GeomFromWKB(0x010100000000000000000000F03F000000000000F03F));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string_quote()` and include the result in a query string that is sent to the server. See [Section 26.8.7.56](#), “`mysql_real_escape_string_quote()`”.

### 12.5.3.4 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `ST_AsText()` function converts a geometry from internal format to a WKT string.

```
SELECT ST_AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `ST_AsBinary()` function converts a geometry from internal format to a `BLOB` containing the WKB value.

```
SELECT ST_AsBinary(g) FROM geom;
```

### 12.5.3.5 Optimizing Spatial Analysis

For `MyISAM` and (as of MySQL 5.7.5) `InnoDB` tables, search operations in columns containing spatial data can be optimized using `SPATIAL` indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` and `InnoDB` support both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 14.1.14](#), “`CREATE INDEX Syntax`”.

### 12.5.3.6 Creating Spatial Indexes

For [MyISAM](#) and (as of MySQL 5.7.5) [InnoDB](#) tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the [SPATIAL](#) keyword. Columns in spatial indexes must be declared [NOT NULL](#). The following examples demonstrate how to create spatial indexes:

- With [CREATE TABLE](#):

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g)) ENGINE=MyISAM;
```

- With [ALTER TABLE](#):

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With [CREATE INDEX](#):

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

[SPATIAL INDEX](#) creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see [Section 14.1.14](#), “[CREATE INDEX Syntax](#)”.

To drop spatial indexes, use [ALTER TABLE](#) or [DROP INDEX](#):

- With [ALTER TABLE](#):

```
ALTER TABLE geom DROP INDEX g;
```

- With [DROP INDEX](#):

```
DROP INDEX sp_index ON geom;
```

Example: Suppose that a table [geom](#) contains more than 32,000 geometries, which are stored in the column [g](#) of type [GEOMETRY](#). The table also has an [AUTO\\_INCREMENT](#) column [fid](#) for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11)   |      | PRI | NULL    | auto_increment |
| g     | geometry  |      |     |         |                |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
|      32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column [g](#), use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g) ENGINE=MyISAM;
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

### 12.5.3.7 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g);
```

| fid | ST_AsText(g)  |
|-----|---|
| 21  | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ... |
| 22  | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ... |
| 23  | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ... |
| 24  | LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ... |
| 25  | LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ... |
| 26  | LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ... |
| 249 | LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ... |
| 1   | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |
| 2   | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136, ... |
| 3   | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ... |
| 4   | LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ... |
| 5   | LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ... |
| 6   | LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ... |
| 7   | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ... |
| 10  | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ... |
| 11  | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ... |
| 13  | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ... |
| 154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ... |
| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ... |
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ... |

```
20 rows in set (0.00 sec)
```

Use `EXPLAIN` to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
          key: g
        key_len: 32
          ref: NULL
         rows: 50
       Extra: Using where
1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
```

```

31000 15000,
31000 16000,
30000 16000,
30000 15000));
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: ALL
possible_keys: NULL
         key: NULL
        key_len: NULL
         ref: NULL
         rows: 32376
      Extra: Using where
1 row in set (0.00 sec)

```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
31000 15000,
31000 16000,
30000 16000,
30000 15000));';
mysql> SELECT fid,ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(ST_GeomFromText(@poly),g);
+-----+
| fid | ST_AsText(g) |
+-----+
| 1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |

20 rows in set (0.46 sec)

```

## 12.6 The JSON Data Type

As of MySQL 5.7.8, MySQL supports a native `JSON` data type that enables efficient access to data in JSON (JavaScript Object Notation) documents. The `JSON` data type provides these advantages over storing JSON-format strings in a string column:

- Automatic validation of JSON documents stored in `JSON` columns. Invalid documents produce an error.
- Optimized storage format. JSON documents stored in `JSON` columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value stored in this binary format, the value need not be parsed from a text representation.

The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

**Note**

This discussion uses `JSON` in monospace to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The size of JSON documents stored in `JSON` columns is limited to the value of the `max_allowed_packet` system variable. (While the server manipulates a JSON value internally in memory, it can be larger; the limit applies when the server stores it.)

`JSON` columns cannot have a default value.

`JSON` columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the `JSON` column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

MySQL Cluster NDB 7.5.2 and later supports `JSON` columns and MySQL JSON functions, including creation of an index on a column generated from a `JSON` column as a workaround for being unable to index a `JSON` column. A maximum of 3 `JSON` columns per NDB table is supported.

The following discussion covers these topics:

- [Creating JSON Values](#)
- [Normalization, Merging, and Autowrapping of JSON Values](#)
- [Searching and Modifying JSON Values](#)
- [Comparison and Ordering of JSON Values](#)
- [Aggregation of JSON Values](#)

Along with the `JSON` data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The follow discussion shows examples of these operations. For details about individual functions, see [Section 13.16, “JSON Functions”](#).

A set of spatial functions for operating on GeoJSON values is also available. See [Section 13.15.11, “Spatial GeoJSON Functions”](#).

## Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within `[` and `]` characters:

```
[ "abc", 10, null, true, false ]
```

A JSON object contains a set of key/value pairs separated by commas and enclosed within `{` and `}` characters:

```
{ "k1": "value", "k2": 10 }
```

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

```
[ "12:18:29.000000", "2015-07-29", "2015-07-29 12:18:29.000000" ]
```

Nesting is permitted within JSON array elements and JSON object key values:

```
[ 99, { "id": "HK500", "cost": 75.99 }, [ "hot", "cold" ] ]
{ "k1": "value", "k2": [ 10, 20 ] }
```

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see [Section 13.16.2, “Functions That Create JSON Values”](#)) as well as by casting values of other types to the `JSON` type using `CAST(value AS JSON)` (see [Converting between JSON and non-JSON values](#)). The next several paragraphs describe how MySQL handles JSON values provided as input.

In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value into a column that has the `JSON` data type and passing an argument to a function that expects a JSON value, as the following examples demonstrate:

- Attempting to insert a value into a `JSON` column succeeds if the value is a valid JSON value, but fails if it is not:

```
mysql> CREATE TABLE t1 (jdoc JSON);
Query OK, 0 rows affected (0.20 sec)

mysql> INSERT INTO t1 VALUES('{ "key1": "value1", "key2": "value2" }');
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO t1 VALUES('[ 1, 2, ' ');
ERROR 3140 (22032) at line 2: Invalid JSON text: "Invalid value." at position 6 in value (or column) '[1,
```

Positions for “at position *N*” in such error messages are 0-based, but should be considered rough indications of where the problem in a value actually occurs.

- The `JSON_TYPE()` function expects a JSON argument and attempts to parse it into a JSON value. It returns the value's JSON type if it is valid and produces an error otherwise:

```
mysql> SELECT JSON_TYPE('[ "a", "b", 1 ]');
+-----+
| JSON_TYPE('[ "a", "b", 1 ]') |
+-----+
| ARRAY                          |
+-----+

mysql> SELECT JSON_TYPE('"hello"');
+-----+
| JSON_TYPE('"hello"') |
+-----+
| STRING                |
+-----+

mysql> SELECT JSON_TYPE('hello');
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

MySQL handles strings used in JSON context using the `utf8mb4` character set and `utf8mb4_bin` collation. Strings in other character sets are converted to `utf8mb4` as necessary. (For strings in the `ascii` or `utf8` character sets, no conversion is needed because `ascii` and `utf8` are subsets of `utf8mb4`.)

As an alternative to writing JSON values using literal strings, functions exist for composing JSON values from component elements. `JSON_ARRAY()` takes a (possibly empty) list of values and returns a JSON array containing those values:

```
mysql> SELECT JSON_ARRAY('a', 1, NOW());
+-----+
| JSON_ARRAY('a', 1, NOW()) |
+-----+
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+-----+
```

`JSON_OBJECT()` takes a (possibly empty) list of key/value pairs and returns a JSON object containing those pairs:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc') |
+-----+
| {"key1": 1, "key2": "abc"} |
+-----+
```

`JSON_MERGE()` takes two or more JSON documents and returns the combined result:

```
mysql> SELECT JSON_MERGE('["a", 1]', '{"key": "value"}');
+-----+
| JSON_MERGE('["a", 1]', '{"key": "value"}') |
+-----+
| ["a", 1, {"key": "value"}] |
+-----+
```

For information about the merging rules, see [Normalization, Merging, and Autowrapping of JSON Values](#).

JSON values can be assigned to user-defined variables:

```
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+-----+
| @j |
+-----+
| {"key": "value"} |
+-----+
```

However, user-defined variables cannot be of `JSON` data type, so although `@j` in the preceding example looks like a JSON value and has the same character set and collation as a JSON value, it does *not* have the `JSON` data type. Instead, the result from `JSON_OBJECT()` is converted to a string when assigned to the variable.

Strings produced by converting JSON values have a character set of `utf8mb4` and a collation of `utf8mb4_bin`:

```
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-----+-----+
| CHARSET(@j) | COLLATION(@j) |
+-----+-----+
| utf8mb4 | utf8mb4_bin |
+-----+-----+
```

Because `utf8mb4_bin` is a binary collation, comparison of JSON values is case sensitive.

```
mysql> SELECT JSON_ARRAY('x') = JSON_ARRAY('X');
+-----+
| JSON_ARRAY('x') = JSON_ARRAY('X') |
+-----+
| 0 |
+-----+
```

Case sensitivity also applies to the JSON `null`, `true`, and `false` literals, which always must be written in lowercase:

```
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');
+-----+-----+-----+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
+-----+-----+-----+
| 1 | 0 | 0 |
+-----+-----+-----+

mysql> SELECT CAST('null' AS JSON);
+-----+
| CAST('null' AS JSON) |
+-----+
| null |
+-----+
1 row in set (0.00 sec)

mysql> SELECT CAST('NULL' AS JSON);
ERROR 3141 (22032): Invalid JSON text in argument 1 to function cast_as_json:
"Invalid value." at position 0 in 'NULL'.
```

Case sensitivity of the JSON literals differs from that of the SQL `NULL`, `TRUE`, and `FALSE` literals, which can be written in any lettercase:

```
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);
+-----+-----+-----+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
+-----+-----+-----+
| 1 | 1 | 1 |
+-----+-----+-----+
```

## Normalization, Merging, and Autowrapping of JSON Values

When a string is parsed and found to be a valid JSON document, it is also normalized: Members with keys that duplicate a key found earlier in the document are discarded (even if the values differ). The object value produced by the following `JSON_OBJECT()` call does not include the second `key1` element because that key name occurs earlier in the value:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
+-----+
| {"key1": 1, "key2": "abc"} |
+-----+
```

The normalization performed by MySQL also sorts the keys of a JSON object (for the purpose of making lookups more efficient). The result of this ordering is subject to change and not guaranteed to be consistent across releases. In addition, extra whitespace between keys, values, or elements in the original document is discarded.

MySQL functions that produce JSON values (see [Section 13.16.2, “Functions That Create JSON Values”](#)) always return normalized values.

In contexts that combine multiple arrays, the arrays are merged into a single array by concatenating arrays named later to the end of the first array. In the following example, `JSON_MERGE()` merges its arguments into a single array:

```
mysql> SELECT JSON_MERGE('[1, 2]', ['a', 'b'], '[true, false]');
+-----+
| JSON_MERGE('[1, 2]', ['a', 'b'], '[true, false]') |
+-----+
| [1, 2, "a", "b", true, false] |
+-----+
```

Multiple objects when merged produce a single object. If multiple objects have the same key, the value for that key in the resulting merged object is an array containing the key values:

```
mysql> SELECT JSON_MERGE('{\"a\": 1, \"b\": 2}', '{\"c\": 3, \"a\": 4}');
+-----+
| JSON_MERGE('{\"a\": 1, \"b\": 2}', '{\"c\": 3, \"a\": 4}') |
+-----+
| {\"a\": [1, 4], \"b\": 2, \"c\": 3} |
+-----+
```

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded by `[` and `]` characters to convert it to an array. In the following statement, each argument is autowrapped as an array (`[1]`, `[2]`). These are then merged to produce a single result array:

```
mysql> SELECT JSON_MERGE('1', '2');
+-----+
| JSON_MERGE('1', '2') |
+-----+
| [1, 2] |
+-----+
```

Array and object values are merged by autowrapping the object as an array and merging the two arrays:

```
mysql> SELECT JSON_MERGE('[10, 20]', '{\"a\": \"x\", \"b\": \"y\"}');
+-----+
| JSON_MERGE('[10, 20]', '{\"a\": \"x\", \"b\": \"y\"}') |
+-----+
| [10, 20, {\"a\": \"x\", \"b\": \"y\"}] |
+-----+
```

## Searching and Modifying JSON Values

A JSON path expression selects a value within a JSON document.

Path expressions are useful with functions that extract parts of or modify a JSON document, to specify where within that document to operate. For example, the following query extracts from a JSON document the value of the member with the `name` key:

```
mysql> SELECT JSON_EXTRACT('{\"id\": 14, \"name\": \"Aztalan\"}', '$.name');
+-----+
| JSON_EXTRACT('{\"id\": 14, \"name\": \"Aztalan\"}', '$.name') |
+-----+
| \"Aztalan\" |
+-----+
```

Path syntax uses a leading `$` character to represent the JSON document under consideration, optionally followed by selectors that indicate successively more specific parts of the document:

- A period followed by a key name names the member in an object with the given key. The key name must be specified within double quotation marks if the name without quotes is not legal within path expressions (for example, if it contains a space).
- `[N]` appended to a path that selects an array names the value at position `N` within the array. Array positions are integers beginning with zero.
- Paths can contain `*` or `**` wildcards:
  - `[*]` evaluates to the values of all members in a JSON object.
  - `[*]` evaluates to the values of all elements in a JSON array.

- `prefix**suffix` evaluates to all paths that begin with the named prefix and end with the named suffix.
- A path that does not exist in the document (evaluates to nonexistent data) evaluates to `NULL`.

Let `$` refer to this JSON array with three elements:

```
[3, {"a": [5, 6], "b": 10}, [99, 100]]
```

Then:

- `$.0` evaluates to `3`.
- `$.1` evaluates to `{"a": [5, 6], "b": 10}`.
- `$.2` evaluates to `[99, 100]`.
- `$.3` evaluates to `NULL` (it refers to the fourth array element, which does not exist).

Because `$.1` and `$.2` evaluate to nonscalar values, they can be used as the basis for more-specific path expressions that select nested values. Examples:

- `$.1.a` evaluates to `[5, 6]`.
- `$.1.a[1]` evaluates to `6`.
- `$.1.b` evaluates to `10`.
- `$.2[0]` evaluates to `99`.

As mentioned previously, path components that name keys must be quoted if the unquoted key name is not legal in path expressions. Let `$` refer to this value:

```
{"a fish": "shark", "a bird": "sparrow"}
```

The keys both contain a space and must be quoted:

- `$. "a fish"` evaluates to `shark`.
- `$. "a bird"` evaluates to `sparrow`.

Paths that use wildcards evaluate to an array that can contain multiple values:

```
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*');
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*') |
+-----+
| [1, 2, [3, 4, 5]] |
+-----+
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.c[*]');
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.c[*]') |
+-----+
| [3, 4, 5] |
+-----+
```

In the following example, the path `$**.b` evaluates to multiple paths (`$.a.b` and `$.c.b`) and produces an array of the matching path values:

```
mysql> SELECT JSON_EXTRACT('{ "a": { "b": 1 }, "c": { "b": 2 } }', '$**.b');
+-----+
| JSON_EXTRACT('{ "a": { "b": 1 }, "c": { "b": 2 } }', '$**.b') |
+-----+
```

```
+-----+
| [1, 2] |
+-----+
```

In MySQL 5.7.9 and later, you can use `column->path` with a JSON column identifier and JSON path expression as a synonym for `JSON_EXTRACT(column, path)`. See [Section 13.16.3, “Functions That Search JSON Values”](#), for more information. See also [Indexing a Generated Column to Provide a JSON Column Index](#).

Some functions take an existing JSON document, modify it in some way, and return the resulting modified document. Path expressions indicate where in the document to make changes. For example, the `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions each take a JSON document, plus one or more path/value pairs that describe where to modify the document and the values to use. The functions differ in how they handle existing and nonexisting values within the document.

Consider this document:

```
mysql> SET @j = '{"a", {"b": [true, false]}, [10, 20]}';
```

`JSON_SET()` replaces values for paths that exist and adds values for paths that do not exist:

```
mysql> SELECT JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| [{"a", {"b": [1, false]}, [10, 20, 2]}] |
+-----+
```

In this case, the path `[$[1].b[0]` selects an existing value (`true`), which is replaced with the value following the path argument (`1`). The path `[$[2][2]` does not exist, so the corresponding value (`2`) is added to the value selected by `[$[2]`.

`JSON_INSERT()` adds new values but does not replace existing values:

```
mysql> SELECT JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| [{"a", {"b": [true, false]}, [10, 20, 2]}] |
+-----+
```

`JSON_REPLACE()` replaces existing values and ignores new values:

```
mysql> SELECT JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| [{"a", {"b": [1, false]}, [10, 20]}] |
+-----+
```

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

`JSON_REMOVE()` takes a JSON document and one or more paths that specify values to be removed from the document. The return value is the original document minus the values selected by paths that exist within the document:

```
mysql> SELECT JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]');
+-----+
| JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]') |
+-----+
| [{"a", {"b": [true]}]} |
+-----+
```

The paths have these effects:

- `$(2)` matches `[10, 20]` and removes it.
- The first instance of `$(1).b[1]` matches `false` in the `b` element and removes it.
- The second instance of `$(1).b[1]` matches nothing: That element has already been removed, the path no longer exists, and has no effect.

## Comparison and Ordering of JSON Values

JSON values can be compared using the `=`, `<`, `<=`, `>`, `>=`, `<>`, `!=`, and `<=>` operators.

The following comparison operators and functions are not yet supported with JSON values:

- `BETWEEN`
- `IN( )`
- `GREATEST( )`
- `LEAST( )`

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the `JSON_TYPE( )` function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

```
BLOB
BIT
OPAQUE
DATETIME
TIME
DATE
BOOLEAN
ARRAY
OBJECT
STRING
INTEGER, DOUBLE
NULL
```

For JSON values of the same precedence, the comparison rules are type specific:

- `BLOB`

The first `N` bytes of the two values are compared, where `N` is the number of bytes in the shorter value. If the first `N` bytes of the two values are identical, the shorter value is ordered before the longer value.

- `BIT`

Same rules as for `BLOB`.

- `OPAQUE`

Same rules as for [BLOB](#). [OPAQUE](#) values are values that are not classified as one of the other types.

- [DATETIME](#)

A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL [DATETIME](#) and [TIMESTAMP](#) types, respectively, they are equal if they represent the same point in time.

- [TIME](#)

The smaller of two time values is ordered before the larger one.

- [DATE](#)

The earlier date is ordered before the more recent date.

- [ARRAY](#)

Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.

If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

Example:

```
[ ] < [ "a" ] < [ "ab" ] < [ "ab", "cd", "ef" ] < [ "ab", "ef" ]
```

- [BOOLEAN](#)

The JSON false literal is less than the JSON true literal.

- [OBJECT](#)

Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

Example:

```
{ "a": 1, "b": 2 } = { "b": 2, "a": 1 }
```

The order of two objects that are not equal is unspecified but deterministic.

- [STRING](#)

Strings are ordered lexically on the first [N](#) bytes of the [utf8mb4](#) representation of the two strings being compared, where [N](#) is the length of the shorter string. If the first [N](#) bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

Example:

```
"a" < "ab" < "b" < "bc"
```

This ordering is equivalent to the ordering of SQL strings with collation [utf8mb4\\_bin](#). Because [utf8mb4\\_bin](#) is a binary collation, comparison of JSON values is case sensitive:

```
"A" < "a"
```

- [INTEGER](#), [DOUBLE](#)

JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see [Section 10.1.2, “Number Literals”](#).

The rules for comparing native MySQL numeric types are discussed in [Section 13.2, “Type Conversion in Expression Evaluation”](#), but the rules for comparing numbers within JSON values differ somewhat:

- In a comparison between two columns that use the native MySQL [INT](#) and [DOUBLE](#) numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.
- On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers will be integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
< 9.223372036854776e18 = 9223372036854776000 < 9223372036854776001
```

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

- Integer comparison:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
```

(not defined for 9.223372036854776e18)

- Double comparison:

```
9223372036854775805 = 9223372036854775806 = 9223372036854775807 = 9.223372036854776e18
```

For comparison of any JSON value to SQL [NULL](#), the result is [UNKNOWN](#).

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

**Converting between JSON and non-JSON values.** The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

**Table 12.1 JSON Conversion Rules**

| other type   | CAST(other type AS JSON)  | CAST(JSON AS other type)   |
|--|---|--|
| JSON   | No change   | No change  |
| utf8 character type<br>( <a href="#">utf8mb4</a> , <a href="#">utf8</a> ,<br><a href="#">ascii</a> ) | The string is parsed into a JSON value.   | The JSON value is serialized into a <a href="#">utf8mb4</a> string.  |
| Other character types  | Other character encodings are implicitly converted to <a href="#">utf8mb4</a> and treated as described for utf8 character type. | The JSON value is serialized into a <a href="#">utf8mb4</a> string, then cast to the other character encoding. The result may not be meaningful. |
| <a href="#">NULL</a>   | Results in a <a href="#">NULL</a> value of type JSON.   | Not applicable.  |

| other type      | CAST(other type AS JSON)  | CAST(JSON AS other type)  |
|-----------------|---|---|
| Geometry types  | The geometry value is converted into a JSON document by calling <code>ST_AsGeoJSON()</code> . | Illegal operation. Workaround: Pass the result of <code>CAST(json_val AS CHAR)</code> to <code>ST_GeomFromGeoJSON()</code> .  |
| All other types | Results in a JSON document consisting of a single scalar value.                               | Succeeds if the JSON document consists of a single scalar value of the target type and that scalar value can be cast to the target type. Otherwise, returns <code>NULL</code> and produces a warning. |

`ORDER BY` and `GROUP BY` for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.
- For ascending sorts, SQL `NULL` orders before all JSON values, including the JSON null literal; for descending sorts, SQL `NULL` orders after all JSON values, including the JSON null literal.
- Sort keys for JSON values are bound by the value of the `max_sort_length` system variable, so keys that differ only after the first `max_sort_length` bytes compare as equal.
- Sorting of nonscalar values is not currently supported and a warning occurs.

For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named `jdoc` contains JSON objects having a member consisting of an `id` key and a nonnegative value, use this expression to sort by `id` values:

```
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the `ORDER BY`, the MySQL optimizer recognizes that and considers using the index for the query execution plan. See [Section 9.3.9, “Optimizer Use of Generated Column Indexes”](#).

## Aggregation of JSON Values

For aggregation of JSON values, SQL `NULL` values are ignored as for other data types.

Non-`NULL` values are converted to a numeric type and aggregated, except for `MIN()`, `MAX()`, and `GROUP_CONCAT()`. The conversion to number should produce a meaningful result for JSON values that are numeric scalars, although (depending on the values) truncation and loss of precision may occur. Conversion to number of other JSON values may not produce a meaningful result.

## 12.7 Data Type Default Values

The `DEFAULT value` clause in a data type specification indicates a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for `TIMESTAMP` and `DATETIME` columns. See [Section 12.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

`BLOB`, `TEXT`, `GEOMETRY`, and `JSON` columns cannot be assigned a default value.

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as the value, MySQL defines the column with no explicit `DEFAULT` clause. Exception: If the column is defined as part of a `PRIMARY KEY` but not explicitly as `NOT NULL`,

MySQL creates it as a `NOT NULL` column (because `PRIMARY KEY` columns must be `NOT NULL`). Before MySQL 5.7.3, the column is also assigned a `DEFAULT` clause using the implicit default value. To prevent this, include an explicit `NOT NULL` in the definition of any `PRIMARY KEY` column.

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.
- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```
INSERT INTO t VALUES();  
INSERT INTO t VALUES(DEFAULT);  
INSERT INTO t VALUES(DEFAULT(i));
```

See [Section 6.1.8, “Server SQL Modes”](#).

For a given table, you can use the `SHOW CREATE TABLE` statement to see which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is `0`, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.
- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` system variable is enabled (see [Section 6.1.5, “Server System Variables”](#)). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See [Section 12.3, “Date and Time Types”](#).
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

## 12.8 Data Type Storage Requirements

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes `BLOB` or `TEXT` columns, which contribute only 9 to 12 bytes toward this size. For `BLOB` and `TEXT` data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see [Chapter 16, \*Alternative Storage Engines\*](#), and [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

## Storage Requirements for InnoDB Tables

See [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#) for information about storage requirements for `InnoDB` tables.

## Storage Requirements for NDB Tables

### Important

`NDB` tables use *4-byte alignment*; all `NDB` data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an `NDB` table. For example, in `NDB` tables, the `TINYINT`, `SMALLINT`, `MEDIUMINT`, and `INTEGER (INT)` column types each require 4 bytes storage per record due to the alignment factor.

Each `BIT(M)` column takes *M* bits of storage space. Although an individual `BIT` column is *not* 4-byte aligned, `NDB` reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for `BIT` columns, then another 4 bytes for bits 33-64, and so on.

While a `NULL` itself does not require any storage space, `NDB` reserves 4 bytes per row if the table definition contains any columns defined as `NULL`, up to 32 `NULL` columns. (If a MySQL Cluster table is defined with more than 32 `NULL` columns up to 64 `NULL` columns, then 8 bytes per row are reserved.)

Every table using the `NDB` storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by `NDB`. This hidden primary key consumes 31-35 bytes per table record.

You can use the `ndb_size.pl` Perl script to estimate `NDB` storage requirements. It connects to a current MySQL (not MySQL Cluster) database and creates a report on how much space that database would require if it used the `NDB` storage engine. See [Section 20.4.25, “`ndb\_size.pl` — NDBCLUSTER Size Requirement Estimator”](#) for more information.

## Storage Requirements for Numeric Types

| Data Type                               | Storage Required   |
|---|--|
| <code>TINYINT</code>                    | 1 byte   |
| <code>SMALLINT</code>                   | 2 bytes  |
| <code>MEDIUMINT</code>                  | 3 bytes  |
| <code>INT</code> , <code>INTEGER</code> | 4 bytes  |
| <code>BIGINT</code>                     | 8 bytes  |
| <code>FLOAT(p)</code>                   | 4 bytes if $0 \leq p \leq 24$ , 8 bytes if $25 \leq p \leq 53$ |
| <code>FLOAT</code>                      | 4 bytes  |

| Data Type                               | Storage Required                 |
|---|----------------------------------|
| <code>DOUBLE [PRECISION], REAL</code>   | 8 bytes                          |
| <code>DECIMAL(M,D), NUMERIC(M,D)</code> | Varies; see following discussion |
| <code>BIT(M)</code>                     | approximately $(M+7)/8$ bytes    |

Values for `DECIMAL` (and `NUMERIC`) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

| Leftover Digits | Number of Bytes |
|-----------------|-----------------|
| 0               | 0               |
| 1               | 1               |
| 2               | 1               |
| 3               | 2               |
| 4               | 2               |
| 5               | 3               |
| 6               | 3               |
| 7               | 4               |
| 8               | 4               |

## Storage Requirements for Date and Time Types

For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

| Data Type              | Storage Required Before MySQL 5.6.4 | Storage Required as of MySQL 5.6.4   |
|------------------------|-------------------------------------|--------------------------------------|
| <code>YEAR</code>      | 1 byte                              | 1 byte                               |
| <code>DATE</code>      | 3 bytes                             | 3 bytes                              |
| <code>TIME</code>      | 3 bytes                             | 3 bytes + fractional seconds storage |
| <code>DATETIME</code>  | 8 bytes                             | 5 bytes + fractional seconds storage |
| <code>TIMESTAMP</code> | 4 bytes                             | 4 bytes + fractional seconds storage |

As of MySQL 5.6.4, storage for `YEAR` and `DATE` remains unchanged. However, `TIME`, `DATETIME`, and `TIMESTAMP` are represented differently. `DATETIME` is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

| Fractional Seconds Precision | Storage Required |
|------------------------------|------------------|
| 0                            | 0 bytes          |
| 1, 2                         | 1 byte           |
| 3, 4                         | 2 bytes          |
| 5, 6                         | 3 bytes          |

For example, `TIME(0)`, `TIME(2)`, `TIME(4)`, and `TIME(6)` use 3, 4, 5, and 6 bytes, respectively. `TIME` and `TIME(0)` are equivalent and require the same storage.

For details about internal representation of temporal values, see [MySQL Internals: Important Algorithms and Structures](#).

## Storage Requirements for String Types

In the following table, *M* represents the declared column length in characters for nonbinary string types and bytes for binary string types. *L* represents the actual length in bytes of a given string value.

| Data Type   | Storage Required  |
|---|---|
| <code>CHAR(M)</code>                                | $M \times w$ bytes, $0 \leq M \leq 255$ , where <i>w</i> is the number of bytes required for the maximum-length character in the character set. See <a href="#">Section 15.8.3, “Physical Row Structure of InnoDB Tables”</a> for information about <code>CHAR</code> data type storage requirements for InnoDB tables. |
| <code>BINARY(M)</code>                              | <i>M</i> bytes, $0 \leq M \leq 255$   |
| <code>VARCHAR(M)</code> , <code>VARBINARY(M)</code> | <i>L</i> + 1 bytes if column values require 0 – 255 bytes, <i>L</i> + 2 bytes if values may require more than 255 bytes   |
| <code>TINYBLOB</code> , <code>TINYTEXT</code>       | <i>L</i> + 1 bytes, where $L < 2^8$   |
| <code>BLOB</code> , <code>TEXT</code>               | <i>L</i> + 2 bytes, where $L < 2^{16}$  |
| <code>MEDIUMBLOB</code> , <code>MEDIUMTEXT</code>   | <i>L</i> + 3 bytes, where $L < 2^{24}$  |
| <code>LONGBLOB</code> , <code>LONGTEXT</code>       | <i>L</i> + 4 bytes, where $L < 2^{32}$  |
| <code>ENUM('value1', 'value2', ...)</code>          | 1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)   |
| <code>SET('value1', 'value2', ...)</code>           | 1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)   |

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is *L* (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires *L* bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a `utf8` Unicode character set, you must keep in mind that not all characters use the same number of bytes. `utf8mb3` and `utf8mb4` character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of `utf8mb3` or `utf8mb4` characters, see [Section 11.1.9, “Unicode Support”](#).

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string (*L*), plus one byte to record the length of the string. For the string `'abcd'`, *L* is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of `'abcd'` is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of *bytes* that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multibyte characters, the effective maximum number of *characters* is less. For example, `utf8mb3` characters can require up to three bytes per character, so a `VARCHAR` column

that uses the `utf8mb3` character set can be declared to be a maximum of 21,844 characters. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

`InnoDB` encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

The `NDB` storage engine supports variable-width columns. This means that a `VARCHAR` column in a MySQL Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string `'abcd'` stored in a `VARCHAR(50)` column using the `latin1` character set requires 8 bytes (rather than 5 bytes for the same column value in a `MyISAM` table).

`TEXT` and `BLOB` columns are implemented differently in the `NDB` storage engine, wherein each row in a `TEXT` column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden table. The rows in this second table are always 2,000 bytes long. This means that the size of a `TEXT` column is 256 if  $size \leq 256$  (where  $size$  represents the size of the row); otherwise, the size is  $256 + size + (2000 - (size - 256) \% 2000)$ .

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See [Section 12.4.4, “The ENUM Type”](#).

The size of a `SET` object is determined by the number of different set members. If the set size is  $N$ , the object occupies  $(N+7) / 8$  bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See [Section 12.4.5, “The SET Type”](#).

## 12.9 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, -, \*, and /) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See [Section 12.1.1, “Numeric Type Overview”](#).

If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

`PROCEDURE ANALYSE` can be used to obtain suggestions for optimal column data types. For more information, see [Section 9.4.2.4, “Using PROCEDURE ANALYSE”](#).

## 12.10 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

| Other Vendor Type                 | MySQL Type              |
|-----------------------------------|-------------------------|
| <code>BOOL</code>                 | <code>TINYINT</code>    |
| <code>BOOLEAN</code>              | <code>TINYINT</code>    |
| <code>CHARACTER VARYING(M)</code> | <code>VARCHAR(M)</code> |
| <code>FIXED</code>                | <code>DECIMAL</code>    |
| <code>FLOAT4</code>               | <code>FLOAT</code>      |

| Other Vendor Type | MySQL Type |
|-------------------|------------|
| FLOAT8            | DOUBLE     |
| INT1              | TINYINT    |
| INT2              | SMALLINT   |
| INT3              | MEDIUMINT  |
| INT4              | INT        |
| INT8              | BIGINT     |
| LONG VARBINARY    | MEDIUMBLOB |
| LONG VARCHAR      | MEDIUMTEXT |
| LONG              | MEDIUMTEXT |
| MIDDLEINT         | MEDIUMINT  |
| NUMERIC           | DECIMAL    |

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> DESCRIBE t;
```

| Field | Type          | Null | Key | Default | Extra |
|-------|---------------|------|-----|---------|-------|
| a     | tinyint(1)    | YES  |     | NULL    |       |
| b     | double        | YES  |     | NULL    |       |
| c     | mediumtext    | YES  |     | NULL    |       |
| d     | decimal(10,0) | YES  |     | NULL    |       |

```
4 rows in set (0.01 sec)
```

---

## Chapter 13 Functions and Operators

### Table of Contents

|  |      |
|--|------|
| 13.1 Function and Operator Reference .....                                   | 1533 |
| 13.2 Type Conversion in Expression Evaluation .....                          | 1545 |
| 13.3 Operators .....   | 1548 |
| 13.3.1 Operator Precedence .....   | 1549 |
| 13.3.2 Comparison Functions and Operators .....                              | 1550 |
| 13.3.3 Logical Operators .....   | 1556 |
| 13.3.4 Assignment Operators .....  | 1557 |
| 13.4 Control Flow Functions .....  | 1559 |
| 13.5 String Functions .....  | 1560 |
| 13.5.1 String Comparison Functions .....                                     | 1576 |
| 13.5.2 Regular Expressions .....   | 1579 |
| 13.5.3 Character Set and Collation of Function Results .....                 | 1585 |
| 13.6 Numeric Functions and Operators .....                                   | 1586 |
| 13.6.1 Arithmetic Operators .....  | 1587 |
| 13.6.2 Mathematical Functions .....  | 1589 |
| 13.7 Date and Time Functions .....   | 1597 |
| 13.8 What Calendar Is Used By MySQL? .....                                   | 1619 |
| 13.9 Full-Text Search Functions .....  | 1620 |
| 13.9.1 Natural Language Full-Text Searches .....                             | 1621 |
| 13.9.2 Boolean Full-Text Searches .....                                      | 1624 |

Expressions can be used at several points in [SQL](#) statements, such as in the [ORDER BY](#) or [HAVING](#) clauses of [SELECT](#) statements, in the [WHERE](#) clause of a [SELECT](#), [DELETE](#), or [UPDATE](#) statement, or in [SET](#) statements. Expressions can be written using literal values, column values, [NULL](#), built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in [Section 22.2](#), “Using Stored Routines (Procedures and Functions)”, and [Section 27.4](#), “Adding New Functions to MySQL”. See [Section 10.2.4](#), “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

An expression that contains [NULL](#) always produces a [NULL](#) value unless otherwise indicated in the documentation for a particular function or operator.

#### Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. (See [Section 6.1.8](#), “Server SQL Modes”.) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
|          2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

## 13.1 Function and Operator Reference

**Table 13.1 Functions/Operators**

| Name  | Description  |
|---|--|
| <a href="#">ABS()</a>   | Return the absolute value  |
| <a href="#">ACOS()</a>  | Return the arc cosine  |
| <a href="#">ADDDATE()</a>   | Add time values (intervals) to a date value  |
| <a href="#">ADDTIME()</a>   | Add time   |
| <a href="#">AES_DECRYPT()</a>   | Decrypt using AES  |
| <a href="#">AES_ENCRYPT()</a>   | Encrypt using AES  |
| <a href="#">AND, &amp;&amp;</a>   | Logical AND  |
| <a href="#">ANY_VALUE()</a>   | Suppress ONLY_FULL_GROUP_BY value rejection  |
| <a href="#">Area()</a> (deprecated 5.7.6)                               | Return Polygon or MultiPolygon area  |
| <a href="#">AsBinary()</a> , <a href="#">AsWKB()</a> (deprecated 5.7.6) | Convert from internal geometry format to WKB   |
| <a href="#">ASCII()</a>   | Return numeric value of left-most character  |
| <a href="#">ASIN()</a>  | Return the arc sine  |
| <a href="#">=</a>   | Assign a value (as part of a <a href="#">SET</a> statement, or as part of the <a href="#">SET</a> clause in an <a href="#">UPDATE</a> statement) |
| <a href="#">:=</a>  | Assign a value   |
| <a href="#">AsText()</a> , <a href="#">AsWKT()</a> (deprecated 5.7.6)   | Convert from internal geometry format to WKT   |
| <a href="#">ASYMMETRIC_DECRYPT()</a>                                    | Decrypt ciphertext using private or public key   |
| <a href="#">ASYMMETRIC_DERIVE()</a>                                     | Derive symmetric key from asymmetric keys  |
| <a href="#">ASYMMETRIC_ENCRYPT()</a>                                    | Encrypt cleartext using private or public key  |
| <a href="#">ASYMMETRIC_SIGN()</a>                                       | Generate signature from digest   |
| <a href="#">ASYMMETRIC_VERIFY()</a>                                     | Verify that signature matches digest   |
| <a href="#">ATAN()</a>  | Return the arc tangent   |
| <a href="#">ATAN2()</a> , <a href="#">ATAN()</a>                        | Return the arc tangent of the two arguments  |
| <a href="#">AVG()</a>   | Return the average value of the argument   |
| <a href="#">BENCHMARK()</a>   | Repeatedly execute an expression   |
| <a href="#">BETWEEN ... AND ...</a>                                     | Check whether a value is within a range of values  |
| <a href="#">BIN()</a>   | Return a string containing binary representation of a number   |
| <a href="#">BINARY</a>  | Cast a string to a binary string   |
| <a href="#">BIT_AND()</a>   | Return bitwise AND   |
| <a href="#">BIT_COUNT()</a>   | Return the number of bits that are set   |
| <a href="#">BIT_LENGTH()</a>  | Return length of argument in bits  |
| <a href="#">BIT_OR()</a>  | Return bitwise OR  |
| <a href="#">BIT_XOR()</a>   | Return bitwise XOR   |
| <a href="#">&amp;</a>   | Bitwise AND  |
| <a href="#">~</a>   | Bitwise inversion  |
| <a href="#"> </a>   | Bitwise OR   |
| <a href="#">^</a>   | Bitwise XOR  |

| Name   | Description  |
|--|--|
| <a href="#">Buffer()</a> (deprecated 5.7.6)                                | Return geometry of points within given distance from geometry  |
| <a href="#">CASE</a>   | Case operator  |
| <a href="#">CAST()</a>   | Cast a value as a certain type                                 |
| <a href="#">CEIL()</a>   | Return the smallest integer value not less than the argument   |
| <a href="#">CEILING()</a>  | Return the smallest integer value not less than the argument   |
| <a href="#">Centroid()</a> (deprecated 5.7.6)                              | Return centroid as a point                                     |
| <a href="#">CHAR()</a>   | Return the character for each integer passed                   |
| <a href="#">CHAR_LENGTH()</a>  | Return number of characters in argument                        |
| <a href="#">CHARACTER_LENGTH()</a>   | Synonym for CHAR_LENGTH()                                      |
| <a href="#">CHARSET()</a>  | Return the character set of the argument                       |
| <a href="#">COALESCE()</a>   | Return the first non-NULL argument                             |
| <a href="#">COERCIBILITY()</a>   | Return the collation coercibility value of the string argument |
| <a href="#">COLLATION()</a>  | Return the collation of the string argument                    |
| <a href="#">COMPRESS()</a>   | Return result as a binary string                               |
| <a href="#">CONCAT()</a>   | Return concatenated string                                     |
| <a href="#">CONCAT_WS()</a>  | Return concatenate with separator                              |
| <a href="#">CONNECTION_ID()</a>  | Return the connection ID (thread ID) for the connection        |
| <a href="#">Contains()</a> (deprecated 5.7.6)                              | Whether MBR of one geometry contains MBR of another            |
| <a href="#">CONV()</a>   | Convert numbers between different number bases                 |
| <a href="#">CONVERT()</a>  | Cast a value as a certain type                                 |
| <a href="#">CONVERT_TZ()</a>   | Convert from one time zone to another                          |
| <a href="#">ConvexHull()</a> (deprecated 5.7.6)                            | Return convex hull of geometry                                 |
| <a href="#">COS()</a>  | Return the cosine  |
| <a href="#">COT()</a>  | Return the cotangent   |
| <a href="#">COUNT()</a>  | Return a count of the number of rows returned                  |
| <a href="#">COUNT(DISTINCT)</a>  | Return the count of a number of different values               |
| <a href="#">CRC32()</a>  | Compute a cyclic redundancy check value                        |
| <a href="#">CREATE_ASYMMETRIC_PRIV_KEY()</a>                               | Create private key   |
| <a href="#">CREATE_ASYMMETRIC_PUB_KEY()</a>                                | Create public key  |
| <a href="#">CREATE_DH_PARAMETERS()</a>                                     | Generate shared DH secret                                      |
| <a href="#">CREATE_DIGEST()</a>  | Generate digest from string                                    |
| <a href="#">Crosses()</a> (deprecated 5.7.6)                               | Whether one geometry crosses another                           |
| <a href="#">CURDATE()</a>  | Return the current date  |
| <a href="#">CURRENT_DATE()</a> , <a href="#">CURRENT_DATE</a>              | Synonyms for CURDATE()   |
| <a href="#">CURRENT_TIME()</a> , <a href="#">CURRENT_TIME</a>              | Synonyms for CURTIME()   |
| <a href="#">CURRENT_TIMESTAMP()</a> ,<br><a href="#">CURRENT_TIMESTAMP</a> | Synonyms for NOW()   |
| <a href="#">CURRENT_USER()</a> , <a href="#">CURRENT_USER</a>              | The authenticated user name and host name                      |
| <a href="#">CURTIME()</a>  | Return the current time  |
| <a href="#">DATABASE()</a>   | Return the default (current) database name                     |

| Name  | Description  |
|---|--|
| <a href="#">DATE()</a>                            | Extract the date part of a date or datetime expression   |
| <a href="#">DATE_ADD()</a>                        | Add time values (intervals) to a date value  |
| <a href="#">DATE_FORMAT()</a>                     | Format date as specified   |
| <a href="#">DATE_SUB()</a>                        | Subtract a time value (interval) from a date   |
| <a href="#">DATEDIFF()</a>                        | Subtract two dates   |
| <a href="#">DAY()</a>                             | Synonym for DAYOFMONTH()   |
| <a href="#">DAYNAME()</a>                         | Return the name of the weekday   |
| <a href="#">DAYOFMONTH()</a>                      | Return the day of the month (0-31)   |
| <a href="#">DAYOFWEEK()</a>                       | Return the weekday index of the argument   |
| <a href="#">DAYOFYEAR()</a>                       | Return the day of the year (1-366)   |
| <a href="#">DECODE()</a>                          | Decodes a string encrypted using ENCODE()  |
| <a href="#">DEFAULT()</a>                         | Return the default value for a table column  |
| <a href="#">DEGREES()</a>                         | Convert radians to degrees   |
| <a href="#">DES_DECRYPT()</a> (deprecated 5.7.6)  | Decrypt a string   |
| <a href="#">DES_ENCRYPT()</a> (deprecated 5.7.6)  | Encrypt a string   |
| <a href="#">Dimension()</a> (deprecated 5.7.6)    | Dimension of geometry  |
| <a href="#">Disjoint()</a> (deprecated 5.7.6)     | Whether MBRs of two geometries are disjoint  |
| <a href="#">Distance()</a> (deprecated 5.7.6)     | The distance of one geometry from another  |
| <a href="#">DIV</a>                               | Integer division   |
| <a href="#">/</a>                                 | Division operator  |
| <a href="#">ELT()</a>                             | Return string at index number  |
| <a href="#">ENCODE()</a>                          | Encode a string  |
| <a href="#">ENCRYPT()</a> (deprecated 5.7.6)      | Encrypt a string   |
| <a href="#">EndPoint()</a> (deprecated 5.7.6)     | End Point of LineString  |
| <a href="#">Envelope()</a> (deprecated 5.7.6)     | Return MBR of geometry   |
| <a href="#">=</a>                                 | Equal operator   |
| <a href="#">&lt;=&gt;</a>                         | NULL-safe equal to operator  |
| <a href="#">Equals()</a> (deprecated 5.7.6)       | Whether MBRs of two geometries are equal   |
| <a href="#">EXP()</a>                             | Raise to the power of  |
| <a href="#">EXPORT_SET()</a>                      | Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string |
| <a href="#">ExteriorRing()</a> (deprecated 5.7.6) | Return exterior ring of Polygon  |
| <a href="#">EXTRACT()</a>                         | Extract part of a date   |
| <a href="#">ExtractValue()</a>                    | Extracts a value from an XML string using XPath notation   |
| <a href="#">FIELD()</a>                           | Return the index (position) of the first argument in the subsequent arguments  |
| <a href="#">FIND_IN_SET()</a>                     | Return the index position of the first argument within the second argument   |
| <a href="#">FLOOR()</a>                           | Return the largest integer value not greater than the argument   |

| Name   | Description  |
|--|--|
| <code>FORMAT()</code>  | Return a number formatted to specified number of decimal places  |
| <code>FOUND_ROWS()</code>  | For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause |
| <code>FROM_BASE64()</code>   | Decode to a base-64 string and return result   |
| <code>FROM_DAYS()</code>   | Convert a day number to a date   |
| <code>FROM_UNIXTIME()</code>   | Format Unix timestamp as a date  |
| <code>GeomCollFromText()</code> ,<br><code>GeometryCollectionFromText()</code><br>(deprecated 5.7.6) | Return geometry collection from WKT  |
| <code>GeomCollFromWKB()</code> ,<br><code>GeometryCollectionFromWKB()</code><br>(deprecated 5.7.6)   | Return geometry collection from WKB  |
| <code>GeometryCollection()</code>  | Construct geometry collection from geometries  |
| <code>GeometryN()</code> (deprecated 5.7.6)  | Return N-th geometry from geometry collection  |
| <code>GeometryType()</code> (deprecated 5.7.6)   | Return name of geometry type   |
| <code>GeomFromText()</code> ,<br><code>GeometryFromText()</code> (deprecated 5.7.6)                  | Return geometry from WKT   |
| <code>GeomFromWKB()</code> ,<br><code>GeometryFromWKB()</code> (deprecated 5.7.6)                    | Return geometry from WKB   |
| <code>GET_FORMAT()</code>  | Return a date format string  |
| <code>GET_LOCK()</code>  | Get a named lock   |
| <code>GLength()</code> (deprecated 5.7.6)  | Return length of LineString  |
| <code>&gt;</code>  | Greater than operator  |
| <code>&gt;=</code>   | Greater than or equal operator   |
| <code>GREATEST()</code>  | Return the largest argument  |
| <code>GROUP_CONCAT()</code>  | Return a concatenated string   |
| <code>GTID_SUBSET()</code>   | Return true if all GTIDs in subset are also in set; otherwise false.                                   |
| <code>GTID_SUBTRACT()</code>   | Return all GTIDs in set that are not in subset.  |
| <code>HEX()</code>   | Return a hexadecimal representation of a decimal or string value                                       |
| <code>HOUR()</code>  | Extract the hour   |
| <code>IF()</code>  | If/else construct  |
| <code>IFNULL()</code>  | Null if/else construct   |
| <code>IN()</code>  | Check whether a value is within a set of values  |
| <code>INET_ATON()</code>   | Return the numeric value of an IP address  |
| <code>INET_NTOA()</code>   | Return the IP address from a numeric value   |
| <code>INET6_ATON()</code>  | Return the numeric value of an IPv6 address  |
| <code>INET6_NTOA()</code>  | Return the IPv6 address from a numeric value   |
| <code>INSERT()</code>  | Insert a substring at the specified position up to the specified number of characters                  |

| Name   | Description  |
|--|--|
| <a href="#">INSTR()</a>                            | Return the index of the first occurrence of substring  |
| <a href="#">InteriorRingN()</a> (deprecated 5.7.6) | Return N-th interior ring of Polygon   |
| <a href="#">Intersects()</a> (deprecated 5.7.6)    | Whether MBRs of two geometries intersect   |
| <a href="#">INTERVAL()</a>                         | Return the index of the argument that is less than the first argument  |
| <a href="#">IS</a>                                 | Test a value against a boolean   |
| <a href="#">IS_FREE_LOCK()</a>                     | Whether the named lock is free   |
| <a href="#">IS_IPV4()</a>                          | Whether argument is an IPv4 address  |
| <a href="#">IS_IPV4_COMPAT()</a>                   | Whether argument is an IPv4-compatible address   |
| <a href="#">IS_IPV4_MAPPED()</a>                   | Whether argument is an IPv4-mapped address   |
| <a href="#">IS_IPV6()</a>                          | Whether argument is an IPv6 address  |
| <a href="#">IS NOT</a>                             | Test a value against a boolean   |
| <a href="#">IS NOT NULL</a>                        | NOT NULL value test  |
| <a href="#">IS NULL</a>                            | NULL value test  |
| <a href="#">IS_USED_LOCK()</a>                     | Whether the named lock is in use; return connection identifier if true   |
| <a href="#">IsClosed()</a> (deprecated 5.7.6)      | Whether a geometry is closed and simple  |
| <a href="#">IsEmpty()</a> (deprecated 5.7.6)       | Placeholder function   |
| <a href="#">ISNULL()</a>                           | Test whether the argument is NULL  |
| <a href="#">IsSimple()</a> (deprecated 5.7.6)      | Whether a geometry is simple   |
| <a href="#">JSON_APPEND()</a>                      | Append data to JSON document   |
| <a href="#">JSON_ARRAY()</a>                       | Create JSON array  |
| <a href="#">JSON_ARRAY_APPEND()</a>                | Append data to JSON document   |
| <a href="#">JSON_ARRAY_INSERT()</a>                | Insert into JSON array   |
| <a href="#">-&gt;</a>                              | Return value from JSON column after evaluating path; equivalent to <a href="#">JSON_EXTRACT()</a> .  |
| <a href="#">JSON_CONTAINS()</a>                    | Whether JSON document contains specific object at path   |
| <a href="#">JSON_CONTAINS_PATH()</a>               | Whether JSON document contains any data at path  |
| <a href="#">JSON_DEPTH()</a>                       | Maximum depth of JSON document   |
| <a href="#">JSON_EXTRACT()</a>                     | Return data from JSON document   |
| <a href="#">-&gt;&gt;</a>                          | Return value from JSON column after evaluating path and unquoting the result; equivalent to <a href="#">JSON_UNQUOTE(JSON_EXTRACT())</a> . |
| <a href="#">JSON_INSERT()</a>                      | Insert data into JSON document   |
| <a href="#">JSON_KEYS()</a>                        | Array of keys from JSON document   |
| <a href="#">JSON_LENGTH()</a>                      | Number of elements in JSON document  |
| <a href="#">JSON_MERGE()</a>                       | Merge JSON documents   |
| <a href="#">JSON_OBJECT()</a>                      | Create JSON object   |
| <a href="#">JSON_QUOTE()</a>                       | Quote JSON document  |
| <a href="#">JSON_REMOVE()</a>                      | Remove data from JSON document   |
| <a href="#">JSON_REPLACE()</a>                     | Replace values in JSON document  |
| <a href="#">JSON_SEARCH()</a>                      | Path to value within JSON document   |

| Name  | Description   |
|---|---|
| <code>JSON_SET()</code>   | Insert data into JSON document  |
| <code>JSON_TYPE()</code>  | Type of JSON value  |
| <code>JSON_UNQUOTE()</code>   | Unquote JSON value  |
| <code>JSON_VALID()</code>   | Whether JSON value is valid   |
| <code>LAST_DAY</code>   | Return the last day of the month for the argument                                   |
| <code>LAST_INSERT_ID()</code>   | Value of the AUTOINCREMENT column for the last INSERT                               |
| <code>LCASE()</code>  | Synonym for LOWER()   |
| <code>LEAST()</code>  | Return the smallest argument  |
| <code>LEFT()</code>   | Return the leftmost number of characters as specified                               |
| <code>&lt;&lt;</code>   | Left shift  |
| <code>LENGTH()</code>   | Return the length of a string in bytes  |
| <code>&lt;</code>   | Less than operator  |
| <code>&lt;=</code>  | Less than or equal operator   |
| <code>LIKE</code>   | Simple pattern matching   |
| <code>LineFromText()</code> ,<br><code>LineStringFromText()</code> (deprecated 5.7.6) | Construct LineString from WKT   |
| <code>LineFromWKB()</code> ,<br><code>LineStringFromWKB()</code> (deprecated 5.7.6)   | Construct LineString from WKB   |
| <code>LineString()</code>   | Construct LineString from Point values  |
| <code>LN()</code>   | Return the natural logarithm of the argument  |
| <code>LOAD_FILE()</code>  | Load the named file   |
| <code>LOCALTIME()</code> , <code>LOCALTIME</code>                                     | Synonym for NOW()   |
| <code>LOCALTIMESTAMP</code> ,<br><code>LOCALTIMESTAMP()</code>                        | Synonym for NOW()   |
| <code>LOCATE()</code>   | Return the position of the first occurrence of substring                            |
| <code>LOG()</code>  | Return the natural logarithm of the first argument                                  |
| <code>LOG10()</code>  | Return the base-10 logarithm of the argument  |
| <code>LOG2()</code>   | Return the base-2 logarithm of the argument   |
| <code>LOWER()</code>  | Return the argument in lowercase  |
| <code>LPAD()</code>   | Return the string argument, left-padded with the specified string                   |
| <code>LTRIM()</code>  | Remove leading spaces   |
| <code>MAKE_SET()</code>   | Return a set of comma-separated strings that have the corresponding bit in bits set |
| <code>MAKEDATE()</code>   | Create a date from the year and day of year   |
| <code>MAKETIME()</code>   | Create time from hour, minute, second   |
| <code>MASTER_POS_WAIT()</code>  | Block until the slave has read and applied all updates up to the specified position |
| <code>MATCH</code>  | Perform full-text search  |
| <code>MAX()</code>  | Return the maximum value  |
| <code>MBRContains()</code>  | Whether MBR of one geometry contains MBR of another                                 |

| Name   | Description   |
|--|---|
| <code>MBRCoveredBy()</code>  | Whether one MBR is covered by another                   |
| <code>MBRCovers()</code>   | Whether one MBR covers another                          |
| <code>MBRDisjoint()</code>   | Whether MBRs of two geometries are disjoint             |
| <code>MBREqual()</code> (deprecated 5.7.6)   | Whether MBRs of two geometries are equal                |
| <code>MBREquals()</code>   | Whether MBRs of two geometries are equal                |
| <code>MBRIntersects()</code>   | Whether MBRs of two geometries intersect                |
| <code>MBROverlaps()</code>   | Whether MBRs of two geometries overlap                  |
| <code>MBRTouches()</code>  | Whether MBRs of two geometries touch                    |
| <code>MBRWithin()</code>   | Whether MBR of one geometry is within MBR of another    |
| <code>MD5()</code>   | Calculate MD5 checksum                                  |
| <code>MICROSECOND()</code>   | Return the microseconds from argument                   |
| <code>MID()</code>   | Return a substring starting from the specified position |
| <code>MIN()</code>   | Return the minimum value                                |
| <code>-</code>   | Minus operator  |
| <code>MINUTE()</code>  | Return the minute from the argument                     |
| <code>MLineFromText()</code> ,<br><code>MultiLineStringFromText()</code><br>(deprecated 5.7.6) | Construct MultiLineString from WKT                      |
| <code>MLineFromWKB()</code> ,<br><code>MultiLineStringFromWKB()</code><br>(deprecated 5.7.6)   | Construct MultiLineString from WKB                      |
| <code>MOD()</code>   | Return the remainder                                    |
| <code>%, MOD</code>  | Modulo operator   |
| <code>MONTH()</code>   | Return the month from the date passed                   |
| <code>MONTHNAME()</code>   | Return the name of the month                            |
| <code>MPointFromText()</code> ,<br><code>MultiPointFromText()</code> (deprecated<br>5.7.6)     | Construct MultiPoint from WKT                           |
| <code>MPointFromWKB()</code> ,<br><code>MultiPointFromWKB()</code> (deprecated<br>5.7.6)       | Construct MultiPoint from WKB                           |
| <code>MPolyFromText()</code> ,<br><code>MultiPolygonFromText()</code><br>(deprecated 5.7.6)    | Construct MultiPolygon from WKT                         |
| <code>MPolyFromWKB()</code> ,<br><code>MultiPolygonFromWKB()</code><br>(deprecated 5.7.6)      | Construct MultiPolygon from WKB                         |
| <code>MultiLineString()</code>   | Construct MultiLineString from LineString values        |
| <code>MultiPoint()</code>  | Construct MultiPoint from Point values                  |
| <code>MultiPolygon()</code>  | Construct MultiPolygon from Polygon values              |
| <code>NAME_CONST()</code>  | Causes the column to have the given name                |
| <code>NOT, !</code>  | Negates value   |
| <code>NOT BETWEEN ... AND ...</code>   | Check whether a value is not within a range of values   |
| <code>!=, &lt;&gt;</code>  | Not equal operator                                      |

| Name   | Description   |
|--|---|
| <code>NOT IN()</code>  | Check whether a value is not within a set of values                     |
| <code>NOT LIKE</code>  | Negation of simple pattern matching                                     |
| <code>NOT REGEXP</code>  | Negation of REGEXP  |
| <code>NOW()</code>   | Return the current date and time  |
| <code>NULLIF()</code>  | Return NULL if <code>expr1 = expr2</code>                               |
| <code>NumGeometries()</code> (deprecated 5.7.6)                                    | Return number of geometries in geometry collection                      |
| <code>NumInteriorRings()</code> (deprecated 5.7.6)                                 | Return number of interior rings in Polygon                              |
| <code>NumPoints()</code> (deprecated 5.7.6)  | Return number of points in LineString                                   |
| <code>OCT()</code>   | Return a string containing octal representation of a number             |
| <code>OCTET_LENGTH()</code>  | Synonym for <code>LENGTH()</code>                                       |
| <code>OLD_PASSWORD()</code>  | Return the value of the pre-4.1 implementation of <code>PASSWORD</code> |
| <code>  </code> , <code>OR</code>  | Logical OR  |
| <code>ORD()</code>   | Return character code for leftmost character of the argument            |
| <code>Overlaps()</code> (deprecated 5.7.6)   | Whether MBRs of two geometries overlap                                  |
| <code>PASSWORD()</code> (deprecated 5.7.6)   | Calculate and return a password string                                  |
| <code>PERIOD_ADD()</code>  | Add a period to a year-month  |
| <code>PERIOD_DIFF()</code>   | Return the number of months between periods                             |
| <code>PI()</code>  | Return the value of pi  |
| <code>+</code>   | Addition operator   |
| <code>Point()</code>   | Construct Point from coordinates  |
| <code>PointFromText()</code> (deprecated 5.7.6)                                    | Construct Point from WKT  |
| <code>PointFromWKB()</code> (deprecated 5.7.6)                                     | Construct Point from WKB  |
| <code>PointN()</code> (deprecated 5.7.6)   | Return N-th point from LineString                                       |
| <code>PolyFromText()</code> ,<br><code>PolygonFromText()</code> (deprecated 5.7.6) | Construct Polygon from WKT  |
| <code>PolyFromWKB()</code> ,<br><code>PolygonFromWKB()</code> (deprecated 5.7.6)   | Construct Polygon from WKB  |
| <code>Polygon()</code>   | Construct Polygon from LineString arguments                             |
| <code>POSITION()</code>  | Synonym for <code>LOCATE()</code>                                       |
| <code>POW()</code>   | Return the argument raised to the specified power                       |
| <code>POWER()</code>   | Return the argument raised to the specified power                       |
| <code>PROCEDURE ANALYSE()</code>   | Analyze the results of a query  |
| <code>QUARTER()</code>   | Return the quarter from a date argument                                 |
| <code>QUOTE()</code>   | Escape the argument for use in an SQL statement                         |
| <code>RADIANS()</code>   | Return argument converted to radians                                    |
| <code>RAND()</code>  | Return a random floating-point value                                    |
| <code>RANDOM_BYTES()</code>  | Return a random byte vector   |
| <code>REGEXP</code>  | Pattern matching using regular expressions                              |

| Name                                      | Description   |
|---|---|
| <a href="#">RELEASE_ALL_LOCKS()</a>       | Releases all current named locks                              |
| <a href="#">RELEASE_LOCK()</a>            | Releases the named lock                                       |
| <a href="#">REPEAT()</a>                  | Repeat a string the specified number of times                 |
| <a href="#">REPLACE()</a>                 | Replace occurrences of a specified string                     |
| <a href="#">REVERSE()</a>                 | Reverse the characters in a string                            |
| <a href="#">RIGHT()</a>                   | Return the specified rightmost number of characters           |
| <a href="#">&gt;&gt;</a>                  | Right shift   |
| <a href="#">RLIKE</a>                     | Synonym for REGEXP  |
| <a href="#">ROUND()</a>                   | Round the argument  |
| <a href="#">ROW_COUNT()</a>               | The number of rows updated                                    |
| <a href="#">RPAD()</a>                    | Append string the specified number of times                   |
| <a href="#">RTRIM()</a>                   | Remove trailing spaces  |
| <a href="#">SCHEMA()</a>                  | Synonym for DATABASE()  |
| <a href="#">SEC_TO_TIME()</a>             | Converts seconds to 'HH:MM:SS' format                         |
| <a href="#">SECOND()</a>                  | Return the second (0-59)                                      |
| <a href="#">SESSION_USER()</a>            | Synonym for USER()  |
| <a href="#">SHA1(), SHA()</a>             | Calculate an SHA-1 160-bit checksum                           |
| <a href="#">SHA2()</a>                    | Calculate an SHA-2 checksum                                   |
| <a href="#">SIGN()</a>                    | Return the sign of the argument                               |
| <a href="#">SIN()</a>                     | Return the sine of the argument                               |
| <a href="#">SLEEP()</a>                   | Sleep for a number of seconds                                 |
| <a href="#">SOUNDEX()</a>                 | Return a soundex string                                       |
| <a href="#">SOUNDS LIKE</a>               | Compare sounds  |
| <a href="#">SPACE()</a>                   | Return a string of the specified number of spaces             |
| <a href="#">SQRT()</a>                    | Return the square root of the argument                        |
| <a href="#">SRID()</a> (deprecated 5.7.6) | Return spatial reference system ID for geometry               |
| <a href="#">ST_Area()</a>                 | Return Polygon or MultiPolygon area                           |
| <a href="#">ST_AsBinary(), ST_AsWKB()</a> | Convert from internal geometry format to WKB                  |
| <a href="#">ST_AsGeoJSON()</a>            | Generate GeoJSON object from geometry                         |
| <a href="#">ST_AsText(), ST_AsWKT()</a>   | Convert from internal geometry format to WKT                  |
| <a href="#">ST_Buffer()</a>               | Return geometry of points within given distance from geometry |
| <a href="#">ST_Buffer_Strategy()</a>      | Produce strategy option for ST_Buffer()                       |
| <a href="#">ST_Centroid()</a>             | Return centroid as a point                                    |
| <a href="#">ST_Contains()</a>             | Whether one geometry contains another                         |
| <a href="#">ST_ConvexHull()</a>           | Return convex hull of geometry                                |
| <a href="#">ST_Crosses()</a>              | Whether one geometry crosses another                          |
| <a href="#">ST_Difference()</a>           | Return point set difference of two geometries                 |
| <a href="#">ST_Dimension()</a>            | Dimension of geometry   |
| <a href="#">ST_Disjoint()</a>             | Whether one geometry is disjoint from another                 |
| <a href="#">ST_Distance()</a>             | The distance of one geometry from another                     |

| Name  | Description                                      |
|---|--|
| <code>ST_Distance_Sphere()</code>   | Minimum distance on earth between two geometries |
| <code>ST_EndPoint()</code>  | End Point of LineString                          |
| <code>ST_Envelope()</code>  | Return MBR of geometry                           |
| <code>ST_Equals()</code>  | Whether one geometry is equal to another         |
| <code>ST_ExteriorRing()</code>  | Return exterior ring of Polygon                  |
| <code>ST_GeoHash()</code>   | Produce a geohash value                          |
| <code>ST_GeomCollFromText()</code> ,<br><code>ST_GeometryCollectionFromText()</code> ,<br><code>ST_GeomCollFromTxt()</code> | Return geometry collection from WKT              |
| <code>ST_GeomCollFromWKB()</code> ,<br><code>ST_GeometryCollectionFromWKB()</code>  | Return geometry collection from WKB              |
| <code>ST_GeometryN()</code>   | Return N-th geometry from geometry collection    |
| <code>ST_GeometryType()</code>  | Return name of geometry type                     |
| <code>ST_GeomFromGeoJSON()</code>   | Generate geometry from GeoJSON object            |
| <code>ST_GeomFromText()</code> ,<br><code>ST_GeometryFromText()</code>  | Return geometry from WKT                         |
| <code>ST_GeomFromWKB()</code> ,<br><code>ST_GeometryFromWKB()</code>  | Return geometry from WKB                         |
| <code>ST_InteriorRingN()</code>   | Return N-th interior ring of Polygon             |
| <code>ST_Intersection()</code>  | Return point set intersection of two geometries  |
| <code>ST_Intersects()</code>  | Whether one geometry intersects another          |
| <code>ST_IsClosed()</code>  | Whether a geometry is closed and simple          |
| <code>ST_IsEmpty()</code>   | Placeholder function                             |
| <code>ST_IsSimple()</code>  | Whether a geometry is simple                     |
| <code>ST_IsValid()</code>   | Whether a geometry is valid                      |
| <code>ST_LatFromGeoHash()</code>  | Return latitude from geohash value               |
| <code>ST_Length()</code>  | Return length of LineString                      |
| <code>ST_LineFromText()</code> ,<br><code>ST_LineStringFromText()</code>  | Construct LineString from WKT                    |
| <code>ST_LineFromWKB()</code> ,<br><code>ST_LineStringFromWKB()</code>  | Construct LineString from WKB                    |
| <code>ST_LongFromGeoHash()</code>   | Return longitude from geohash value              |
| <code>ST_MakeEnvelope()</code>  | Rectangle around two points                      |
| <code>ST_MLineFromText()</code> ,<br><code>ST_MultiLineStringFromText()</code>  | Construct MultiLineString from WKT               |
| <code>ST_MLineFromWKB()</code> ,<br><code>ST_MultiLineStringFromWKB()</code>  | Construct MultiLineString from WKB               |
| <code>ST_MPointFromText()</code> ,<br><code>ST_MultiPointFromText()</code>  | Construct MultiPoint from WKT                    |
| <code>ST_MPointFromWKB()</code> ,<br><code>ST_MultiPointFromWKB()</code>  | Construct MultiPoint from WKB                    |
| <code>ST_MPolyFromText()</code> ,<br><code>ST_MultiPolygonFromText()</code>   | Construct MultiPolygon from WKT                  |

| Name  | Description  |
|---|--|
| <code>ST_MPolyFromWKB()</code> ,<br><code>ST_MultiPolygonFromWKB()</code> | Construct MultiPolygon from WKB  |
| <code>ST_NumGeometries()</code>   | Return number of geometries in geometry collection   |
| <code>ST_NumInteriorRing()</code> ,<br><code>ST_NumInteriorRings()</code> | Return number of interior rings in Polygon   |
| <code>ST_NumPoints()</code>   | Return number of points in LineString  |
| <code>ST_Overlaps()</code>  | Whether one geometry overlaps another  |
| <code>ST_PointFromGeoHash()</code>  | Convert geohash value to POINT value   |
| <code>ST_PointFromText()</code>   | Construct Point from WKT   |
| <code>ST_PointFromWKB()</code>  | Construct Point from WKB   |
| <code>ST_PointN()</code>  | Return N-th point from LineString  |
| <code>ST_PolyFromText()</code> ,<br><code>ST_PolygonFromText()</code>     | Construct Polygon from WKT   |
| <code>ST_PolyFromWKB()</code> ,<br><code>ST_PolygonFromWKB()</code>       | Construct Polygon from WKB   |
| <code>ST_Simplify()</code>  | Return simplified geometry   |
| <code>ST_SRID()</code>  | Return spatial reference system ID for geometry  |
| <code>ST_StartPoint()</code>  | Start Point of LineString  |
| <code>ST_SymDifference()</code>   | Return point set symmetric difference of two geometries                                      |
| <code>ST_Touches()</code>   | Whether one geometry touches another   |
| <code>ST_Union()</code>   | Return point set union of two geometries   |
| <code>ST_Validate()</code>  | Return validated geometry  |
| <code>ST_Within()</code>  | Whether one geometry is within another   |
| <code>ST_X()</code>   | Return X coordinate of Point   |
| <code>ST_Y()</code>   | Return Y coordinate of Point   |
| <code>StartPoint()</code> (deprecated 5.7.6)                              | Start Point of LineString  |
| <code>STD()</code>  | Return the population standard deviation   |
| <code>STDDEV()</code>   | Return the population standard deviation   |
| <code>STDDEV_POP()</code>   | Return the population standard deviation   |
| <code>STDDEV_SAMP()</code>  | Return the sample standard deviation   |
| <code>STR_TO_DATE()</code>  | Convert a string to a date   |
| <code>STRCMP()</code>   | Compare two strings  |
| <code>SUBDATE()</code>  | Synonym for <code>DATE_SUB()</code> when invoked with three arguments                        |
| <code>SUBSTR()</code>   | Return the substring as specified  |
| <code>SUBSTRING()</code>  | Return the substring as specified  |
| <code>SUBSTRING_INDEX()</code>  | Return a substring from a string before the specified number of occurrences of the delimiter |
| <code>SUBTIME()</code>  | Subtract times   |
| <code>SUM()</code>  | Return the sum   |
| <code>SYSDATE()</code>  | Return the time at which the function executes   |
| <code>SYSTEM_USER()</code>  | Synonym for <code>USER()</code>  |

| Name  | Description   |
|---|---|
| <a href="#">TAN()</a>                               | Return the tangent of the argument  |
| <a href="#">TIME()</a>                              | Extract the time portion of the expression passed   |
| <a href="#">TIME_FORMAT()</a>                       | Format as time  |
| <a href="#">TIME_TO_SEC()</a>                       | Return the argument converted to seconds  |
| <a href="#">TIMEDIFF()</a>                          | Subtract time   |
| <a href="#">*</a>                                   | Multiplication operator   |
| <a href="#">TIMESTAMP()</a>                         | With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments |
| <a href="#">TIMESTAMPADD()</a>                      | Add an interval to a datetime expression  |
| <a href="#">TIMESTAMPDIFF()</a>                     | Subtract an interval from a datetime expression   |
| <a href="#">TO_BASE64()</a>                         | Return the argument converted to a base-64 string   |
| <a href="#">TO_DAYS()</a>                           | Return the date argument converted to days  |
| <a href="#">TO_SECONDS()</a>                        | Return the date or datetime argument converted to seconds since Year 0  |
| <a href="#">Touches()</a> (deprecated 5.7.6)        | Whether one geometry touches another  |
| <a href="#">TRIM()</a>                              | Remove leading and trailing spaces  |
| <a href="#">TRUNCATE()</a>                          | Truncate to specified number of decimal places  |
| <a href="#">UCASE()</a>                             | Synonym for UPPER()   |
| <a href="#">-</a>                                   | Change the sign of the argument   |
| <a href="#">UNCOMPRESS()</a>                        | Uncompress a string compressed  |
| <a href="#">UNCOMPRESSED_LENGTH()</a>               | Return the length of a string before compression  |
| <a href="#">UNHEX()</a>                             | Return a string containing hex representation of a number   |
| <a href="#">UNIX_TIMESTAMP()</a>                    | Return a Unix timestamp   |
| <a href="#">UpdateXML()</a>                         | Return replaced XML fragment  |
| <a href="#">UPPER()</a>                             | Convert to uppercase  |
| <a href="#">USER()</a>                              | The user name and host name provided by the client  |
| <a href="#">UTC_DATE()</a>                          | Return the current UTC date   |
| <a href="#">UTC_TIME()</a>                          | Return the current UTC time   |
| <a href="#">UTC_TIMESTAMP()</a>                     | Return the current UTC date and time  |
| <a href="#">UUID()</a>                              | Return a Universal Unique Identifier (UUID)   |
| <a href="#">UUID_SHORT()</a>                        | Return an integer-valued universal identifier   |
| <a href="#">VALIDATE_PASSWORD_STRENGTH()</a>        | Determine strength of password  |
| <a href="#">VALUES()</a>                            | Defines the values to be used during an INSERT  |
| <a href="#">VAR_POP()</a>                           | Return the population standard variance   |
| <a href="#">VAR_SAMP()</a>                          | Return the sample variance  |
| <a href="#">VARIANCE()</a>                          | Return the population standard variance   |
| <a href="#">VERSION()</a>                           | Return a string that indicates the MySQL server version   |
| <a href="#">WAIT_FOR_EXECUTED_GTID_SET()</a>        | Wait until the given GTIDs have executed on slave.  |
| <a href="#">WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()</a> | Wait until the given GTIDs have executed on slave.  |
| <a href="#">WEEK()</a>                              | Return the week number  |
| <a href="#">WEEKDAY()</a>                           | Return the weekday index  |

| Name                                       | Description  |
|--|--|
| <code>WEEKOFYEAR ( )</code>                | Return the calendar week of the date (1-53)          |
| <code>WEIGHT_STRING ( )</code>             | Return the weight string for a string                |
| <code>Within ( )</code> (deprecated 5.7.6) | Whether MBR of one geometry is within MBR of another |
| <code>X ( )</code> (deprecated 5.7.6)      | Return X coordinate of Point                         |
| <code>XOR</code>                           | Logical XOR  |
| <code>Y ( )</code> (deprecated 5.7.6)      | Return Y coordinate of Point                         |
| <code>YEAR ( )</code>                      | Return the year                                      |
| <code>YEARWEEK ( )</code>                  | Return the year and week                             |

## 13.2 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts numbers to strings as necessary, and vice versa.

```
mysql> SELECT 1+'1';
      -> 2
mysql> SELECT CONCAT(2,' test');
      -> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST ( )` function. Conversion occurs implicitly with the `CONCAT ( )` function because it expects string arguments.

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
      -> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
      -> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL-safe <=>` equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. Note that this is not done for the arguments to `IN ( )`! To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` with date or time values, use `CAST ( )` to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a `DATETIME` value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as `DATETIME` values, use `CAST ( )` to explicitly convert the subquery value to `DATETIME`.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.

- In all other cases, the arguments are compared as floating-point (real) numbers.

For information about conversion of values from one temporal type to another, see [Section 12.3.7, “Conversion Between Date and Time Types”](#).

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON and the values compared as JSON values. For details, see [Comparison and Ordering of JSON Values](#).

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
      -> 0
mysql> SELECT 7 > '6x';
      -> 1
mysql> SELECT 0 > 'x6';
      -> 0
mysql> SELECT 0 = 'x6';
      -> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If *str\_col* is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1, such as '1', ' 1', or '1a'.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```
mysql> SELECT '18015376320243458' = 18015376320243458;
      -> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
      -> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```
mysql> SELECT '18015376320243459'+0.0;
      -> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
      -> 1
```

For more information about floating-point comparisons, see [Section B.5.4.8, “Problems with Floating-Point Values”](#).

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.

- Because the conversions produced by this library differ in some cases from non-`dt.oa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. `D` represents a value with a `DECIMAL` or string representation, and `F` represents a floating-point number in native binary (IEEE) format.

- $F \rightarrow D$  conversion is done with the best possible precision, returning  $D$  as the shortest string that yields  $F$  when read back in and rounded to the nearest value in native binary format as specified by IEEE.
- $D \rightarrow F$  conversion is done such that  $F$  is the nearest native binary number to the input decimal string  $D$ .

- These properties imply that  $F \rightarrow D \rightarrow F$  conversions are lossless unless  $F$  is `-inf`, `+inf`, or `NaN`. The latter values are not supported because the SQL standard defines them as invalid values for `FLOAT` or `DOUBLE`.

For  $D \rightarrow F \rightarrow D$  conversions, a sufficient condition for losslessness is that  $D$  uses 15 or fewer digits of precision, is not a denormal value, `-inf`, `+inf`, or `NaN`. In some cases, the conversion is lossless even if  $D$  has more than 15 digits of precision, but this is not always the case.

Implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. (These variables commonly are set with `SET NAMES`. For information about connection character sets, see [Section 11.1.4, “Connection Character Sets and Collations”](#).)

This means that such a conversion results in a character (nonbinary) string (a [CHAR](#), [VARCHAR](#), or [LONGTEXT](#) value), except in the case that the connection character set is set to [binary](#). In that case, the conversion result is a binary string (a [BINARY](#), [VARBINARY](#), or [LONGBLOB](#) value).

For integer expressions, the preceding remarks about expression *evaluation* apply somewhat differently for expression *assignment*; for example, in a statement such as this:

```
CREATE TABLE t SELECT integer_expr;
```

In this case, the table in the column resulting from the expression has type `INT` or `BIGINT` depending on the length of the integer expression. If the maximum length of the expression does not fit in an `INT`, `BIGINT` is used instead. The length is taken from the `max_length` value of the `SELECT` result set metadata (see [Section 26.8.5, “C API Data Structures”](#)). This means that you can force a `BIGINT` rather than `INT` by use of a sufficiently long expression:

```
CREATE TABLE t SELECT 00000000000000000000;
```

## 13.3 Operators

Table 13.2 Operators

| Name                    | Description  |
|-------------------------|--|
| AND, &&                 | Logical AND  |
| =                       | Assign a value (as part of a <a href="#">SET</a> statement, or as part of the <a href="#">SET</a> clause in an <a href="#">UPDATE</a> statement) |
| :=                      | Assign a value   |
| BETWEEN ... AND ...     | Check whether a value is within a range of values  |
| BINARY                  | Cast a string to a binary string   |
| &                       | Bitwise AND  |
| ~                       | Bitwise inversion  |
|                         | Bitwise OR   |
| ^                       | Bitwise XOR  |
| CASE                    | Case operator  |
| DIV                     | Integer division   |
| /                       | Division operator  |
| =                       | Equal operator   |
| <=>                     | NULL-safe equal to operator  |
| >                       | Greater than operator  |
| >=                      | Greater than or equal operator   |
| IS                      | Test a value against a boolean   |
| IS NOT                  | Test a value against a boolean   |
| IS NOT NULL             | NOT NULL value test  |
| IS NULL                 | NULL value test  |
| ->                      | Return value from JSON column after evaluating path; equivalent to <a href="#">JSON_EXTRACT()</a> .  |
| ->>                     | Return value from JSON column after evaluating path and unquoting the result; equivalent to <a href="#">JSON_UNQUOTE(JSON_EXTRACT())</a> .       |
| <<                      | Left shift   |
| <                       | Less than operator   |
| <=                      | Less than or equal operator  |
| LIKE                    | Simple pattern matching  |
| -                       | Minus operator   |
| %, MOD                  | Modulo operator  |
| NOT, !                  | Negates value  |
| NOT BETWEEN ... AND ... | Check whether a value is not within a range of values  |
| !=, <>                  | Not equal operator   |
| NOT LIKE                | Negation of simple pattern matching  |
| NOT REGEXP              | Negation of REGEXP   |
| , OR                    | Logical OR   |
| +                       | Addition operator  |

| Name                        | Description                                |
|-----------------------------|--|
| <a href="#">REGEXP</a>      | Pattern matching using regular expressions |
| <code>&gt;&gt;</code>       | Right shift                                |
| <a href="#">RLIKE</a>       | Synonym for REGEXP                         |
| <a href="#">SOUNDS LIKE</a> | Compare sounds                             |
| <code>*</code>              | Multiplication operator                    |
| <code>-</code>              | Change the sign of the argument            |
| <a href="#">XOR</a>         | Logical XOR                                |

### 13.3.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```

INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||
= (assignment), :=

```

The precedence of `=` depends on whether it is used as a comparison operator (`=`) or as an assignment operator (`:=`). When used as a comparison operator, it has the same precedence as `<=>`, `>=`, `>`, `<=`, `<`, `<>`, `!=`, [IS](#), [LIKE](#), [REGEXP](#), and [IN](#). When used as an assignment operator, it has the same precedence as `:=`. [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#), and [Section 10.4, “User-Defined Variables”](#), explain how MySQL determines which interpretation of `=` should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The meaning of some operators depends on the SQL mode:

- By default, `||` is a logical [OR](#) operator. With [PIPES\\_AS\\_CONCAT](#) enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than [NOT](#). With [HIGH\\_NOT\\_PRECEDENCE](#) enabled, `!` and [NOT](#) have the same precedence.

See [Section 6.1.8, “Server SQL Modes”](#).

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```

mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9

```

## 13.3.2 Comparison Functions and Operators

**Table 13.3 Comparison Operators**

| Name                                 | Description   |
|--------------------------------------|---|
| <code>BETWEEN ... AND ...</code>     | Check whether a value is within a range of values                     |
| <code>COALESCE ( )</code>            | Return the first non-NULL argument                                    |
| <code>=</code>                       | Equal operator  |
| <code>&lt;=&gt;</code>               | NULL-safe equal to operator   |
| <code>&gt;</code>                    | Greater than operator   |
| <code>&gt;=</code>                   | Greater than or equal operator  |
| <code>GREATEST ( )</code>            | Return the largest argument   |
| <code>IN ( )</code>                  | Check whether a value is within a set of values                       |
| <code>INTERVAL ( )</code>            | Return the index of the argument that is less than the first argument |
| <code>IS</code>                      | Test a value against a boolean  |
| <code>IS NOT</code>                  | Test a value against a boolean  |
| <code>IS NOT NULL</code>             | NOT NULL value test   |
| <code>IS NULL</code>                 | NULL value test   |
| <code>ISNULL ( )</code>              | Test whether the argument is NULL                                     |
| <code>LEAST ( )</code>               | Return the smallest argument  |
| <code>&lt;</code>                    | Less than operator  |
| <code>&lt;=</code>                   | Less than or equal operator   |
| <code>LIKE</code>                    | Simple pattern matching   |
| <code>NOT BETWEEN ... AND ...</code> | Check whether a value is not within a range of values                 |
| <code>!=, &lt;&gt;</code>            | Not equal operator  |
| <code>NOT IN ( )</code>              | Check whether a value is not within a set of values                   |
| <code>NOT LIKE</code>                | Negation of simple pattern matching                                   |
| <code>STRCMP ( )</code>              | Compare two strings   |

Comparison operations result in a value of `1` (`TRUE`), `0` (`FALSE`), or `NULL`. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see [Section 14.2.10.5, “Row Subqueries”](#).

Some of the functions in this section return values other than `1` (`TRUE`), `0` (`FALSE`), or `NULL`. For example, `LEAST ( )` and `GREATEST ( )`. However, the value they return is based on comparison operations performed according to the rules described in [Section 13.2, “Type Conversion in Expression Evaluation”](#).

To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See [Section 13.10, “Cast Functions and Operators”](#).

By default, string comparisons are not case sensitive and use the current character set. The default is `latin1` (cp1252 West European), which also works well for English.

- `=`

Equal:

```
mysql> SELECT 1 = 0;
      -> 0
mysql> SELECT '0' = 0;
      -> 1
mysql> SELECT '0.0' = 0;
      -> 1
mysql> SELECT '0.01' = 0;
      -> 0
mysql> SELECT '.01' = 0.01;
      -> 1
```

For row comparisons, `(a, b) = (x, y)` is equivalent to:

```
(a = x) AND (b = y)
```

- `<=>`

`NULL`-safe equal. This operator performs an equality comparison like the `=` operator, but returns `1` rather than `NULL` if both operands are `NULL`, and `0` rather than `NULL` if one operand is `NULL`.

The `<=>` operator is equivalent to the standard SQL `IS NOT DISTINCT FROM` operator.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
      -> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
      -> 1, NULL, NULL
```

For row comparisons, `(a, b) <=> (x, y)` is equivalent to:

```
(a <=> x) AND (b <=> y)
```

- `<>`, `!=`

Not equal:

```
mysql> SELECT '.01' <> '0.01';
      -> 1
mysql> SELECT .01 <> '0.01';
      -> 0
mysql> SELECT 'zapp' <> 'zappp';
      -> 1
```

For row comparisons, `(a, b) <> (x, y)` and `(a, b) != (x, y)` are equivalent to:

```
(a <> x) OR (b <> y)
```

- `<=`

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
-> 1
```

For row comparisons,  $(a, b) \leq (x, y)$  is equivalent to:

```
(a < x) OR ((a = x) AND (b <= y))
```

- $<$

Less than:

```
mysql> SELECT 2 < 2;
-> 0
```

For row comparisons,  $(a, b) < (x, y)$  is equivalent to:

```
(a < x) OR ((a = x) AND (b < y))
```

- $\geq$

Greater than or equal:

```
mysql> SELECT 2 >= 2;
-> 1
```

For row comparisons,  $(a, b) \geq (x, y)$  is equivalent to:

```
(a > x) OR ((a = x) AND (b >= y))
```

- $>$

Greater than:

```
mysql> SELECT 2 > 2;
-> 0
```

For row comparisons,  $(a, b) > (x, y)$  is equivalent to:

```
(a > x) OR ((a = x) AND (b > y))
```

- `IS boolean_value`

Tests a value against a boolean value, where *boolean\_value* can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- `IS NOT boolean_value`

Tests a value against a boolean value, where *boolean\_value* can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- `IS NULL`

Tests whether a value is `NULL`.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL`:

- If `sql_auto_is_null` variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 13.14, "Information Functions"](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison can be disabled by setting `sql_auto_is_null = 0`. See [Section 6.1.5, "Server System Variables"](#).

The default value of `sql_auto_is_null` is 0.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date '0000-00-00' by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a '0000-00-00' date value.

See [Obtaining Auto-Increment Values](#), and the description for the `FLAG_AUTO_IS_NULL` option at [Connector/ODBC Connection Parameters](#).

- `IS NOT NULL`

Tests whether a value is not `NULL`.

```
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

- `expr BETWEEN min AND max`

If `expr` is greater than or equal to `min` and `expr` is less than or equal to `max`, `BETWEEN` returns 1, otherwise it returns 0. This is equivalent to the expression `(min <= expr AND expr <= max)` if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in [Section 13.2, "Type Conversion in Expression Evaluation"](#), but applied to all the three arguments.

```
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

For best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type. Examples: If you compare a `DATETIME` to two `DATE` values,

convert the `DATE` values to `DATETIME` values. If you use a string constant such as `'2001-1-1'` in a comparison to a `DATE`, cast the string to a `DATE`.

- `expr NOT BETWEEN min AND max`

This is the same as `NOT (expr BETWEEN min AND max)`.

- `COALESCE(value,...)`

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.

```
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
```

- `GREATEST(value1,value2,...)`

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST()`.

```
mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'
```

`GREATEST()` returns `NULL` if any argument is `NULL`.

- `expr IN (value,...)`

Returns `1` if `expr` is equal to any of the values in the `IN` list, else returns `0`. If all values are constants, they are evaluated according to the type of `expr` and sorted. The search for the item then is done using a binary search. This means `IN` is very quick if the `IN` value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described in [Section 13.2, "Type Conversion in Expression Evaluation"](#), but applied to all the arguments.

```
mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1
```

`IN` can be used to compare row constructors:

```
mysql> SELECT (3,4) IN ((1,2),(3,4));
-> 1
mysql> SELECT (3,4) IN ((1,2),(3,5));
-> 0
```

You should never mix quoted and unquoted values in an `IN` list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an `IN` expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

The number of values in the `IN` list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, `IN` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

`IN()` syntax can also be used to write certain types of subqueries. See [Section 14.2.10.3, “Subqueries with ANY, IN, or SOME”](#).

- `expr NOT IN (value,...)`

This is the same as `NOT (expr IN (value,...))`.

- `ISNULL(expr)`

If `expr` is `NULL`, `ISNULL()` returns `1`, otherwise it returns `0`.

```
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1
```

`ISNULL()` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields `NULL`.)

The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `INTERVAL(N,N1,N2,N3,...)`

Returns `0` if `N < N1`, `1` if `N < N2` and so on or `-1` if `N` is `NULL`. All arguments are treated as integers. It is required that `N1 < N2 < N3 < ... < Nn` for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- `LEAST(value1,value2,...)`

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is `NULL`, the result is `NULL`. No comparison is needed.
- If the return value is used in an `INTEGER` context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a `REAL` context or all arguments are real-valued, they are compared as reals.
- If the arguments comprise a mix of numbers and strings, they are compared as numbers.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

```
mysql> SELECT LEAST(2,0);
-> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
```

```
mysql> SELECT LEAST('B','A','C');
-> 'A'
```

Note that the preceding conversion rules can produce strange results in some borderline cases:

```
mysql> SELECT CAST(LEAST(3600, 9223372036854775808.0) AS SIGNED);
-> -9223372036854775808
```

This happens because MySQL reads `9223372036854775808.0` in an integer context. The integer representation is not good enough to hold the value, so it wraps to a signed integer.

### 13.3.3 Logical Operators

Table 13.4 Logical Operators

| Name    | Description   |
|---------|---------------|
| AND, && | Logical AND   |
| NOT, !  | Negates value |
| , OR    | Logical OR    |
| XOR     | Logical XOR   |

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as 1 (`TRUE`), 0 (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- `NOT, !`

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and `NOT NULL` returns `NULL`.

```
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces 1 because the expression evaluates the same way as `(!1)+1`.

- `AND, &&`

Logical AND. Evaluates to 1 if all operands are nonzero and not `NULL`, to 0 if one or more operands are 0, otherwise `NULL` is returned.

```
mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
```

```

-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0

```

- **OR, ||**

Logical OR. When both operands are non-**NULL**, the result is **1** if any operand is nonzero, and **0** otherwise. With a **NULL** operand, the result is **1** if the other operand is nonzero, and **NULL** otherwise. If both operands are **NULL**, the result is **NULL**.

```

mysql> SELECT 1 OR 1;
-> 1
mysql> SELECT 1 OR 0;
-> 1
mysql> SELECT 0 OR 0;
-> 0
mysql> SELECT 0 OR NULL;
-> NULL
mysql> SELECT 1 OR NULL;
-> 1

```

- **XOR**

Logical XOR. Returns **NULL** if either operand is **NULL**. For non-**NULL** operands, evaluates to **1** if an odd number of operands is nonzero, otherwise **0** is returned.

```

mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1

```

$a \text{ XOR } b$  is mathematically equal to  $(a \text{ AND } (\text{NOT } b)) \text{ OR } ((\text{NOT } a) \text{ AND } b)$ .

### 13.3.4 Assignment Operators

Table 13.5 Assignment Operators

| Name      | Description   |
|-----------|---|
| <b>=</b>  | Assign a value (as part of a <b>SET</b> statement, or as part of the <b>SET</b> clause in an <b>UPDATE</b> statement) |
| <b>:=</b> | Assign a value  |

- **:=**

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same **SET** statement. You can perform multiple assignments in the same statement.

Unlike **=**, the **:=** operator is never interpreted as a comparison operator. This means you can use **:=** in any valid SQL statement (not just in **SET** statements) to assign a value to a variable.

```

mysql> SELECT @var1, @var2;
-> NULL, NULL

```

```
mysql> SELECT @var1 := 1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
      -> 1, 1
mysql> SELECT @var1, @var2;
      -> 1, 1

mysql> SELECT @var1:=COUNT(*) FROM t1;
      -> 4
mysql> SELECT @var1;
      -> 4
```

You can make value assignments using `:=` in other statements besides `SELECT`, such as `UPDATE`, as shown here:

```
mysql> SELECT @var1;
      -> 4
mysql> SELECT * FROM t1;
      -> 1, 3, 5, 7

mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT @var1;
      -> 1
mysql> SELECT * FROM t1;
      -> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the `:=` operator, this is not recommended. [Section 10.4, “User-Defined Variables”](#), explains why you should avoid doing this.

## • =

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a `SET` statement, `=` is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, `=` is treated identically to `:=`.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a [comparison operator](#).

```
mysql> SELECT @var1, @var2;
      -> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
      -> 1, 1
mysql> SELECT @var1, @var2;
      -> 1, 1
```

For more information, see [Section 14.7.4.1](#), “SET Syntax for Variable Assignment”, [Section 14.2.11](#), “UPDATE Syntax”, and [Section 14.2.10](#), “Subquery Syntax”.

## 13.4 Control Flow Functions

**Table 13.6 Flow Control Operators**

| Name                     | Description                               |
|--------------------------|---|
| <a href="#">CASE</a>     | Case operator                             |
| <a href="#">IF()</a>     | If/else construct                         |
| <a href="#">IFNULL()</a> | Null if/else construct                    |
| <a href="#">NULLIF()</a> | Return NULL if <code>expr1 = expr2</code> |

- `CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END`

`CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END`

The first version returns the `result` where `value=compare_value`. The second version returns the result for the first condition that is true. If there was no matching result value, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
->      WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
->      WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

The return type of a `CASE` expression is the compatible aggregated type of all return values, but also depends on the context in which it is used. If used in a string context, the result is returned as a string. If used in a numeric context, the result is returned as a decimal, real, or integer value.

### Note

The syntax of the `CASE expression` shown here differs slightly from that of the SQL `CASE statement` described in [Section 14.6.5.1](#), “CASE Syntax”, for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

- `IF(expr1,expr2,expr3)`

If `expr1` is TRUE (`expr1 <> 0` and `expr1 <> NULL`) then `IF()` returns `expr2`; otherwise it returns `expr3`. `IF()` returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

If only one of `expr2` or `expr3` is explicitly `NULL`, the result type of the `IF()` function is the type of the non-`NULL` expression.

The default return type of `IF()` (which may matter when it is stored into a temporary table) is calculated as follows.

| Expression  | Return Value   |
|---|----------------|
| <code>expr2</code> or <code>expr3</code> returns a string               | string         |
| <code>expr2</code> or <code>expr3</code> returns a floating-point value | floating-point |
| <code>expr2</code> or <code>expr3</code> returns an integer             | integer        |

If `expr2` and `expr3` are both strings, the result is case sensitive if either string is case sensitive.

#### Note

There is also an `IF statement`, which differs from the `IF()` function described here. See [Section 14.6.5.2, “IF Syntax”](#).

- `IFNULL(expr1,expr2)`

If `expr1` is not `NULL`, `IFNULL()` returns `expr1`; otherwise it returns `expr2`. `IFNULL()` returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default result value of `IFNULL(expr1,expr2)` is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| test  | varbinary(4)  | NO   |     |         |       |
+-----+-----+-----+-----+-----+-----+
```

In this example, the type of the `test` column is `VARBINARY(4)`.

- `NULLIF(expr1,expr2)`

Returns `NULL` if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

```
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

Note that MySQL evaluates `expr1` twice if the arguments are not equal.

## 13.5 String Functions

**Table 13.7 String Operators**

| <b>Name</b>                       | <b>Description</b>   |
|-----------------------------------|--|
| <code>ASCII ( )</code>            | Return numeric value of left-most character  |
| <code>BIN ( )</code>              | Return a string containing binary representation of a number   |
| <code>BIT_LENGTH ( )</code>       | Return length of argument in bits  |
| <code>CHAR ( )</code>             | Return the character for each integer passed   |
| <code>CHAR_LENGTH ( )</code>      | Return number of characters in argument  |
| <code>CHARACTER_LENGTH ( )</code> | Synonym for <code>CHAR_LENGTH()</code>   |
| <code>CONCAT ( )</code>           | Return concatenated string   |
| <code>CONCAT_WS ( )</code>        | Return concatenate with separator  |
| <code>ELT ( )</code>              | Return string at index number  |
| <code>EXPORT_SET ( )</code>       | Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string |
| <code>FIELD ( )</code>            | Return the index (position) of the first argument in the subsequent arguments  |
| <code>FIND_IN_SET ( )</code>      | Return the index position of the first argument within the second argument   |
| <code>FORMAT ( )</code>           | Return a number formatted to specified number of decimal places  |
| <code>FROM_BASE64 ( )</code>      | Decode to a base-64 string and return result   |
| <code>HEX ( )</code>              | Return a hexadecimal representation of a decimal or string value   |
| <code>INSERT ( )</code>           | Insert a substring at the specified position up to the specified number of characters  |
| <code>INSTR ( )</code>            | Return the index of the first occurrence of substring  |
| <code>LCASE ( )</code>            | Synonym for <code>LOWER()</code>   |
| <code>LEFT ( )</code>             | Return the leftmost number of characters as specified  |
| <code>LENGTH ( )</code>           | Return the length of a string in bytes   |
| <code>LIKE</code>                 | Simple pattern matching  |
| <code>LOAD_FILE ( )</code>        | Load the named file  |
| <code>LOCATE ( )</code>           | Return the position of the first occurrence of substring   |
| <code>LOWER ( )</code>            | Return the argument in lowercase   |
| <code>LPAD ( )</code>             | Return the string argument, left-padded with the specified string  |
| <code>LTRIM ( )</code>            | Remove leading spaces  |
| <code>MAKE_SET ( )</code>         | Return a set of comma-separated strings that have the corresponding bit in bits set  |
| <code>MATCH</code>                | Perform full-text search   |
| <code>MID ( )</code>              | Return a substring starting from the specified position  |
| <code>NOT LIKE</code>             | Negation of simple pattern matching  |
| <code>NOT REGEXP</code>           | Negation of <code>REGEXP</code>  |
| <code>OCT ( )</code>              | Return a string containing octal representation of a number  |
| <code>OCTET_LENGTH ( )</code>     | Synonym for <code>LENGTH()</code>  |

| Name                           | Description  |
|--------------------------------|--|
| <code>ORD()</code>             | Return character code for leftmost character of the argument                                 |
| <code>POSITION()</code>        | Synonym for <code>LOCATE()</code>  |
| <code>QUOTE()</code>           | Escape the argument for use in an SQL statement  |
| <code>REGEXP</code>            | Pattern matching using regular expressions   |
| <code>REPEAT()</code>          | Repeat a string the specified number of times  |
| <code>REPLACE()</code>         | Replace occurrences of a specified string  |
| <code>REVERSE()</code>         | Reverse the characters in a string   |
| <code>RIGHT()</code>           | Return the specified rightmost number of characters  |
| <code>RLIKE</code>             | Synonym for <code>REGEXP</code>  |
| <code>RPAD()</code>            | Append string the specified number of times  |
| <code>RTRIM()</code>           | Remove trailing spaces   |
| <code>SOUNDEX()</code>         | Return a soundex string  |
| <code>SOUNDS LIKE</code>       | Compare sounds   |
| <code>SPACE()</code>           | Return a string of the specified number of spaces  |
| <code>STRCMP()</code>          | Compare two strings  |
| <code>SUBSTR()</code>          | Return the substring as specified  |
| <code>SUBSTRING()</code>       | Return the substring as specified  |
| <code>SUBSTRING_INDEX()</code> | Return a substring from a string before the specified number of occurrences of the delimiter |
| <code>TO_BASE64()</code>       | Return the argument converted to a base-64 string  |
| <code>TRIM()</code>            | Remove leading and trailing spaces   |
| <code>UCASE()</code>           | Synonym for <code>UPPER()</code>   |
| <code>UNHEX()</code>           | Return a string containing hex representation of a number                                    |
| <code>UPPER()</code>           | Convert to uppercase   |
| <code>WEIGHT_STRING()</code>   | Return the weight string for a string  |

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See [Section 6.1.1, “Configuring the Server”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- `ASCII(str)`

Returns the numeric value of the leftmost character of the string `str`. Returns 0 if `str` is the empty string. Returns `NULL` if `str` is `NULL`. `ASCII()` works for 8-bit characters.

```
mysql> SELECT ASCII('2');
-> 50
mysql> SELECT ASCII(2);
-> 50
mysql> SELECT ASCII('dx');
-> 100
```

See also the `ORD()` function.

- `BIN(N)`

Returns a string representation of the binary value of *N*, where *N* is a longlong (**BIGINT**) number. This is equivalent to **CONV(N,10,2)**. Returns **NULL** if *N* is **NULL**.

```
mysql> SELECT BIN(12);
-> '1100'
```

- **BIT\_LENGTH(*str*)**

Returns the length of the string *str* in bits.

```
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- **CHAR(*N*,... [USING *charset\_name*])**

**CHAR()** interprets each argument *N* as an integer and returns a string consisting of the characters given by the code values of those integers. **NULL** values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
-> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
-> 'MMM'
```

**CHAR()** arguments larger than 255 are converted into multiple result bytes. For example, **CHAR(256)** is equivalent to **CHAR(1,0)**, and **CHAR(256\*256)** is equivalent to **CHAR(1,0,0)**:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100          | 0100          |
+-----+-----+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000         | 010000         |
+-----+-----+
```

By default, **CHAR()** returns a binary string. To produce a string in a given character set, use the optional **USING** clause:

```
mysql> SELECT CHARSET(CHAR(X'65')), CHARSET(CHAR(X'65' USING utf8));
+-----+-----+
| CHARSET(CHAR(X'65')) | CHARSET(CHAR(X'65' USING utf8)) |
+-----+-----+
| binary              | utf8                             |
+-----+-----+
```

If **USING** is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from **CHAR()** becomes **NULL**.

- **CHAR\_LENGTH(*str*)**

Returns the length of the string *str*, measured in characters. A multibyte character counts as a single character. This means that for a string containing five 2-byte characters, **LENGTH()** returns 10, whereas **CHAR\_LENGTH()** returns 5.

- **CHARACTER\_LENGTH(*str*)**

**CHARACTER\_LENGTH()** is a synonym for **CHAR\_LENGTH()**.

- `CONCAT(str1,str2,...)`

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

`CONCAT()` returns `NULL` if any argument is `NULL`.

```
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

- `CONCAT_WS(separator,str1,str2,...)`

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
-> 'First name,Last Name'
```

`CONCAT_WS()` does not skip empty strings. However, it does skip any `NULL` values after the separator argument.

- `ELT(N,str1,str2,str3,...)`

`ELT()` returns the *N*th element of the list of strings: *str1* if *N* = 1, *str2* if *N* = 2, and so on. Returns `NULL` if *N* is less than 1 or greater than the number of arguments. `ELT()` is the complement of `FIELD()`.

```
mysql> SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
-> 'ej'
mysql> SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
-> 'foo'
```

- `EXPORT_SET(bits,on,off[,separator[,number_of_bits]])`

Returns a string such that for every bit set in the value *bits*, you get an *on* string and for every bit not set in the value, you get an *off* string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the *separator* string (the default being the comma character ,). The number of bits examined is given by *number\_of\_bits*, which has a default of 64 if not specified. *number\_of\_bits* is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of -1 is effectively the same as 64.

```
mysql> SELECT EXPORT_SET(5, 'Y', 'N', '', ', ', 4);
-> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', '', ', ', 10);
-> '0,1,1,0,0,0,0,0,0,0'
```

- `FIELD(str, str1, str2, str3, ...)`

Returns the index (position) of `str` in the `str1, str2, str3, ...` list. Returns 0 if `str` is not found.

If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If `str` is `NULL`, the return value is 0 because `NULL` fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```
mysql> SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 2
mysql> SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 0
```

- `FIND_IN_SET(str, strlist)`

Returns a value in the range of 1 to `N` if the string `str` is in the string list `strlist` consisting of `N` substrings. A string list is a string composed of substrings separated by `,` characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if `str` is not in `strlist` or if `strlist` is the empty string. Returns `NULL` if either argument is `NULL`. This function does not work properly if the first argument contains a comma (`,`) character.

```
mysql> SELECT FIND_IN_SET('b', 'a,b,c,d');
-> 2
```

- `FORMAT(X, D[, locale])`

Formats the number `X` to a format like `'#,###,###.##'`, rounded to `D` decimal places, and returns the result as a string. If `D` is 0, the result has no decimal point or fractional part.

The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable (see [Section 11.7, "MySQL Server Locale Support"](#)). If no locale is specified, the default is `'en_US'`.

```
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1, 4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2, 0);
-> '12,332'
mysql> SELECT FORMAT(12332.2, 2, 'de_DE');
-> '12.332,20'
```

- `FROM_BASE64(str)`

Takes a string encoded with the base-64 encoded rules used by `TO_BASE64()` and returns the decoded result as a binary string. The result is `NULL` if the argument is `NULL` or not a valid base-64 string. See the description of `TO_BASE64()` for details about the encoding and decoding rules.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

- `HEX(str), HEX(N)`

For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

For a numeric argument *N*, `HEX()` returns a hexadecimal string representation of the value of *N* treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`. The inverse of this operation is performed by `CONV(HEX(N),16,10)`.

```
mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
      -> 'abc', 616263, 'abc'
mysql> SELECT HEX(255), CONV(HEX(255),16,10);
      -> 'FF', 255
```

- `INSERT(str,pos,len,newstr)`

Returns the string *str*, with the substring beginning at position *pos* and *len* characters long replaced by the string *newstr*. Returns the original string if *pos* is not within the length of the string. Replaces the rest of the string from position *pos* if *len* is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
      -> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
      -> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
      -> 'QuWhat'
```

This function is multibyte safe.

- `INSTR(str,substr)`

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
      -> 4
mysql> SELECT INSTR('xbar', 'foobar');
      -> 0
```

This function is multibyte safe, and is case sensitive only if at least one argument is a binary string.

- `LCASE(str)`

`LCASE()` is a synonym for `LOWER()`.

In MySQL 5.7, `LCASE()` used in a view is rewritten as `LOWER()` when storing the view's definition. (Bug #12844279)

- `LEFT(str,len)`

Returns the leftmost *len* characters from the string *str*, or `NULL` if any argument is `NULL`.

```
mysql> SELECT LEFT('foobarbar', 5);
      -> 'fooba'
```

This function is multibyte safe.

- `LENGTH(str)`

Returns the length of the string *str*, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```
mysql> SELECT LENGTH('text');
```

-&gt; 4

**Note**

The `Length()` OpenGIS spatial function is named `ST_Length()` in MySQL.

- `LOAD_FILE(file_name)`

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the `FILE` privilege. The file must be readable by all and its size less than `max_allowed_packet` bytes. If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The `character_set_filesystem` system variable controls interpretation of file names that are given as literal strings.

```
mysql> UPDATE t
      SET blob_col=LOAD_FILE('/tmp/picture')
      WHERE id=1;
```

- `LOCATE(substr, str)`, `LOCATE(substr, str, pos)`

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`. Returns `NULL` if `substr` or `str` is `NULL`.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
      -> 4
mysql> SELECT LOCATE('xbar', 'foobar');
      -> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
      -> 7
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LOWER(str)`

Returns the string `str` with all characters changed to lowercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```
mysql> SELECT LOWER('QUADRATICALLY');
      -> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion, convert the string to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

For collations of Unicode character sets, `LOWER()` and `UPPER()` work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, `utf8_unicode_520_ci` works according to UCA 5.2.0, whereas

`utf8_unicode_ci` works according to UCA 4.0.0. See [Section 11.1.10.1](#), “Unicode Character Sets”.

This function is multibyte safe.

In previous versions of MySQL, `LOWER()` used within a view was rewritten as `LCASE()` when storing the view's definition. In MySQL 5.7, `LOWER()` is never rewritten in such cases, but `LCASE()` used within views is instead rewritten as `LOWER()`. (Bug #12844279)

- `LPAD(str, len, padstr)`

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT LPAD('hi',4,'?');
-> '??hi'
mysql> SELECT LPAD('hi',1,'?');
-> 'h'
```

- `LTRIM(str)`

Returns the string `str` with leading space characters removed.

```
mysql> SELECT LTRIM('  barbar');
-> 'barbar'
```

This function is multibyte safe.

- `MAKE_SET(bits, str1, str2, ...)`

Returns a set value (a string containing substrings separated by `,` characters) consisting of the strings that have the corresponding bit in `bits` set. `str1` corresponds to bit 0, `str2` to bit 1, and so on. `NULL` values in `str1`, `str2`, ... are not appended to the result.

```
mysql> SELECT MAKE_SET(1,'a','b','c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
-> 'hello,world'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
-> 'hello'
mysql> SELECT MAKE_SET(0,'a','b','c');
-> ''
```

- `MID(str, pos, len)`

`MID(str, pos, len)` is a synonym for `SUBSTRING(str, pos, len)`.

- `OCT(N)`

Returns a string representation of the octal value of `N`, where `N` is a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 8)`. Returns `NULL` if `N` is `NULL`.

```
mysql> SELECT OCT(12);
-> '14'
```

- `OCTET_LENGTH(str)`

`OCTET_LENGTH()` is a synonym for `LENGTH()`.

- `ORD(str)`

If the leftmost character of the string *str* is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code * 256)
+ (3rd byte code * 2562) ...
```

If the leftmost character is not a multibyte character, `ORD( )` returns the same value as the `ASCII( )` function.

```
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr, str)`.

- `QUOTE(str)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (`\`), single quote (`'`), ASCII `NUL`, and Control+Z preceded by a backslash. If the argument is `NULL`, the return value is the word “NULL” without enclosing single quotation marks.

```
mysql> SELECT QUOTE('Don\'t!');
-> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

For comparison, see the quoting rules for literal strings and within the C API in [Section 10.1.1, “String Literals”](#), and [Section 26.8.7.56, “mysql\\_real\\_escape\\_string\\_quote\(\)”](#).

- `REPEAT(str, count)`

Returns a string consisting of the string *str* repeated *count* times. If *count* is less than 1, returns an empty string. Returns `NULL` if *str* or *count* are `NULL`.

```
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str, from_str, to_str)`

Returns the string *str* with all occurrences of the string *from\_str* replaced by the string *to\_str*. `REPLACE( )` performs a case-sensitive match when searching for *from\_str*.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe.

- `REVERSE(str)`

Returns the string *str* with the order of the characters reversed.

```
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- `RIGHT(str, len)`

Returns the rightmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multibyte safe.

- `RPAD(str, len, padstr)`

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT RPAD('hi', 5, '?');
-> 'hi???'
mysql> SELECT RPAD('hi', 1, '?');
-> 'h'
```

This function is multibyte safe.

- `RTRIM(str)`

Returns the string `str` with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
-> 'barbar'
```

This function is multibyte safe.

- `SOUNDEX(str)`

Returns a soundex string from `str`. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All nonalphabetic characters in `str` are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

### Important

When using `SOUNDEX()`, you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including `utf-8`.

We hope to remove these limitations in a future release. See Bug #22638 for more information.

```
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

### Note

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is

that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2`

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

- `SPACE(N)`

Returns a string consisting of `N` space characters.

```
mysql> SELECT SPACE(6);
-> '      '
```

- `SUBSTR(str,pos)`, `SUBSTR(str FROM pos)`, `SUBSTR(str,pos,len)`, `SUBSTR(str FROM pos FOR len)`

`SUBSTR()` is a synonym for `SUBSTRING()`.

- `SUBSTRING(str,pos)`, `SUBSTRING(str FROM pos)`, `SUBSTRING(str,pos,len)`, `SUBSTRING(str FROM pos FOR len)`

The forms without a `len` argument return a substring from string `str` starting at position `pos`. The forms with a `len` argument return a substring `len` characters long from string `str`, starting at position `pos`. The forms that use `FROM` are standard SQL syntax. It is also possible to use a negative value for `pos`. In this case, the beginning of the substring is `pos` characters from the end of the string, rather than the beginning. A negative value may be used for `pos` in any of the forms of this function.

For all forms of `SUBSTRING()`, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
-> 'ratica'
mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'
```

This function is multibyte safe.

If `len` is less than 1, the result is the empty string.

- `SUBSTRING_INDEX(str,delim,count)`

Returns the substring from string `str` before `count` occurrences of the delimiter `delim`. If `count` is positive, everything to the left of the final delimiter (counting from the left) is returned. If `count` is negative, everything to the right of the final delimiter (counting from the right) is returned. `SUBSTRING_INDEX()` performs a case-sensitive match when searching for `delim`.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'
```

This function is multibyte safe.

- `TO_BASE64(str)`

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is `NULL` if the argument is `NULL`. Base-64 encoded strings can be decoded using the `FROM_BASE64()` function.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

Different base-64 encoding schemes exist. These are the encoding and decoding rules used by `TO_BASE64()` and `FROM_BASE64()`:

- The encoding for alphabet value 62 is '+'.
  - The encoding for alphabet value 63 is '/'.
  - Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with '=' characters to a length of 4.
  - A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
  - Decoding recognizes and ignores newline, carriage return, tab, and space.
- `TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)`

Returns the string `str` with all `remstr` prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. `remstr` is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
-> 'barx'
```

This function is multibyte safe.

- `UCASE(str)`

`UCASE()` is a synonym for `UPPER()`.

In MySQL 5.7, `UCASE()` used in a view is rewritten as `UPPER()` when storing the view's definition. (Bug #12844279)

- `UNHEX(str)`

For a string argument `str`, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
-> 'MySQL'
mysql> SELECT X'4D7953514C';
-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
```

```

-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'

```

The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, the result is `NULL`:

```

mysql> SELECT UNHEX('GG');
+-----+
| UNHEX('GG') |
+-----+
| NULL        |
+-----+

```

A `NULL` result can occur if the argument to `UNHEX()` is a `BINARY` column, because values are padded with 0x00 bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a `CHAR(3)` column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so `UNHEX()` for the column value returns 'A'. By contrast '41' is stored into a `BINARY(3)` column as '41\0' and retrieved as '41\0' (with the trailing pad 0x00 byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` for the column value returns `NULL`.

For a numeric argument *N*, the inverse of `HEX(N)` is not performed by `UNHEX()`. Use `CONV(HEX(N), 16, 10)` instead. See the description of `HEX()`.

- `UPPER(str)`

Returns the string *str* with all characters changed to uppercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```

mysql> SELECT UPPER('Hej');
-> 'HEJ'

```

See the description of `LOWER()` for information that also applies to `UPPER()`. This included information about how to perform lettercase conversion of binary strings (`BINARY`, `VARBINARY`, `BLOB`) for which these functions are ineffective, and information about case folding for Unicode character sets.

This function is multibyte safe.

In previous versions of MySQL, `UPPER()` used within a view was rewritten as `UCASE()` when storing the view's definition. In MySQL 5.7, `UPPER()` is never rewritten in such cases, but `UCASE()` used within views is instead rewritten as `UPPER()`. (Bug #12844279)

- `WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [LEVEL levels] [flags])`

*levels*: *N* [ASC|DESC|REVERSE] [, *N* [ASC|DESC|REVERSE]] ...

This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string. It has these properties:

- If `WEIGHT_STRING(str1) = WEIGHT_STRING(str2)`, then *str1* = *str2* (*str1* and *str2* are considered equal)
- If `WEIGHT_STRING(str1) < WEIGHT_STRING(str2)`, then *str1* < *str2* (*str1* sorts before *str2*)

`WEIGHT_STRING()` is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See [Section 11.4, “Adding a Collation to a Character Set”](#).

The input string, *str*, is a string expression. If the input is a nonbinary (character) string such as a [CHAR](#), [VARCHAR](#), or [TEXT](#) value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a [BINARY](#), [VARBINARY](#), or [BLOB](#) value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is [NULL](#), [WEIGHT\\_STRING\( \)](#) returns [NULL](#).

Examples:

```
mysql> SET @s = _latin1 'AB' COLLATE latin1_swedish_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
|----|---------|------------------------|
| AB | 4142    | 4142                   |

```
mysql> SET @s = _latin1 'ab' COLLATE latin1_swedish_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
|----|---------|------------------------|
| ab | 6162    | 4142                   |

```
mysql> SET @s = CAST('AB' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
|----|---------|------------------------|
| AB | 4142    | 4142                   |

```
mysql> SET @s = CAST('ab' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
|----|---------|------------------------|
| ab | 6162    | 6162                   |

The preceding examples use [HEX\( \)](#) to display the [WEIGHT\\_STRING\( \)](#) result. Because the result is a binary value, [HEX\( \)](#) can be especially useful when the result contains nonprinting values, to display it in printable form:

```
mysql> SET @s = CONVERT('C39F' USING utf8) COLLATE utf8_czech_ci;
mysql> SELECT HEX(WEIGHT_STRING(@s));
```

| HEX(WEIGHT_STRING(@s)) |
|------------------------|
| 0FEA0FEA               |

For non-[NULL](#) return values, the data type of the value is [VARBINARY](#) if its length is within the maximum length for [VARBINARY](#), otherwise the data type is [BLOB](#).

The [AS](#) clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- [AS CHAR\(N\)](#) casts the string to a nonbinary string and pads it on the right with spaces to a length of *N* characters. *N* must be at least 1. If *N* is less than the length of the input string, the string is truncated to *N* characters. No warning occurs for truncation.

- `AS BINARY(N)` is similar but casts the string to a binary string, *N* is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).

```
mysql> SET NAMES 'latin1';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 41422020                             |
+-----+
mysql> SET NAMES 'utf8';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 0041004200200020                     |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING('ab' AS BINARY(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS BINARY(4))) |
+-----+
| 61620000                             |
+-----+
```

The `LEVEL` clause may be given to specify that the return value should contain weights for specific collation levels.

The `levels` specifier following the `LEVEL` keyword may be given either as a list of one or more integers separated by commas, or as a range of two integers separated by a dash. Whitespace around the punctuation characters does not matter.

Examples:

```
LEVEL 1
LEVEL 2, 3, 5
LEVEL 1-3
```

Any level less than 1 is treated as 1. Any level greater than the maximum for the input string collation is treated as maximum for the collation. The maximum varies per collation, but is never greater than 6.

In a list of levels, levels must be given in increasing order. In a range of levels, if the second number is less than the first, it is treated as the first number (for example, 4-2 is the same as 4-4).

If the `LEVEL` clause is omitted, MySQL assumes `LEVEL 1 - max`, where *max* is the maximum level for the collation.

If `LEVEL` is specified using list syntax (not range syntax), any level number can be followed by these modifiers:

- `ASC`: Return the weights without modification. This is the default.
- `DESC`: Return bitwise-inverted weights (for example, `0x78f0 DESC = 0x870f`).
- `REVERSE`: Return the weights in reverse order (that is, the weights for the reversed string, with the first character last and the last first).

Examples:

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1));
```

```
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1)) |
+-----+
| 007FFF                                |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC));
```

```
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC)) |
+-----+
| FF8000                                |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE));
```

```
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE)) |
+-----+
| FF7F00                                |
+-----+
```

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC REVERSE));
```

```
+-----+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC REVERSE)) |
+-----+
| 0080FF                                |
+-----+
```

The *flags* clause currently is unused.

## 13.5.1 String Comparison Functions

Table 13.8 String Comparison Operators

| Name                  | Description                         |
|-----------------------|-------------------------------------|
| <code>LIKE</code>     | Simple pattern matching             |
| <code>NOT LIKE</code> | Negation of simple pattern matching |
| <code>STRCMP()</code> | Compare two strings                 |

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

- `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using an SQL pattern. Returns 1 (`TRUE`) or 0 (`FALSE`). If either *expr* or *pat* is `NULL`, the result is `NULL`.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
```

```
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
| 0 |
+-----+
```

```
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
```

```
+-----+
```

```
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
|                                     1 |
+-----+
```

In particular, trailing spaces are significant, which is not true for [CHAR](#) or [VARCHAR](#) comparisons performed with the `=` operator:

```
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a ';
+-----+-----+
| 'a' = 'a ' | 'a' LIKE 'a ' |
+-----+-----+
|          1 |             0 |
+-----+-----+
1 row in set (0.00 sec)
```

With [LIKE](#) you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

```
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the [ESCAPE](#) character, `\` is assumed.

- `\%` matches one `%` character.
- `\_` matches one `_` character.

```
mysql> SELECT 'David!' LIKE 'David\_%';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the [ESCAPE](#) clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be empty or one character long. The expression must evaluate as a constant at execution time. If the [NO\\_BACKSLASH\\_ESCAPES](#) SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case sensitive unless one of the operands is a case sensitive (uses a case-sensitive collation or is a binary string):

```
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_general_cs;
-> 0
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_bin;
-> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

As an extension to standard SQL, MySQL permits [LIKE](#) on numeric expressions.

```
mysql> SELECT 10 LIKE '1%';
-> 1
```

### Note

Because MySQL uses C escape syntax in strings (for example, `\n` to represent a newline character), you must double any `\` that you use in `LIKE` strings. For example, to search for `\n`, specify it as `\\n`. To search for `\`, specify it as `\\\\`; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```
mysql> SELECT filename FROM t1;
+-----+
| filename |
+-----+
| C:       |
| C:\      |
| C:\Programs |
| C:\Programs\ |
+-----+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\' |
+-----+-----+
| C:       | 0 |
| C:\      | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+

mysql> SELECT filename, filename LIKE '%\\\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\\\' |
+-----+-----+
| C:       | 0 |
| C:\      | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+
```

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

### Note

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));

INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving `NULL` and comparisons using `NOT RLIKE` or `NOT REGEXP`. In such cases, you must test explicitly for `NOT NULL` using `OR` (and not `AND`), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1,expr2)`

`STRCMP()` returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _latin1 'x' COLLATE latin1_general_ci;
mysql> SET @s2 = _latin1 'X' COLLATE latin1_general_ci;
mysql> SET @s3 = _latin1 'x' COLLATE latin1_general_cs;
mysql> SET @s4 = _latin1 'X' COLLATE latin1_general_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+-----+-----+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See [Section 11.1.8.4, “Collation of Expressions”](#).

```
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (latin1_general_ci,IMPLICIT)
and (latin1_general_cs,IMPLICIT) for operation 'strcmp'
mysql> SELECT STRCMP(@s1, @s3 COLLATE latin1_general_ci);
+-----+
| STRCMP(@s1, @s3 COLLATE latin1_general_ci) |
+-----+
| 0 |
+-----+
```

## 13.5.2 Regular Expressions

Table 13.9 String Regular Expression Operators

| Name                    | Description                                |
|-------------------------|--|
| <code>NOT REGEXP</code> | Negation of <code>REGEXP</code>            |
| <code>REGEXP</code>     | Pattern matching using regular expressions |
| <code>RLIKE</code>      | Synonym for <code>REGEXP</code>            |

A regular expression is a powerful way of specifying a pattern for a complex search.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. MySQL uses the extended version to support pattern-matching operations performed with the `REGEXP` operator in SQL statements.

This section summarizes, with examples, the special characters and constructs that can be used in MySQL for `REGEXP` operations. It does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory. See also [Section 4.3.4.7, “Pattern Matching”](#).

## Regular Expression Operators

- `expr NOT REGEXP pat, expr NOT RLIKE pat`

This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat, expr RLIKE pat`

Performs a pattern match of a string expression `expr` against a pattern `pat`. The pattern can be an extended regular expression, the syntax for which is discussed later in this section. Returns `1` if `expr` matches `pat`; otherwise it returns `0`. If either `expr` or `pat` is `NULL`, the result is `NULL`. `RLIKE` is a synonym for `REGEXP`.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

### Note

Because MySQL uses the C escape syntax in strings (for example, `\n` to represent the newline character), you must double any `\` that you use in your `REGEXP` strings.

`REGEXP` is not case sensitive, except when used with binary strings.

```
mysql> SELECT 'Monty!' REGEXP '.*';
-> 1
mysql> SELECT 'new*\n*line' REGEXP 'new\\*\\.\\*line';
-> 1
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
-> 1 0
mysql> SELECT 'a' REGEXP '^[a-d]';
-> 1
```

`REGEXP` and `RLIKE` use the character set and collations of the arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in [Section 11.1.8.4, “Collation of Expressions”](#).

### Warning

The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

## Syntax of Regular Expressions

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|word` matches either the string `hello` or the string `word`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`

Match the beginning of a string.

```
mysql> SELECT 'fo\nfo' REGEXP '^fo$';          -> 0
mysql> SELECT 'fofo' REGEXP '^fo';             -> 1
```

- `$`

Match the end of a string.

```
mysql> SELECT 'fo\no' REGEXP 'fo\no$';         -> 1
mysql> SELECT 'fo\no' REGEXP 'fo$';            -> 0
```

- `.`

Match any character (including carriage return and newline).

```
mysql> SELECT 'fofo' REGEXP '^f.*$';           -> 1
mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$';      -> 1
```

- `a*`

Match any sequence of zero or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba*n';            -> 1
mysql> SELECT 'Baaan' REGEXP '^Ba*n';         -> 1
mysql> SELECT 'Bn' REGEXP '^Ba*n';            -> 1
```

- `a+`

Match any sequence of one or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba+n';            -> 1
mysql> SELECT 'Bn' REGEXP '^Ba+n';            -> 0
```

- `a?`

Match either zero or one `a` character.

```
mysql> SELECT 'Bn' REGEXP '^Ba?n';            -> 1
mysql> SELECT 'Ban' REGEXP '^Ba?n';           -> 1
mysql> SELECT 'Baan' REGEXP '^Ba?n';          -> 0
```

- `de|abc`

Match either of the sequences `de` or `abc`.

```
mysql> SELECT 'pi' REGEXP 'pi|apa';            -> 1
mysql> SELECT 'axe' REGEXP 'pi|apa';           -> 0
mysql> SELECT 'apa' REGEXP 'pi|apa';           -> 1
mysql> SELECT 'apa' REGEXP '^(pi|apa)$';       -> 1
mysql> SELECT 'pi' REGEXP '^(pi|apa)$';        -> 1
mysql> SELECT 'pix' REGEXP '^(pi|apa)$';       -> 0
```

- `(abc)*`

Match zero or more instances of the sequence `abc`.

```
mysql> SELECT 'pi' REGEXP '^ (pi)*$';          -> 1
mysql> SELECT 'pip' REGEXP '^ (pi)*$';         -> 0
mysql> SELECT 'pypi' REGEXP '^ (pi)*$';        -> 1
```

- `{1}`, `{2,3}`

`{n}` or `{m,n}` notation provides a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

- `a*`

Can be written as `a{0,}`.

- `a+`

Can be written as `a{1,}`.

- `a?`

Can be written as `a{0,1}`.

To be more precise, `a{n}` matches exactly `n` instances of `a`. `a{n,}` matches `n` or more instances of `a`. `a{m,n}` matches `m` through `n` instances of `a`, inclusive.

`m` and `n` must be in the range from 0 to `RE_DUP_MAX` (default 255), inclusive. If both `m` and `n` are given, `m` must be less than or equal to `n`.

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{2}e';      -> 0
mysql> SELECT 'abcde' REGEXP 'a[bcd]{3}e';      -> 1
mysql> SELECT 'abcde' REGEXP 'a[bcd]{1,10}e';    -> 1
```

- `[a-dX]`, `[^a-dX]`

Matches any character that is (or is not, if `^` is used) either `a`, `b`, `c`, `d` or `X`. A `-` character between two other characters forms a range that matches all characters from the first character to the second. For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately follow the opening bracket `[`. To include a literal `-` character, it must be written first or last. Any character that does not have a defined special meaning inside a `[ ]` pair matches only itself.

```
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]';         -> 1
mysql> SELECT 'aXbc' REGEXP '^ [a-dXYZ]$';      -> 0
mysql> SELECT 'aXbc' REGEXP '^ [a-dXYZ]+$';      -> 1
mysql> SELECT 'aXbc' REGEXP '^ [^a-dXYZ]+$';     -> 0
mysql> SELECT 'gheis' REGEXP '^ [^a-dXYZ]+$';    -> 1
mysql> SELECT 'gheisa' REGEXP '^ [^a-dXYZ]+$';   -> 0
```

- `[.characters.]`

Within a bracket expression (written using `[` and `]`), matches the sequence of characters of that collating element. `characters` is either a single character or a character name like `newline`. The following table lists the permissible character names.

The following table shows the permissible character names and the characters that they match. For characters given as numeric values, the values are represented in octal.

| Name | Character | Name | Character |
|------|-----------|------|-----------|
| NUL  | 0         | SOH  | 001       |

| Name              | Character | Name                | Character |
|-------------------|-----------|---------------------|-----------|
| STX               | 002       | ETX                 | 003       |
| EOT               | 004       | ENQ                 | 005       |
| ACK               | 006       | BEL                 | 007       |
| alert             | 007       | BS                  | 010       |
| backspace         | '\b'      | HT                  | 011       |
| tab               | '\t'      | LF                  | 012       |
| newline           | '\n'      | VT                  | 013       |
| vertical-tab      | '\v'      | FF                  | 014       |
| form-feed         | '\f'      | CR                  | 015       |
| carriage-return   | '\r'      | SO                  | 016       |
| SI                | 017       | DLE                 | 020       |
| DC1               | 021       | DC2                 | 022       |
| DC3               | 023       | DC4                 | 024       |
| NAK               | 025       | SYN                 | 026       |
| ETB               | 027       | CAN                 | 030       |
| EM                | 031       | SUB                 | 032       |
| ESC               | 033       | IS4                 | 034       |
| FS                | 034       | IS3                 | 035       |
| GS                | 035       | IS2                 | 036       |
| RS                | 036       | IS1                 | 037       |
| US                | 037       | space               | ' '       |
| exclamation-mark  | '!'       | quotation-mark      | '\"'      |
| number-sign       | '#'       | dollar-sign         | '\$'      |
| percent-sign      | '%'       | ampersand           | '&'       |
| apostrophe        | '\''      | left-parenthesis    | '('       |
| right-parenthesis | ')'       | asterisk            | '*'       |
| plus-sign         | '+'       | comma               | ','       |
| hyphen            | '-'       | hyphen-minus        | '-'       |
| period            | '.'       | full-stop           | '.'       |
| slash             | '/'       | solidus             | '/'       |
| zero              | '0'       | one                 | '1'       |
| two               | '2'       | three               | '3'       |
| four              | '4'       | five                | '5'       |
| six               | '6'       | seven               | '7'       |
| eight             | '8'       | nine                | '9'       |
| colon             | ':'       | semicolon           | ';'       |
| less-than-sign    | '<'       | equals-sign         | '='       |
| greater-than-sign | '>'       | question-mark       | '?'       |
| commercial-at     | '@'       | left-square-bracket | '['       |
| backslash         | '\\'      | reverse-solidus     | '\\'      |

| Name                 | Character | Name               | Character |
|----------------------|-----------|--------------------|-----------|
| right-square-bracket | ' ] '     | circumflex         | ' ^ '     |
| circumflex-accent    | ' ^ '     | underscore         | ' _ '     |
| low-line             | ' _ '     | grave-accent       | ' ` '     |
| left-brace           | ' { '     | left-curly-bracket | ' { '     |
| vertical-line        | '   '     | right-brace        | ' } '     |
| right-curly-bracket  | ' } '     | tilde              | ' ~ '     |
| DEL                  | 177       |                    |           |

```
mysql> SELECT '~' REGEXP '[[.~.]]';          -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]';      -> 1
```

- `[=character_class=]`

Within a bracket expression (written using `[` and `]`), `[=character_class=]` represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if `o` and `(+)` are the members of an equivalence class, `[[=o=]]`, `[[=(+)=]]`, and `[o(+)]` are all synonymous. An equivalence class may not be used as an endpoint of a range.

- `[ :character_class: ]`

Within a bracket expression (written using `[` and `]`), `[ :character_class: ]` represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the `ctype(3)` manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

| Character Class Name | Meaning                                  |
|----------------------|--|
| <code>alnum</code>   | Alphanumeric characters                  |
| <code>alpha</code>   | Alphabetic characters                    |
| <code>blank</code>   | Whitespace characters                    |
| <code>cntrl</code>   | Control characters                       |
| <code>digit</code>   | Digit characters                         |
| <code>graph</code>   | Graphic characters                       |
| <code>lower</code>   | Lowercase alphabetic characters          |
| <code>print</code>   | Graphic or space characters              |
| <code>punct</code>   | Punctuation characters                   |
| <code>space</code>   | Space, tab, newline, and carriage return |
| <code>upper</code>   | Uppercase alphabetic characters          |
| <code>xdigit</code>  | Hexadecimal digit characters             |

```
mysql> SELECT 'justalnums' REGEXP '[[[:alnum:]]]+';          -> 1
mysql> SELECT '!!!' REGEXP '[[[:alnum:]]]+';                -> 0
```

- `[[[:<:]]]`, `[[[:>:]]]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (`_`).

```
mysql> SELECT 'a word a' REGEXP '[:<:]word[:>:]';    -> 1
mysql> SELECT 'a xword a' REGEXP '[:<:]word[:>:]';    -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2';                    -> 0
mysql> SELECT '1+2' REGEXP '1\+2';                    -> 0
mysql> SELECT '1+2' REGEXP '1\\+2';                    -> 1
```

### 13.5.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

#### Note

The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary              | binary                |
+-----+-----+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set

and collation (see [Section 11.1.4, “Connection Character Sets and Collations”](#)). This applies only to `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+-----+-----+-----+
| USER()          | CHARSET(USER()) | COLLATION(USER()) |
+-----+-----+-----+
| test@localhost  | utf8            | utf8_general_ci   |
+-----+-----+-----+
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+-----+-----+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
+-----+-----+
| binary                  | binary                     |
+-----+-----+
```

## 13.6 Numeric Functions and Operators

Table 13.10 Numeric Functions and Operators

| Name                         | Description  |
|------------------------------|--|
| <code>ABS()</code>           | Return the absolute value                                      |
| <code>ACOS()</code>          | Return the arc cosine  |
| <code>ASIN()</code>          | Return the arc sine  |
| <code>ATAN()</code>          | Return the arc tangent   |
| <code>ATAN2(), ATAN()</code> | Return the arc tangent of the two arguments                    |
| <code>CEIL()</code>          | Return the smallest integer value not less than the argument   |
| <code>CEILING()</code>       | Return the smallest integer value not less than the argument   |
| <code>CONV()</code>          | Convert numbers between different number bases                 |
| <code>COS()</code>           | Return the cosine  |
| <code>COT()</code>           | Return the cotangent   |
| <code>CRC32()</code>         | Compute a cyclic redundancy check value                        |
| <code>DEGREES()</code>       | Convert radians to degrees                                     |
| <code>DIV</code>             | Integer division   |
| <code>/</code>               | Division operator  |
| <code>EXP()</code>           | Raise to the power of  |
| <code>FLOOR()</code>         | Return the largest integer value not greater than the argument |
| <code>LN()</code>            | Return the natural logarithm of the argument                   |
| <code>LOG()</code>           | Return the natural logarithm of the first argument             |
| <code>LOG10()</code>         | Return the base-10 logarithm of the argument                   |
| <code>LOG2()</code>          | Return the base-2 logarithm of the argument                    |
| <code>-</code>               | Minus operator   |
| <code>MOD()</code>           | Return the remainder   |
| <code>%, MOD</code>          | Modulo operator  |
| <code>PI()</code>            | Return the value of pi   |
| <code>+</code>               | Addition operator  |
| <code>POW()</code>           | Return the argument raised to the specified power              |

| Name                      | Description                                       |
|---------------------------|---|
| <code>POWER ( )</code>    | Return the argument raised to the specified power |
| <code>RADIANS ( )</code>  | Return argument converted to radians              |
| <code>RAND ( )</code>     | Return a random floating-point value              |
| <code>ROUND ( )</code>    | Round the argument                                |
| <code>SIGN ( )</code>     | Return the sign of the argument                   |
| <code>SIN ( )</code>      | Return the sine of the argument                   |
| <code>SQRT ( )</code>     | Return the square root of the argument            |
| <code>TAN ( )</code>      | Return the tangent of the argument                |
| <code>*</code>            | Multiplication operator                           |
| <code>TRUNCATE ( )</code> | Truncate to specified number of decimal places    |
| <code>-</code>            | Change the sign of the argument                   |

## 13.6.1 Arithmetic Operators

**Table 13.11 Arithmetic Operators**

| Name                | Description                     |
|---------------------|---------------------------------|
| <code>DIV</code>    | Integer division                |
| <code>/</code>      | Division operator               |
| <code>-</code>      | Minus operator                  |
| <code>%, MOD</code> | Modulo operator                 |
| <code>+</code>      | Addition operator               |
| <code>*</code>      | Multiplication operator         |
| <code>-</code>      | Change the sign of the argument |

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both operands are integers.
- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is signed even if any operand is unsigned.
- If any of the operands of a `+`, `-`, `/`, `*`, `%` is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See [Section 13.10, “Cast Functions and Operators”](#).

For information about handling of overflow in numeric expression evaluation, see [Section 12.2.6, “Out-of-Range and Overflow Handling”](#).

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()`; see [Section 13.7, “Date and Time Functions”](#).

- `+`

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- `-`

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- `-`

Unary minus. This operator changes the sign of the operand.

```
mysql> SELECT - 2;
-> -2
```

#### Note

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of  $-2^{63}$ .

- `*`

Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
-> out-of-range error
```

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See [Section 12.2, “Numeric Types”](#).)

- `/`

Division:

```
mysql> SELECT 3/5;
-> 0.60
```

Division by zero produces a `NULL` result:

```
mysql> SELECT 102/(1-1);
-> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- `DIV`

Integer division. Discards from the division result any fractional part to the right of the decimal point.

If either operand has a noninteger type, the operands are converted to [DECIMAL](#) and divided using [DECIMAL](#) arithmetic before converting the result to [BIGINT](#). If the result exceeds [BIGINT](#) range, an error occurs.

```
mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
        -> 2, -2, -2, 2
```

- $N \% M, N \text{ MOD } M$

Modulo operation. Returns the remainder of  $N$  divided by  $M$ . For more information, see the description for the [MOD\( \)](#) function in [Section 13.6.2, “Mathematical Functions”](#).

## 13.6.2 Mathematical Functions

**Table 13.12 Mathematical Functions**

| Name                              | Description  |
|-----------------------------------|--|
| <a href="#">ABS( )</a>            | Return the absolute value                                      |
| <a href="#">ACOS( )</a>           | Return the arc cosine  |
| <a href="#">ASIN( )</a>           | Return the arc sine  |
| <a href="#">ATAN( )</a>           | Return the arc tangent   |
| <a href="#">ATAN2( ), ATAN( )</a> | Return the arc tangent of the two arguments                    |
| <a href="#">CEIL( )</a>           | Return the smallest integer value not less than the argument   |
| <a href="#">CEILING( )</a>        | Return the smallest integer value not less than the argument   |
| <a href="#">CONV( )</a>           | Convert numbers between different number bases                 |
| <a href="#">COS( )</a>            | Return the cosine  |
| <a href="#">COT( )</a>            | Return the cotangent   |
| <a href="#">CRC32( )</a>          | Compute a cyclic redundancy check value                        |
| <a href="#">DEGREES( )</a>        | Convert radians to degrees                                     |
| <a href="#">EXP( )</a>            | Raise to the power of  |
| <a href="#">FLOOR( )</a>          | Return the largest integer value not greater than the argument |
| <a href="#">LN( )</a>             | Return the natural logarithm of the argument                   |
| <a href="#">LOG( )</a>            | Return the natural logarithm of the first argument             |
| <a href="#">LOG10( )</a>          | Return the base-10 logarithm of the argument                   |
| <a href="#">LOG2( )</a>           | Return the base-2 logarithm of the argument                    |
| <a href="#">MOD( )</a>            | Return the remainder   |
| <a href="#">PI( )</a>             | Return the value of pi   |
| <a href="#">POW( )</a>            | Return the argument raised to the specified power              |
| <a href="#">POWER( )</a>          | Return the argument raised to the specified power              |
| <a href="#">RADIANS( )</a>        | Return argument converted to radians                           |
| <a href="#">RAND( )</a>           | Return a random floating-point value                           |
| <a href="#">ROUND( )</a>          | Round the argument   |
| <a href="#">SIGN( )</a>           | Return the sign of the argument                                |
| <a href="#">SIN( )</a>            | Return the sine of the argument                                |
| <a href="#">SQRT( )</a>           | Return the square root of the argument                         |

| Name                    | Description                                    |
|-------------------------|--|
| <code>TAN()</code>      | Return the tangent of the argument             |
| <code>TRUNCATE()</code> | Truncate to specified number of decimal places |

All mathematical functions return `NULL` in the event of an error.

- `ABS(X)`

Returns the absolute value of `X`.

```
mysql> SELECT ABS(2);
      -> 2
mysql> SELECT ABS(-32);
      -> 32
```

This function is safe to use with `BIGINT` values.

- `ACOS(X)`

Returns the arc cosine of `X`, that is, the value whose cosine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

```
mysql> SELECT ACOS(1);
      -> 0
mysql> SELECT ACOS(1.0001);
      -> NULL
mysql> SELECT ACOS(0);
      -> 1.5707963267949
```

- `ASIN(X)`

Returns the arc sine of `X`, that is, the value whose sine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

```
mysql> SELECT ASIN(0.2);
      -> 0.20135792079033
mysql> SELECT ASIN('foo');

+-----+
| ASIN('foo') |
+-----+
|          0 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;

+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+-----+-----+-----+
```

- `ATAN(X)`

Returns the arc tangent of `X`, that is, the value whose tangent is `X`.

```
mysql> SELECT ATAN(2);
      -> 1.1071487177941
mysql> SELECT ATAN(-2);
      -> -1.1071487177941
```

- `ATAN(Y,X)`, `ATAN2(Y,X)`

Returns the arc tangent of the two variables *X* and *Y*. It is similar to calculating the arc tangent of *Y* / *X*, except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2,2);
-> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
-> 1.5707963267949
```

- `CEIL(X)`

`CEIL( )` is a synonym for `CEILING( )`.

- `CEILING(X)`

Returns the smallest integer value not less than *X*.

```
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEILING(-1.23);
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `CONV(N,from_base,to_base)`

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from\_base* to base *to\_base*. Returns `NULL` if any argument is `NULL`. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *from\_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. `CONV( )` works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
-> '1010'
mysql> SELECT CONV('6E',18,8);
-> '172'
mysql> SELECT CONV(-17,10,-18);
-> '-H'
mysql> SELECT CONV(10+'10'+ '10'+X'0a',10,10);
-> '40'
```

- `COS(X)`

Returns the cosine of *X*, where *X* is given in radians.

```
mysql> SELECT COS(PI());
-> -1
```

- `COT(X)`

Returns the cotangent of *X*.

```
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> NULL
```

- `CRC32(expr)`

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
      -> 3259397556
mysql> SELECT CRC32('mysql');
      -> 2501908538
```

- `DEGREES(X)`

Returns the argument `X`, converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
      -> 180
mysql> SELECT DEGREES(PI() / 2);
      -> 90
```

- `EXP(X)`

Returns the value of *e* (the base of natural logarithms) raised to the power of `X`. The inverse of this function is `LOG()` (using a single argument only) or `LN()`.

```
mysql> SELECT EXP(2);
      -> 7.3890560989307
mysql> SELECT EXP(-2);
      -> 0.13533528323661
mysql> SELECT EXP(0);
      -> 1
```

- `FLOOR(X)`

Returns the largest integer value not greater than `X`.

```
mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
      -> 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `FORMAT(X,D)`

Formats the number `X` to a format like '`#,###,###.##`', rounded to `D` decimal places, and returns the result as a string. For details, see [Section 13.5, "String Functions"](#).

- `HEX(N_or_S)`

This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in [Section 13.5, "String Functions"](#), for details.

- `LN(X)`

Returns the natural logarithm of `X`; that is, the base-*e* logarithm of `X`. If `X` is less than or equal to 0.0E0, the function returns `NULL` and (as of MySQL 5.7.4) a warning "Invalid argument for logarithm" is reported.

```
mysql> SELECT LN(2);
      -> 0.69314718055995
mysql> SELECT LN(-2);
      -> NULL
```

This function is synonymous with `LOG(X)`. The inverse of this function is the `EXP( )` function.

- `LOG(X)`, `LOG(B,X)`

If called with one parameter, this function returns the natural logarithm of *X*. If *X* is less than or equal to 0.0E0, the function returns `NULL` and (as of MySQL 5.7.4) a warning “Invalid argument for logarithm” is reported.

The inverse of this function (when called with a single argument) is the `EXP( )` function.

```
mysql> SELECT LOG(2);
      -> 0.69314718055995
mysql> SELECT LOG(-2);
      -> NULL
```

If called with two parameters, this function returns the logarithm of *X* to the base *B*. If *X* is less than or equal to 0, or if *B* is less than or equal to 1, then `NULL` is returned.

```
mysql> SELECT LOG(2,65536);
      -> 16
mysql> SELECT LOG(10,100);
      -> 2
mysql> SELECT LOG(1,100);
      -> NULL
```

`LOG(B,X)` is equivalent to `LOG(X) / LOG(B)`.

- `LOG2(X)`

Returns the base-2 logarithm of *X*. If *X* is less than or equal to 0.0E0, the function returns `NULL` and (as of MySQL 5.7.4) a warning “Invalid argument for logarithm” is reported.

```
mysql> SELECT LOG2(65536);
      -> 16
mysql> SELECT LOG2(-100);
      -> NULL
```

`LOG2( )` is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression `LOG(X) / LOG(2)`.

- `LOG10(X)`

Returns the base-10 logarithm of *X*. If *X* is less than or equal to 0.0E0, the function returns `NULL` and (as of MySQL 5.7.4) a warning “Invalid argument for logarithm” is reported.

```
mysql> SELECT LOG10(2);
      -> 0.30102999566398
mysql> SELECT LOG10(100);
      -> 2
mysql> SELECT LOG10(-100);
      -> NULL
```

`LOG10(X)` is equivalent to `LOG(10,X)`.

- `MOD(N,M)`, `N % M`, `N MOD M`

Modulo operation. Returns the remainder of *N* divided by *M*.

```
mysql> SELECT MOD(234, 10);
      -> 4
mysql> SELECT 253 % 7;
```

```
-> 1
mysql> SELECT MOD(29,9);
-> 2
mysql> SELECT 29 MOD 9;
-> 2
```

This function is safe to use with `BIGINT` values.

`MOD( )` also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
-> 1.5
```

`MOD(N,0)` returns `NULL`.

- `PI( )`

Returns the value of  $\pi$  (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
-> 3.141592653589793116
```

- `POW(X,Y)`

Returns the value of `X` raised to the power of `Y`.

```
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2,-2);
-> 0.25
```

- `POWER(X,Y)`

This is a synonym for `POW( )`.

- `RADIANS(X)`

Returns the argument `X`, converted from degrees to radians. (Note that  $\pi$  radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- `RAND( [N] )`

Returns a random floating-point value `v` in the range  $0 \leq v < 1.0$ . To obtain a random integer `R` in the range  $i \leq R < j$ , use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range the range  $7 \leq R < 12$ , use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

If an integer argument `N` is specified, it is used as the seed value:

- With a constant initializer argument, the seed is initialized once when the statement is compiled, prior to execution.

- With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of `RAND()`.

One implication of this behavior is that for equal argument values, `RAND(N)` returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by `RAND(3)` is the same both places it occurs.

```
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i      | RAND() |
+-----+-----+
| 1      | 0.61914388706828 |
| 2      | 0.93845168309142 |
| 3      | 0.83482678498591 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i      | RAND(3) |
+-----+-----+
| 1      | 0.90576975597606 |
| 2      | 0.37307905813035 |
| 3      | 0.14808605345719 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i      | RAND() |
+-----+-----+
| 1      | 0.35877890638893 |
| 2      | 0.28941420772058 |
| 3      | 0.37073435016976 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i      | RAND(3) |
+-----+-----+
| 1      | 0.90576975597606 |
| 2      | 0.37307905813035 |
| 3      | 0.14808605345719 |
+-----+-----+
3 rows in set (0.01 sec)
```

`RAND()` in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, `RAND()` is not a constant value and cannot be used for index optimizations. For more information, see [Function Call Optimization](#).

Use of a column with `RAND()` values in an `ORDER BY` or `GROUP BY` clause may yield unexpected results because for either clause a `RAND()` expression can be evaluated multiple times for the same row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:

```
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine `ORDER BY RAND()` with `LIMIT`:

```
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

`RAND()` is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #49222)

- `ROUND(X), ROUND(X,D)`

Rounds the argument `X` to `D` decimal places. The rounding algorithm depends on the data type of `X`. `D` defaults to 0 if not specified. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

```
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
```

The return type is the same type as that of the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
| 150.00 | 150 |
+-----+-----+
```

`ROUND()` uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3 | 2 |
+-----+-----+
```

For more information, see [Section 13.21, “Precision Math”](#).

- `SIGN(X)`

Returns the sign of the argument as `-1`, `0`, or `1`, depending on whether *X* is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
      -> -1
mysql> SELECT SIGN(0);
      -> 0
mysql> SELECT SIGN(234);
      -> 1
```

- `SIN(X)`

Returns the sine of *X*, where *X* is given in radians.

```
mysql> SELECT SIN(PI());
      -> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
      -> 0
```

- `SQRT(X)`

Returns the square root of a nonnegative number *X*.

```
mysql> SELECT SQRT(4);
      -> 2
mysql> SELECT SQRT(20);
      -> 4.4721359549996
mysql> SELECT SQRT(-16);
      -> NULL
```

- `TAN(X)`

Returns the tangent of *X*, where *X* is given in radians.

```
mysql> SELECT TAN(PI());
      -> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
      -> 1.5574077246549
```

- `TRUNCATE(X,D)`

Returns the number *X*, truncated to *D* decimal places. If *D* is `0`, the result has no decimal point or fractional part. *D* can be negative to cause *D* digits left of the decimal point of the value *X* to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
      -> 1.2
mysql> SELECT TRUNCATE(1.999,1);
      -> 1.9
mysql> SELECT TRUNCATE(1.999,0);
      -> 1
mysql> SELECT TRUNCATE(-1.999,1);
      -> -1.9
mysql> SELECT TRUNCATE(122,-2);
      -> 100
mysql> SELECT TRUNCATE(10.28*100,0);
      -> 1028
```

All numbers are rounded toward zero.

## 13.7 Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 12.3, “Date and Time Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

**Table 13.13 Date/Time Functions**

| Name  | Description  |
|---|--|
| ADDDATE ( )                                 | Add time values (intervals) to a date value            |
| ADDTIME ( )                                 | Add time   |
| CONVERT_TZ ( )                              | Convert from one time zone to another                  |
| CURDATE ( )                                 | Return the current date                                |
| CURRENT_DATE ( ), CURRENT_DATE              | Synonyms for CURDATE()                                 |
| CURRENT_TIME ( ), CURRENT_TIME              | Synonyms for CURTIME()                                 |
| CURRENT_TIMESTAMP ( ),<br>CURRENT_TIMESTAMP | Synonyms for NOW()                                     |
| CURTIME ( )                                 | Return the current time                                |
| DATE ( )                                    | Extract the date part of a date or datetime expression |
| DATE_ADD ( )                                | Add time values (intervals) to a date value            |
| DATE_FORMAT ( )                             | Format date as specified                               |
| DATE_SUB ( )                                | Subtract a time value (interval) from a date           |
| DATEDIFF ( )                                | Subtract two dates                                     |
| DAY ( )                                     | Synonym for DAYOFMONTH()                               |
| DAYNAME ( )                                 | Return the name of the weekday                         |
| DAYOFMONTH ( )                              | Return the day of the month (0-31)                     |
| DAYOFWEEK ( )                               | Return the weekday index of the argument               |
| DAYOFYEAR ( )                               | Return the day of the year (1-366)                     |
| EXTRACT ( )                                 | Extract part of a date                                 |
| FROM_DAYS ( )                               | Convert a day number to a date                         |
| FROM_UNIXTIME ( )                           | Format Unix timestamp as a date                        |
| GET_FORMAT ( )                              | Return a date format string                            |
| HOUR ( )                                    | Extract the hour                                       |
| LAST_DAY                                    | Return the last day of the month for the argument      |
| LOCALTIME ( ), LOCALTIME                    | Synonym for NOW()                                      |
| LOCALTIMESTAMP,<br>LOCALTIMESTAMP ( )       | Synonym for NOW()                                      |
| MAKEDATE ( )                                | Create a date from the year and day of year            |
| MAKETIME ( )                                | Create time from hour, minute, second                  |
| MICROSECOND ( )                             | Return the microseconds from argument                  |
| MINUTE ( )                                  | Return the minute from the argument                    |
| MONTH ( )                                   | Return the month from the date passed                  |
| MONTHNAME ( )                               | Return the name of the month                           |
| NOW ( )                                     | Return the current date and time                       |
| PERIOD_ADD ( )                              | Add a period to a year-month                           |
| PERIOD_DIFF ( )                             | Return the number of months between periods            |
| QUARTER ( )                                 | Return the quarter from a date argument                |

| Name                             | Description   |
|----------------------------------|---|
| <a href="#">SEC_TO_TIME()</a>    | Converts seconds to 'HH:MM:SS' format   |
| <a href="#">SECOND()</a>         | Return the second (0-59)  |
| <a href="#">STR_TO_DATE()</a>    | Convert a string to a date  |
| <a href="#">SUBDATE()</a>        | Synonym for <a href="#">DATE_SUB()</a> when invoked with three arguments  |
| <a href="#">SUBTIME()</a>        | Subtract times  |
| <a href="#">SYSDATE()</a>        | Return the time at which the function executes  |
| <a href="#">TIME()</a>           | Extract the time portion of the expression passed   |
| <a href="#">TIME_FORMAT()</a>    | Format as time  |
| <a href="#">TIME_TO_SEC()</a>    | Return the argument converted to seconds  |
| <a href="#">TIMEDIFF()</a>       | Subtract time   |
| <a href="#">TIMESTAMP()</a>      | With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments |
| <a href="#">TIMESTAMPADD()</a>   | Add an interval to a datetime expression  |
| <a href="#">TIMESTAMPDIFF()</a>  | Subtract an interval from a datetime expression   |
| <a href="#">TO_DAYS()</a>        | Return the date argument converted to days  |
| <a href="#">TO_SECONDS()</a>     | Return the date or datetime argument converted to seconds since Year 0  |
| <a href="#">UNIX_TIMESTAMP()</a> | Return a Unix timestamp   |
| <a href="#">UTC_DATE()</a>       | Return the current UTC date   |
| <a href="#">UTC_TIME()</a>       | Return the current UTC time   |
| <a href="#">UTC_TIMESTAMP()</a>  | Return the current UTC date and time  |
| <a href="#">WEEK()</a>           | Return the week number  |
| <a href="#">WEEKDAY()</a>        | Return the weekday index  |
| <a href="#">WEEKOFYEAR()</a>     | Return the calendar week of the date (1-53)   |
| <a href="#">YEAR()</a>           | Return the year   |
| <a href="#">YEARWEEK()</a>       | Return the year and week  |

Here is an example that uses date functions. The following query selects all rows with a [date\\_col](#) value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
      -> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as [NOW\(\)](#) within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to [CURDATE\(\)](#), [CURTIME\(\)](#), [UTC\\_DATE\(\)](#), [UTC\\_TIME\(\)](#), [UTC\\_TIMESTAMP\(\)](#), and to any of their synonyms.

The [CURRENT\\_TIMESTAMP\(\)](#), [CURRENT\\_TIME\(\)](#), [CURRENT\\_DATE\(\)](#), and [FROM\\_UNIXTIME\(\)](#) functions return values in the connection's current time zone, which is available as the value of the

`time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the current time zone. See [Section 11.6, “MySQL Server Time Zone Support”](#).

Some date functions can be used with “zero” dates or incomplete dates such as `'2001-11-00'`, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
      -> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
      -> NULL
mysql> SELECT DAYNAME('2006-05-00');
      -> NULL
```

Several functions are more strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero. These functions are affected: `CONVERT_TZ()`, `DATE_ADD()`, `DATE_SUB()`, `DAYOFYEAR()`, `LAST_DAY()` (permits a day part of zero), `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`.

Fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values are supported, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.

- `ADDDATE(date,INTERVAL expr unit),ADDDATE(expr,days)`

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
      -> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
      -> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('2008-01-02', 31);
      -> '2008-02-02'
```

- `ADDTIME(expr1,expr2)`

`ADDTIME()` adds `expr2` to `expr1` and returns the result. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
      -> '2008-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
      -> '03:00:01.999997'
```

- `CONVERT_TZ(dt,from_tz,to_tz)`

`CONVERT_TZ()` converts a datetime value `dt` from the time zone given by `from_tz` to the time zone given by `to_tz` and returns the resulting value. Time zones are specified as described in [Section 11.6, “MySQL Server Time Zone Support”](#). This function returns `NULL` if the arguments are invalid.

If the value falls out of the supported range of the `TIMESTAMP` type when converted from *from\_tz* to UTC, no conversion occurs. The `TIMESTAMP` range is described in [Section 12.1.2, “Date and Time Type Overview”](#).

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','+10:00');
-> '2004-01-01 22:00:00'
```

#### Note

To use named time zones such as `'MET'` or `'Europe/Moscow'`, the time zone tables must be properly set up. See [Section 11.6, “MySQL Server Time Zone Support”](#), for instructions.

- `CURDATE()`

Returns the current date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- `CURRENT_DATE`, `CURRENT_DATE()`

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for `CURDATE()`.

- `CURRENT_TIME`, `CURRENT_TIME([fsp])`

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- `CURRENT_TIMESTAMP`, `CURRENT_TIMESTAMP([fsp])`

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- `CURTIME([fsp])`

Returns the current time as a value in `'HH:MM:SS'` or `HHMMSS` format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- `DATE(expr)`

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- `DATEDIFF(expr1,expr2)`

`DATEDIFF()` returns `expr1 - expr2` expressed as a value in days from one date to the other. `expr1` and `expr2` are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

- `DATE_ADD(date, INTERVAL expr unit), DATE_SUB(date, INTERVAL expr unit)`

These functions perform date arithmetic. The `date` argument specifies the starting date or datetime value. `expr` is an expression specifying the interval value to be added or subtracted from the starting date. `expr` is a string; it may start with a `-` for negative intervals. `unit` is a keyword indicating the units in which the expression should be interpreted.

The `INTERVAL` keyword and the `unit` specifier are not case sensitive.

The following table shows the expected form of the `expr` argument for each `unit` value.

| <code>unit</code> Value         | Expected <code>expr</code> Format                          |
|---------------------------------|--|
| <code>MICROSECOND</code>        | <code>MICROSECONDS</code>                                  |
| <code>SECOND</code>             | <code>SECONDS</code>                                       |
| <code>MINUTE</code>             | <code>MINUTES</code>                                       |
| <code>HOURL</code>              | <code>HOURS</code>   |
| <code>DAY</code>                | <code>DAYS</code>  |
| <code>WEEK</code>               | <code>WEEKS</code>   |
| <code>MONTH</code>              | <code>MONTHS</code>  |
| <code>QUARTER</code>            | <code>QUARTERS</code>                                      |
| <code>YEAR</code>               | <code>YEARS</code>   |
| <code>SECOND_MICROSECOND</code> | <code>'SECONDS.MICROSECONDS'</code>                        |
| <code>MINUTE_MICROSECOND</code> | <code>'MINUTES:SECONDS.MICROSECONDS'</code>                |
| <code>MINUTE_SECOND</code>      | <code>'MINUTES:SECONDS'</code>                             |
| <code>HOURL_MICROSECOND</code>  | <code>'HOURS:MINUTES:SECONDS.MICROSECONDS'</code>          |
| <code>HOURL_SECOND</code>       | <code>'HOURS:MINUTES:SECONDS'</code>                       |
| <code>HOURL_MINUTE</code>       | <code>'HOURS:MINUTES'</code>                               |
| <code>DAY_MICROSECOND</code>    | <code>'DAYS<br/>HOURS:MINUTES:SECONDS.MICROSECONDS'</code> |
| <code>DAY_SECOND</code>         | <code>'DAYS HOURS:MINUTES:SECONDS'</code>                  |
| <code>DAY_MINUTE</code>         | <code>'DAYS HOURS:MINUTES'</code>                          |
| <code>DAY_HOUR</code>           | <code>'DAYS HOURS'</code>                                  |
| <code>YEAR_MONTH</code>         | <code>'YEARS-MONTHS'</code>                                |

The return value depends on the arguments:

- `DATETIME` if the first argument is a `DATETIME` (or `TIMESTAMP`) value, or if the first argument is a `DATE` and the `unit` value uses `HOURS`, `MINUTES`, or `SECONDS`.
- String otherwise.

To ensure that the result is `DATETIME`, you can use `CAST()` to convert the first argument to `DATETIME`.

MySQL permits any punctuation delimiter in the `expr` format. Those shown in the table are the suggested delimiters. If the `date` argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts), the result is a `DATE` value. Otherwise, the result is a `DATETIME` value.

Date arithmetic also can be performed using `INTERVAL` together with the `+` or `-` operator:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

`INTERVAL expr unit` is permitted on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `-` operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2009-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2008-12-31';
-> '2009-01-01'
mysql> SELECT '2005-01-01' - INTERVAL 1 SECOND;
-> '2004-12-31 23:59:59'
mysql> SELECT DATE_ADD('2000-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2001-01-01 00:00:00'
mysql> SELECT DATE_ADD('2010-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2011-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2005-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2004-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the `unit` keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a `unit` of `DAY_SECOND`, the value of `expr` is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

Because `expr` is treated as a string, be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `hour_minute`, `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```
mysql> SELECT 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2009-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2009-01-04 12:20:00'
```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```
mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00',
-> INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 DAY);
-> '2013-01-02'
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 HOUR);
-> '2013-01-01 01:00:00'
```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('2009-01-30', INTERVAL 1 MONTH);
-> '2009-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2006-07-00'` or badly malformed dates:

```
mysql> SELECT DATE_ADD('2006-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```

- `DATE_FORMAT(date, format)`

Formats the *date* value according to the *format* string.

The following specifiers may be used in the *format* string. The `%` character is required before format specifier characters.

| Specifier       | Description   |
|-----------------|---|
| <code>%a</code> | Abbreviated weekday name ( <code>Sun..Sat</code> )                            |
| <code>%b</code> | Abbreviated month name ( <code>Jan..Dec</code> )                              |
| <code>%c</code> | Month, numeric ( <code>0..12</code> )   |
| <code>%D</code> | Day of the month with English suffix ( <code>0th, 1st, 2nd, 3rd, ...</code> ) |
| <code>%d</code> | Day of the month, numeric ( <code>00..31</code> )                             |
| <code>%e</code> | Day of the month, numeric ( <code>0..31</code> )                              |
| <code>%f</code> | Microseconds ( <code>000000..999999</code> )                                  |
| <code>%H</code> | Hour ( <code>00..23</code> )  |
| <code>%h</code> | Hour ( <code>01..12</code> )  |
| <code>%I</code> | Hour ( <code>01..12</code> )  |
| <code>%i</code> | Minutes, numeric ( <code>00..59</code> )                                      |
| <code>%j</code> | Day of year ( <code>001..366</code> )   |
| <code>%k</code> | Hour ( <code>0..23</code> )   |
| <code>%l</code> | Hour ( <code>1..12</code> )   |

| Specifier | Description  |
|-----------|--|
| %M        | Month name ( <a href="#">January..December</a> )   |
| %m        | Month, numeric (00..12)  |
| %p        | AM or PM   |
| %r        | Time, 12-hour ( <a href="#">hh:mm:ss</a> followed by <a href="#">AM</a> or <a href="#">PM</a> )        |
| %S        | Seconds (00..59)   |
| %s        | Seconds (00..59)   |
| %T        | Time, 24-hour ( <a href="#">hh:mm:ss</a> )   |
| %U        | Week (00..53), where Sunday is the first day of the week; <a href="#">WEEK( )</a> mode 0               |
| %u        | Week (00..53), where Monday is the first day of the week; <a href="#">WEEK( )</a> mode 1               |
| %V        | Week (01..53), where Sunday is the first day of the week; <a href="#">WEEK( )</a> mode 2; used with %X |
| %v        | Week (01..53), where Monday is the first day of the week; <a href="#">WEEK( )</a> mode 3; used with %x |
| %W        | Weekday name ( <a href="#">Sunday..Saturday</a> )  |
| %w        | Day of the week (0=Sunday..6=Saturday)   |
| %X        | Year for the week where Sunday is the first day of the week, numeric, four digits; used with %V        |
| %x        | Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v       |
| %Y        | Year, numeric, four digits   |
| %y        | Year, numeric (two digits)   |
| %%        | A literal % character  |
| %x        | x, for any “x” not listed above  |

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as '2014-00-00'.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable ([Section 11.7, “MySQL Server Locale Support”](#)).

For the %U, %u, %V, and %v specifiers, see the description of the [WEEK\( \)](#) function for information about the mode values. The mode affects how week numbering occurs.

[DATE\\_FORMAT\( \)](#) returns a string with a character set and collation given by [character\\_set\\_connection](#) and [collation\\_connection](#) so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00',
-> '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
-> '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)`

See the description for `DATE_ADD()`.

- `DAY(date)`

`DAY()` is a synonym for `DAYOFMONTH()`.

- `DAYNAME(date)`

Returns the name of the weekday for *date*. The language used for the name is controlled by the value of the `lc_time_names` system variable ([Section 11.7, “MySQL Server Locale Support”](#)).

```
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- `DAYOFMONTH(date)`

Returns the day of the month for *date*, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

- `DAYOFWEEK(date)`

Returns the weekday index for *date* (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- `DAYOFYEAR(date)`

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- `EXTRACT(unit FROM date)`

The `EXTRACT()` function uses the same kinds of unit specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic.

```
mysql> SELECT EXTRACT(YEAR FROM '2009-07-02');
-> 2009
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
-> 200907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND
-> FROM '2003-01-02 10:30:00.000123');
-> 123
```

- `FROM_DAYS(N)`

Given a day number *N*, returns a `DATE` value.

```
mysql> SELECT FROM_DAYS(730669);
-> '2007-07-03'
```

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 13.8, “What Calendar Is Used By MySQL?”](#).

- `FROM_UNIXTIME(unix_timestamp), FROM_UNIXTIME(unix_timestamp, format)`

Returns a representation of the *unix\_timestamp* argument as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. *unix\_timestamp* is an internal timestamp value such as is produced by the `UNIX_TIMESTAMP()` function.

If *format* is given, the result is formatted according to the *format* string, which is used the same way as listed in the entry for the `DATE_FORMAT()` function.

```
mysql> SELECT FROM_UNIXTIME(1447430881);
      -> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
      -> 20151113100801
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
      ->          '%Y %D %M %h:%i:%s %x');
      -> '2015 13th November 10:08:01 2015'
```

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT({DATE|TIME|DATETIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})`

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

| Function Call                                 | Result              |
|---|---------------------|
| <code>GET_FORMAT(DATE, 'USA')</code>          | '%m.%d.%Y'          |
| <code>GET_FORMAT(DATE, 'JIS')</code>          | '%Y-%m-%d'          |
| <code>GET_FORMAT(DATE, 'ISO')</code>          | '%Y-%m-%d'          |
| <code>GET_FORMAT(DATE, 'EUR')</code>          | '%d.%m.%Y'          |
| <code>GET_FORMAT(DATE, 'INTERNAL')</code>     | '%Y%m%d'            |
| <code>GET_FORMAT(DATETIME, 'USA')</code>      | '%Y-%m-%d %H.%i.%s' |
| <code>GET_FORMAT(DATETIME, 'JIS')</code>      | '%Y-%m-%d %H:%i:%s' |
| <code>GET_FORMAT(DATETIME, 'ISO')</code>      | '%Y-%m-%d %H:%i:%s' |
| <code>GET_FORMAT(DATETIME, 'EUR')</code>      | '%Y-%m-%d %H.%i.%s' |
| <code>GET_FORMAT(DATETIME, 'INTERNAL')</code> | '%Y%m%d%H%i%s'      |
| <code>GET_FORMAT(TIME, 'USA')</code>          | '%h:%i:%s p'        |
| <code>GET_FORMAT(TIME, 'JIS')</code>          | '%H:%i:%s'          |
| <code>GET_FORMAT(TIME, 'ISO')</code>          | '%H:%i:%s'          |
| <code>GET_FORMAT(TIME, 'EUR')</code>          | '%H.%i.%s'          |
| <code>GET_FORMAT(TIME, 'INTERNAL')</code>     | '%H%i%s'            |

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()`, in which case the function returns the same values as for `DATETIME`.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- `HOUR(time)`

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOUR` can return values greater than 23.

```
mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272
```

- `LAST_DAY(date)`

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

- `LOCALTIME, LOCALTIME([fsp])`

`LOCALTIME` and `LOCALTIME()` are synonyms for `NOW()`.

- `LOCALTIMESTAMP, LOCALTIMESTAMP([fsp])`

`LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for `NOW()`.

- `MAKEDATE(year,dayofyear)`

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is `NULL`.

```
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
-> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
-> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
-> NULL
```

- `MAKETIME(hour,minute,second)`

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

The *second* argument can have a fractional part.

```
mysql> SELECT MAKETIME(12,15,30);
-> '12:15:30'
```

- `MICROSECOND(expr)`

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
-> 123456
mysql> SELECT MICROSECOND('2009-12-31 23:59:59.000010');
-> 10
```

- `MINUTE(time)`

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('2008-02-03 10:05:03');
-> 5
```

- `MONTH(date)`

Returns the month for *date*, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```
mysql> SELECT MONTH('2008-02-03');
-> 2
```

- `MONTHNAME(date)`

Returns the full name of the month for *date*. The language used for the name is controlled by the value of the `lc_time_names` system variable ([Section 11.7, “MySQL Server Locale Support”](#)).

```
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

- `NOW([fsp])`

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
| 2006-04-12 13:47:44 | 0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. Setting the timestamp to a nonzero value causes each subsequent invocation of `NOW()` to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` once again returns the current date and time.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)`

Adds *N* months to period *P* (in the format `YYMM` or `YYYYMM`). Returns a value in the format `YYYYMM`. Note that the period argument *P* is *not* a date value.

```
mysql> SELECT PERIOD_ADD(200801,2);
-> 200803
```

- `PERIOD_DIFF(P1,P2)`

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format `YYMM` or `YYYYMM`. Note that the period arguments *P1* and *P2* are *not* date values.

```
mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11
```

- `QUARTER(date)`

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('2008-04-01');
-> 2
```

- `SECOND(time)`

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
-> 3
```

- `SEC_TO_TIME(seconds)`

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str,format)`

This is the inverse of the `DATE_FORMAT()` function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from *str* is illegal, `STR_TO_DATE()` returns `NULL` and produces a warning.

The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with %. Literal characters in *format* must match literally in *str*. Format specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` function description.

```
mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
-> '2013-05-01'
mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

```
mysql> SELECT STR_TO_DATE('a09:30:17','%a%h:%i:%s');
-> '09:30:17'
mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
-> NULL
mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

```
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('9','%m');
-> '0000-09-00'
mysql> SELECT STR_TO_DATE('9','%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in [Section 12.3.1, “The DATE, DATETIME, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000','%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004','%m/%d/%Y');
-> '2004-04-31'
```

If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled, zero dates or part of dates are disallowed. In that case, `STR_TO_DATE()` returns `NULL` and generates a warning:

```
mysql> SET sql_mode = '';
mysql> SELECT STR_TO_DATE('15:35:00','%H:%i:%s');
+-----+
| STR_TO_DATE('15:35:00','%H:%i:%s') |
+-----+
| 15:35:00 |
+-----+
mysql> SET sql_mode = 'NO_ZERO_IN_DATE';
mysql> SELECT STR_TO_DATE('15:35:00','%h:%i:%s');
+-----+
| STR_TO_DATE('15:35:00','%h:%i:%s') |
+-----+
| NULL |
+-----+
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1411
Message: Incorrect datetime value: '15:35:00' for function str_to_date
```

**Note**

You cannot use format `"%X%V"` to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

- `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form enables the use of an integer value for *days*. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression *expr*.

```
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```

- `SUBTIME(expr1, expr2)`

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as *expr1*. *expr1* is a time or datetime expression, and *expr2* is a time expression.

```
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
-> '-00:59:59.999999'
```

- `SYSDATE([fsp])`

Returns the current date and time as a value in `'YYYY-MM-DD HH:MM:SS'` or `YYYYMMDDHHMMSS` format, depending on whether the function is used in a string or numeric context.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
```

```
+-----+-----+
| 2006-04-12 13:47:44 |      0 | 2006-04-12 13:47:46 |
+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This works if the option is used on both the master and the slave.

The nondeterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

- `TIME(expr)`

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

- `TIMEDIFF(expr1,expr2)`

`TIMEDIFF()` returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are time or date-and-time expressions, but both must be of the same type.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
-> '2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001',
-> '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

- `TIMESTAMP(expr)`, `TIMESTAMP(expr1,expr2)`

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

```
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'
```

- `TIMESTAMPADD(unit,interval,datetime_expr)`

Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The *unit* value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

- `TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)`

Returns *datetime\_expr2* - *datetime\_expr1*, where *datetime\_expr1* and *datetime\_expr2* are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the *unit* argument. The legal values for *unit* are the same as those listed in the description of the `TIMESTAMPADD()` function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

#### Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- `TIME_FORMAT(time,format)`

This is used like the `DATE_FORMAT()` function, but the *format* string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or 0.

If the *time* value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- `TO_DAYS(date)`

Given a date *date*, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was

changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 13.8, “What Calendar Is Used By MySQL?”](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 12.3, “Date and Time Types”](#). For example, `'2008-10-07'` and `'08-10-07'` are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_DAYS()` returns the values shown here:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----+
| to_days('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');
+-----+
| to_days('0000-01-01') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `TO_SECONDS(expr)`

Given a date or datetime *expr*, returns the number of seconds since the year 0. If *expr* is not a valid date or datetime value, returns `NULL`.

```
mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS(NOW());
-> 63426721458
```

Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 13.8, “What Calendar Is Used By MySQL?”](#), for details.

Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in [Section 12.3, “Date and Time Types”](#).

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_SECONDS()` returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+-----+
| TO_SECONDS('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_SECONDS('0000-01-01');
+-----+
| TO_SECONDS('0000-01-01') |
+-----+
| 86400 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `UNIX_TIMESTAMP()`, `UNIX_TIMESTAMP(date)`

If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' UTC). The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or `DECIMAL` if an argument is given that includes a fractional seconds part.

If `UNIX_TIMESTAMP()` is called with a *date* argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. *date* may be a `DATE` string, a `DATETIME` string, a `TIMESTAMP`, or a number in the format `YYMMDD` or `YYYYMMDD`, optionally including a fractional seconds part. The server interprets *date* as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in [Section 11.6, “MySQL Server Time Zone Support”](#).

```
mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
-> 1447431619
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
-> 1447431619.012
```

When `UNIX_TIMESTAMP()` is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0.

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two `UNIX_TIMESTAMP()` to map two `TIMESTAMP` values to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original `TIMESTAMP` values. Here is an example, using `TIMESTAMP` values in the `CET` time zone:

```
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See [Section 13.10, “Cast Functions and Operators”](#).

- `UTC_DATE`, `UTC_DATE()`

Returns the current UTC date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME`, `UTC_TIME([fsp])`

Returns the current UTC time as a value in `'HH:MM:SS'` or `HHMMSS` format, depending on whether the function is used in a string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

- `UTC_TIMESTAMP`, `UTC_TIMESTAMP([fsp])`

Returns the current UTC date and time as a value in `'YYYY-MM-DD HH:MM:SS'` or `YYYYMMDDHHMMSS` format, depending on whether the function is used in a string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- `WEEK(date[,mode])`

This function returns the week number for `date`. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the `mode` argument is omitted, the value of the `default_week_format` system variable is used. See [Section 6.1.5, “Server System Variables”](#).

The following table describes how the `mode` argument works.

| Mode | First day of week | Range | Week 1 is the first week ...  |
|------|-------------------|-------|-------------------------------|
| 0    | Sunday            | 0-53  | with a Sunday in this year    |
| 1    | Monday            | 0-53  | with 4 or more days this year |
| 2    | Sunday            | 1-53  | with a Sunday in this year    |
| 3    | Monday            | 1-53  | with 4 or more days this year |
| 4    | Sunday            | 0-53  | with 4 or more days this year |
| 5    | Monday            | 0-53  | with a Monday in this year    |
| 6    | Sunday            | 1-53  | with 4 or more days this year |
| 7    | Monday            | 1-53  | with a Monday in this year    |

For *mode* values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53
```

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that `WEEK()` should return 52 because the given date actually occurs in the 52nd week of 1999. `WEEK()` returns 0 instead so that the return value is “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
```

```
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- `WEEKOFYEAR(date)`

Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date, 3)`.

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- `YEAR(date)`

Returns the year for `date`, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- `YEARWEEK(date)`, `YEARWEEK(date, mode)`

Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year.

The `mode` argument works exactly like the `mode` argument to `WEEK()`. For the single-argument syntax, a `mode` value of 0 is used. Unlike `WEEK()`, the value of `default_week_format` does not influence `YEARWEEK()`.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198652
```

Note that the week number is different from what the `WEEK()` function would return (0) for optional arguments 0 or 1, as `WEEK()` then returns the week in the context of the given year.

## 13.8 What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

| Monday | Tuesday | Wednesday | Thursday | Friday | Saturday | Sunday |
|--------|---------|-----------|----------|--------|----------|--------|
| 1      | 2       | 3         | 4        | 15     | 16       | 17     |
| 18     | 19      | 20        | 21       | 22     | 23       | 24     |
| 25     | 26      | 27        | 28       | 29     | 30       | 31     |

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

## 13.9 Full-Text Search Functions

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

```
search_modifier:
{
    IN NATURAL LANGUAGE MODE
  | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
  | IN BOOLEAN MODE
  | WITH QUERY EXPANSION
}
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
- As of MySQL 5.7.6, `MySQL` provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in [Section 13.9.8, “ngram Full-Text Parser”](#), and [Section 13.9.9, “MeCab Full-Text Parser Plugin”](#).
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.
- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators. The stopwords list applies. For more information about stopwords lists, see [Section 13.9.4, “Full-Text Stopwords”](#).

Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see [Section 13.9.1, “Natural Language Full-Text Searches”](#).

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 13.9.2, “Boolean Full-Text Searches”](#).
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 13.9.3, “Full-Text Searches with Query Expansion”](#).

For information about `FULLTEXT` query performance, see [Section 9.3.4, “Column Indexes”](#).

For more information about `InnoDB FULLTEXT` indexes, see [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#).

Constraints on full-text searching are listed in [Section 13.9.5, “Full-Text Restrictions”](#).

The `myisam_ftdump` utility dumps the contents of a `MyISAM` full-text index. This may be helpful for debugging full-text queries. See [Section 5.6.2, “myisam\\_ftdump — Display Full-Text Index information”](#).

### 13.9.1 Natural Language Full-Text Searches

By default or with the `IN NATURAL LANGUAGE MODE` modifier, the `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

```
mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO articles (title,body) VALUES
    ('MySQL Tutorial','DBMS stands for DataBase ...'),
    ('How To Use MySQL Well','After you went through a ...'),
    ('Optimizing MySQL','In this tutorial we will show ...'),
    ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
    ('MySQL vs. YourSQL','In the following database comparison ...'),
    ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.00 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM articles
    WHERE MATCH (title,body)
    AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a binary collation for the indexed columns. For example, a column that uses the `latin1` character set of can be assigned a collation of `latin1_bin` to make it case sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

#### Note

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
      WHERE MATCH (title,body)
      AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+
| COUNT(*) |
+-----+
|         2 |
+-----+
1 row in set (0.00 sec)
```

You might find it quicker to rewrite the query as follows:

```
mysql> SELECT
      COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
      AS count
      FROM articles;
+-----+
| count |
+-----+
|      2 |
+-----+
1 row in set (0.03 sec)
```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in [Section 13.9.2, “Boolean Full-Text Searches”](#), and [Section 13.9.3, “Full-Text Searches with Query Expansion”](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. For `MyISAM` tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body)
      AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
      FROM articles;
+-----+
| id | score |
+-----+
| 1 | 0.22764469683170319 |
| 2 | 0 |
| 3 | 0.22764469683170319 |
| 4 | 0 |
| 5 | 0 |
| 6 | 0 |
+-----+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the

`SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
      ('Security implications of running MySQL as root'
      IN NATURAL LANGUAGE MODE) AS score
      FROM articles WHERE MATCH (title,body) AGAINST
      ('Security implications of running MySQL as root'
      IN NATURAL LANGUAGE MODE);
```

| id | body                                | score           |
|----|-------------------------------------|-----------------|
| 4  | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
| 6  | When configured properly, MySQL ... | 1.3114095926285 |

2 rows in set (0.00 sec)

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (`'`), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa 'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa'bbb'` would be parsed as `aaa'bbb`.

The built-in `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, (space), (comma), and (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index that uses the built-in `FULLTEXT` parser, you must preprocess them so that they are separated by some arbitrary delimiter such as `"`. Alternatively, as of MySQL 5.7.6, you can create `FULLTEXT` indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).

It is possible to write a plugin that replaces the built-in full-text parser. For details, see [Section 27.2, “The MySQL Plugin API”](#). For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for `InnoDB` search indexes, or four characters for `MyISAM`. You can control the cutoff by setting a configuration option before creating the index: `innodb_ft_min_token_size` configuration option for `InnoDB` search indexes, or `ft_min_word_len` for `MyISAM`.

#### Note

This behavior does not apply to `FULLTEXT` indexes that use the ngram parser. For the ngram parser, token length is defined by the `ngram_token_size` option.

- Words in the stopwords list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopwords list, but it can be overridden by a user-defined list. The stopwords lists and related configuration options are different for `InnoDB` search indexes and `MyISAM` ones. Stopword processing is controlled by the configuration options `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for `InnoDB` search indexes, and `ft_stopword_file` for `MyISAM` ones.

See [Section 13.9.4, “Full-Text Stopwords”](#) to view default stopwords lists and how to change them. The default minimum word length can be changed as described in [Section 13.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

### MyISAM Limitation

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on [MyISAM](#) tables. For example, although the word “MySQL” is present in every row of the [articles](#) table shown earlier, a search for the word in a [MyISAM](#) search index produces no results:

```
mysql> SELECT * FROM articles
      WHERE MATCH (title,body)
      AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopwords. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes [InnoDB](#) tables more suited to experimentation with full-text searches. If you create a [MyISAM](#) table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on [InnoDB](#) tables, or use the boolean search mode explained in [Section 13.9.2, “Boolean Full-Text Searches”](#).

## 13.9.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the [IN BOOLEAN MODE](#) modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the [+](#) and [-](#) operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
      AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

| id | title                 | body                                |
|----|-----------------------|-------------------------------------|
| 1  | MySQL Tutorial        | DBMS stands for DataBase ...        |

### Note

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- [+](#) stands for [AND](#)

- `-` stands for `NOT`
- `[no operator]` implies `OR`

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.
- `InnoDB` tables require a `FULLTEXT` index on all columns of the `MATCH()` expression to perform boolean queries. Boolean queries against a `MyISAM` search index can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply to `FULLTEXT` indexes created using the built-in `FULLTEXT` parser and MeCab parser plugin. `innodb_ft_min_token_size` and `innodb_ft_max_token_size` are used for `InnoDB` search indexes. `ft_min_word_len` and `ft_max_word_len` are used for `MyISAM` search indexes.

Minimum and maximum word length full-text parameters do not apply to `FULLTEXT` indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

- The stopwords list applies, controlled by `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for `InnoDB` search indexes, and `ft_stopword_file` for `MyISAM` ones.
- `InnoDB` full-text search does not support the use of multiple operators on a single search word, as in this example: `'++apple'`. Use of multiple operators on a single search word returns a syntax error to standard out. `MyISAM` full-text search will successfully process the same search ignoring all operators except for the operator immediately adjacent to the search word.
- `InnoDB` full-text search only supports leading plus or minus signs. For example, `InnoDB` supports `'+apple'` but does not support `'apple+'`. Specifying a trailing plus or minus sign causes `InnoDB` to report a syntax error.
- `InnoDB` full-text search does not support the use of a leading plus sign with wildcard (`'+*'` ), a plus and minus sign combination (`'+-'` ), or leading a plus and minus sign combination (`'+-apple'` ). These invalid queries return a syntax error.
- `InnoDB` full-text search does not support the use of the `@` symbol in boolean full-text searches. The `@` symbol is reserved for use by the `@distance` proximity search operator.
- They do not use the 50% threshold that applies to `MyISAM` search indexes.

The boolean full-text search capability supports the following operators:

- `+`

A leading or trailing plus sign indicates that this word *must* be present in each row that is returned. `InnoDB` only supports leading plus signs.

- `-`

A leading or trailing minus sign indicates that this word must *not* be present in any of the rows that are returned. `InnoDB` only supports leading minus signs.

Note: The `-` operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by `-` returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither `+` nor `-` is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH() ... AGAINST()` without the `IN BOOLEAN MODE` modifier.

- `@distance`

This operator works on `InnoDB` tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the `@distance` operator, for example, `MATCH(col1) AGAINST('word1 word2 word3' @8' IN BOOLEAN MODE)`

- `>` `<`

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The `>` operator increases the contribution and the `<` operator decreases it. See the example following this list.

- `( )`

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- `~`

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the `-` operator.

- `*`

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is *appended* to the word to be affected. Words match if they begin with the word preceding the `*` operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the `innodb_ft_min_token_size` setting for `InnoDB` tables, or `ft_min_word_len` for `MyISAM` tables. These options are not applicable to `FULLTEXT` indexes that use the ngram parser.

The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for `'+word +the*'` could return fewer rows than a search for `'+word +the'`, because the second query ignores the too-short search term `the`.

- `"`

A phrase that is enclosed within double quote (`"`) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `'+apple +juice'`

Find rows that contain both words.

- `'+apple macintosh'`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the `"` characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

## Relevancy Rankings for InnoDB Boolean Mode Search

InnoDB full-text search is modeled on the [Sphinx](#) full-text search engine, and the algorithms used are based on [BM25](#) and [TF-IDF](#) ranking algorithms. For these reasons, relevancy rankings for InnoDB boolean full-text search may differ from [MyISAM](#) relevancy rankings.

InnoDB uses a variation of the “term frequency-inverse document frequency” ([TF-IDF](#)) weighting system to rank a document's relevance for a given full-text search query. The [TF-IDF](#) weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.

## How Relevancy Ranking is Calculated

The term frequency ([TF](#)) value is the number of times that a word appears in a document. The inverse document frequency ([IDF](#)) value of a word is calculated using the following formula, where [total\\_records](#) is the number of records in the collection, and [matching\\_records](#) is the number of records that the search term appears in.

```
${IDF} = log10( ${total_records} / ${matching_records} )
```

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

```
${TF} * ${IDF}
```

Using the [TF](#) and [IDF](#) values, the relevancy ranking for a document is calculated using this formula:

```
${rank} = ${TF} * ${IDF} * ${IDF}
```

The formula is demonstrated in the following examples.

## Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.

```
mysql> CREATE TABLE articles (
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
title VARCHAR(200),
body TEXT,
FULLTEXT (title,body)
) ENGINE=InnoDB;
Query OK, 0 rows affected (1.04 sec)

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','This database tutorial ...'),
('How To Use MySQL','After you went through a ...'),
('Optimizing Your Database','In this database tutorial ...'),
('MySQL vs. YourSQL','When comparing databases ...'),
('MySQL Security','When configured properly, MySQL ...'),
('Database, Database, Database','database database database'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL Full-Text Indexes','MySQL fulltext indexes use a ..');
Query OK, 8 rows affected (0.06 sec)
Records: 8 Duplicates: 0 Warnings: 0

mysql> SELECT id, title, body, MATCH (title,body) AGAINST ('database' IN BOOLEAN MODE)
AS score FROM articles ORDER BY score DESC;
```

| id | title                        | body                                | score               |
|----|------------------------------|-------------------------------------|---------------------|
| 6  | Database, Database, Database | database database database          | 1.0886961221694946  |
| 3  | Optimizing Your Database     | In this database tutorial ...       | 0.36289870738983154 |
| 1  | MySQL Tutorial               | This database tutorial ...          | 0.18144935369491577 |
| 2  | How To Use MySQL             | After you went through a ...        | 0                   |
| 4  | MySQL vs. YourSQL            | When comparing databases ...        | 0                   |
| 5  | MySQL Security               | When configured properly, MySQL ... | 0                   |
| 7  | 1001 MySQL Tricks            | 1. Never run mysqld as root. 2. ... | 0                   |
| 8  | MySQL Full-Text Indexes      | MySQL fulltext indexes use a ..     | 0                   |

```
8 rows in set (0.00 sec)
```

There are 8 records in total, with 3 that match the “database” search term. The first record ([id 6](#)) contains the search term 6 times and has a relevancy ranking of [1.0886961221694946](#). This ranking value is calculated using a **TF** value of 6 (the “database” search term appears 6 times in record [id 6](#)) and an **IDF** value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

```
${IDF} = log10( 8 / 3 ) = 0.42596873216370745
```

The **TF** and **IDF** values are then entered into the ranking formula:

```
${rank} = ${TF} * ${IDF} * ${IDF}
```

Performing the calculation in the MySQL command-line client returns a ranking value of [1.088696164686938](#).

```
mysql> SELECT 6*log10(8/3)*log10(8/3);
+-----+
| 6*log10(8/3)*log10(8/3) |
+-----+
| 1.088696164686938 |
+-----+
1 row in set (0.00 sec)
```

### Note

You may notice a slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client ([1.0886961221694946](#) versus [1.088696164686938](#)). The difference is due to how the casts between integers and floats/doubles are performed

internally by [InnoDB](#) (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

## Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the [articles](#) table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

$$\${rank} = \${TF} * \${IDF} * \${IDF} + \${TF} * \${IDF} * \${IDF}$$

Performing a search on two terms ('mysql tutorial') returns the following results:

```
mysql> SELECT id, title, body, MATCH (title,body) AGAINST ('mysql tutorial' IN BOOLEAN MODE)
      AS score FROM articles ORDER BY score DESC;
```

| id | title                        | body                                | score                |
|----|------------------------------|-------------------------------------|----------------------|
| 1  | MySQL Tutorial               | This database tutorial ...          | 0.7405621409416199   |
| 3  | Optimizing Your Database     | In this database tutorial ...       | 0.3624762296676636   |
| 5  | MySQL Security               | When configured properly, MySQL ... | 0.031219376251101494 |
| 8  | MySQL Full-Text Indexes      | MySQL fulltext indexes use a ..     | 0.031219376251101494 |
| 2  | How To Use MySQL             | After you went through a ...        | 0.015609688125550747 |
| 4  | MySQL vs. YourSQL            | When comparing databases ...        | 0.015609688125550747 |
| 7  | 1001 MySQL Tricks            | 1. Never run mysqld as root. 2. ... | 0.015609688125550747 |
| 6  | Database, Database, Database | database database database          | 0                    |

8 rows in set (0.00 sec)

In the first record (id 8), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

```
mysql> SELECT (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2));
```

| (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2)) |
|---|
| 0.7405621541938003                                    |

1 row in set (0.00 sec)

### Note

The slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client is explained in the preceding example.

## 13.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
WHERE MATCH (title,body)
AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

| id | title             | body                                     |
|----|-------------------|--|
| 1  | MySQL Tutorial    | DBMS stands for DataBase ...             |
| 5  | MySQL vs. YourSQL | In the following database comparison ... |

```
2 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM articles
WHERE MATCH (title,body)
AGAINST ('database' WITH QUERY EXPANSION);
```

| id | title                 | body                                     |
|----|-----------------------|--|
| 5  | MySQL vs. YourSQL     | In the following database comparison ... |
| 1  | MySQL Tutorial        | DBMS stands for DataBase ...             |
| 3  | Optimizing MySQL      | In this tutorial we will show ...        |
| 6  | MySQL Security        | When configured properly, MySQL ...      |
| 2  | How To Use MySQL Well | After you went through a ...             |
| 4  | 1001 MySQL Tricks     | 1. Never run mysqld as root. 2. ...      |

```
6 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

#### Note

Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

## 13.9.4 Full-Text Stopwords

The stopwords list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopwords lookups if the stopwords file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopwords lookups depends on the server collation. For example, lookups are case insensitive if the collation is `latin1_swedish_ci`, whereas lookups are case sensitive if the collation is `latin1_general_cs` or `latin1_bin`.

### Stopwords for InnoDB Search Indexes

InnoDB has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default InnoDB stopwords list, query the `INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD` table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
```

| value |
|-------|
| a     |
| about |
| an    |
| are   |

```

| as      |
| at      |
| be      |
| by      |
| com     |
| de      |
| en      |
| for     |
| from    |
| how     |
| i       |
| in      |
| is      |
| it      |
| la      |
| of      |
| on      |
| or      |
| that    |
| the     |
| this    |
| to      |
| was     |
| what    |
| when    |
| where   |
| who     |
| will    |
| with    |
| und     |
| the     |
| www     |
+-----+
36 rows in set (0.00 sec)

```

To define your own stopwords list for all [InnoDB](#) tables, define a table with the same structure as the [INNODB\\_FT\\_DEFAULT\\_STOPWORD](#) table, populate it with stopwords, and set the value of the [innodb\\_ft\\_server\\_stopword\\_table](#) option to a value in the form [db\\_name/table\\_name](#) before creating the full-text index. The stopwords table must have a single [VARCHAR](#) column named [value](#). The following example demonstrates creating and configuring a new global stopwords table for [InnoDB](#).

```

-- Create a new stopwords table

mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)

-- Insert stopwords (for simplicity, a single stopwords is used in this example)

mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table

mysql> CREATE TABLE opening_lines (
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
opening_line TEXT(500),
author VARCHAR(200),
title VARCHAR(200)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
('It was love at first sight.','Joseph Heller','Catch-22'),
('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),

```

```
( 'It was a pleasure to burn.', 'Ray Bradbury', 'Fahrenheit 451' );
Query OK, 8 rows affected (0.00 sec)
Records: 8 Duplicates: 0 Warnings: 0

-- Set the innodb_ft_server_stopword_table option to the new stopwords table

mysql> SET GLOBAL innodb_ft_server_stopword_table = 'test/my_stopwords';
Query OK, 0 rows affected (0.00 sec)

-- Create the full-text index (which rebuilds the table if no FTS_DOC_ID column is defined)

mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 1
```

Verify that the specified stopwords ('Ishmael') does not appear by querying the words in `INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE`.

### Note

By default, words less than 3 characters in length or greater than 84 characters in length do not appear in an `InnoDB` full-text search index. Maximum and minimum word length values are configurable using the `innodb_ft_max_token_size` and `innodb_ft_min_token_size` variables. This default behavior does not apply to the ngram parser plugin. ngram token size is defined by the `ngram_token_size` option.

```
mysql> SET GLOBAL innodb_ft_aux_table='test/opening_lines';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT word FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 15;
+-----+
| word |
+-----+
| across |
| all |
| burn |
| buy |
| call |
| comes |
| dalloway |
| first |
| flowers |
| happened |
| herself |
| invisible |
| less |
| love |
| man |
+-----+
15 rows in set (0.00 sec)
```

To create stopwords lists on a table-by-table basis, create other stopwords tables and use the `innodb_ft_user_stopword_table` option to specify the stopwords table that you want to use before you create the full-text index.

## Stopwords for MyISAM Search Indexes

The stopwords file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`.

To override the default stopwords list for MyISAM tables, set the `ft_stopword_file` system variable. (See [Section 6.1.5, “Server System Variables”](#).) The variable value should be the path name of the file containing the stopwords list, or the empty string to disable stopwords filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopwords file, restart the server and rebuild your `FULLTEXT` indexes.

The stopwords list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (`_`) and a single apostrophe (`'`) which are treated as part of a word. The character set of the stopwords list is the server's default character set; see [Section 11.1.3.2, "Server Character Set and Collation"](#).

The following table shows the default list of stopwords for [MyISAM](#) search indexes. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

|               |             |            |             |              |
|---------------|-------------|------------|-------------|--------------|
| a's           | able        | about      | above       | according    |

### 13.9.5 Full-Text Restrictions

- Full-text searches are supported for [InnoDB](#) and [MyISAM](#) tables only.
- Full-text searches are not supported for partitioned tables. See [Section 21.6, “Restrictions and Limitations on Partitioning”](#).
- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the [utf8](#) character set can be used, but not the [ucs2](#) character set. Although [FULLTEXT](#) indexes on [ucs2](#) columns cannot be used, you can perform [IN BOOLEAN MODE](#) searches on a [ucs2](#) column that has no such index.

The remarks for [utf8](#) also apply to [utf8mb4](#), and the remarks for [ucs2](#) also apply to [utf16](#), [utf16le](#), and [utf32](#).

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser *cannot determine where words begin and end in these and other such languages*.

In MySQL 5.7.6, a character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with [InnoDB](#) and [MyISAM](#) tables.

- Although the use of multiple character sets within a single table is supported, all columns in a [FULLTEXT](#) index must use the same character set and collation.
- The [MATCH \( \)](#) column list must match exactly the column list in some [FULLTEXT](#) index definition for the table, unless this [MATCH \( \)](#) is [IN BOOLEAN MODE](#) on a [MyISAM](#) table. For [MyISAM](#) tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.
- The argument to [AGAINST \( \)](#) must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.
- Index hints are more limited for [FULLTEXT](#) searches than for non-[FULLTEXT](#) searches. See [Section 9.9.4, “Index Hints”](#).
- For [InnoDB](#), all DML operations ([INSERT](#), [UPDATE](#), [DELETE](#)) involving columns with full-text indexes are processed at transaction commit time. For example, for an [INSERT](#) operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.
- The '%' character is not a supported wildcard character for full-text searches.

### 13.9.6 Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.9, “Installing MySQL from Source”](#).

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the [FULLTEXT](#) indexes in your tables. Instructions for doing so are given later in this section.

#### Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the [innodb\\_ft\\_min\\_token\\_size](#) and [innodb\\_ft\\_max\\_token\\_size](#) for [InnoDB](#) search indexes, and [ft\\_min\\_word\\_len](#) and [ft\\_max\\_word\\_len](#) for [MyISAM](#) ones.

#### Note

Minimum and maximum word length full-text parameters do not apply to [FULLTEXT](#) indexes created using the ngram parser. ngram token size is defined by the [ngram\\_token\\_size](#) option.

After changing any of these options, rebuild your [FULLTEXT](#) indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```
[mysqld]
innodb_ft_min_token_size=2
```

```
ft_min_word_len=2
```

Then restart the server and rebuild your `FULLTEXT` indexes. For `MyISAM` tables, note the remarks regarding `myisamchk` in the instructions that follow for rebuilding `MyISAM` full-text indexes.

## Configuring the Natural Language Search Threshold

For `MyISAM` search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

### Note

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH ( )` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

## Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on `MyISAM` tables, set the `ft_boolean_syntax` system variable. (`InnoDB` does not have an equivalent setting.) This variable can be changed while the server is running, but you must have the `SUPER` privilege to do so. No rebuilding of indexes is necessary in this case. See [Section 6.1.5, “Server System Variables”](#), which describes the rules governing how to set this variable.

## Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character ('-') as a word character. Use one of these methods:

- Modify the MySQL source: In `storage/innobase/handler/ha_innodb.cc` (for `InnoDB`), or in `storage/myisam/ftdefs.h` (for `MyISAM`), see the `true_word_char ( )` and `misc_word_char ( )` macros. Add '-' to one of those macros and recompile MySQL.
- Modify a character set file: This requires no recompilation. The `true_word_char ( )` macro uses a “character type” table to distinguish letters and numbers from other characters. . You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see [Section 11.3.1, “Character Definition Arrays”](#).
- Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see [Section 11.4, “Adding a Collation to a Character Set”](#). For an example specific to full-text indexing, see [Section 13.9.7, “Adding a Collation for Full-Text Indexing”](#).

## Rebuilding InnoDB Full-Text Indexes

If you modify full-text variables that affect indexing (`innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `innodb_ft_server_stopword_table`,

`innodb_ft_user_stopword_table`, `innodb_ft_enable_stopword`, `ngram_token_size` you must rebuild your `FULLTEXT` indexes after making the changes. Modifying the `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, or `ngram_token_size` variables, which cannot be set dynamically, require restarting the server and rebuilding the indexes.

To rebuild the `FULLTEXT` indexes for an `InnoDB` table, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each index.

## Optimizing InnoDB Full-Text Indexes

Running `OPTIMIZE TABLE` on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE`.

```
mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> OPTIMIZE TABLE opening_lines;
```

```
+-----+-----+-----+-----+
| Table           | Op       | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.opening_lines | optimize | status   | OK        |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time `OPTIMIZE TABLE` is run. The default setting is 2000, which means that 2000 words are optimized each time `OPTIMIZE TABLE` is run. Subsequent `OPTIMIZE TABLE` operations continue from where the preceding `OPTIMIZE TABLE` operation ended.

## Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopwords file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server.

To rebuild the `FULLTEXT` indexes for a `MyISAM` table, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` as just described. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies `MyISAM` table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopwords file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for MyISAM table index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

### 13.9.7 Adding a Collation for Full-Text Indexing

This section describes how to add a new collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the `'-'` character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in [Section 11.4, “Adding a Collation to a Character Set”](#); it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use this procedure:

1. Add a collation to the `Index.xml` file. The collation ID must be unused, so choose a value different from 1000 if that ID is already taken on your system.

```
<charset name="latin1">
...
<collation name="latin1_fulltext_ci" id="1000"/>
</charset>
```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

```
<collation name="latin1_fulltext_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 DE DF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 5D F7 D8 55 55 55 59 59 DE FF
</map>
</collation>
```

3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the `'-'` character) from 10 (punctuation) to 01 (small letter). In the following array, this is the element in the fourth row down, third value from the end.

```

<ctype>
<map>
00
20 20 20 20 20 20 20 20 20 20 28 28 28 28 28 20 20
20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
48 10 10 10 10 10 10 10 10 10 10 10 10 01 10 10
84 84 84 84 84 84 84 84 84 84 10 10 10 10 10 10
10 81 81 81 81 81 81 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 01 01 01 01 01 10 10 10 10
10 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 02 02 02 02 10 10 10 10 20
10 00 10 02 10 10 10 10 10 10 01 10 01 00 01 00
00 10 10 10 10 10 10 10 10 10 02 10 02 00 02 01
48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 10 01 01 01 01 01 01 02
02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 10 02 02 02 02 02 02 02
</map>
</ctype>

```

4. Restart the server.
5. To employ the new collation, include it in the definition of columns that are to use it:

```

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
  a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
  FULLTEXT INDEX(a)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.47 sec)

```

6. Test the collation to verify that hyphen is considered as a word character:

```

mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+-----+
| a      |
+-----+
| ----  |
+-----+
1 row in set (0.00 sec)

```

## 13.9.8 ngram Full-Text Parser

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese, Japanese, and Korean (CJK). The ngram full-text parser is supported for use with [InnoDB](#) and [MyISAM](#).

### Note

MySQL also provides a MeCab full-text parser plugin for Japanese, which tokenizes documents into meaningful words. For more information, see [Section 13.9.9, “MeCab Full-Text Parser Plugin”](#).

An ngram is a contiguous sequence of *n* characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of *n* characters. For example, you can tokenize “abcd” for different values of *n* using the ngram full-text parser.

```
n=1: 'a', 'b', 'c', 'd'
n=2: 'ab', 'bc', 'cd'
n=3: 'abc', 'bcd'
n=4: 'abcd'
```

The ngram full-text parser, introduced in MySQL 5.7.6, is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in [Section 13.9, “Full-Text Search Functions”](#) applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration options, except for minimum and maximum word length options (`innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, `ft_max_word_len`) are also applicable.

## Configuring ngram Token Size

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the `ngram_token_size` configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, `ngram_token_size` is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set `ngram_token_size` to 1. A smaller token size produces a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set `ngram_token_size` accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as “happy”. To search on two-character words such as these, set `ngram_token_size` to a value of 2 or higher.

As a read-only variable, `ngram_token_size` may only be set as part of a startup string or in a configuration file:

- Startup string:

```
mysqld --ngram_token_size=2
```

- Configuration file:

```
[mysqld]
ngram_token_size=2
```

### Note

The following minimum and maximum word length configuration options are ignored for `FULLTEXT` indexes that use the ngram parser: `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, and `ft_max_word_len`.

## Creating a FULLTEXT Index that Uses the ngram Parser

To create a `FULLTEXT` index that uses the ngram parser, specify `WITH PARSEr ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

The following example demonstrates creating a table with an `ngram FULLTEXT` index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
```

```
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
title VARCHAR(200),
body TEXT,
FULLTEXT (title,body) WITH PARSEr ngram
) ENGINE=InnoDB CHARACTER SET utf8mb4;

mysql> SET NAMES utf8mb4;

INSERT INTO articles (title,body) VALUES
('数据库管理','在本教程中我将向你展示如何管理数据库'),
('数据库应用开发','学习开发数据库应用程序');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a [FULLTEXT](#) index to an existing table, you can use [ALTER TABLE](#) or [CREATE INDEX](#). For example:

```
CREATE TABLE articles (
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
title VARCHAR(200),
body TEXT
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSEr ngram;

# Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSEr ngram;
```

## ngram Parser Space Handling

The ngram parser eliminates spaces when parsing. For example:

- “ab cd” is parsed to “ab”, “cd”
- “a bc” is parsed to “bc”

## ngram Parser Stopword Handling

The built-in MySQL full-text parser compares words to entries in the stopwords list. If a word is equal to an entry in the stopwords list, the word is excluded from the index. For the ngram parser, stopwords handling is performed differently. Instead of excluding tokens that are equal to entries in the stopwords list, the ngram parser excludes tokens that *contain* stopwords. For example, assuming [ngram\\_token\\_size=2](#), a document that contains “a,b” is parsed to “a,” and “,b”. If a comma (“,”) is defined as a stopwords, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopwords list, which contains a list of English stopwords. For a stopwords list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopwords list, see [Section 13.9.4, “Full-Text Stopwords”](#).

Stopwords greater in length than [ngram\\_token\\_size](#) are ignored.

## ngram Parser Term Search

For *natural language mode* search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming [ngram\\_token\\_size=2](#)) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For *boolean mode* search, the search term is converted to an ngram phrase search. For example, the string 'abc' (assuming [ngram\\_token\\_size=2](#)) is converted to “ab bc”. Given two documents, one

containing 'ab' and the other containing 'abc', the search phrase "ab bc" only matches the document containing 'abc'.

## ngram Parser Wildcard Search

Because an ngram [FULLTEXT](#) index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram [FULLTEXT](#) search indexes:

- If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming `ngram_token_size=2`, a search on "a\*" returns all rows starting with "a".
- If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming `ngram_token_size=2`, an "abc\*" wildcard search is converted to "ab bc".

## ngram Parser Phrase Search

Phrase searches are converted to ngram phrase searches. For example, The search phrase "abc" is converted to "ab bc", which returns documents containing "abc" and "ab bc".

The search phrase "abc def" is converted to "ab bc de ef", which returns documents containing "abc def" and "ab bc de ef". A document that contains "abcdef" is not returned.

### 13.9.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with [InnoDB](#) and [MyISAM](#).

#### Note

MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see [Section 13.9.8, "ngram Full-Text Parser"](#).

The MeCab full-text parser plugin, introduced in MySQL 5.7.6, is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes "データベース管理" ("Database Management") into "データベース" ("Database") and "管理" ("Management"). By comparison, the [ngram](#) full-text parser tokenizes text into a contiguous sequence of *n* characters, where *n* represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.

The full-text search syntax described in [Section 13.9, "Full-Text Search Functions"](#) applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the [MeCab Documentation](#) on the [Google Developers](#) site.

## Installing the MeCab Parser Plugin

The MeCab parser plugin requires `mecab` and `mecab-ipadic`.

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system `mecab` version is too old), MySQL dynamically links to the system `mecab` installation if it is installed to

the default location. On other supported Unix-like platforms, `libmecab.so` is statically linked in `libpluginmecab.so`, which is located in the MySQL plugin directory. `mecab-ipadic` is included in MySQL binaries and is located in `MYSQL_HOME/lib/mecab`.

You can install `mecab` and `mecab-ipadic` using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build `mecab` and `mecab-ipadic` from source. For information about installing `mecab` and `mecab-ipadic` using a native package management utility, see [Installing MeCab From a Binary Distribution \(Optional\)](#). If you want to build `mecab` and `mecab-ipadic` from source, see [Building MeCab From Source \(Optional\)](#).

On Windows, `libmecab.dll` is found in the MySQL `bin` directory. `mecab-ipadic` is located in `MYSQL_HOME/lib/mecab`.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the `mecab_rc_file` configuration option to the location of the `mecabrc` configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the `mecabrc` file is located in `MYSQL_HOME/lib/mecab/etc/`.

```
[mysqld]
loose-mecab-rc-file=MYSQL_HOME/lib/mecab/etc/mecabrc
```

The `loose` prefix is an [option modifier](#). The `mecab_rc_file` option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The `loose` prefix allows you restart MySQL without encountering an error due to an unrecognized variable.

If you use your own MeCab installation, or build MeCab from source, the location of the `mecabrc` configuration file may differ.

For information about the MySQL configuration file and its location, see [Section 5.2.6, “Using Option Files”](#).

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For `InnoDB` tables, minimum token size is defined by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For `MyISAM` tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

```
[mysqld]
innodb_ft_min_token_size=1
```

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains an entry similar to the following:

```
dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp
```

To use the `ipadic_utf-8` dictionary, for example, modify the entry as follows:

```
dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8
```

If you are using your own MeCab installation or have built MeCab from source, the default `dicdir` entry in the `mecabrc` file will differ, as will the dictionaries and their location.

#### Note

After the MeCab parser plugin is installed, you can use the `mecab_charset` status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

- The `ipadic_euc-jp` dictionary supports the `ujis` and `eucjpms` character sets.
- The `ipadic_sjis` dictionary supports the `sjis` and `cp932` character sets. `cp932` support was added in MySQL 5.7.7.
- The `ipadic_utf-8` dictionary supports the `utf8` and `utf8mb4` character sets. `utf8mb4` support was added in MySQL 5.7.7.

`mecab_charset` only reports the first supported character set. For example, the `ipadic_utf-8` dictionary supports both `utf8` and `utf8mb4`. `mecab_charset` always reports `utf8` when this dictionary is in use.

4. Restart MySQL.
5. Install the MeCab parser plugin:

The MeCab parser plugin is installed using `INSTALL PLUGIN` syntax. The plugin name is `mecab`, and the shared library name is `libpluginmecab.so`. For additional information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

```
INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';
```

Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the `SHOW PLUGINS` statement.

```
mysql> SHOW PLUGINS;
```

A `mecab` plugin should appear in the list of plugins.

## Creating a FULLTEXT Index that uses the MeCab Parser

To create a `FULLTEXT` index that uses the mecab parser, specify `WITH PARSE ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

This example demonstrates creating a table with a `mecab FULLTEXT` index, inserting sample data, and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table:

```
mysql> USE test;

mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body) WITH PARSE mecab
) ENGINE=InnoDB CHARACTER SET utf8;

mysql> SET NAMES utf8;

mysql> INSERT INTO articles (title,body) VALUES
    ('データベース管理','このチュートリアルでは、私はどのようにデータベースを管理する方法を紹介します'),
    ('データベースアプリケーション開発','データベースアプリケーションを開発することを学ぶ');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a `FULLTEXT` index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

```
CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
```

```
body TEXT
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSEr mecab;

# Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSEr mecab;
```

## MeCab Parser Space Handling

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes 'データベース管理' as 'データベース' and '管理'.

## MeCab Parser Stopword Handling

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see [Section 13.9.4, “Full-Text Stopwords”](#).

## MeCab Parser Term Search

For natural language mode search, the search term is converted to a union of tokens. For example, 'データベース管理' is converted to 'データベース 管理'.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, 'データベース管理' is converted to '"データベース 管理"'.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

## MeCab Parser Wildcard Search

Wildcard search terms are not tokenized. A search on 'データベース管理\*' is performed on the prefix, 'データベース管理'.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース*' IN BOOLEAN MODE);
```

## MeCab Parser Phrase Search

Phrases are tokenized. For example, "データベース管理" is tokenized as "データベース 管理".

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('"データベース管理"' IN BOOLEAN MODE);
```

## Installing MeCab From a Binary Distribution (Optional)

This section describes how to install [mecab](#) and [mecab-ipadic](#) from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```
yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```
apt-get install mecab
apt-get install mecab-ipadic
```

## Installing MeCab From Source (Optional)

If you want to build [mecab](#) and [mecab-ipadic](#) from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for `mecab` and `mecab-ipadic` from <http://taku910.github.io/mecab/#download>. As of February, 2016, the latest available packages are `mecab-0.996.tar.gz` and `mecab-ipadic-2.7.0-20070801.tar.gz`.

2. Install `mecab`:

```
tar xzfv mecab-0.996.tar
cd mecab-0.996
./configure
make
make check
su
make install
```

3. Install `mecab-ipadic`:

```
tar xzfv mecab-ipadic-2.7.0-20070801.tar
cd mecab-ipadic-2.7.0-20070801
./configure
make
su
make install
```

4. Compile MySQL using the `WITH_MECAB` CMake option. Set the `WITH_MECAB` option to `system` if you have installed `mecab` and `mecab-ipadic` to the default location.

```
-DWITH_MECAB=system
```

If you defined a custom installation directory, set `WITH_MECAB` to the custom directory. For example:

```
-DWITH_MECAB=/path/to/mecab
```

## 13.10 Cast Functions and Operators

Table 13.14 Cast Functions and Operators

| Name                   | Description                      |
|------------------------|----------------------------------|
| <code>BINARY</code>    | Cast a string to a binary string |
| <code>CAST()</code>    | Cast a value as a certain type   |
| <code>CONVERT()</code> | Cast a value as a certain type   |

Cast functions and operators enable conversion of values from one data type to another.

`CONVERT()` with a `USING` clause provides a way to convert data between different character sets:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8_table (utf8_column)
  SELECT CONVERT(latin1_column USING utf8) FROM latin1_table;
```

You can also use `CONVERT()` without `USING` or `CAST()` to convert strings between different character sets:

```
CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset_name)
```

Examples:

```
SELECT CONVERT('test', CHAR CHARACTER SET utf8);
SELECT CAST('test' AS CHAR CHARACTER SET utf8);
```

If you specify `CHARACTER SET charset_name` as just shown, the resulting character set and collation are *charset\_name* and the default collation of *charset\_name*. If you omit `CHARACTER SET charset_name`, the resulting character set and collation are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 11.1.4, “Connection Character Sets and Collations”](#)).

A `COLLATE` clause is not permitted within a `CONVERT()` or `CAST()` call, but you can apply it to the function result. For example, this is legal:

```
SELECT CAST('test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

But this is illegal:

```
SELECT CAST('test' AS CHAR CHARACTER SET utf8 COLLATE utf8_bin);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings use the `binary` character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, use the `CONVERT()` or `CAST()` function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result character set has a case-insensitive collation, a `LIKE` operation is not case sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1)
FROM tbl_name;
```

To use a different character set, substitute its name for `latin1` in the preceding statement. To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` call:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) COLLATE latin1_german1_ci
FROM tbl_name;
```

`CONVERT()` and `CAST()` can be used more generally for comparing strings that are represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (latin2_general_ci,IMPLICIT) for operation '='

```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+-----+
| @s1 = CONVERT(@s2 USING latin1) |
+-----+
| 1 |
+-----+
```

For string literals, another way to specify the character set is to use a character set introducer (`_latin1` and `_latin2` in the preceding example are instances of introducers). Unlike conversion functions such as `CAST()`, or `CONVERT()`, which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see [Section 11.1.3.8, “Character Set Introducers”](#).

Character set conversion is also useful preceding lettercase conversion of binary strings. `LOWER()` and `UPPER()` are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| New York    | new york                          |
+-----+-----+
```

If you convert an indexed column using `BINARY`, `CAST()`, or `CONVERT()`, MySQL may not be able to use the index efficiently.

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table\G
***** 1. row *****
      Table: new_table
Create Table: CREATE TABLE `new_table` (
  `c1` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ', CAST(NOW() AS DATE))`.

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See [Section 13.7, “Date and Time Functions”](#).

To cast a string to a number, you normally need do nothing other than use the string value in numeric context:

```
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see [Section 13.2, “Type Conversion in Expression Evaluation”](#).

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see [Section 13.6.1, “Arithmetic Operators”](#)). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT 1 - 2;
      -> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
      -> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
      -> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
      -> -1.0
```

The SQL mode affects the result of conversion operations (see [Section 6.1.8, “Server SQL Modes”](#)). Examples:

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

The following list describes the available cast functions and operators:

- `BINARY expr`

The `BINARY` operator converts the expression to a binary string. A common use for `BINARY` is to force a character string comparison to be done byte by byte rather than character by character, in effect becoming case sensitive. The `BINARY` operator also causes trailing spaces in comparisons to be significant.

```
mysql> SELECT 'a' = 'A';
      -> 1
mysql> SELECT BINARY 'a' = 'A';
      -> 0
mysql> SELECT 'a' = 'a ';
      -> 1
mysql> SELECT BINARY 'a' = 'a ';
      -> 0
```

In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

For purposes of converting a string expression to a binary string, these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If a value is a string literal, it can be designated as a binary string without performing any conversion by using the `_binary` character set introducer:

```
mysql> SELECT 'a' = 'A';
      -> 1
mysql> SELECT _binary 'a' = 'A';
      -> 0
```

For information about introducers, see [Section 11.1.3.8, “Character Set Introducers”](#).

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. A character column defined with the `BINARY` attribute is assigned table default character set and the binary (`_bin`) collation of that character set. Every nonbinary character set has a `_bin` collation. For example, the binary collation for the `utf8` character set is `utf8_bin`, so if the table default character set is `utf8`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin
```

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

- `CAST(expr AS type)`

The `CAST()` function takes an expression of any type and produces a result value of the specified type, similar to `CONVERT()`. For more information, see the description of `CONVERT()`.

`CAST()` is standard SQL syntax.

- `CONVERT(expr, type)`, `CONVERT(expr USING transcoding_name)`

The `CONVERT()` function takes an expression of any type and produces a result value of the specified type.

Discussion of `CONVERT(expr, type)` syntax here also applies to `CAST(expr AS type)`, which is equivalent.

`CONVERT(... USING ...)` is standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

`CONVERT()` with `USING` converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string `'abc'` in the default character set to the corresponding string in the `utf8` character set:

```
SELECT CONVERT('abc' USING utf8);
```

`CONVERT()` without `USING` and `CAST()` take an expression and a `type` value specifying the result type. These `type` values are permitted:

- `BINARY[(N)]`

Produces a string with the `BINARY` data type. See [Section 12.4.2, “The BINARY and VARBINARY Types”](#) for a description of how this affects comparisons. If the optional length `N` is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than `N` bytes are padded with `0x00` bytes to a length of `N`.

- `CHAR[(N)] [charset_info]`

Produces a string with the `CHAR` data type. If the optional length *N* is given, `CHAR(N)` causes the cast to use no more than *N* characters of the argument. No padding occurs for values shorter than *N* characters.

With no `charset_info` clause, `CHAR` produces a string with the default character set. To specify the character set explicitly, these `charset_info` values are permitted:

- `CHARACTER SET charset_name`: Produces a string with the given character set.
- `ASCII`: Shorthand for `CHARACTER SET latin1`.
- `UNICODE`: Shorthand for `CHARACTER SET ucs2`.

In all cases, the string has the default collation for the character set.

- `DATE`

Produces a `DATE` value.

- `DATETIME`

Produces a `DATETIME` value.

- `DECIMAL[ (M[,D]) ]`

Produces a `DECIMAL` value. If the optional *M* and *D* values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale).

- `JSON` (added in MySQL 5.7.8)

Produces a `JSON` value. For details on the rules for conversion of values between `JSON` and other types, see [Comparison and Ordering of JSON Values](#).

- `NCHAR[ (N) ]`

Like `CHAR`, but produces a string with the national character set. See [Section 11.1.3.7, “The National Character Set”](#).

Unlike `CHAR`, `NCHAR` does not permit trailing character set information to be specified.

- `SIGNED [INTEGER]`

Produces a signed integer value.

- `TIME`

Produces a `TIME` value.

- `UNSIGNED [INTEGER]`

Produces an unsigned integer value.

## 13.11 XML Functions

**Table 13.15 XML Functions**

| Name                        | Description  |
|-----------------------------|--|
| <code>ExtractValue()</code> | Extracts a value from an XML string using XPath notation |
| <code>UpdateXML()</code>    | Return replaced XML fragment                             |

This section discusses XML and related functionality in MySQL.

**Note**

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See [Section 5.5.1](#), “`mysql` — The MySQL Command-Line Tool”, and [Section 5.5.4](#), “`mysqldump` — A Database Backup Program”.

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this Manual, and you should refer to the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

**Note**

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.7 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax `$_variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) `$_myvariable` is used where `$myvariable` was intended.

Example:

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i =1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[$_i]');
+-----+-----+
| @i    | ExtractValue(@xml, '//b[$_i]') |
+-----+-----+
| 1     | X                               |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[$_j]');
+-----+-----+
| @j    | ExtractValue(@xml, '//b[$_j]') |
+-----+-----+
| 2     | Y                               |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @k, ExtractValue(@xml, '//b[$_k]');
+-----+-----+
| @k    | ExtractValue(@xml, '//b[$_k]') |
+-----+-----+
| NULL  |                                |
+-----+-----+
1 row in set (0.00 sec)
```

- **Variables in stored programs (strong checking).** Variables using the syntax `$_variable_name` can be declared and used with these functions when they are called inside stored programs. Such

variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
->   DECLARE i INT DEFAULT 1;
->   DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
->
->   WHILE i < 4 DO
->     SELECT xml, i, ExtractValue(xml, '//a[$i]');
->     SET i = i+1;
->   END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> CALL myproc();
+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 1 | X                             |
+-----+-----+-----+
1 row in set (0.00 sec)

+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 2 | Y                             |
+-----+-----+-----+
1 row in set (0.01 sec)

+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 3 | Z                             |
+-----+-----+-----+
1 row in set (0.01 sec)
```

**Parameters.** Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

#### Note

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup *xml\_frag* and an XPath expression *xpath\_expr* (also known as a *locator*); it returns the text (CDATA) of the first text node which is a child of the elements or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the *xpath\_expr* after appending `/text()`. In other words, `ExtractValue('<a><b>Sakila</b></a>', '/a/b')` and `ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()')` produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as *xpath\_expr* is valid, and *xml\_frag* consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in *xml\_frag* or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b></b></a>', '/a/b');
+-----+
| ExtractValue('<a><b></b></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c></a>', '/a/b');
+-----+
| ExtractValue('<a><c></c></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b></b></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><b></b></a>', 'count(/a/b)') |
+-----+
| 1                                           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c></c></a>', 'count(/a/b)') |
+-----+
| 0                                           |
+-----+
1 row in set (0.01 sec)
```

### Important

`ExtractValue()` returns only **CDATA**, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
->   ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
->   ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
->   ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
->   ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
->   ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
+-----+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5 |
+-----+-----+-----+-----+-----+
| ccc  | ddd  | ddd  |      | ddd eee |
```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see [Section 11.1.8.4, “Collation of Expressions”](#), for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL                                     |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
        END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c                                           |
+-----+
1 row in set (0.00 sec)
```

- `UpdateXML(xml_target, xpath_expr, new_xml)`

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user.

If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

```
mysql> SELECT
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
->   UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

#### Note

A discussion in depth of XPath syntax and usage are beyond the scope of this Manual. Please see the [XML Path Language \(XPath\) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who

are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](https://zvon.org/learn/paths/tutorial/), which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a><b/></a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<b><a/></b>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a><b/></a>` because it is a child of the root element `a`. It does not have a match in `<b><a/></b>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c><b/></c></a>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><b><c/></b></a>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><b><c/></b></a>`; `<c><a><b/></a></b>`; `<c><b><a/></b></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a><b/></a>` or `<a><b><c/></b></a>`

#### Note

`//tag` is the equivalent of `/descendant-or-self::*/*tag`. A common error is to confuse this with `/descendant-or-self::tag`, although the latter expression can actually lead to very different results, as can be seen here:

```
mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----+
| @xml                                     |
+-----+
| <a><b><c>w</c><b>x</b><d>y</d>z</b></a>      |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[1]');
+-----+
| ExtractValue(@xml, '//b[1]')           |
+-----+
| x z                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+-----+
| ExtractValue(@xml, '//b[2]')           |
+-----+
```

```

+-----+
|
+-----+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[1]') |
+-----+
| x z |
+-----+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[2]') |
+-----+
| |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
+-----+
| z |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-----+
| x |
+-----+
1 row in set (0.00 sec)

```

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `*/b` matches the `b` element in either of the XML fragments `<a><b/></a>` or `<c><b/></c>`. However, the expression does not produce a match in the fragment `<b><a/></b>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `*/b/*` will match any child of a `b` element that is itself not the root element.
- You can match any of several locators using the `|` (UNION) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/></a>`. To match against *any* element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical `or` operator for this purpose: `//b[@c="23" or @c="17"]`.

#### Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

**XPath Limitations.** The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- All of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
->   '<a><b c="1">X</b><b c="2">Y</b></a>',
->   'a/b'
-> ) AS result;
+-----+
| result |
+-----+
| X Y    |
+-----+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[@c="1"]/d`:

```
mysql> SELECT ExtractValue(
->   '<a>
->     <b c="1"><d>X</d></b>
->     <b c="2"><d>X</d></b>
->   </a>',
->   'a/b/d[../@c="1"]'
-> ) AS result;
+-----+
| result |
+-----+
| X      |
+-----+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:
  - `axis::comment()`
  - `axis::text()`
  - `axis::processing-instructions()`
  - `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b') |
+-----+
| x                                             |
+-----+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*');
```

```

+-----+
| ExtractValue(' <a><b>x</b><c>y</c></a>', '/a/child:*') |
+-----+
| x y |
+-----+
1 row in set (0.01 sec)

```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).
- The following XPath functions are not supported, or have known issues as indicated:
  - `id()`
  - `lang()`
  - `local-name()`
  - `name()`
  - `namespace-uri()`
  - `normalize-space()`
  - `starts-with()`
  - `string()`
  - `substring-after()`
  - `substring-before()`
  - `translate()`
- The following axes are not supported:
  - `following-sibling`
  - `following`
  - `preceding-sibling`
  - `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```

mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+

```

```
| <a>111<g:h>555</g:h></a> |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

**Error handling.** For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '//*[@a]');
ERROR 1105 (HY000): XPATH syntax error: '//*[@a]'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//*[@a]');
+-----+
| ExtractValue('<a>c</a><b', '//*[@a]') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//*[@a]');
+-----+
| ExtractValue('<a>c</a><b/>', '//*[@a]') |
+-----+
| c |
+-----+
1 row in set (0.00 sec)
```

### Important

The replacement XML used as the third argument to `UpdateXML()` is *not* checked to determine whether it consists solely of elements which are properly nested and closed.

**XPath Injection.** *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='lc3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='lc3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```
<?php

$file      =   "users.xml";

$login     =   $_POST["login"];
$password  =   $_POST["password"];

$xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

if( file_exists($file) )
{
    $xml = simplexml_load_file($file);

    if($result = $xml->xpath($xpath))
        echo "You are now logged in as user $result[0].";
    else
        echo "Invalid login name or password.";
}
else
    exit("Failed to open $file.");

?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()=' ' or 1=1 and password/text()=' ' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "//user[login/text()='$_login' and password/text()='$_password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper [Blind XPath Injection](#) (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```
mysql> SELECT ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()=' ' or 1=1 and password/text()=' ' or 1=1]/attribute::id'
-> ) AS id;
```

```

+-----+
| id      |
+-----+
| 00327 13579 02403 42354 28570 |
+-----+
1 row in set (0.01 sec)

```

Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```

mysql> SELECT @id = ExtractValue(
->   LOAD_FILE('users.xml'),
->   '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
->   INSTR(@id, ' ') = 0,
->   @id,
->   'Unable to retrieve user ID')
-> AS singleID;
+-----+
| singleID |
+-----+
| Unable to retrieve user ID |
+-----+
1 row in set (0.00 sec)

```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

## 13.12 Bit Functions and Operators

**Table 13.16 Bit Functions and Operators**

| Name                     | Description                            |
|--------------------------|--|
| <code>BIT_COUNT()</code> | Return the number of bits that are set |
| <code>&amp;</code>       | Bitwise AND                            |
| <code>~</code>           | Bitwise inversion                      |
| <code> </code>           | Bitwise OR                             |
| <code>^</code>           | Bitwise XOR                            |
| <code>&lt;&lt;</code>    | Left shift                             |
| <code>&gt;&gt;</code>    | Right shift                            |

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` functions are aggregate functions described at [Section 13.19.1, “Aggregate \(GROUP BY\) Function Descriptions”](#).) Currently, bit functions and operators require `BIGINT` (64-bit integer) arguments and return `BIGINT` values, so they have a maximum range of 64 bits. Arguments of other types are converted to `BIGINT` and truncation might occur.

An extension for MySQL 8.0 changes this cast-to-`BIGINT` behavior: Bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types), enabling them to take arguments and produce return values larger than 64 bits. Consequently, bit operations on binary arguments in MySQL 5.7 might produce different results in MySQL 8.0. To provide advance notice about this potential change in behavior, the server produces warnings as of MySQL 5.7.11 for bit

operations for which binary arguments are not converted to integer in MySQL 8.0. These warnings afford an opportunity to rewrite affected statements. To explicitly produce MySQL 5.7 behavior in a way that will not change after an upgrade to 8.0, cast bit-operation binary arguments to convert them to integer.

The five problematic expression types to watch out for are:

```
nonliteral_binary { & | ^ } binary
binary { & | ^ } nonliteral_binary
nonliteral_binary { << >> } anything
~ nonliteral_binary
AGGR_BIT_FUNC(nonliteral_binary)
```

Those expressions return `BIGINT` in MySQL 5.7, binary string in 8.0.

Explanation of notation:

- `{ op1 op2 ... }`: List of operators that apply to the given expression type.
- `binary`: Any kind of binary string argument, including a hexadecimal literal, bit literal, or `NULL` literal.
- `nonliteral_binary`: An argument that is a binary string value other than a hexadecimal literal, bit literal, or `NULL` literal.
- `AGGR_BIT_FUNC`: An aggregate function that takes bit-value arguments: `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`.

The server produces a single warning for each problematic expression in a statement, not a warning for each row processed. Suppose that a statement containing two problematic expressions selects three rows from a table. The number of warnings per statement execution is two, not six. The following example illustrates this.

```
mysql> CREATE TABLE t(vbin1 VARBINARY(32), vbin2 VARBINARY(32));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (3,1), (3,2), (3,3);
Query OK, 3 rows affected (0.01 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT HEX(vbin1 & vbin2) AS op1,
-> HEX(vbin1 | vbin2) AS op2
-> FROM t;
+-----+-----+
| op1  | op2  |
+-----+-----+
| 1    | 3    |
| 2    | 3    |
| 3    | 3    |
+-----+-----+
3 rows in set, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: Bitwise operations on BINARY will change behavior in a future
version, check the 'Bit functions' section in the manual.
***** 2. row *****
Level: Warning
Code: 1287
Message: Bitwise operations on BINARY will change behavior in a future
version, check the 'Bit functions' section in the manual.
2 rows in set (0.00 sec)
```

To avoid having an affected statement produce a different result after an upgrade to MySQL 8.0, rewrite it so that it generates no bit-operation warnings. To do this, cast at least one binary argument

to `BIGINT` with `CAST(... AS UNSIGNED)`. This makes the MySQL 5.7 implicit binary-to-integer cast explicit:

```
mysql> SELECT HEX(CAST(vbin1 AS UNSIGNED) & CAST(vbin2 AS UNSIGNED)) AS op1,
-> HEX(CAST(vbin1 AS UNSIGNED) | CAST(vbin2 AS UNSIGNED)) AS op2
-> FROM t;
+-----+-----+
| op1   | op2   |
+-----+-----+
| 1     | 3     |
| 2     | 3     |
| 3     | 3     |
+-----+-----+
3 rows in set (0.01 sec)

mysql> SHOW WARNINGS\G
Empty set (0.00 sec)
```

With the statement rewritten as shown, MySQL 8.0 respects the intention to treat the binary arguments as integers and produces the same result as in 5.7. Also, replicating the statement from MySQL 5.7 to 8.0 does not produce different results on different servers.

An affected statement that cannot be rewritten is subject to these potential problems with respect to upgrades and replication:

- The statement might return a different result after an upgrade to MySQL 8.0.
- Replication to MySQL 8.0 from older versions might fail for statement-based and mixed-format binary logging. This is also true for replaying older binary logs on an 8.0 server (for example, using `mysqlbinlog`). To avoid this, switch to row-based binary logging on the older master server.

The following list describes available bit functions and operators:

- `|`

Bitwise OR.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 29 | 15;
-> 31
```

- `&`

Bitwise AND.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 29 & 15;
-> 13
```

- `^`

Bitwise XOR.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
```

- <<

Shifts a longlong (**BIGINT**) number to the left.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```
mysql> SELECT 1 << 2;
-> 4
```

- >>

Shifts a longlong (**BIGINT**) number to the right.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```
mysql> SELECT 4 >> 2;
-> 1
```

- ~

Invert all bits.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 5 & ~1;
-> 4
```

- **BIT\_COUNT(N)**

Returns the number of bits that are set in the argument *N* as an unsigned 64-bit integer, or **NULL** if the argument is **NULL**.

```
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
-> 4, 3
```

## 13.13 Encryption and Compression Functions

**Table 13.17 Encryption Functions**

| Name                             | Description                                      |
|----------------------------------|--|
| <b>AES_DECRYPT()</b>             | Decrypt using AES                                |
| <b>AES_ENCRYPT()</b>             | Encrypt using AES                                |
| <b>ASYMMETRIC_DECRYPT()</b>      | Decrypt ciphertext using private or public key   |
| <b>ASYMMETRIC_DERIVE()</b>       | Derive symmetric key from asymmetric keys        |
| <b>ASYMMETRIC_ENCRYPT()</b>      | Encrypt cleartext using private or public key    |
| <b>ASYMMETRIC_SIGN()</b>         | Generate signature from digest                   |
| <b>ASYMMETRIC_VERIFY()</b>       | Verify that signature matches digest             |
| <b>COMPRESS()</b>                | Return result as a binary string                 |
| <b>CREATEASYMMETRICPRIVKEY()</b> | Create private key                               |
| <b>CREATEASYMMETRICPUBKEY()</b>  | Create public key                                |
| <b>CREATE_DH_PARAMETERS()</b>    | Generate shared DH secret                        |
| <b>CREATE_DIGEST()</b>           | Generate digest from string                      |
| <b>DECODE()</b>                  | Decodes a string encrypted using <b>ENCODE()</b> |

| Name   | Description  |
|--|--|
| <a href="#">DES_DECRYPT()</a> (deprecated 5.7.6) | Decrypt a string   |
| <a href="#">DES_ENCRYPT()</a> (deprecated 5.7.6) | Encrypt a string   |
| <a href="#">ENCODE()</a>                         | Encode a string  |
| <a href="#">ENCRYPT()</a> (deprecated 5.7.6)     | Encrypt a string   |
| <a href="#">MD5()</a>                            | Calculate MD5 checksum                                     |
| <a href="#">OLD_PASSWORD()</a>                   | Return the value of the pre-4.1 implementation of PASSWORD |
| <a href="#">PASSWORD()</a> (deprecated 5.7.6)    | Calculate and return a password string                     |
| <a href="#">RANDOM_BYTES()</a>                   | Return a random byte vector                                |
| <a href="#">SHA1()</a> , <a href="#">SHA()</a>   | Calculate an SHA-1 160-bit checksum                        |
| <a href="#">SHA2()</a>                           | Calculate an SHA-2 checksum                                |
| <a href="#">UNCOMPRESS()</a>                     | Uncompress a string compressed                             |
| <a href="#">UNCOMPRESSED_LENGTH()</a>            | Return the length of a string before compression           |
| <a href="#">VALIDATE_PASSWORD_STRENGTH()</a>     | Determine strength of password                             |

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a [VARBINARY](#) or [BLOB](#) binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type ([CHAR](#), [VARCHAR](#), [TEXT](#)).

Some encryption functions return strings of ASCII characters: [MD5\(\)](#), [OLD\\_PASSWORD\(\)](#), [PASSWORD\(\)](#), [SHA\(\)](#), [SHA1\(\)](#), [SHA2\(\)](#). In MySQL 5.7, their return value is a nonbinary string that has a character set and collation determined by the [character\\_set\\_connection](#) and [collation\\_connection](#) system variables.

For versions in which functions such as [MD5\(\)](#) or [SHA1\(\)](#) return a string of hexadecimal digits as a binary string, the return value cannot be converted to uppercase or compared in case-insensitive fashion as is. You must convert the value to a nonbinary string. See the discussion of binary string conversion in [Section 13.10, “Cast Functions and Operators”](#).

If an application stores values from a function such as [MD5\(\)](#) or [SHA1\(\)](#) that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using [UNHEX\(\)](#) and storing the result in a [BINARY\(N\)](#) column. Each pair of hexadecimal digits requires one byte in binary form, so the value of *N* depends on the length of the hex string. *N* is 16 for an [MD5\(\)](#) value and 20 for a [SHA1\(\)](#) value. For [SHA2\(\)](#), *N* ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a [CHAR](#) column is at least two times, up to eight times if the value is stored in a column that uses the [utf8](#) character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores [MD5\(\)](#) string values in a [CHAR\(32\)](#) column:

```
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use [UNHEX\(\)](#) and [BINARY\(16\)](#) instead as follows:

```
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

#### Note

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using one of the other encryption functions described in this section instead, such as `SHA2()`.

#### Caution

Passwords or other sensitive values supplied as arguments to encryption functions are sent in cleartext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- `AES_DECRYPT(crypt_str,key_str[,init_vector])`

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of `AES_ENCRYPT()`.

The optional initialization vector argument, *init\_vector*, is available as of MySQL 5.7.4. As of that version, statements that use `AES_DECRYPT()` are unsafe for statement-based replication and cannot be stored in the query cache.

- `AES_ENCRYPT(str,key_str[,init_vector])`

`AES_ENCRYPT()` and `AES_DECRYPT()` implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. As of MySQL 5.7.4, key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

`AES_ENCRYPT()` encrypts the string *str* using the key string *key\_str* and returns a binary string containing the encrypted output. `AES_DECRYPT()` decrypts the encrypted string *crypt\_str* using the key string *key\_str* and returns the original cleartext string. If either function argument is `NULL`, the function returns `NULL`.

The *str* and *crypt\_str* arguments can be any length, and padding is automatically added to *str* so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the `AES_DECRYPT()` function. The length of *crypt\_str* can be calculated using this formula:

```
16 * (trunc(string_length / 16) + 1)
```

For a key length of 128 bits, the most secure way to pass a key to the *key\_str* argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));
```

Do not pass a password or passphrase directly to `crypt_str`, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

As of MySQL 5.7.4, `AES_ENCRYPT()` and `AES_DECRYPT()` permit control of the block encryption mode and take an optional `init_vector` initialization vector argument:

- The `block_encryption_mode` system variable controls the mode for block-based encryption algorithms. Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see [Section 6.1.5, “Server System Variables”](#).
- The optional `init_vector` argument provides an initialization vector for block encryption modes that require it.

For modes that require the optional `init_vector` argument, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing.

For modes that do not require `init_vector`, it is ignored and a warning is generated if it is specified.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`. For encryption modes that require an initialization vector, the same vector must be used for encryption and decryption.

```
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT AES_DECRYPT(@crypt_str,@key_str,@init_vector);
+-----+
| AES_DECRYPT(@crypt_str,@key_str,@init_vector) |
+-----+
| text                                         |
+-----+
```

The following table lists each permitted block encryption mode, the SSL libraries that support it, and whether the initialization vector argument is required.

| Block Encryption Mode | SSL Libraries that Support Mode | Initialization Vector Required |
|-----------------------|---------------------------------|--------------------------------|
| ECB                   | OpenSSL, yaSSL                  | No                             |
| CBC                   | OpenSSL, yaSSL                  | Yes                            |
| CFB1                  | OpenSSL                         | Yes                            |
| CFB8                  | OpenSSL                         | Yes                            |
| CFB128                | OpenSSL                         | Yes                            |
| OFB                   | OpenSSL                         | Yes                            |

As of MySQL 5.7.4, statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication and cannot be stored in the query cache.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
      -> 21
mysql> SELECT LENGTH(COMPRESS(''));
      -> 0
mysql> SELECT LENGTH(COMPRESS('a'));
      -> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
      -> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra `.` character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)
- `DECODE(crypt_str,pass_str)`

`DECODE()` decrypts the encrypted string *crypt\_str* using *pass\_str* as the password. *crypt\_str* should be a string returned from `ENCODE()`.

#### Note

The `ENCODE()` and `DECODE()` functions are deprecated in MySQL 5.7, will be removed in a future MySQL release, and should no longer be used. Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- `DES_DECRYPT(crypt_str[,key_str])`

Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns `NULL`.

This function works only if MySQL has been configured with SSL support. See [Section 7.4, “Using Secure Connections”](#).

If no *key\_str* argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the `SUPER` privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a *key\_str* argument, that string is used as the key for decrypting the message.

If the *crypt\_str* argument does not appear to be an encrypted string, MySQL returns the given *crypt\_str*.

#### Note

The `DES_ENCRYPT()` and `DES_DECRYPT()` functions are deprecated as of MySQL 5.7.6, will be removed in a future MySQL release, and should no longer be used. Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- `DES_ENCRYPT(str[,{key_num|key_str}])`

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MySQL has been configured with SSL support. See [Section 7.4, “Using Secure Connections”](#).

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given. With no argument, the first key from the DES key file is used. With a `key_num` argument, the given key number (0 to 9) from the DES key file is used. With a `key_str` argument, the given key string is used to encrypt `str`.

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, `key_num` is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each `key_num` value must be a number in the range from 0 to 9. Lines in the file may be in any order. `des_key_str` is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

#### Note

The `DES_ENCRYPT()` and `DES_DECRYPT()` functions are deprecated as of MySQL 5.7.6, will be removed in a future MySQL release, and should no longer be used. Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

```
mysql> SELECT customer_address FROM customer_table
> WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

- `ENCODE(str, pass_str)`

`ENCODE()` encrypts `str` using `pass_str` as the password. The result is a binary string of the same length as `str`. To decrypt the result, use `DECODE()`.

#### Note

The `ENCODE()` and `DECODE()` functions are deprecated in MySQL 5.7, will be removed in a future MySQL release, and should no longer be used.

If you still need to use `ENCODE()`, a salt value must be used with it to reduce risk. For example:

```
ENCODE('cleartext', CONCAT('my_random_salt','my_secret_password'))
```

A new random salt value must be used whenever a password is updated.

- `ENCRYPT(str[,salt])`

Encrypts *str* using the Unix `crypt()` system call and returns a binary string. The *salt* argument must be a string with at least two characters or the result will be `NULL`. If no *salt* argument is given, a random value is used.

#### Note

The `ENCRYPT()` function is deprecated as of MySQL 5.7.6, will be removed in a future MySQL release, and should no longer be used. Consider using `AES_ENCRYPT()` instead.

```
mysql> SELECT ENCRYPT('hello');
-> 'VxuFAJXVAROc'
```

`ENCRYPT()` ignores all but the first eight characters of *str*, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

The use of `ENCRYPT()` with the `ucs2`, `utf16`, `utf16le`, or `utf32` multibyte character sets is not recommended because the system call expects a string terminated by a zero byte.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` always returns `NULL`.

- `MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a nonbinary string in the connection character set.

```
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

- `OLD_PASSWORD(str)`

`OLD_PASSWORD()` was added when the implementation of `PASSWORD()` was changed in MySQL 4.1 to improve security. `OLD_PASSWORD()` returns the value of the pre-4.1 implementation of `PASSWORD()` as a string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your version MySQL 5.7 server without locking them out. See [Section 7.1.2.4, “Password Hashing in MySQL”](#).

The return value is a nonbinary string in the connection character set.

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed

in MySQL 5.7.5. Consequently, `OLD_PASSWORD( )` is deprecated and is removed in MySQL 5.7.5.

- `PASSWORD(str)`

#### Note

This function is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release.

Returns a hashed password string calculated from the cleartext password `str`. The return value is a nonbinary string in the connection character set, or `NULL` if the argument is `NULL`. This function is the SQL interface to the algorithm used by the server to encrypt MySQL passwords for storage in the `mysql.user` grant table.

The `old_passwords` system variable controls the password hashing method used by the `PASSWORD( )` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

| Value | Password Hashing Method  | Associated Authentication Plugin   |
|-------|--------------------------|------------------------------------|
| 0     | MySQL 4.1 native hashing | <code>mysql_native_password</code> |
| 1     | Pre-4.1 ("old") hashing  | <code>mysql_old_password</code>    |
| 2     | SHA-256 hashing          | <code>sha256_password</code>       |

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed in MySQL 5.7.5. Consequently, `old_passwords=1`, which causes `PASSWORD( )` to generate pre-4.1 password hashes, is not permitted as of 5.7.5. For account upgrade instructions, see [Section 7.5.1.3, "Migrating Away from Pre-4.1 Password Hashing and the `mysql\_old\_password` Plugin"](#).

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

```
mysql> SET old_passwords = 0;
mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
+-----+-----+
| PASSWORD('mypass') | OLD_PASSWORD('mypass') |
+-----+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 | 6f8c114b58f2ce9e |
+-----+-----+

mysql> SET old_passwords = 1;
mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
+-----+-----+
| PASSWORD('mypass') | OLD_PASSWORD('mypass') |
+-----+-----+
| 6f8c114b58f2ce9e | 6f8c114b58f2ce9e |
+-----+-----+
```

SHA-256 password hashing (`old_passwords=2`) uses a random salt value, which makes the result from `PASSWORD( )` nondeterministic. Consequently, statements that use this function are not safe for statement-based replication and cannot be stored in the query cache.

Encryption performed by `PASSWORD()` is one-way (not reversible). It is not the same type of encryption used for Unix passwords; for that, use `ENCRYPT()`.

#### Note

`PASSWORD()` is used by the authentication system in MySQL Server; you should *not* use it in your own applications. For that purpose, consider `MD5()` or `SHA2()` instead. Also see [RFC 2195, section 2 \(Challenge-Response Authentication Mechanism \(CRAM\)\)](#), for more information about handling passwords and authentication securely in your applications.

#### Caution

Under some circumstances, statements that invoke `PASSWORD()` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 7.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 5.5.1.3, “mysql Logging”](#).

- `RANDOM_BYTES(len)`

This function returns a binary string of `len` random bytes generated using the random number generator of the SSL library (OpenSSL or yaSSL). Permitted values of `len` range from 1 to 1024. For values outside that range, `RANDOM_BYTES()` generates a warning and returns `NULL`.

`RANDOM_BYTES()` can be used to provide the initialization vector for the `AES_DECRYPT()` and `AES_ENCRYPT()` functions. For use in that context, `len` must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

`RANDOM_BYTES()` generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication and cannot be stored in the query cache.

This function is available as of MySQL 5.7.4.

- `SHA1(str)`, `SHA(str)`

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. You can also use `SHA1()` as a cryptographic function for storing passwords. `SHA()` is synonymous with `SHA1()`.

The return value is a nonbinary string in the connection character set.

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` can be considered a cryptographically more secure equivalent of `MD5()`. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `SHA2(str, hash_length)`

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the cleartext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is `NULL` or the hash length is not one of the permitted values, the return value is

**NULL**. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a nonbinary string in the connection character set.

```
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d8228642a477bda255b32aadfce4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See [Section 7.4, “Using Secure Connections”](#).

`SHA2()` can be considered cryptographically more secure than `MD5()` or `SHA1()`.

- `UNCOMPRESS(string_to_uncompress)`

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is **NULL**. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always **NULL**.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- `UNCOMPRESSED_LENGTH(compressed_string)`

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

- `VALIDATE_PASSWORD_STRENGTH(str)`

Given an argument representing a cleartext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` is done by the `validate_password` plugin. If that plugin is not installed, the function always returns 0. For information about installing the `validate_password` plugin, see [Section 7.5.3, “The Password Validation Plugin”](#). To examine or configure the parameters that affect password testing, check or set the system variables implemented by `validate_password` plugin. See [Section 7.5.3.2, “Password Validation Plugin Options and Variables”](#).

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the `validate_password_check_user_name` system variable is enabled and the password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

| Password Test  | Return Value |
|--|--------------|
| Length < 4   | 0            |
| Length ≥ 4 and < <code>validate_password_length</code> | 25           |
| Satisfies policy 1 ( <b>LOW</b> )                      | 50           |
| Satisfies policy 2 ( <b>MEDIUM</b> )                   | 75           |
| Satisfies policy 3 ( <b>STRONG</b> )                   | 100          |

**Table 13.18 Information Functions**

| Name  | Description   |
|---|---|
| <code>BENCHMARK()</code>                                | Repeatedly execute an expression  |
| <code>CHARSET()</code>                                  | Return the character set of the argument  |
| <code>COERCIBILITY()</code>                             | Return the collation coercibility value of the string argument  |
| <code>COLLATION()</code>                                | Return the collation of the string argument   |
| <code>CONNECTION_ID()</code>                            | Return the connection ID (thread ID) for the connection   |
| <code>CURRENT_USER()</code> , <code>CURRENT_USER</code> | The authenticated user name and host name   |
| <code>DATABASE()</code>                                 | Return the default (current) database name  |
| <code>FOUND_ROWS()</code>                               | For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause |
| <code>LAST_INSERT_ID()</code>                           | Value of the <code>AUTOINCREMENT</code> column for the last <code>INSERT</code>   |
| <code>ROW_COUNT()</code>                                | The number of rows updated  |
| <code>SCHEMA()</code>                                   | Synonym for <code>DATABASE()</code>   |
| <code>SESSION_USER()</code>                             | Synonym for <code>USER()</code>   |
| <code>SYSTEM_USER()</code>                              | Synonym for <code>USER()</code>   |
| <code>USER()</code>                                     | The user name and host name provided by the client  |
| <code>VERSION()</code>                                  | Return a string that indicates the MySQL server version   |

- `BENCHMARK(count,expr)`

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is always 0. The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000,ENCODE('hello','goodbye'));
+-----+
| BENCHMARK(1000000,ENCODE('hello','goodbye')) |
+-----+
| 0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.
- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
      -> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
      -> 'utf8'
mysql> SELECT CHARSET(USER());
      -> 'utf8'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
      -> 0
mysql> SELECT COERCIBILITY(USER());
      -> 3
mysql> SELECT COERCIBILITY('abc');
      -> 4
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

| Coercibility | Meaning            | Example   |
|--------------|--------------------|---|
| 0            | Explicit collation | Value with <code>COLLATE</code> clause                            |
| 1            | No collation       | Concatenation of strings with different collations                |
| 2            | Implicit collation | Column value, stored routine parameter or local variable          |
| 3            | System constant    | <code>USER()</code> return value                                  |
| 4            | Coercible          | Literal string  |
| 5            | Ignorable          | <code>NULL</code> or an expression derived from <code>NULL</code> |

- `COLLATION(str)`

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
      -> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
      -> 'utf8_general_ci'
```

- `CONNECTION_ID()`

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

```
mysql> SELECT CONNECTION_ID();
      -> 23786
```

- `CURRENT_USER, CURRENT_USER()`

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication in different releases of MySQL 5.7, see [Section 18.4.1.8, “Replication of `CURRENT\_USER\(\)`”](#).

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- `FOUND_ROWS()`

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include a `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.

- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

### Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Prior to MySQL 5.7.3, this function was not replicated correctly if replication filtering rules were in use. (Bug #17234370, Bug #69861)

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection* basis. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be

affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

### Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;
Database changed
mysql> CREATE TABLE t (
  ->   id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
  ->   name VARCHAR(10) NOT NULL
  -> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t VALUES (NULL, 'Bob');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
+----+-----+
1 row in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO t VALUES
  -> (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
|  2 | Mary |
|  3 | Jane |
|  4 | Lisa |
+----+-----+
4 rows in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                2 |
+-----+
1 row in set (0.00 sec)
```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to `1` or `2`, as demonstrated in the following example:

```
mysql> USE test;
Database changed

mysql> SELECT @@innodb_autoinc_lock_mode;
+-----+
| @@innodb_autoinc_lock_mode |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE `t` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `val` INT(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
Query OK, 0 rows affected (0.02 sec)

-- Insert two rows

mysql> INSERT INTO t (val) VALUES (1),(2);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

-- With auto_increment_offset=1, the inserted rows
-- result in an AUTO_INCREMENT value of 3

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=MyISAM AUTO_INCREMENT=3 DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

-- LAST_INSERT_ID() returns the first automatically generated
-- value that is successfully inserted for the AUTO_INCREMENT column

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

-- The attempted insertion of duplicate rows fail but errors are ignored

mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2 Duplicates: 2 Warnings: 0

-- With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
-- is incremented for the ignored rows
```

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=MyISAM AUTO_INCREMENT=5 DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

-- The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+
1 row in set (0.00 sec)
```

See [Section 15.8.6, “AUTO\\_INCREMENT Handling in InnoDB”](#) for more information.

If *expr* is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```
mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);
```

2. Use the table to generate sequence numbers like this:

```
mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();
```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [Section 26.8.7.38, “mysql\\_insert\\_id\(\)”](#).

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- `ROW_COUNT()`

`ROW_COUNT()` returns a value as follows:

- DDL statements: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- DML statements other than `SELECT`: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA INFILE`.

- **SELECT**: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1, ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name', ROW_COUNT()` returns the number of rows written to the file.
- **SIGNAL** statements: 0.

For **UPDATE** statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the **WHERE** clause.

For **REPLACE** statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For **INSERT ... ON DUPLICATE KEY UPDATE** statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          3 |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          2 |
+-----+
1 row in set (0.00 sec)
```

### Important

`ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- **SCHEMA()**

This function is a synonym for `DATABASE()`.

- **SESSION\_USER()**

`SESSION_USER()` is a synonym for `USER()`.

- **SYSTEM\_USER()**

`SYSTEM_USER()` is a synonym for `USER()`.

- **USER()**

Returns the current MySQL user name and host name as a string in the `utf8` character set.

```
mysql> SELECT USER();
-> 'davida@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`.

- `VERSION()`

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set. The value might have a suffix in addition to the version number. See the description of the `version` system variable in [Section 6.1.5, “Server System Variables”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT VERSION();
-> '5.7.18-standard'
```

## 13.15 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see [Section 12.5, “Extensions for Spatial Data”](#).

### 13.15.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

**Table 13.19 Spatial Functions**

| Name  | Description   |
|---|---|
| <code>Area()</code> (deprecated 5.7.6)                            | Return Polygon or MultiPolygon area                           |
| <code>AsBinary()</code> , <code>AsWKB()</code> (deprecated 5.7.6) | Convert from internal geometry format to WKB                  |
| <code>AsText()</code> , <code>AsWKT()</code> (deprecated 5.7.6)   | Convert from internal geometry format to WKT                  |
| <code>Buffer()</code> (deprecated 5.7.6)                          | Return geometry of points within given distance from geometry |
| <code>Centroid()</code> (deprecated 5.7.6)                        | Return centroid as a point                                    |
| <code>Contains()</code> (deprecated 5.7.6)                        | Whether MBR of one geometry contains MBR of another           |
| <code>ConvexHull()</code> (deprecated 5.7.6)                      | Return convex hull of geometry                                |
| <code>Crosses()</code> (deprecated 5.7.6)                         | Whether one geometry crosses another                          |
| <code>Dimension()</code> (deprecated 5.7.6)                       | Dimension of geometry   |

| Name   | Description  |
|--|--|
| <code>Disjoint()</code> (deprecated 5.7.6)   | Whether MBRs of two geometries are disjoint          |
| <code>Distance()</code> (deprecated 5.7.6)   | The distance of one geometry from another            |
| <code>EndPoint()</code> (deprecated 5.7.6)   | End Point of LineString                              |
| <code>Envelope()</code> (deprecated 5.7.6)   | Return MBR of geometry                               |
| <code>Equals()</code> (deprecated 5.7.6)   | Whether MBRs of two geometries are equal             |
| <code>ExteriorRing()</code> (deprecated 5.7.6)   | Return exterior ring of Polygon                      |
| <code>GeomCollFromText()</code> ,<br><code>GeometryCollectionFromText()</code><br>(deprecated 5.7.6) | Return geometry collection from WKT                  |
| <code>GeomCollFromWKB()</code> ,<br><code>GeometryCollectionFromWKB()</code><br>(deprecated 5.7.6)   | Return geometry collection from WKB                  |
| <code>GeometryCollection()</code>  | Construct geometry collection from geometries        |
| <code>GeometryN()</code> (deprecated 5.7.6)  | Return N-th geometry from geometry collection        |
| <code>GeometryType()</code> (deprecated 5.7.6)   | Return name of geometry type                         |
| <code>GeomFromText()</code> ,<br><code>GeometryFromText()</code> (deprecated 5.7.6)                  | Return geometry from WKT                             |
| <code>GeomFromWKB()</code> ,<br><code>GeometryFromWKB()</code> (deprecated 5.7.6)                    | Return geometry from WKB                             |
| <code>GLength()</code> (deprecated 5.7.6)  | Return length of LineString                          |
| <code>InteriorRingN()</code> (deprecated 5.7.6)  | Return N-th interior ring of Polygon                 |
| <code>Intersects()</code> (deprecated 5.7.6)   | Whether MBRs of two geometries intersect             |
| <code>IsClosed()</code> (deprecated 5.7.6)   | Whether a geometry is closed and simple              |
| <code>IsEmpty()</code> (deprecated 5.7.6)  | Placeholder function                                 |
| <code>IsSimple()</code> (deprecated 5.7.6)   | Whether a geometry is simple                         |
| <code>LineFromText()</code> ,<br><code>LineStringFromText()</code> (deprecated 5.7.6)                | Construct LineString from WKT                        |
| <code>LineFromWKB()</code> ,<br><code>LineStringFromWKB()</code> (deprecated 5.7.6)                  | Construct LineString from WKB                        |
| <code>LineString()</code>  | Construct LineString from Point values               |
| <code>MBRContains()</code>   | Whether MBR of one geometry contains MBR of another  |
| <code>MBRCoveredBy()</code>  | Whether one MBR is covered by another                |
| <code>MBRCovers()</code>   | Whether one MBR covers another                       |
| <code>MBRDisjoint()</code>   | Whether MBRs of two geometries are disjoint          |
| <code>MBREqual()</code> (deprecated 5.7.6)   | Whether MBRs of two geometries are equal             |
| <code>MBREquals()</code>   | Whether MBRs of two geometries are equal             |
| <code>MBRIntersects()</code>   | Whether MBRs of two geometries intersect             |
| <code>MBROverlaps()</code>   | Whether MBRs of two geometries overlap               |
| <code>MBRTouches()</code>  | Whether MBRs of two geometries touch                 |
| <code>MBRWithin()</code>   | Whether MBR of one geometry is within MBR of another |

| Name   | Description   |
|--|---|
| <code>MLineFromText()</code> ,<br><code>MultiLineStringFromText()</code><br>(deprecated 5.7.6) | Construct MultiLineString from WKT                            |
| <code>MLineFromWKB()</code> ,<br><code>MultiLineStringFromWKB()</code><br>(deprecated 5.7.6)   | Construct MultiLineString from WKB                            |
| <code>MPointFromText()</code> ,<br><code>MultiPointFromText()</code> (deprecated 5.7.6)        | Construct MultiPoint from WKT                                 |
| <code>MPointFromWKB()</code> ,<br><code>MultiPointFromWKB()</code> (deprecated 5.7.6)          | Construct MultiPoint from WKB                                 |
| <code>MPolyFromText()</code> ,<br><code>MultiPolygonFromText()</code><br>(deprecated 5.7.6)    | Construct MultiPolygon from WKT                               |
| <code>MPolyFromWKB()</code> ,<br><code>MultiPolygonFromWKB()</code><br>(deprecated 5.7.6)      | Construct MultiPolygon from WKB                               |
| <code>MultiLineString()</code>   | Construct MultiLineString from LineString values              |
| <code>MultiPoint()</code>  | Construct MultiPoint from Point values                        |
| <code>MultiPolygon()</code>  | Construct MultiPolygon from Polygon values                    |
| <code>NumGeometries()</code> (deprecated 5.7.6)  | Return number of geometries in geometry collection            |
| <code>NumInteriorRings()</code> (deprecated 5.7.6)   | Return number of interior rings in Polygon                    |
| <code>NumPoints()</code> (deprecated 5.7.6)  | Return number of points in LineString                         |
| <code>Overlaps()</code> (deprecated 5.7.6)   | Whether MBRs of two geometries overlap                        |
| <code>Point()</code>   | Construct Point from coordinates                              |
| <code>PointFromText()</code> (deprecated 5.7.6)  | Construct Point from WKT                                      |
| <code>PointFromWKB()</code> (deprecated 5.7.6)   | Construct Point from WKB                                      |
| <code>PointN()</code> (deprecated 5.7.6)   | Return N-th point from LineString                             |
| <code>PolyFromText()</code> ,<br><code>PolygonFromText()</code> (deprecated 5.7.6)             | Construct Polygon from WKT                                    |
| <code>PolyFromWKB()</code> ,<br><code>PolygonFromWKB()</code> (deprecated 5.7.6)               | Construct Polygon from WKB                                    |
| <code>Polygon()</code>   | Construct Polygon from LineString arguments                   |
| <code>SRID()</code> (deprecated 5.7.6)   | Return spatial reference system ID for geometry               |
| <code>ST_Area()</code>   | Return Polygon or MultiPolygon area                           |
| <code>ST_AsBinary()</code> , <code>ST_AsWKB()</code>   | Convert from internal geometry format to WKB                  |
| <code>ST_AsGeoJSON()</code>  | Generate GeoJSON object from geometry                         |
| <code>ST_AsText()</code> , <code>ST_AsWKT()</code>   | Convert from internal geometry format to WKT                  |
| <code>ST_Buffer()</code>   | Return geometry of points within given distance from geometry |
| <code>ST_Buffer_Strategy()</code>  | Produce strategy option for <code>ST_Buffer()</code>          |
| <code>ST_Centroid()</code>   | Return centroid as a point                                    |

| Name  | Description                                      |
|---|--|
| <code>ST_Contains()</code>  | Whether one geometry contains another            |
| <code>ST_ConvexHull()</code>  | Return convex hull of geometry                   |
| <code>ST_Crosses()</code>   | Whether one geometry crosses another             |
| <code>ST_Difference()</code>  | Return point set difference of two geometries    |
| <code>ST_Dimension()</code>   | Dimension of geometry                            |
| <code>ST_Disjoint()</code>  | Whether one geometry is disjoint from another    |
| <code>ST_Distance()</code>  | The distance of one geometry from another        |
| <code>ST_Distance_Sphere()</code>   | Minimum distance on earth between two geometries |
| <code>ST_EndPoint()</code>  | End Point of LineString                          |
| <code>ST_Envelope()</code>  | Return MBR of geometry                           |
| <code>ST_Equals()</code>  | Whether one geometry is equal to another         |
| <code>ST_ExteriorRing()</code>  | Return exterior ring of Polygon                  |
| <code>ST_GeoHash()</code>   | Produce a geohash value                          |
| <code>ST_GeomCollFromText()</code> ,<br><code>ST_GeometryCollectionFromText()</code> ,<br><code>ST_GeomCollFromTxt()</code> | Return geometry collection from WKT              |
| <code>ST_GeomCollFromWKB()</code> ,<br><code>ST_GeometryCollectionFromWKB()</code>  | Return geometry collection from WKB              |
| <code>ST_GeometryN()</code>   | Return N-th geometry from geometry collection    |
| <code>ST_GeometryType()</code>  | Return name of geometry type                     |
| <code>ST_GeomFromGeoJSON()</code>   | Generate geometry from GeoJSON object            |
| <code>ST_GeomFromText()</code> ,<br><code>ST_GeometryFromText()</code>  | Return geometry from WKT                         |
| <code>ST_GeomFromWKB()</code> ,<br><code>ST_GeometryFromWKB()</code>  | Return geometry from WKB                         |
| <code>ST_InteriorRingN()</code>   | Return N-th interior ring of Polygon             |
| <code>ST_Intersection()</code>  | Return point set intersection of two geometries  |
| <code>ST_Intersects()</code>  | Whether one geometry intersects another          |
| <code>ST_IsClosed()</code>  | Whether a geometry is closed and simple          |
| <code>ST_IsEmpty()</code>   | Placeholder function                             |
| <code>ST_IsSimple()</code>  | Whether a geometry is simple                     |
| <code>ST_IsValid()</code>   | Whether a geometry is valid                      |
| <code>ST_LatFromGeoHash()</code>  | Return latitude from geohash value               |
| <code>ST_Length()</code>  | Return length of LineString                      |
| <code>ST_LineFromText()</code> ,<br><code>ST_LineStringFromText()</code>  | Construct LineString from WKT                    |
| <code>ST_LineFromWKB()</code> ,<br><code>ST_LineStringFromWKB()</code>  | Construct LineString from WKB                    |
| <code>ST_LongFromGeoHash()</code>   | Return longitude from geohash value              |
| <code>ST_MakeEnvelope()</code>  | Rectangle around two points                      |
| <code>ST_MLineFromText()</code> ,<br><code>ST_MultiLineStringFromText()</code>  | Construct MultiLineString from WKT               |

| Name   | Description   |
|--|---|
| <code>ST_MLineFromWKB()</code> ,<br><code>ST_MultiLineStringFromWKB()</code> | Construct MultiLineString from WKB                      |
| <code>ST_MPointFromText()</code> ,<br><code>ST_MultiPointFromText()</code>   | Construct MultiPoint from WKT                           |
| <code>ST_MPointFromWKB()</code> ,<br><code>ST_MultiPointFromWKB()</code>     | Construct MultiPoint from WKB                           |
| <code>ST_MPolyFromText()</code> ,<br><code>ST_MultiPolygonFromText()</code>  | Construct MultiPolygon from WKT                         |
| <code>ST_MPolyFromWKB()</code> ,<br><code>ST_MultiPolygonFromWKB()</code>    | Construct MultiPolygon from WKB                         |
| <code>ST_NumGeometries()</code>  | Return number of geometries in geometry collection      |
| <code>ST_NumInteriorRing()</code> ,<br><code>ST_NumInteriorRings()</code>    | Return number of interior rings in Polygon              |
| <code>ST_NumPoints()</code>  | Return number of points in LineString                   |
| <code>ST_Overlaps()</code>   | Whether one geometry overlaps another                   |
| <code>ST_PointFromGeoHash()</code>   | Convert geohash value to POINT value                    |
| <code>ST_PointFromText()</code>  | Construct Point from WKT                                |
| <code>ST_PointFromWKB()</code>   | Construct Point from WKB                                |
| <code>ST_PointN()</code>   | Return N-th point from LineString                       |
| <code>ST_PolyFromText()</code> ,<br><code>ST_PolygonFromText()</code>        | Construct Polygon from WKT                              |
| <code>ST_PolyFromWKB()</code> ,<br><code>ST_PolygonFromWKB()</code>          | Construct Polygon from WKB                              |
| <code>ST_Simplify()</code>   | Return simplified geometry                              |
| <code>ST_SRID()</code>   | Return spatial reference system ID for geometry         |
| <code>ST_StartPoint()</code>   | Start Point of LineString                               |
| <code>ST_SymDifference()</code>  | Return point set symmetric difference of two geometries |
| <code>ST_Touches()</code>  | Whether one geometry touches another                    |
| <code>ST_Union()</code>  | Return point set union of two geometries                |
| <code>ST_Validate()</code>   | Return validated geometry                               |
| <code>ST_Within()</code>   | Whether one geometry is within another                  |
| <code>ST_X()</code>  | Return X coordinate of Point                            |
| <code>ST_Y()</code>  | Return Y coordinate of Point                            |
| <code>StartPoint()</code> (deprecated 5.7.6)                                 | Start Point of LineString                               |
| <code>Touches()</code> (deprecated 5.7.6)                                    | Whether one geometry touches another                    |
| <code>Within()</code> (deprecated 5.7.6)                                     | Whether MBR of one geometry is within MBR of another    |
| <code>X()</code> (deprecated 5.7.6)  | Return X coordinate of Point                            |
| <code>Y()</code> (deprecated 5.7.6)  | Return Y coordinate of Point                            |

### 13.15.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described at [Section 12.5.2.2, “Geometry Class”](#). The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional argument-handling characteristics, as discussed in the sections where those function descriptions occur.

Spatial functions are defined only for valid geometry values. If an invalid geometry is passed to a spatial function, the result is undefined.

The spatial reference identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is  $2^{32}-1$ . If a larger value is given, only the lower 32 bits are used.

In MySQL, all computations are done assuming SRID 0, regardless of the actual SRID value. SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. In the future, computations may use the specified SRID values. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.

As of MySQL 5.7.5, spatial functions that take multiple geometry arguments require those arguments to have the same SRID value (that is, same value in the lower 32 bits). Assuming equal SRIDs, spatial functions do nothing with them after performing the equality check; geometry values are implicitly handled using Cartesian coordinates (SRID 0). If a spatial function returns [ER\\_GIS\\_DIFFERENT\\_SRIDS](#), it means that the geometry arguments did not all have the same SRID. You must modify them to have the same SRID.

As of MySQL 5.7.5, spatial functions return an [ER\\_GIS\\_INVALID\\_DATA](#) error if passed an invalid geometry argument.

In MySQL 5.7.5 to 5.7.8, if an input polygon has an open ring, the ring is stored as a closed ring by adding its first point to the point sequence. However, the Open Geospatial Consortium guidelines require that input polygons already be closed, so as of MySQL 5.7.9, unclosed polygons are rejected as invalid rather than being closed (just as before 5.7.5).

As of MySQL 5.7.5, empty geometry-collection handling is improved. An empty WKT input geometry collection may be specified as `'GEOMETRYCOLLECTION()'`. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection. Before 5.7.5, empty geometry collections are returned as [NULL](#).

As of MySQL 5.7.5, during parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

### 13.15.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

[ST\\_GeomFromText\(\)](#) accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKT format, see [Well-Known Text \(WKT\) Format](#).

- [GeomCollFromText\(wkt\[,srid\]\)](#), [GeometryCollectionFromText\(wkt\[,srid\]\)](#)

[ST\\_GeomCollFromText\(\)](#), [ST\\_GeometryCollectionFromText\(\)](#), [ST\\_GeomCollFromTtxt\(\)](#), [GeomCollFromText\(\)](#), and [GeometryCollectionFromText\(\)](#) are synonyms. For more information, see the description of [ST\\_GeomCollFromText\(\)](#).

[GeomCollFromText\(\)](#) and [GeometryCollectionFromText\(\)](#) are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use [ST\\_GeomCollFromText\(\)](#) and [ST\\_GeometryCollectionFromText\(\)](#) instead.

- `GeomFromText(wkt[,srid]), GeometryFromText(wkt[,srid])`

`ST_GeomFromText()`, `ST_GeometryFromText()`, `GeomFromText()`, and `GeometryFromText()` are synonyms. For more information, see the description of `ST_GeomFromText()`.

`GeomFromText()` and `GeometryFromText()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_GeomFromText()` and `ST_GeometryFromText()` instead.

- `LineFromText(wkt[,srid]), LineStringFromText(wkt[,srid])`

`ST_LineFromText()`, `ST_LineStringFromText()`, `LineFromText()`, and `LineStringFromText()` are synonyms. For more information, see the description of `ST_LineFromText()`.

`LineFromText()` and `LineStringFromText()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_LineFromText()` and `ST_LineStringFromText()` instead.

- `MLineFromText(wkt[,srid]), MultiLineStringFromText(wkt[,srid])`

`ST_MLineFromText()`, `ST_MultiLineStringFromText()`, `MLineFromText()`, and `MultiLineStringFromText()` are synonyms. For more information, see the description of `ST_MLineFromText()`.

`MLineFromText()` and `MultiLineStringFromText()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_MLineFromText()` and `ST_MultiLineStringFromText()` instead.

- `MPointFromText(wkt[,srid]), MultiPointFromText(wkt[,srid])`

`ST_MPointFromText()`, `ST_MultiPointFromText()`, `MPointFromText()`, and `MultiPointFromText()` are synonyms. For more information, see the description of `ST_MPointFromText()`.

`MPointFromText()` and `MultiPointFromText()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_MPointFromText()` and `ST_MultiPointFromText()` instead.

- `MPolyFromText(wkt[,srid]), MultiPolygonFromText(wkt[,srid])`

`ST_MPolyFromText()`, `ST_MultiPolygonFromText()`, `MPolyFromText()`, and `MultiPolygonFromText()` are synonyms. For more information, see the description of `ST_MPolyFromText()`.

`MPolyFromText()` and `MultiPolygonFromText()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_MPolyFromText()` and `ST_MultiPolygonFromText()` instead.

- `PointFromText(wkt[,srid])`

`ST_PointFromText()` and `PointFromText()` are synonyms. For more information, see the description of `ST_PointFromText()`.

`PointFromText()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_PointFromText()` instead.

- `PolyFromText(wkt[,srid]), PolygonFromText(wkt[,srid])`

`ST_PolyFromText()`, `ST_PolygonFromText()`, `PolyFromText()`, and `PolygonFromText()` are synonyms. For more information, see the description of `ST_PolyFromText()`.

`PolyFromText()` and `PolygonFromText()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_PolyFromText()` and `ST_PolygonFromText()` instead.

- `ST_GeomCollFromText(wkt[,srid])`, `ST_GeometryCollectionFromText(wkt[,srid])`, `ST_GeomCollFromTxt(wkt[,srid])`

Constructs a `GeometryCollection` value using its WKT representation and SRID.

```
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10));"
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+-----+
| ST_AsText(ST_GeomCollFromText(@g)) |
+-----+
| MULTILINESTRING((10 10,11 11),(9 9,10 10)) |
+-----+
```

`ST_GeomCollFromText()`, `ST_GeometryCollectionFromText()`, `ST_GeomCollFromTxt()`, `GeomCollFromText()`, and `GeometryCollectionFromText()` are synonyms. `ST_GeomCollFromTxt()` was added in MySQL 5.7.6.

- `ST_GeomFromText(wkt[,srid])`, `ST_GeometryFromText(wkt[,srid])`

Constructs a geometry value of any type using its WKT representation and SRID.

`ST_GeomFromText()`, `ST_GeometryFromText()`, `GeomFromText()`, and `GeometryFromText()` are synonyms.

- `ST_LineFromText(wkt[,srid])`, `ST_LineStringFromText(wkt[,srid])`

Constructs a `LineString` value using its WKT representation and SRID.

`ST_LineFromText()`, `ST_LineStringFromText()`, `LineFromText()`, and `LineStringFromText()` are synonyms.

- `ST_MLineFromText(wkt[,srid])`, `ST_MultiLineStringFromText(wkt[,srid])`

Constructs a `MultiLineString` value using its WKT representation and SRID.

`ST_MLineFromText()`, `ST_MultiLineStringFromText()`, `MLineFromText()`, and `MultiLineStringFromText()` are synonyms.

`ST_MLineFromText()` and `ST_MultiLineStringFromText()` were added in MySQL 5.7.6.

- `ST_MPointFromText(wkt[,srid])`, `ST_MultiPointFromText(wkt[,srid])`

Constructs a `MultiPoint` value using its WKT representation and SRID.

As of MySQL 5.7.9, spatial functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid, whereas before MySQL 5.7.9 the second one produces an error:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

`ST_MPointFromText()`, `ST_MultiPointFromText()`, `MPointFromText()`, and `MultiPointFromText()` are synonyms.

`ST_MPointFromText()` and `ST_MultiPointFromText()` were added in MySQL 5.7.6.

- `ST_MPolyFromText(wkt[,srid])`, `ST_MultiPolygonFromText(wkt[,srid])`

Constructs a `MultiPolygon` value using its WKT representation and SRID.

`ST_MPolyFromText()`, `ST_MultiPolygonFromText()`, `MPolyFromText()`, and `MultiPolygonFromText()` are synonyms.

`ST_MPolyFromText()` and `ST_MultiPolygonFromText()` were added in MySQL 5.7.6.

- `ST_PointFromText(wkt[,srid])`

Constructs a `Point` value using its WKT representation and SRID.

`ST_PointFromText()` and `PointFromText()` are synonyms.

- `ST_PolyFromText(wkt[,srid])`, `ST_PolygonFromText(wkt[,srid])`

Constructs a `Polygon` value using its WKT representation and SRID.

`ST_PolyFromText()`, `ST_PolygonFromText()`, `PolyFromText()`, and `PolygonFromText()` are synonyms.

### 13.15.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a `BLOB` containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

These functions also accept geometry objects for compatibility with the return value of the functions in [Section 13.15.5, “MySQL-Specific Functions That Create Geometry Values”](#). Thus, those functions may be used to provide the first argument to the functions in this section.

`ST_GeomFromWKB()` accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

- `GeomCollFromWKB(wkb[,srid])`, `GeometryCollectionFromWKB(wkb[,srid])`

`ST_GeomCollFromWKB()`, `ST_GeometryCollectionFromWKB()`, `GeomCollFromWKB()`, and `GeometryCollectionFromWKB()` are synonyms. For more information, see the description of `ST_GeomCollFromWKB()`.

`GeomCollFromWKB()` and `GeometryCollectionFromWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_GeomCollFromWKB()` and `ST_GeometryCollectionFromWKB()` instead.

- `GeomFromWKB(wkb[,srid])`, `GeometryFromWKB(wkb[,srid])`

`ST_GeomFromWKB()`, `ST_GeometryFromWKB()`, `GeomFromWKB()`, and `GeometryFromWKB()` are synonyms. For more information, see the description of `ST_GeomFromWKB()`.

`GeomFromWKB()` and `GeometryFromWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_GeomFromWKB()` and `ST_GeometryFromWKB()` instead.

- `LineFromWKB(wkb[,srid])`, `LineStringFromWKB(wkb[,srid])`

`ST_LineFromWKB()`, `ST_LineStringFromWKB()`, `LineFromWKB()`, and `LineStringFromWKB()` are synonyms. For more information, see the description of `ST_LineFromWKB()`.

`LineFromWKB()` and `LineStringFromWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_LineFromWKB()` and `ST_LineStringFromWKB()` instead.

- `MLineFromWKB(wkb[,srid]), MultiLineStringFromWKB(wkb[,srid])`

`ST_MLineFromWKB()`, `ST_MultiLineStringFromWKB()`, `MLineFromWKB()`, and `MultiLineStringFromWKB()` are synonyms. For more information, see the description of `ST_MLineFromWKB()`.

`MLineFromWKB()` and `MultiLineStringFromWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_MLineFromWKB()` and `ST_MultiLineStringFromWKB()` instead.

- `MPointFromWKB(wkb[,srid]), MultiPointFromWKB(wkb[,srid])`

`ST_MPointFromWKB()`, `ST_MultiPointFromWKB()`, `MPointFromWKB()`, and `MultiPointFromWKB()` are synonyms. For more information, see the description of `ST_MPointFromWKB()`.

`MPointFromWKB()` and `MultiPointFromWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_MPointFromWKB()` and `ST_MultiPointFromWKB()` instead.

- `MPolyFromWKB(wkb[,srid]), MultiPolygonFromWKB(wkb[,srid])`

`ST_MPolyFromWKB()`, `ST_MultiPolygonFromWKB()`, `MPolyFromWKB()`, and `MultiPolygonFromWKB()` are synonyms. For more information, see the description of `ST_MPolyFromWKB()`.

`MPolyFromWKB()` and `MultiPolygonFromWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_MPolyFromWKB()` and `ST_MultiPolygonFromWKB()` instead.

- `PointFromWKB(wkb[,srid])`

`ST_PointFromWKB()` and `PointFromWKB()` are synonyms. For more information, see the description of `ST_PointFromWKB()`.

`PointFromWKB()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_PointFromWKB()` instead.

- `PolyFromWKB(wkb[,srid]), PolygonFromWKB(wkb[,srid])`

`ST_PolyFromWKB()`, `ST_PolygonFromWKB()`, `PolyFromWKB()`, and `PolygonFromWKB()` are synonyms. For more information, see the description of `ST_PolyFromWKB()`.

`PolyFromWKB()` and `PolygonFromWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_PolyFromWKB()` and `ST_PolygonFromWKB()` instead.

- `ST_GeomCollFromWKB(wkb[,srid]), ST_GeometryCollectionFromWKB(wkb[,srid])`

Constructs a `GeometryCollection` value using its WKB representation and SRID.

`ST_GeomCollFromWKB()`, `ST_GeometryCollectionFromWKB()`, `GeomCollFromWKB()`, and `GeometryCollectionFromWKB()` are synonyms.

- `ST_GeomFromWKB(wkb[,srid]), ST_GeometryFromWKB(wkb[,srid])`

Constructs a geometry value of any type using its WKB representation and SRID.

`ST_GeomFromWKB()`, `ST_GeometryFromWKB()`, `GeomFromWKB()`, and `GeometryFromWKB()` are synonyms.

- `ST_LineFromWKB(wkb[,srid]), ST_LineStringFromWKB(wkb[,srid])`

Constructs a `LineString` value using its WKB representation and SRID.

`ST_LineFromWKB()`, `ST_LineStringFromWKB()`, `LineFromWKB()`, and `LineStringFromWKB()` are synonyms.

- `ST_MLineFromWKB(wkb[,srid])`, `ST_MultiLineStringFromWKB(wkb[,srid])`

Constructs a `MultiLineString` value using its WKB representation and SRID.

`ST_MLineFromWKB()`, `ST_MultiLineStringFromWKB()`, `MLineFromWKB()`, and `MultiLineStringFromWKB()` are synonyms.

`ST_MLineFromWKB()` and `ST_MultiLineStringFromWKB()` were added in MySQL 5.7.6.

- `ST_MPointFromWKB(wkb[,srid])`, `ST_MultiPointFromWKB(wkb[,srid])`

Constructs a `MultiPoint` value using its WKB representation and SRID.

`ST_MPointFromWKB()`, `ST_MultiPointFromWKB()`, `MPointFromWKB()`, and `MultiPointFromWKB()` are synonyms.

`ST_MPointFromWKB()` and `ST_MultiPointFromWKB()` were added in MySQL 5.7.6.

- `ST_MPolyFromWKB(wkb[,srid])`, `ST_MultiPolygonFromWKB(wkb[,srid])`

Constructs a `MultiPolygon` value using its WKB representation and SRID.

`ST_MPolyFromWKB()`, `ST_MultiPolygonFromWKB()`, `MPolyFromWKB()`, and `MultiPolygonFromWKB()` are synonyms.

`ST_MPolyFromWKB()` and `ST_MultiPolygonFromWKB()` were added in MySQL 5.7.6.

- `ST_PointFromWKB(wkb[,srid])`

Constructs a `Point` value using its WKB representation and SRID.

`ST_PointFromWKB()` and `PointFromWKB()` are synonyms.

- `ST_PolyFromWKB(wkb[,srid])`, `ST_PolygonFromWKB(wkb[,srid])`

Constructs a `Polygon` value using its WKB representation and SRID.

`ST_PolyFromWKB()`, `ST_PolygonFromWKB()`, `PolyFromWKB()`, and `PolygonFromWKB()` are synonyms.

## 13.15.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is `NULL`.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- `GeometryCollection(g1,g2,...)`

Constructs a `GeometryCollection`.

As of MySQL 5.7.5, `GeometryCollection()` returns all the proper geometries contained in the argument even if a nonsupported geometry is present. Before 5.7.5, if the argument contains a nonsupported geometry, the return value is `NULL`.

As of MySQL 5.7.8, `GeometryCollection()` with no arguments is permitted as a way to create an empty geometry.

- `LineString(pt1,pt2,...)`

Constructs a `LineString` value from a number of `Point` or WKB `Point` arguments. If the number of arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls1,ls2,...)`

Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- `MultiPoint(pt1,pt2,...)`

Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- `MultiPolygon(poly1,poly2,...)`

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- `Point(x,y)`

Constructs a `Point` using its coordinates.

- `Polygon(ls1,ls2,...)`

Constructs a `Polygon` value from a number of `LineString` or WKB `LineString` arguments. If any argument does not represent a `LinearRing` (that is, not a closed and simple `LineString`), the return value is `NULL`.

### 13.15.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See [Section 13.15.3, “Functions That Create Geometry Values from WKT Values”](#), and [Section 13.15.4, “Functions That Create Geometry Values from WKB Values”](#).

- `AsBinary(g)`, `AsWKB(g)`

`ST_AsBinary()`, `ST_AsWKB()`, `AsBinary()`, and `AsWKB()` are synonyms. For more information, see the description of `ST_AsBinary()`.

`AsBinary()` and `AsWKB()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_AsBinary()` and `ST_AsWKB()` instead.

- `AsText(g)`, `AsWKT(g)`

`ST_AsText()`, `ST_AsWKT()`, `AsText()`, and `AsWKT()` are synonyms. For more information, see the description of `ST_AsText()`.

`AsText()` and `AsWKT()` are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_AsText()` and `ST_AsWKT()` instead.

- `ST_AsBinary(g)`, `ST_AsWKB(g)`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

The result is `NULL` if the geometry argument is `NULL`. If the argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs as of MySQL 5.7.5. The result is `NULL` prior to MySQL 5.7.5.

```
SELECT ST_AsBinary(g) FROM geom;
```

`ST_AsBinary()`, `ST_AsWKB()`, `AsBinary()`, and `AsWKB()` are synonyms.

- `ST_AsText(g)`, `ST_AsWKT(g)`

Converts a value in internal geometry format to its WKT representation and returns the string result.

The result is `NULL` if the geometry argument is `NULL`. If the argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs as of MySQL 5.7.5. The result is `NULL` prior to MySQL 5.7.5.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@g));
+-----+
| ST_AsText(ST_GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3)         |
+-----+
```

`ST_AsText()`, `ST_AsWKT()`, `AsText()`, and `AsWKT()` are synonyms.

As of MySQL 5.7.9, output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----+
| ST_AsText(ST_GeomFromText(@mp)) |
+-----+
| MULTIPOINT((1 1),(2 2),(3 3))    |
+-----+
```

Before MySQL 5.7.9, output for the same value does not include parentheses around each point:

```
mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----+
| ST_AsText(ST_GeomFromText(@mp)) |
+-----+
| MULTIPOINT(1 1,2 2,3 3)          |
+-----+
```

## 13.15.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, the `ST_Area()` polygon function returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

### 13.15.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

`ST_Dimension()` and `Dimension()` are synonyms. For more information, see the description of `ST_Dimension()`.

`Dimension()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Dimension()` instead.

- `Envelope(g)`

`ST_Envelope()` and `Envelope()` are synonyms. For more information, see the description of `ST_Envelope()`.

`Envelope()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Envelope()` instead.

- `GeometryType(g)`

`ST_GeometryType()` and `GeometryType()` are synonyms. For more information, see the description of `ST_GeometryType()`.

`GeometryType()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_GeometryType()` instead.

- `IsEmpty(g)`

`ST_IsEmpty()` and `IsEmpty()` are synonyms. For more information, see the description of `ST_IsEmpty()`.

`IsEmpty()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_IsEmpty()` instead.

- `IsSimple(g)`

`ST_IsSimple()` and `IsSimple()` are synonyms. For more information, see the description of `ST_IsSimple()`.

`IsSimple()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_IsSimple()` instead.

- `SRID(g)`

`ST_SRID()` and `SRID()` are synonyms. For more information, see the description of `ST_SRID()`.

`SRID()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_SRID()` instead.

- `ST_Dimension(g)`

Returns the inherent dimension of the geometry value *g*, or `NULL` if the argument is `NULL`. The dimension can be -1, 0, 1, or 2. The meaning of these values is given in [Section 12.5.2.2, "Geometry Class"](#).

```
mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
+-----+
| ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

`ST_Dimension()` and `Dimension()` are synonyms.

- `ST_Envelope(g)`

Returns the minimum bounding rectangle (MBR) for the geometry value *g*, or `NULL` if the argument is `NULL`. The result is returned as a `Polygon` value that is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

As of MySQL 5.7.6, if the argument is a point or a vertical or horizontal line segment, `ST_Envelope()` returns the point or the line segment as its MBR rather than returning an invalid polygon:

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')) |
+-----+
| LINESTRING(1 1,1 2) |
+-----+
```

`ST_Envelope()` and `Envelope()` are synonyms.

- `ST_GeometryType(g)`

Returns a binary string indicating the name of the geometry type of which the geometry instance *g* is a member, or `NULL` if the argument is `NULL`. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
+-----+
| ST_GeometryType(ST_GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

`ST_GeometryType()` and `GeometryType()` are synonyms.

- `ST_IsEmpty(g)`

This function is a placeholder that returns 0 for any valid geometry value, 1 for any invalid geometry value, or `NULL` if the argument is `NULL`.

MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

`ST_IsEmpty()` and `IsEmpty()` are synonyms.

- `ST_IsSimple(g)`

Returns 1 if the geometry value *g* has no anomalous geometric points, such as self-intersection or self-tangency. `ST_IsSimple()` returns 0 if the argument is not simple, and `NULL` if the argument is `NULL`.

The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple. (See [Section 12.5.2.1, “The Geometry Class Hierarchy”](#).)

`ST_IsSimple()` and `IsSimple()` are synonyms.

- `ST_SRID(g)`

Returns an integer indicating the spatial reference system ID associated with the geometry value *g*, or `NULL` if the argument is `NULL`.

```
mysql> SELECT ST_SRID(ST_GeomFromText('LineString(1 1,2 2)',101));
+-----+
| ST_SRID(ST_GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
| 101 |
+-----+
```

`ST_SRID()` and `SRID()` are synonyms.

### 13.15.7.2 Point Property Functions

A `Point` consists of X and Y coordinates, which may be obtained using the following functions:

- `ST_X(p)`

Returns the X-coordinate value for the `Point` object *p* as a double-precision number.

```
mysql> SELECT ST_X(POINT(56.7, 53.34));
+-----+
| ST_X(POINT(56.7, 53.34)) |
+-----+
| 56.7 |
+-----+
```

`ST_X()` and `X()` are synonyms.

- `ST_Y(p)`

Returns the Y-coordinate value for the `Point` object *p* as a double-precision number.

```
mysql> SELECT ST_Y(POINT(56.7, 53.34));
+-----+
| ST_Y(POINT(56.7, 53.34)) |
+-----+
| 53.34 |
+-----+
```

`ST_Y()` and `Y()` are synonyms.

- `X(p)`

`ST_X()` and `X()` are synonyms. For more information, see the description of `ST_X()`.

`X()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_X()` instead.

- `Y(p)`

`ST_Y()` and `Y()` are synonyms. For more information, see the description of `ST_Y()`.

`Y()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Y()` instead.

### 13.15.7.3 LineString and MultiLineString Property Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

Some functions in this section also work for `MultiLineString` values.

- `EndPoint(ls)`

`ST_EndPoint()` and `EndPoint()` are synonyms. For more information, see the description of `ST_EndPoint()`.

`EndPoint()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_EndPoint()` instead.

- `GLength(ls)`

`GLength()` is a nonstandard name. It corresponds to the OpenGIS `ST_Length()` function. (There is an existing SQL function `Length()` that calculates the length of string values.)

`GLength()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Length()` instead.

- `IsClosed(ls)`

`ST_IsClosed()` and `IsClosed()` are synonyms. For more information, see the description of `ST_IsClosed()`.

`IsClosed()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_IsClosed()` instead.

- `NumPoints(ls)`

`ST_NumPoints()` and `NumPoints()` are synonyms. For more information, see the description of `ST_NumPoints()`.

`NumPoints()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_NumPoints()` instead.

- `PointN(ls,N)`

`ST_PointN()` and `PointN()` are synonyms. For more information, see the description of `ST_PointN()`.

`PointN()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_PointN()` instead.

- `ST_EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
+-----+
| ST_AsText(ST_EndPoint(ST_GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

`ST_EndPoint()` and `EndPoint()` are synonyms.

- `ST_IsClosed(ls)`

For a `LineString` value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, its `ST_StartPoint()` and `ST_EndPoint()` values are the same).

For a `MultiLineString` value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, the `ST_StartPoint()` and `ST_EndPoint()` values are the same for each `LineString` in `ls`).

`ST_IsClosed()` returns 0 if `ls` is not closed, and `NULL` if `ls` is `NULL`.

```
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls1)) |
+-----+
| 0 |
+-----+

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls2)) |
+-----+
| 1 |
+-----+

mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls3)) |
+-----+
| 0 |
+-----+
```

`ST_IsClosed()` and `IsClosed()` are synonyms.

- `ST_Length(ls)`

Returns a double-precision number indicating the length of the `LineString` or `MultiLineString` value `ls` in its associated spatial reference. The length of a `MultiLineString` value is equal to the sum of the lengths of its elements.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_Length(ST_GeomFromText(@ls));
+-----+
| ST_Length(ST_GeomFromText(@ls)) |
+-----+
| 2.8284271247461903 |
+-----+

mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT ST_Length(ST_GeomFromText(@mls));
+-----+
| ST_Length(ST_GeomFromText(@mls)) |
+-----+
| 4.242640687119286 |
+-----+
```

`ST_Length()` was added in MySQL 5.7.6. It should be used in preference to `GLength()`, which has a nonstandard name.

- `ST_NumPoints(ls)`

Returns the number of `Point` objects in the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
+-----+
| ST_NumPoints(ST_GeomFromText(@ls)) |
+-----+
| 3 |
+-----+
```

`ST_NumPoints()` and `NumPoints()` are synonyms.

- `ST_PointN(ls,N)`

Returns the *N*-th [Point](#) in the [LineString](#) value *ls*. Points are numbered beginning with 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls),2));
+-----+
| ST_AsText(ST_PointN(ST_GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

`ST_PointN()` and `PointN()` are synonyms.

- `ST_StartPoint(ls)`

Returns the [Point](#) that is the start point of the [LineString](#) value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));
+-----+
| ST_AsText(ST_StartPoint(ST_GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

`ST_StartPoint()` and `StartPoint()` are synonyms.

- `StartPoint(ls)`

`ST_StartPoint()` and `StartPoint()` are synonyms. For more information, see the description of `ST_StartPoint()`.

`StartPoint()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_StartPoint()` instead.

#### 13.15.7.4 Polygon and MultiPolygon Property Functions

These functions return properties of [Polygon](#) or [MultiPolygon](#) values.

- `Area(poly)`

`ST_Area()` and `Area()` are synonyms. For more information, see the description of `ST_Area()`.

`Area()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Area()` instead.

- `Centroid(mpoly)`

`ST_Centroid()` and `Centroid()` are synonyms. For more information, see the description of `ST_Centroid()`.

`Centroid()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Centroid()` instead.

- `ExteriorRing(poly)`

`ST_ExteriorRing()` and `ExteriorRing()` are synonyms. For more information, see the description of `ST_ExteriorRing()`.

`ExteriorRing()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_ExteriorRing()` instead.

- `InteriorRingN(poly,N)`

`ST_InteriorRingN()` and `InteriorRingN()` are synonyms. For more information, see the description of `ST_InteriorRingN()`.

`InteriorRingN()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_InteriorRingN()` instead.

- `NumInteriorRings(poly)`

`ST_NumInteriorRings()` and `NumInteriorRings()` are synonyms. For more information, see the description of `ST_NumInteriorRings()`.

`NumInteriorRings()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_NumInteriorRings()` instead.

- `ST_Area(poly)`

Returns a double-precision number indicating the area of the argument, as measured in its spatial reference system. For arguments of dimension 0 or 1, the result is 0.

Additionally, as of MySQL 5.7.5: The result is the sum of the area values of all components for a geometry collection. If a geometry collection is empty, its area is returned as 0.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+-----+
| ST_Area(ST_GeomFromText(@poly)) |
+-----+
| 4 |
+-----+

mysql> SET @mpoly =
-> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+-----+
| ST_Area(ST_GeomFromText(@mpoly)) |
+-----+
| 8 |
+-----+
```

`ST_Area()` and `Area()` are synonyms.

- `ST_Centroid(mpoly)`

Returns the mathematical centroid for the `MultiPolygon` value `mpoly` as a `Point`. The result is not guaranteed to be on the `MultiPolygon`.

As of MySQL 5.7.5, this function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single `MultiPolygon`, `MultiLineString`, or `MultiPoint` for centroid computation. If the argument is an empty geometry collection, the return value is `NULL`.

```
mysql> SET @poly =
-> ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+-----+-----+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly)) |
+-----+-----+
| POLYGON | POINT(4.958333333333333 4.958333333333333) |
+-----+-----+
```

`ST_Centroid()` and `Centroid()` are synonyms.

- `ST_ExteriorRing(poly)`

Returns the exterior ring of the `Polygon` value `poly` as a `LineString`.

```
mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
+-----+
| ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+
```

`ST_ExteriorRing()` and `ExteriorRing()` are synonyms.

- `ST_InteriorRingN(poly,N)`

Returns the `N`-th interior ring for the `Polygon` value `poly` as a `LineString`. Rings are numbered beginning with 1.

```
mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
+-----+
| ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+
```

`ST_InteriorRingN()` and `InteriorRingN()` are synonyms.

- `ST_NumInteriorRing(poly)`, `ST_NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value `poly`.

```
mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
+-----+
| ST_NumInteriorRings(ST_GeomFromText(@poly)) |
+-----+
| 1 |
+-----+
```

`ST_NumInteriorRing()`, `ST_NumInteriorRings()`, and `NumInteriorRings()` are synonyms. `ST_NumInteriorRing()` was added in MySQL 5.7.8.

### 13.15.7.5 GeometryCollection Property Functions

These functions return properties of `GeometryCollection` values.

- `GeometryN(gc,N)`

`ST_GeometryN()` and `GeometryN()` are synonyms. For more information, see the description of `ST_GeometryN()`.

`GeometryN()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_GeometryN()` instead.

- `NumGeometries(gc)`

`ST_NumGeometries()` and `NumGeometries()` are synonyms. For more information, see the description of `ST_NumGeometries()`.

`NumGeometries()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_NumGeometries()` instead.

- `ST_GeometryN(gc,N)`

Returns the *N*-th geometry in the `GeometryCollection` value *gc*. Geometries are numbered beginning with 1.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
+-----+
| ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
+-----+
| POINT(1 1) |
+-----+
```

`ST_GeometryN()` and `GeometryN()` are synonyms.

- `ST_NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value *gc*.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
+-----+
| ST_NumGeometries(ST_GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

`ST_NumGeometries()` and `NumGeometries()` are synonyms.

## 13.15.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators.

As of MySQL 5.7.5, these functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

- `Buffer(g,d[,strategy1[,strategy2[,strategy3]]])`

`ST_Buffer()` and `Buffer()` are synonyms. For more information, see the description of `ST_Buffer()`.

`Buffer()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Buffer()` instead.

- `ConvexHull(g)`

`ST_ConvexHull()` and `ConvexHull()` are synonyms. For more information, see the description of `ST_ConvexHull()`.

`ConvexHull()` was added in MySQL 5.7.5.

`ConvexHull()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_ConvexHull()` instead.

- `ST_Buffer(g,d[,strategy1[,strategy2[,strategy3]]])`

Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*, or `NULL` if any argument is `NULL`. The SRID of the geometry argument

must be 0 because `ST_Buffer()` supports only the Cartesian coordinate system. For an invalid geometry argument, an `ER_GIS_INVALID_DATA` error occurs.

If the geometry argument is empty, `ST_Buffer()` returns an empty geometry.

If the distance is 0, `ST_Buffer()` returns the geometry argument unchanged:

```
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
+-----+
| ST_AsText(ST_Buffer(@pt, 0)) |
+-----+
| POINT(0 0)                   |
+-----+
```

`ST_Buffer()` supports negative distances for `Polygon` and `MultiPolygon` values, and for geometry collections containing `Polygon` or `MultiPolygon` values. The result may be an empty geometry. An `ER_WRONG_ARGUMENTS` error occurs for `ST_Buffer()` with a negative distance for `Point`, `MultiPoint`, `LineString`, and `MultiLineString` values, and for geometry collections not containing any `Polygon` or `MultiPolygon` values.

As of MySQL 5.7.7, `ST_Buffer()` permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the `ST_Buffer_Strategy()` function, to be used for point, join, and end strategies:

- Point strategies apply to `Point` and `MultiPoint` geometries. If no point strategy is specified, the default is `ST_Buffer_Strategy('point_circle', 32)`.
- Join strategies apply to `LineString`, `MultiLineString`, `Polygon`, and `MultiPolygon` geometries. If no join strategy is specified, the default is `ST_Buffer_Strategy('join_round', 32)`.
- End strategies apply to `LineString` and `MultiLineString` geometries. If no end strategy is specified, the default is `ST_Buffer_Strategy('end_round', 32)`.

Up to one strategy of each type may be specified, and they may be given in any order. If multiple strategies of a given type are specified, an `ER_WRONG_ARGUMENTS` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
+-----+
| ST_AsText(ST_Buffer(@pt, 2, @pt_strategy)) |
+-----+
| POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2))      |
+-----+
```

```
mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end_flat');
mysql> SET @join_strategy = ST_Buffer_Strategy('join_round', 10);
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
+-----+
| ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy)) |
+-----+
| POLYGON((5 5,5 10,0 10,-3.5355339059327373 8.535533905932738, |
| -5 5,-5 0,0 0,5 0,5 5))                                     |
+-----+
```

`ST_Buffer()` and `Buffer()` are synonyms.

- `ST_Buffer_Strategy(strategy[, points_per_circle])`

This function returns a strategy byte string for use with `ST_Buffer()` to influence buffer computation. The result is `NULL` if any argument is `NULL`. If any argument is invalid, an `ER_WRONG_ARGUMENTS` error occurs.

Information about strategies is available at [Boost.org](http://Boost.org).

The first argument must be a string indicating a strategy option:

- For point strategies, permitted values are `'point_circle'` and `'point_square'`.
- For join strategies, permitted values are `'join_round'` and `'join_miter'`.
- For end strategies, permitted values are `'end_round'` and `'end_flat'`.

If the first argument is `'point_circle'`, `'join_round'`, `'join_miter'`, or `'end_round'`, the `points_per_circle` argument must be given as a positive numeric value. The maximum `points_per_circle` value is the value of the `max_points_in_geometry` system variable as of MySQL 5.7.8, 65,536 before that. If the first argument is `'point_square'` or `'end_flat'`, the `points_per_circle` argument must not be given or an `ER_WRONG_ARGUMENTS` error occurs.

For examples, see the description of `ST_Buffer()`.

This function was added in MySQL 5.7.7.

- `ST_ConvexHull(g)`

Returns a geometry that represents the convex hull of the geometry value *g*.

This function computes a geometry's convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a `MultiPoint` value from them, and computing its convex hull. If the argument is an empty geometry collection, the return value is `NULL`.

```
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----+
| POLYGON((5 0,25 0,15 25,5 0))                |
+-----+
```

`ST_ConvexHull()` and `ConvexHull()` are synonyms.

`ST_ConvexHull()` was added in MySQL 5.7.5.

- `ST_Difference(g1, g2)`

Returns a geometry that represents the point set difference of the geometry values *g1* and *g2*.

```
mysql> SET @g1 = POINT(1,1), @g2 = POINT(2,2);
mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
+-----+
| ST_AsText(ST_Difference(@g1, @g2)) |
+-----+
| POINT(1 1)                         |
+-----+
```

- `ST_Intersection(g1, g2)`

Returns a geometry that represents the point set intersection of the geometry values *g1* and *g2*.

```
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
+-----+
| ST_AsText(ST_Intersection(@g1, @g2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `ST_SymDifference(g1, g2)`

Returns a geometry that represents the point set symmetric difference of the geometry values *g1* and *g2*, which is defined as:

```
g1 symdifference g2 := (g1 union g2) difference (g1 intersection g2)
```

Or, in function call notation:

```
ST_SymDifference(g1, g2) = ST_Difference(ST_Union(g1, g2), ST_Intersection(g1, g2))
```

```
mysql> SET @g1 = POINT(1,1), @g2 = POINT(2,2);
mysql> SELECT ST_AsText(ST_SymDifference(@g1, @g2));
+-----+
| ST_AsText(ST_SymDifference(@g1, @g2)) |
+-----+
| GEOMETRYCOLLECTION(POINT(1 1),POINT(2 2)) |
+-----+
```

- `ST_Union(g1, g2)`

Returns a geometry that represents the point set union of the geometry values *g1* and *g2*.

```
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
+-----+
| ST_AsText(ST_Union(@g1, @g2)) |
+-----+
| MULTILINESTRING((1 1,3 3),(1 3,3 1)) |
+-----+
```

In addition, [Section 13.15.7, “Geometry Property Functions”](#), discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `ST_Envelope(g)`
- `ST_StartPoint(ls)`
- `ST_EndPoint(ls)`
- `ST_PointN(ls,N)`
- `ST_ExteriorRing(poly)`
- `ST_InteriorRingN(poly,N)`
- `ST_GeometryN(gc,N)`

## 13.15.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

There is also a MySQL-specific set of MBR-based functions available to test the relationship between two geometry values.

### 13.15.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions. They test the relationship between two geometry values `g1` and `g2`, using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except for `ST_Distance()` and `Distance()`, which return distance values.

As of MySQL 5.7.5, these functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification. They return false if called with an inapplicable geometry argument type combination. For example, `ST_Overlaps()` returns false if called with geometries of different dimensions.

- `Crosses(g1,g2)`

`ST_Crosses()` and `Crosses()` are synonyms. For more information, see the description of `ST_Crosses()`.

`Crosses()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Crosses()` instead.

- `Distance(g1,g2)`

`ST_Distance()` and `Distance()` are synonyms. For more information, see the description of `ST_Distance()`.

`Distance()` was added in MySQL 5.7.5.

`Distance()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Distance()` instead.

- `ST_Contains(g1,g2)`

Returns 1 or 0 to indicate whether `g1` completely contains `g2`. This tests the opposite relationship as `ST_Within()`.

- `ST_Crosses(g1,g2)`

Returns 1 if `g1` spatially crosses `g2`. Returns `NULL` if `g1` is a `Polygon` or a `MultiPolygon`, or if `g2` is a `Point` or a `MultiPoint`. Otherwise, returns 0.

As of MySQL 5.7.5, this function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if the first argument is a `Polygon` or `MultiPolygon` and/or the second argument is a `Point` or `MultiPoint`.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

`ST_Crosses()` and `Crosses()` are synonyms.

- `ST_Disjoint(g1,g2)`

Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.

- `ST_Distance(g1,g2)`

Returns the distance between *g1* and *g2*.

As of MySQL 5.7.5, this function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments. If either argument is an empty geometry collection, the return value is `NULL`.

As of MySQL 5.7.6, if an intermediate or final result produces NaN or a negative number, this function produces a `ER_GIS_INVALID_DATA` error.

```
mysql> SET @g1 = POINT(1,1), @g2 = POINT(2,2);
mysql> SELECT ST_Distance(@g1, @g2);
+-----+
| ST_Distance(@g1, @g2) |
+-----+
| 1.4142135623730951 |
+-----+
```

`ST_Distance()` and `Distance()` are synonyms.

- `ST_Equals(g1,g2)`

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

```
mysql> SET @g1 = POINT(1,1), @g2 = POINT(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+-----+-----+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

- `ST_Intersects(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.

- `ST_Overlaps(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

As of MySQL 5.7.5, this function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if called with geometries of different dimensions or any argument is a `Point`.

- `ST_Touches(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

As of MySQL 5.7.5, this function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if either of the arguments is a `Point` or `MultiPoint`.

`ST_Touches()` and `Touches()` are synonyms.

- `ST_Within(g1,g2)`

Returns 1 or 0 to indicate whether *g1* is spatially within *g2*. This tests the opposite relationship as `ST_Contains()`.

- `Touches(g1,g2)`

`ST_Touches()` and `Touches()` are synonyms. For more information, see the description of `ST_Touches()`.

`Touches()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `ST_Touches()` instead.

### 13.15.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles (MBRs)

The OpenGIS specification defines the following functions that test the relationship between two geometry values *g1* and *g2*. The MySQL implementation uses minimum bounding rectangles, so these functions return the same result as the corresponding MBR-based functions. The return values 1 and 0 indicate true and false, respectively.

These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

- `Contains(g1,g2)`

`MBRContains()` and `Contains()` are synonyms. For more information, see the description of `MBRContains()`.

`Contains()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `MBRContains()` instead.

- `Disjoint(g1,g2)`

`MBRDisjoint()` and `Disjoint()` are synonyms. For more information, see the description of `MBRDisjoint()`.

`Disjoint()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `MBRDisjoint()` instead.

- `Equals(g1,g2)`

`MBREquals()` and `Equals()` are synonyms. For more information, see the description of `MBREquals()`.

`Equals()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `MBREquals()` instead.

- `Intersects(g1,g2)`

`MBRIntersects()` and `Intersects()` are synonyms. For more information, see the description of `MBRIntersects()`.

`Intersects()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `MBRIntersects()` instead.

- `Overlaps(g1,g2)`

`MBROverlaps()` and `Overlaps()` are synonyms. For more information, see the description of `MBROverlaps()`.

`Overlaps()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `MBROverlaps()` instead.

- `Within(g1,g2)`

`MBRWithin()` and `Within()` are synonyms. For more information, see the description of `MBRWithin()`.

`Within()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `MBRWithin()` instead.

### 13.15.9.3 MySQL-Specific Spatial Relation Functions That Use Minimum Bounding Rectangles (MBRs)

MySQL provides several MySQL-specific functions that test relations between minimum bounding rectangles of two geometries `g1` and `g2`. The return values 1 and 0 indicate true and false, respectively.

- `MBRContains(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of `g1` contains the minimum bounding rectangle of `g2`. This tests the opposite relationship as `MBRWithin()`.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);
```

| MBRContains(@g1,@g2) | MBRWithin(@g2,@g1) |
|----------------------|--------------------|
| 1                    | 1                  |

`MBRContains()` and `Contains()` are synonyms.

- `MBRCoveredBy(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of `g1` is covered by the minimum bounding rectangle of `g2`. This tests the opposite relationship as `MBRCovers()`.

`MBRCoveredBy()` and `MBRCovers()` handle their arguments and return a value as follows:

- Return `NULL` if either argument is `NULL` or an empty geometry
- Return `ER_GIS_INVALID_DATA` if either argument is not a valid geometry byte string (SRID plus WKB value)
- Otherwise, return non-`NULL`

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRCovers(@g1,@g2), MBRCoveredBy(@g1,@g2);
```

| MBRCovers(@g1,@g2) | MBRCoveredBy(@g1,@g2) |
|--------------------|-----------------------|
| 1                  | 0                     |

```
mysql> SELECT MBRCovers(@g2,@g1), MBRCoveredBy(@g2,@g1);
```

| MBRCovers(@g2,@g1) | MBRCoveredBy(@g2,@g1) |
|--------------------|-----------------------|
| 0                  | 1                     |

- `MBRCovers(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of `g1` covers the minimum bounding rectangle of `g2`. This tests the opposite relationship as `MBRCoveredBy()`. See the description of `MBRCoveredBy()` for examples and information about argument handling.

- `MBRDisjoint(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).

`MBRDisjoint()` and `Disjoint()` are synonyms.

- `MBREqual(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are the same.

`MBREqual()` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. Use `MBREquals()` instead.

- `MBREquals(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are the same.

`MBREquals()`, `MBREqual()`, and `Equals()` are synonyms.

This function was added in MySQL 5.7.6.

- `MBRIntersects(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* intersect.

`MBRIntersects()` and `Intersects()` are synonyms.

- `MBROverlaps(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* overlap. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

`MBROverlaps()` and `Overlaps()` are synonyms.

- `MBRTouches(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* touch. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- `MBRWithin(g1,g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* is within the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRContains()`.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

`MBRWithin()` and `Within()` are synonyms.

### 13.15.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvwxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

- `ST_GeoHash(longitude, latitude, max_length), ST_GeoHash(point, max_length)`

Returns a geohash string in the connection character set and collation. The result is `NULL` if any argument is `NULL`. An error occurs if any argument is invalid.

For the first syntax, the `longitude` must be a number in the range  $[-180, 180]$ , and the `latitude` must be a number in the range  $[-90, 90]$ . For the second syntax, a `POINT` value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

The resulting string is no longer than `max_length` characters, which has an upper limit of 100. The string might be shorter than `max_length` characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or `max_length` characters, whichever comes first.

This function was added in MySQL 5.7.5.

```
mysql> SELECT ST_GeoHash(180,0,10), ST_GeoHash(-180,-90,15);
+-----+-----+
| ST_GeoHash(180,0,10) | ST_GeoHash(-180,-90,15) |
+-----+-----+
| xbpbbpbbpbbp      | 0000000000000000      |
+-----+-----+
```

- `ST_LatFromGeoHash(geohash_str)`

Returns the latitude from a geohash string value, as a `DOUBLE` value in the range  $[-90, 90]$ . The result is `NULL` if any argument is `NULL`. An error occurs if the argument is invalid.

The `ST_LatFromGeoHash()` decoding function reads no more than 433 characters from the `geohash_str` argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

This function was added in MySQL 5.7.5.

```
mysql> SELECT ST_LatFromGeoHash(ST_GeoHash(45,-20,10));
+-----+
| ST_LatFromGeoHash(ST_GeoHash(45,-20,10)) |
+-----+
| -20 |
+-----+
```

- `ST_LongFromGeoHash(geohash_str)`

Returns the longitude from a geohash string value, as a `DOUBLE` value in the range  $[-180, 180]$ . The result is `NULL` if any argument is `NULL`. An error occurs if the argument is invalid.

The remarks in the description of `ST_LatFromGeoHash()` regarding the maximum number of characters processed from the `geohash_str` argument also apply to `ST_LongFromGeoHash()`.

This function was added in MySQL 5.7.5.

```
mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45,-20,10));
+-----+
| ST_LongFromGeoHash(ST_GeoHash(45,-20,10)) |
+-----+
| 45 |
+-----+
```

- `ST_PointFromGeoHash(geohash_str, srid)`

Returns a `POINT` value containing the decoded geohash value, given a geohash string value. The X and Y coordinates of the point are the longitude in the range [-180, 180] and the latitude in the range [-90, 90], respectively. The `srid` value is an unsigned 32-bit integer. The result is `NULL` if any argument is `NULL`. An error occurs if any argument is invalid.

The remarks in the description of `ST_LatFromGeoHash()` regarding the maximum number of characters processed from the `geohash_str` argument also apply to `ST_PointFromGeoHash()`.

This function was added in MySQL 5.7.5.

```
mysql> SET @gh = ST_GeoHash(45,-20,10);
mysql> SELECT ST_AsText(ST_PointFromGeoHash(@gh,0));
+-----+
| ST_AsText(ST_PointFromGeoHash(@gh,0)) |
+-----+
| POINT(45 -20) |
+-----+
```

### 13.15.11 Spatial GeoJSON Functions

This section describes functions for converting between GeoJSON documents and spatial values. GeoJSON is an open standard for encoding geometric/geographical features. For more information, see <http://geojson.org>. The functions discussed here follow GeoJSON specification revision 1.0.

GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS support is limited to values that identify an SRID.

MySQL also supports a native `JSON` data type and a set of SQL functions to enable operations on JSON values. For more information, see [Section 12.6, “The JSON Data Type”](#), and [Section 13.16, “JSON Functions”](#).

- `ST_AsGeoJSON(g [, max_dec_digits [, options]])`

Generates a GeoJSON object from the geometry `g`. The object string has the connection character set and collation.

`max_dec_digits`, if specified, limits the number of decimal digits for coordinates and causes rounding of output. If not specified, this argument defaults to its maximum value of  $2^{32} - 1$ . The minimum is 0.

`options`, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry argument has an SRID of 0, no CRS object is produced even for those flag values that request one.

| Flag Value | Meaning  |
|------------|--|
| 0          | No options. This is the default if <code>options</code> is not specified.                                  |
| 1          | Add a bounding box to the output.  |
| 2          | Add a short-format CRS URN to the output. The default format is a short format ( <code>EPSG:srid</code> ). |

| Flag Value | Meaning  |
|------------|--|
| 4          | Add a long-format CRS URN ( <code>urn:ogc:def:crs:EPSG::srid</code> ). This flag overrides flag 2. For example, option values of 5 and 7 mean the same (add a bounding box and a long-format CRS URN). |

If any argument is `NULL`, the return value is `NULL`. If any non-`NULL` argument is invalid, an error occurs.

```
mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.1111 12.2222)'),2);
+-----+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.1111 12.2222)'),2) |
+-----+
| {"type": "Point", "coordinates": [11.11, 12.22]}           |
+-----+
```

This function was added in MySQL 5.7.5.

- `ST_GeomFromGeoJSON(str [, options [, srid]])`

Parses a string `str` representing a GeoJSON object and returns a geometry.

`options`, if given, describes how to handle GeoJSON documents that contain geometries with coordinate dimensions higher than 2. The following table shows the permitted `options` values.

| Option Value | Meaning   |
|--------------|---|
| 1            | Reject the document and produce an error. This is the default if <code>options</code> is not specified. |
| 2, 3, 4      | Accept the document and strip off the coordinates for higher coordinate dimensions.                     |

`options` values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate dimensions higher than 2 are supported in the future, these values will produce different effects.

The `srid` argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value has an SRID of 4326.

GeoJSON geometry, feature, and feature collection objects may have a `crs` property. The parsing function parses named CRS URNs in the `urn:ogc:def:crs:EPSG::srid` and `EPSG:srid` namespaces, but not CRSs given as link objects. Also, `urn:ogc:def:crs:OGC:1.3:CRS84` is recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the exception that if the optional `srid` argument is given, any CRS is ignored even if it is invalid.

As specified in the GeoJSON specification, parsing is case sensitive for the `type` member of the GeoJSON input (`Point`, `LineString`, and so forth). The specification is silent regarding case sensitivity for other parsing, which in MySQL is not case sensitive.

If any argument is `NULL`, the return value is `NULL`. If any non-`NULL` argument is invalid, an error occurs.

This example shows the parsing result for a simple GeoJSON object:

```
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0]}';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+-----+
| ST_AsText(ST_GeomFromGeoJSON(@json)) |
+-----+
| POINT(102 0)                         |
+-----+
```

This function was added in MySQL 5.7.5.

### 13.15.12 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

- `ST_Distance_Sphere(g1, g2 [, radius])`

Returns the minimum spherical distance between two points and/or multipoints on a sphere, in meters, or `NULL` if any geometry argument is `NULL` or empty.

Calculations use a spherical earth and a configurable radius. The optional `radius` argument should be given in meters. If omitted, the default radius is 6,370,986 meters. An `ER_WRONG_ARGUMENTS` error occurs if the `radius` argument is present but not positive.

The geometry arguments should consist of points that specify (longitude, latitude) coordinate values:

- Longitude and latitude are the first and second coordinates of the point, respectively.
- Both coordinates are in degrees.
- Longitude values must be in the range (-180, 180]. Positive values are east of the prime meridian.
- Latitude values must be in the range [-90, 90]. Positive values are north of the equator.

Supported argument combinations are (`Point`, `Point`), (`Point`, `MultiPoint`), and (`MultiPoint`, `Point`). An `ER_GIS_UNSUPPORTED_ARGUMENT` error occurs for other combinations.

An `ER_GIS_INVALID_DATA` error occurs if any geometry argument is not a valid geometry byte string.

```
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
+-----+
| ST_Distance_Sphere(@pt1, @pt2) |
+-----+
| 20015042.813723423 |
+-----+
```

This function was added in MySQL 5.7.6.

- `ST_IsValid(g)`

Checks whether a geometry is valid, as defined by the OGC specification. `ST_IsValid()` returns 1 if the argument is a valid geometry byte string and is geometrically valid, 0 if the argument is not a valid geometry byte string or is not geometrically valid, `NULL` if the argument is `NULL`.

The only valid empty geometry is represented in the form of an empty geometry collection value. `ST_IsValid()` returns 1 in this case.

`ST_IsValid()` works only for the Cartesian coordinate system and requires a geometry argument with an SRID of 0. An `ER_WRONG_ARGUMENTS` error occurs otherwise.

```
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
+-----+
| ST_IsValid(@ls1) |
+-----+
| 0 |
+-----+
```

```
mysql> SELECT ST_IsValid(@ls2);
+-----+
| ST_IsValid(@ls2) |
+-----+
| 1 |
+-----+
```

This function was added in MySQL 5.7.6.

- `ST_MakeEnvelope(pt1, pt2)`

Returns the rectangle that forms the envelope around two points. The returned geometry is a [Point](#), [LineString](#), or [Polygon](#), or [NULL](#) if any argument is [NULL](#).

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points *pt1* and *pt2*, `ST_MakeEnvelope()` creates the result geometry on an abstract plane like this:

- If *pt1* and *pt2* are equal, the result is the point *pt1*.
- Otherwise, if (*pt1*, *pt2*) is a vertical or horizontal line segment, the result is the line segment (*pt1*, *pt2*).
- Otherwise, the result is a polygon using *pt1* and *pt2* as diagonal points.

The result geometry has an SRID of 0.

`ST_MakeEnvelope()` requires [Point](#) geometry arguments with an SRID of 0. An [ER\\_WRONG\\_ARGUMENTS](#) error occurs otherwise.

An [ER\\_GIS\\_INVALID\\_DATA](#) occurs if any argument is not a valid geometry byte string, or if any coordinate value of the two points is infinite (that is, NaN).

```
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+-----+
| ST_AsText(ST_MakeEnvelope(@pt1, @pt2)) |
+-----+
| POLYGON((0 0,1 0,1 1,0 1,0 0)) |
+-----+
```

This function was added in MySQL 5.7.6.

- `ST_Simplify(g, max_distance)`

Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type, or [NULL](#) if any argument is [NULL](#).

The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

The *max\_distance* argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed. An [ER\\_WRONG\\_ARGUMENTS](#) error occurs if the *max\_distance* argument is not positive, or is NaN.

According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. If you want to check the validity of the result, pass it to `ST_IsValid()`.

An [ER\\_GIS\\_INVALID\\_DATA](#) error occurs if the geometry argument is not a valid geometry byte string.

```
mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,1 2,2 2,2 3,3 3)');
mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
+-----+
| ST_AsText(ST_Simplify(@g, 0.5)) |
+-----+
| LINESTRING(0 0,0 1,1 2 3,3 3) |
+-----+
mysql> SELECT ST_AsText(ST_Simplify(@g, 1.0));
+-----+
| ST_AsText(ST_Simplify(@g, 1.0)) |
+-----+
| LINESTRING(0 0,3 3) |
+-----+
mysql> SELECT ST_AsText(ST_Simplify(@g));
```

This function was added in MySQL 5.7.6.

- [ST\\_Validate\(g\)](#)

Validates a geometry according to the OGC specification. [ST\\_Validate\(\)](#) returns the geometry if it is a valid geometry byte string and is geometrically valid, [NULL](#) if the argument is not a valid geometry byte string or is not geometrically valid or is [NULL](#).

A geometry can be a valid geometry byte string (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid: [POLYGON\(\(0 0, 0 0, 0 0, 0 0, 0 0\)\)](#)

[ST\\_Validate\(\)](#) can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input [Polygon](#) or [MultiPolygon](#) has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. [ST\\_Validate\(\)](#) returns it directly without further checks in this case.

[ST\\_Validate\(\)](#) works only for the Cartesian coordinate system and requires a geometry argument with an SRID of 0. An [ER\\_WRONG\\_ARGUMENTS](#) error occurs otherwise.

```
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_AsText(ST_Validate(@ls1));
+-----+
| ST_AsText(ST_Validate(@ls1)) |
+-----+
| NULL |
+-----+
mysql> SELECT ST_AsText(ST_Validate(@ls2));
+-----+
| ST_AsText(ST_Validate(@ls2)) |
+-----+
| LINESTRING(0 0,1 1) |
+-----+
```

This function was added in MySQL 5.7.6.

## 13.16 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the `JSON` data type and additional examples showing how to use these functions, see [Section 12.6, “The JSON Data Type”](#).

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value.

Unless otherwise indicated, the JSON functions were added in MySQL 5.7.8.

A set of spatial functions for operating on GeoJSON values is also available. See [Section 13.15.11, “Spatial GeoJSON Functions”](#).

## 13.16.1 JSON Function Reference

**Table 13.20 JSON Functions**

| Name                              | Description   |
|-----------------------------------|---|
| <code>JSON_APPEND()</code>        | Append data to JSON document  |
| <code>JSON_ARRAY()</code>         | Create JSON array   |
| <code>JSON_ARRAY_APPEND()</code>  | Append data to JSON document  |
| <code>JSON_ARRAY_INSERT()</code>  | Insert into JSON array  |
| <code>-&gt;</code>                | Return value from JSON column after evaluating path; equivalent to <code>JSON_EXTRACT()</code> .  |
| <code>JSON_CONTAINS()</code>      | Whether JSON document contains specific object at path  |
| <code>JSON_CONTAINS_PATH()</code> | Whether JSON document contains any data at path   |
| <code>JSON_DEPTH()</code>         | Maximum depth of JSON document  |
| <code>JSON_EXTRACT()</code>       | Return data from JSON document  |
| <code>-&gt;&gt;</code>            | Return value from JSON column after evaluating path and unquoting the result; equivalent to <code>JSON_UNQUOTE(JSON_EXTRACT())</code> . |
| <code>JSON_INSERT()</code>        | Insert data into JSON document  |
| <code>JSON_KEYS()</code>          | Array of keys from JSON document  |
| <code>JSON_LENGTH()</code>        | Number of elements in JSON document   |
| <code>JSON_MERGE()</code>         | Merge JSON documents  |
| <code>JSON_OBJECT()</code>        | Create JSON object  |
| <code>JSON_QUOTE()</code>         | Quote JSON document   |
| <code>JSON_REMOVE()</code>        | Remove data from JSON document  |
| <code>JSON_REPLACE()</code>       | Replace values in JSON document   |
| <code>JSON_SEARCH()</code>        | Path to value within JSON document  |
| <code>JSON_SET()</code>           | Insert data into JSON document  |
| <code>JSON_TYPE()</code>          | Type of JSON value  |
| <code>JSON_UNQUOTE()</code>       | Unquote JSON value  |
| <code>JSON_VALID()</code>         | Whether JSON value is valid   |

## 13.16.2 Functions That Create JSON Values

The functions in this section compose JSON values from component elements.

- `JSON_ARRAY([val[, val] ...])`

Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

```
mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
+-----+
| JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME()) |
+-----+
| [1, "abc", null, true, "11:30:24.000000"] |
+-----+
```

- `JSON_OBJECT([key, val[, key, val] ...])`

Evaluates a (possibly empty) list of key/value pairs and returns a JSON object containing those pairs. An error occurs if any key name is `NULL` or the number of arguments is odd.

```
mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
+-----+
| JSON_OBJECT('id', 87, 'name', 'carrot') |
+-----+
| {"id": 87, "name": "carrot"} |
+-----+
```

- `JSON_QUOTE(json_val)`

Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior quote and other characters, then returning the result as a `utf8mb4` string. Returns `NULL` if the argument is `NULL`.

This function is typically used to produce a valid JSON string literal for inclusion within a JSON document.

Certain special characters are escaped with backslashes per the escape sequences shown in [Table 13.21, “JSON\\_UNQUOTE\(\) Special Character Escape Sequences”](#).

```
mysql> SELECT JSON_QUOTE('null'), JSON_QUOTE('"null"');
+-----+
| JSON_QUOTE('null') | JSON_QUOTE('"null"') |
+-----+
| "null" | "\"null\"" |
+-----+

mysql> SELECT JSON_QUOTE('[1, 2, 3]');
+-----+
| JSON_QUOTE('[1, 2, 3]') |
+-----+
| "[1, 2, 3]" |
+-----+
```

You can also obtain JSON values by casting values of other types to the `JSON` type using `CAST(value AS JSON)`; see [Converting between JSON and non-JSON values](#), for more information.

### 13.16.3 Functions That Search JSON Values

The functions in this section perform search operations on JSON values to extract data from them, report whether data exists at a location within them, or report the path to data within them.

- `JSON_CONTAINS(json_doc, val[, path])`

Returns 0 or 1 to indicate whether a specific value is contained in a target JSON document, or, if a `path` argument is given, at a specific path within the target document. Returns `NULL` if any argument is `NULL` or the path argument does not identify a section of the target document. An error occurs if either document argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

The following rules define containment:

- A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.
- A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.
- A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.
- A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

Otherwise, the candidate value is not contained in the target document.

```
mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}';
mysql> SET @j2 = '1';
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-----+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.b');
+-----+
| JSON_CONTAINS(@j, @j2, '$.b') |
+-----+
| 0 |
+-----+

mysql> SET @j2 = '{"d": 4}';
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-----+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-----+
| 0 |
+-----+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.c');
+-----+
| JSON_CONTAINS(@j, @j2, '$.c') |
+-----+
| 1 |
+-----+
```

- `JSON_CONTAINS_PATH(json_doc, one_or_all, path[, path] ...)`

Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, or `one_or_all` is not `'one'` or `'all'`.

To check for a specific value at a path, use `JSON_CONTAINS()` instead.

The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the `one_or_all` argument:

- `'one'`: 1 if at least one path exists within the document, 0 otherwise.
- `'all'`: 1 if all paths exist within the document, 0 otherwise.

```
mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}';
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e');
+-----+
```

```
| JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e');
+-----+
| JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e') |
+-----+
| 0 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.c.d');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.c.d') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a.d');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.a.d') |
+-----+
| 0 |
+-----+
```

- `JSON_EXTRACT(json_doc, path[, path] ...)`

Returns data from a JSON document, selected from the parts of the document matched by the *path* arguments. Returns `NULL` if any argument is `NULL` or no paths locate a value in the document. An error occurs if the *json\_doc* argument is not a valid JSON document or any *path* argument is not a valid path expression.

The return value consists of all values matched by the *path* arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.

```
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]') |
+-----+
| 20 |
+-----+
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]') |
+-----+
| [20, 10] |
+-----+
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]') |
+-----+
| [30, 40] |
+-----+
```

MySQL 5.7.9 and later supports the `->` operator as shorthand for this function as used with 2 arguments where the left hand side is a `JSON` column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- `column->path`

In MySQL 5.7.9 and later, the `->` operator serves as an alias for the `JSON_EXTRACT()` function when used with two arguments, a column identifier on the left and a JSON path on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column identifiers wherever they occur in SQL statements.

The two `SELECT` statements shown here produce the same output:

```
mysql> SELECT c, JSON_EXTRACT(c, "$.id"), g
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY JSON_EXTRACT(c, "$.name");
```

| c                             | c->"\$.id" | g |
|-------------------------------|------------|---|
| {"id": "3", "name": "Barney"} | "3"        | 3 |
| {"id": "4", "name": "Betty"}  | "4"        | 4 |
| {"id": "2", "name": "Wilma"}  | "2"        | 2 |

3 rows in set (0.00 sec)

```
mysql> SELECT c, c->"$.id", g
> FROM jemp
> WHERE c->"$.id" > 1
> ORDER BY c->"$.name";
```

| c                             | c->"\$.id" | g |
|-------------------------------|------------|---|
| {"id": "3", "name": "Barney"} | "3"        | 3 |
| {"id": "4", "name": "Betty"}  | "4"        | 4 |
| {"id": "2", "name": "Wilma"}  | "2"        | 2 |

3 rows in set (0.00 sec)

This functionality is not limited to `SELECT`, as shown here:

```
mysql> ALTER TABLE jemp ADD COLUMN n INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
```

| c                             | c->"\$.id" | g | n    |
|-------------------------------|------------|---|------|
| {"id": "3", "name": "Barney"} | "3"        | 3 | NULL |
| {"id": "4", "name": "Betty"}  | "4"        | 4 | 1    |
| {"id": "2", "name": "Wilma"}  | "2"        | 2 | NULL |

3 rows in set (0.00 sec)

```
mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)

mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
```

| c                             | c->"\$.id" | g | n    |
|-------------------------------|------------|---|------|
| {"id": "3", "name": "Barney"} | "3"        | 3 | NULL |
| {"id": "2", "name": "Wilma"}  | "2"        | 2 | NULL |

2 rows in set (0.00 sec)

(See [Indexing a Generated Column to Provide a JSON Column Index](#), for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

```
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10
  > VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,[22,44,66]]", 0);
Query OK, 1 row affected (0.04 sec)

mysql> SELECT a->"$[4]" FROM tj10;
+-----+
| a->"$[4]" |
+-----+
| 44        |
| [22, 44, 66] |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
+-----+-----+
| a | b |
+-----+-----+
| [3, 10, 5, 17, 44] | 33 |
| [3, 10, 5, 17, [22, 44, 66]] | 0 |
+-----+-----+
2 rows in set (0.00 sec)
```

Nested arrays are supported. An expression using `->` evaluates as `NULL` if no matching key is found in the target JSON document, as shown here:

```
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
+-----+-----+
| a | b |
+-----+-----+
| [3, 10, 5, 17, [22, 44, 66]] | 0 |
+-----+-----+

mysql> SELECT a->"$[4][1]" FROM tj10;
+-----+
| a->"$[4][1]" |
+-----+
| NULL         |
| 44           |
+-----+
2 rows in set (0.00 sec)
```

This is the same behavior as seen in such cases when using `JSON_EXTRACT()`:

```
mysql> SELECT JSON_EXTRACT(a, "$[4][1]") FROM tj10;
+-----+
| JSON_EXTRACT(a, "$[4][1]") |
+-----+
| NULL                        |
| 44                          |
+-----+
2 rows in set (0.00 sec)
```

- `column->>path`

This is an improved, unquoting extraction operator available in MySQL 5.7.13 and later. Whereas the `->` operator simply extracts a value, the `->>` operator in addition unquotes the extracted result. In other words, given a `JSON` column value `column` and a path expression `path`, the following three expressions return the same value:

- `JSON_UNQUOTE( JSON_EXTRACT(column, path) )`
- `JSON_UNQUOTE(column ->> path)`

- `column->>path`

The `->>` operator can be used wherever `JSON_UNQUOTE(JSON_EXTRACT( ))` would be allowed. This includes (but is not limited to) `SELECT` lists, `WHERE` and `HAVING` clauses, and `ORDER BY` and `GROUP BY` clauses.

The next few statements demonstrate some `->>` operator equivalences with other expressions in the `mysql` client:

```
mysql> SELECT * FROM jemp WHERE g > 2;
+-----+-----+
| c          | g    |
+-----+-----+
| {"id": "3", "name": "Barney"} | 3    |
| {"id": "4", "name": "Betty"}  | 4    |
+-----+-----+
2 rows in set (0.01 sec)
```

```
mysql> SELECT c->'$.name' AS name
->      FROM jemp WHERE g > 2;
+-----+
| name    |
+-----+
| "Barney" |
| "Betty"  |
+-----+
2 rows in set (0.00 sec)
```

```
mysql> SELECT JSON_UNQUOTE(c->'$.name') AS name
->      FROM jemp WHERE g > 2;
+-----+
| name    |
+-----+
| Barney  |
| Betty   |
+-----+
2 rows in set (0.00 sec)
```

```
mysql> SELECT c->>'$.name' AS name
->      FROM jemp WHERE g > 2;
+-----+
| name    |
+-----+
| Barney  |
| Betty   |
+-----+
2 rows in set (0.00 sec)
```

See [Indexing a Generated Column to Provide a JSON Column Index](#), for the SQL statements used to create and populate the `jemp` table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

```
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)
```

```
mysql> INSERT INTO tj10 VALUES
->      ('[3,10,5,"x",44]', 33),
->      ('[3,10,5,17,[22,"y",66]]', 0);
Query OK, 2 rows affected (0.04 sec)
Records: 2  Duplicates: 0  Warnings: 0
```

```
mysql> SELECT a->"$[3]", a->"$[4][1]" FROM tj10;
+-----+-----+
| a->"$[3]" | a->"$[4][1]" |
+-----+-----+
| "x"      | NULL         |
+-----+-----+
```

```
| 17          | "y"          |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT a->>"$[3]", a->>"$[4][1]" FROM tj10;
+-----+-----+
| a->>"$[3]" | a->>"$[4][1]" |
+-----+-----+
| x         | NULL         |
| 17        | y            |
+-----+-----+
2 rows in set (0.00 sec)
```

As with `->`, the `->>` operator is always expanded in the output of `EXPLAIN`, as the following example demonstrates:

```
mysql> EXPLAIN SELECT c->>'$.name' AS name
->      FROM jemp WHERE g > 2\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: jemp
    partitions: NULL
      type: range
possible_keys: i
      key: i
     key_len: 5
        ref: NULL
         rows: 2
    filtered: 100.00
      Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1003
  Message: /* select#1 */ select
json_unquote(json_extract(`jtest`.`jemp`.`c`, '$.name')) AS `name` from
`jtest`.`jemp` where (`jtest`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

This is similar to how MySQL expands the `->` operator in the same circumstances.

The `->>` operator was added in MySQL 5.7.13.

- `JSON_KEYS(json_doc[, path])`

Returns the keys from the top-level value of a JSON object as a JSON array, or, if a `path` argument is given, the top-level keys from the selected path. Returns `NULL` if any argument is `NULL`, the `json_doc` argument is not an object, or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the return value does not include keys from those subobjects.

```
mysql> SELECT JSON_KEYS('{ "a": 1, "b": { "c": 30 } }');
+-----+
| JSON_KEYS('{ "a": 1, "b": { "c": 30 } }') |
+-----+
| ["a", "b"]                                |
+-----+

mysql> SELECT JSON_KEYS('{ "a": 1, "b": { "c": 30 } }', '$.b');
+-----+
| JSON_KEYS('{ "a": 1, "b": { "c": 30 } }', '$.b') |
+-----+
```

```
| ["c"] |
+-----+
```

- `JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])`

Returns the path to the given string within a JSON document. Returns `NULL` if any of the `json_doc`, `search_str`, or `path` arguments are `NULL`; no `path` exists within the document; or `search_str` is not found. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, `one_or_all` is not `'one'` or `'all'`, or `escape_char` is not a constant expression.

The `one_or_all` argument affects the search as follows:

- `'one'`: The search terminates after the first match and returns one path string. It is undefined which match is considered first.
- `'all'`: The search returns all matching path strings such that no duplicate paths are included. If there are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.

Within the `search_str` search string argument, the `%` and `_` characters work as for the `LIKE` operator: `%` matches any number of characters (including zero characters), and `_` matches exactly one character.

To specify a literal `%` or `_` character in the search string, precede it by the escape character. The default is `\` if the `escape_char` argument is missing or `NULL`. Otherwise, `escape_char` must be a constant that is empty or one character.

For more information about matching and escape character behavior, see the description of `LIKE` in [Section 13.5.1, “String Comparison Functions”](#). For escape character handling, a difference from the `LIKE` behavior is that the escape character for `JSON_SEARCH()` must evaluate to a constant at compile time, not just at execution time. For example, if `JSON_SEARCH()` is used in a prepared statement and the `escape_char` argument is supplied using a `?` parameter, the parameter value might be constant at execution time, but is not at compile time.

```
mysql> SET @j = '["abc", [{"k": "10"}, "def"], {"x": "abc"}, {"y": "bcd"}]';

mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-----+
| JSON_SEARCH(@j, 'one', 'abc') |
+-----+
| "$[0]"                        |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-----+
| JSON_SEARCH(@j, 'all', 'abc') |
+-----+
| ["$[0]", "$[2].x"]           |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
+-----+
| JSON_SEARCH(@j, 'all', 'ghi') |
+-----+
| NULL                          |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10');
+-----+
| JSON_SEARCH(@j, 'all', '10')  |
+-----+
| "$[1][0].k"                  |
+-----+
```

```
mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$') |
+-----+
| "$[1][0].k"                             |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*]');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*]') |

+-----+
| NULL |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', '', '$[1]');
+-----+
| JSON_SEARCH(@j, 'all', '%b%', '', '$[1]') |
+-----+
| NULL |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', '', '$[3]');
+-----+
| JSON_SEARCH(@j, 'all', '%b%', '', '$[3]') |
+-----+
| "$[3].y" |
+-----+
```

For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators `*` and `**`, see [Section 13.16.6, “JSON Path Syntax”](#).

## 13.16.4 Functions That Modify JSON Values

The functions in this section modify JSON values and return the result.

- `JSON_APPEND(json_doc, path, val[, path, val] ...)`

Appends values to the end of the indicated arrays within a JSON document and returns the result. This function was renamed to `JSON_ARRAY_APPEND()` in MySQL 5.7.9.

- `JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)`

Appends values to the end of the indicated arrays within a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the *json\_doc* argument is not a valid JSON document or any *path* argument is not a valid path expression or contains a `*` or `**` wildcard.

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

If a path selects a scalar or object value, that value is autowrapped within an array and the new value is added to that array. Pairs for which the path does not identify any value in the JSON document are ignored.

```
mysql> SET @j = '["a", ["b", "c"], "d"]';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1]', 1);
+-----+
| JSON_ARRAY_APPEND(@j, '$[1]', 1) |
+-----+
| ["a", ["b", "c", 1], "d"] |
+-----+

mysql> SELECT JSON_ARRAY_APPEND(@j, '$[0]', 2);
+-----+
| JSON_ARRAY_APPEND(@j, '$[0]', 2) |
+-----+
| [{"a", 2}, ["b", "c"], "d"] |
+-----+

mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1][0]', 3);
+-----+
| JSON_ARRAY_APPEND(@j, '$[1][0]', 3) |
```

```

+-----+
| ["a", [{"b": 3}, "c"], "d"] |
+-----+

mysql> SET @j = '{"a": 1, "b": [2, 3], "c": 4}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$.b', 'x');
+-----+
| JSON_ARRAY_APPEND(@j, '$.b', 'x') |
+-----+
| {"a": 1, "b": [2, 3, "x"], "c": 4} |
+-----+

mysql> SELECT JSON_ARRAY_APPEND(@j, '$.c', 'y');
+-----+
| JSON_ARRAY_APPEND(@j, '$.c', 'y') |
+-----+
| {"a": 1, "b": [2, 3], "c": [4, "y"]} |
+-----+

mysql> SET @j = '{"a": 1}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$', 'z');
+-----+
| JSON_ARRAY_APPEND(@j, '$', 'z') |
+-----+
| [{"a": 1}, "z"] |
+-----+
    
```

- `JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)`

Updates a JSON document, inserting into an array within the document and returning the modified document. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard or does not end with an array element identifier.

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.

```

mysql> SET @j = '{"a", {"b": [1, 2]}, [3, 4]}';
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[1]', 'x') |
+-----+
| ["a", "x", {"b": [1, 2]}, [3, 4]] |
+-----+

mysql> SELECT JSON_ARRAY_INSERT(@j, '$[100]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[100]', 'x') |
+-----+
| ["a", {"b": [1, 2]}, [3, 4], "x"] |
+-----+

mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x') |
+-----+
| ["a", {"b": ["x", 1, 2]}, [3, 4]] |
+-----+

mysql> SELECT JSON_ARRAY_INSERT(@j, '$[2][1]', 'y');
+-----+
| JSON_ARRAY_INSERT(@j, '$[2][1]', 'y') |
+-----+
| ["a", {"b": [1, 2]}, [3, "y", 4]] |
+-----+

mysql> SELECT JSON_ARRAY_INSERT(@j, '$[0]', 'x', '$[2][1]', 'y');
+-----+
    
```

```
| JSON_ARRAY_INSERT(@j, '$[0]', 'x', '$[2][1]', 'y') |
+-----+
| ["x", "a", {"b": [1, 2]}, [3, 4]] |
+-----+
```

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- `JSON_INSERT(json_doc, path, val[, path, val] ...)`

Inserts data into a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path/value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path/value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path/value pair for a nonexisting path in the document is ignored and has no effect.

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

```
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 1, "b": [2, 3], "c": "[true, false]"} |
+-----+
```

- `JSON_MERGE(json_doc, json_doc[, json_doc] ...)`

Merges two or more JSON documents and returns the merged result. Returns `NULL` if any argument is `NULL`. An error occurs if any argument is not a valid JSON document.

Merging takes place according to the following rules. For additional information, see [Normalization, Merging, and Autowrapping of JSON Values](#).

- Adjacent arrays are merged to a single array.
- Adjacent objects are merged to a single object.
- A scalar value is autowrapped as an array and merged as an array.
- An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

```
mysql> SELECT JSON_MERGE('[1, 2]', '[true, false]');
+-----+
| JSON_MERGE('[1, 2]', '[true, false]') |
+-----+
| [1, 2, true, false] |
+-----+
```

```
+-----+
mysql> SELECT JSON_MERGE('{\"name\": \"x\"}', '{\"id\": 47}');
+-----+
| JSON_MERGE('{\"name\": \"x\"}', '{\"id\": 47}') |
+-----+
| {\"id\": 47, \"name\": \"x\"} |
+-----+
mysql> SELECT JSON_MERGE('1', 'true');
+-----+
| JSON_MERGE('1', 'true') |
+-----+
| [1, true] |
+-----+
mysql> SELECT JSON_MERGE('[1, 2]', '{\"id\": 47}');
+-----+
| JSON_MERGE('[1, 2]', '{\"id\": 47}') |
+-----+
| [1, 2, {\"id\": 47}] |
+-----+
```

- `JSON_REMOVE(json_doc, path[, path] ...)`

Removes data from a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the *json\_doc* argument is not a valid JSON document or any *path* argument is not a valid path expression or is `$` or contains a `*` or `**` wildcard.

The *path* arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

```
mysql> SET @j = '['a', ['b', 'c'], 'd'];
mysql> SELECT JSON_REMOVE(@j, '$[1]');
+-----+
| JSON_REMOVE(@j, '$[1]') |
+-----+
| ['a', 'd'] |
+-----+
```

- `JSON_REPLACE(json_doc, path, val[, path, val] ...)`

Replaces existing values in a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the *json\_doc* argument is not a valid JSON document or any *path* argument is not a valid path expression or contains a `*` or `**` wildcard.

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path/value pair for an existing path in the document overwrites the existing document value with the new value. A path/value pair for a nonexisting path in the document is ignored and has no effect.

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

```
mysql> SET @j = '{ \"a\": 1, \"b\": [2, 3]}';
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {\"a\": 10, \"b\": [2, 3]} |
+-----+
```

- `JSON_SET(json_doc, path, val[, path, val] ...)`

Inserts or updates data in a JSON document and returns the result. Returns `NULL` if any argument is `NULL` or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path/value pair for an existing path in the document overwrites the existing document value with the new value. A path/value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path/value pair for a nonexisting path in the document is ignored and has no effect.

The `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions are related:

- `JSON_SET()` replaces existing values and adds nonexisting values.
- `JSON_INSERT()` inserts values without replacing existing values.
- `JSON_REPLACE()` replaces *only* existing values.

The following examples illustrate these differences, using one path that does exist in the document (`$.a`) and another that does not exist (`$.c`):

```
mysql> SET @j = '{ "a": 1, "b": [2, 3] }';
mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_SET(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 10, "b": [2, 3], "c": "[true, false]"}      |
+-----+
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 1, "b": [2, 3], "c": "[true, false]"}        |
+-----+
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 10, "b": [2, 3]}                               |
+-----+
```

- `JSON_UNQUOTE(val)`

Unquotes JSON value and returns the result as a `utf8mb4` string. Returns `NULL` if the argument is `NULL`. An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in [Table 13.21, “JSON\\_UNQUOTE\(\) Special Character Escape Sequences”](#). For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These

sequences are case sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`.

**Table 13.21 JSON\_UNQUOTE() Special Character Escape Sequences**

| Escape Sequence     | Character Represented by Sequence               |
|---------------------|---|
| <code>\ "</code>    | A double quote (") character                    |
| <code>\b</code>     | A backspace character                           |
| <code>\f</code>     | A formfeed character                            |
| <code>\n</code>     | A newline (linefeed) character                  |
| <code>\r</code>     | A carriage return character                     |
| <code>\t</code>     | A tab character                                 |
| <code>\\</code>     | A backslash (\) character                       |
| <code>\uXXXX</code> | UTF-8 bytes for Unicode value <code>XXXX</code> |

Two simple examples of the use of this function are shown here:

```
mysql> SET @j = '"abc"';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----+-----+
| @j      | JSON_UNQUOTE(@j) |
+-----+-----+
| "abc"   | abc               |
+-----+-----+
mysql> SET @j = '[1, 2, 3]';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----+-----+
| @j      | JSON_UNQUOTE(@j) |
+-----+-----+
| [1, 2, 3] | [1, 2, 3]        |
+-----+-----+
```

The following set of examples shows how `JSON_UNQUOTE` handles escapes with `NO_BACKSLASH_ESCAPES` disabled and enabled:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+

mysql> SELECT JSON_UNQUOTE('"\\t\\u0032"');
+-----+
| JSON_UNQUOTE('"\\t\\u0032"') |
+-----+
| 2                             |
+-----+

mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE('"\\t\\u0032"');
+-----+
| JSON_UNQUOTE('"\\t\\u0032"') |
+-----+
| \\t\\u0032                    |
+-----+

mysql> SELECT JSON_UNQUOTE('"\\t\\u0032"');
+-----+
| JSON_UNQUOTE('"\\t\\u0032"') |
+-----+
```

```
| 2 |
+-----+
```

## 13.16.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- `JSON_DEPTH(json_doc)`

Returns the maximum depth of a JSON document. Returns `NULL` if the argument is `NULL`. An error occurs if the argument is not a valid JSON document.

An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.

```
mysql> SELECT JSON_DEPTH('{}'), JSON_DEPTH('[]'), JSON_DEPTH('true');
+-----+-----+-----+
| JSON_DEPTH('{}') | JSON_DEPTH('[]') | JSON_DEPTH('true') |
+-----+-----+-----+
| 1 | 1 | 1 |
+-----+-----+-----+
mysql> SELECT JSON_DEPTH('[10, 20]'), JSON_DEPTH('[[], {}]');
+-----+-----+
| JSON_DEPTH('[10, 20]') | JSON_DEPTH('[[], {}]') |
+-----+-----+
| 2 | 2 |
+-----+-----+
mysql> SELECT JSON_DEPTH('[10, {"a": 20}]');
+-----+
| JSON_DEPTH('[10, {"a": 20}]') |
+-----+
| 3 |
+-----+
```

- `JSON_LENGTH(json_doc[, path])`

Returns the length of JSON document, or, if a *path* argument is given, the length of the value within the document identified by the path. Returns `NULL` if any argument is `NULL` or the *path* argument does not identify a value in the document. An error occurs if the *json\_doc* argument is not a valid JSON document or the *path* argument is not a valid path expression or contains a `*` or `**` wildcard.

The length of a document is determined as follows:

- The length of a scalar is 1.
- The length of an array is the number of array elements.
- The length of an object is the number of object members.
- The length does not count the length of nested arrays or objects.

```
mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
+-----+
| JSON_LENGTH('[1, 2, {"a": 3}]') |
+-----+
| 3 |
+-----+
mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}');
+-----+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}') |
+-----+
| 2 |
+-----+
mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b');
```

```
+-----+
| JSON_LENGTH('{ "a": 1, "b": { "c": 30 } }', '$.b') |
+-----+
| 1 |
+-----+
```

- `JSON_TYPE(json_val)`

Returns a `utf8mb4` string indicating the type of a JSON value:

```
mysql> SET @j = '{"a": [10, true]}';
mysql> SELECT JSON_TYPE(@j);
+-----+
| JSON_TYPE(@j) |
+-----+
| OBJECT        |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
+-----+
| ARRAY          |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
+-----+
| INTEGER        |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
+-----+
| BOOLEAN        |
+-----+
```

`JSON_TYPE()` returns `NULL` if the argument is `NULL`:

```
mysql> SELECT JSON_TYPE(NULL);
+-----+
| JSON_TYPE(NULL) |
+-----+
| NULL            |
+-----+
```

An error occurs if the argument is not a valid JSON value:

```
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

For a non-`NULL`, non-error result, the following list describes the possible `JSON_TYPE()` return values:

- Purely JSON types:
  - `OBJECT`: JSON objects
  - `ARRAY`: JSON arrays
  - `BOOLEAN`: The JSON true and false literals
  - `NULL`: The JSON null literal
- Numeric types:

- **INTEGER**: MySQL `TINYINT`, `SMALLINT`, `MEDIUMINT` and `INT` and `BIGINT` scalars
- **DOUBLE**: MySQL `DOUBLE` `FLOAT` scalars
- **DECIMAL**: MySQL `DECIMAL` and `NUMERIC` scalars
- Temporal types:
  - **DATETIME**: MySQL `DATETIME` and `TIMESTAMP` scalars
  - **DATE**: MySQL `DATE` scalars
  - **TIME**: MySQL `TIME` scalars
- String types:
  - **STRING**: MySQL `utf8` character type scalars: `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET`
- Binary types:
  - **BLOB**: MySQL binary type scalars: `BINARY`, `VARBINARY`, `BLOB`
  - **BIT**: MySQL `BIT` scalars
- All other types:
  - **OPAQUE** (raw bits)
- `JSON_VALID(val)`

Returns 0 or 1 to indicate whether a value is a valid JSON document. Returns `NULL` if the argument is `NULL`.

```
mysql> SELECT JSON_VALID('{\"a\": 1}');
+-----+
| JSON_VALID('{\"a\": 1}') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_VALID('hello'), JSON_VALID('\"hello\"');
+-----+-----+
| JSON_VALID('hello') | JSON_VALID('\"hello\"') |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

### 13.16.6 JSON Path Syntax

Many of the functions described in previous sections require a path expression in order to identify a specific element in a JSON document. A path consists of the path's scope followed by one or more path legs. For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading `$` character. Path legs are separated by period characters (`.`). Cells in arrays are represented by `[N]`, where `N` is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see <http://www.ecma-international.org/ecma-262/5.1/#sec-7.6>). Path expressions, like JSON text, should be encoded using the `ascii`, `utf8`, or `utf8mb4` character sets. Other character encodings are implicitly coerced to `utf8mb4`. The complete syntax is shown here:

```
pathExpression:
    scope[(pathLeg)*]

pathLeg:
```

```

member | arrayLocation | doubleAsterisk

member:
    period ( keyName | asterisk )

arrayLocation:
    leftBracket ( nonNegativeInteger | asterisk ) rightBracket

keyName:
    ESIdentifier | doubleQuotedString

doubleAsterisk:
    ' ** '

period:
    ' . '

asterisk:
    ' * '

leftBracket:
    ' [ '

rightBracket:
    ' ] '

```

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as `$`. You can use `'$'` as a synonym for the document in JSON path expressions.

#### Note

Some implementations support column references for scopes of JSON paths; currently, MySQL does not support these.

The wildcard `*` and `**` tokens are used as follows:

- `.*` represents the values of all members in the object.
- `[*]` represents the values of all cells in the array.
- `[prefix]**suffix` represents all paths beginning with `prefix` and ending with `suffix`. `prefix` is optional, while `suffix` is required; in other words, a path may not end in `**`.

In addition, a path may not contain the sequence `***`.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as `JSON_CONTAINS_PATH()` and `JSON_REPLACE()`. For examples which include the use of the `*` and `**` wildcards, see the description of the `JSON_SEARCH()` function.

## 13.17 Functions Used with Global Transaction IDs

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments—as such, the GTID sets must always be quoted when used with them. See [GTID Sets](#) for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```

CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
  RETURNS TEXT DETERMINISTIC
  RETURN CONCAT(g1, ', ', g2);

```

For more information about GTIDs and how these GTID functions are used in practice, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

Table 13.22 GTID Functions

| Name   | Description  |
|--|--|
| <code>GTID_SUBSET()</code>                       | Return true if all GTIDs in subset are also in set; otherwise false. |
| <code>GTID_SUBTRACT()</code>                     | Return all GTIDs in set that are not in subset.                      |
| <code>WAIT_FOR_EXECUTED_GTID_SET()</code>        | Wait until the given GTIDs have executed on slave.                   |
| <code>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()</code> | Wait until the given GTIDs have executed on slave.                   |

- `GTID_SUBSET(subset, set)`

Given two sets of global transaction IDs *subset* and *set*, returns true if all GTIDs in *subset* are also in *set*. Returns false otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

```
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 0
1 row in set (0.00 sec)
```

- `GTID_SUBTRACT(set, subset)`

Given two sets of global transaction IDs *subset* and *set*, returns only those GTIDs from *set* that are not in *subset*.

All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:

```
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:26-57
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
```

```
'3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:21-22:25-57
1 row in set (0.01 sec)
```

- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout][, channel])`

Wait until the slave SQL thread has executed all of the transactions whose global transaction identifiers are contained in *gtid\_set* (see [Section 18.1.3.1, “GTID Concepts”](#), for a definition of “GTID sets”), or until *timeout* seconds have elapsed, whichever occurs first. *timeout* is optional; the default timeout is 0 seconds, in which case the function waits until all of the transactions in the GTID set have been executed.

For more information, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```
mysql> SELECT WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 5
```

The return value is the number of transactional events that were executed. If GTID-based replication is not active (that is, if the value of the `gtid_mode` variable is `OFF`), then this value is undefined and thus `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` returns `NULL`. If the slave is not running then this function also returns `NULL`.

The *channel* option, added in MySQL 5.7.6, enables you to choose which replication channel the function applies to. If no *channel* is set and no channels other than the default replication channel exist, the function applies to the default replication channel as found in versions of MySQL prior to 5.7.6. If you are using multiple replication channels you must specify a *channel* as otherwise it is not known which replication channel the function should act on. See [Section 18.2.3, “Replication Channels”](#) for more information on replication channels.

- `WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])`

Introduced in MySQL 5.7.5, `WAIT_FOR_EXECUTED_GTID_SET()` is similar to `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` in that it waits until a server has executed all of the transactions whose global transaction identifiers are contained in *gtid\_set*, or until *timeout* seconds have elapsed, whichever occurs first. Unlike `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`, `WAIT_FOR_EXECUTED_GTID_SET()` does not take into account whether the slave is running or not, and an error is returned if GTID-based replication is not enabled.

In addition, `WAIT_FOR_EXECUTED_GTID_SET()` returns only the state of the query, where 0 represents success, 1 represents timeout, and any other failures return the error message.

## 13.18 MySQL Enterprise Encryption Functions

### Note

MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <http://www.mysql.com/products/>.

As of MySQL 5.7.9, MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption

- Use cryptographic hashing for digital signing and data verification and validation

Enterprise Encryption supports the RSA, DSA, and DH cryptographic algorithms.

Enterprise Encryption is supplied as a user-defined function (UDF) library, from which individual functions can be installed individually.

## 13.18.1 Enterprise Encryption Installation

Enterprise Encryption functions are located in a user-defined function (UDF) library file installed in the plugin directory (the directory named by the `plugin_dir` system variable). The UDF library base name is `openssl_udf` and the suffix is platform dependent. For example, the file name on Linux or Windows is `openssl_udf.so` or `openssl_udf.dll`, respectively.

To install functions from the library file, use the `CREATE FUNCTION` statement. To load all functions from the library, use this set of statements (adjust the file name suffix as necessary):

```
CREATE FUNCTION asymmetric_decrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_derive RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_encrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_sign RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_verify RETURNS INTEGER
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_priv_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_pub_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_dh_parameters RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_digest RETURNS STRING
  SONAME 'openssl_udf.so';
```

Once installed, UDFs remain installed across server restarts. To unload UDFs, use the `DROP FUNCTION` statement. For example, to unload the key-generation functions, do this:

```
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
```

In the `CREATE FUNCTION` and `DROP FUNCTION` statements, the function names must be specified in lowercase. This differs from their use at function invocation time, for which you can use any lettercase.

The `CREATE FUNCTION` and `DROP FUNCTION` statements require the `INSERT` and `DROP` privilege, respectively, for the `mysql` database.

## 13.18.2 Enterprise Encryption Usage and Examples

To use Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks:

- [Create a private/public key pair using RSA encryption](#)
- [Use the private key to encrypt data and the public key to decrypt it](#)
- [Generate a digest from a string](#)
- [Use the digest with a key pair](#)
- [Create a symmetric key](#)

- [Limit CPU usage by key-generation operations](#)

## Create a private/public key pair using RSA encryption

```
-- Encryption algorithm; can be 'DSA' or 'DH' instead
SET @algo = 'RSA';
-- Key length in bits; make larger for stronger keys
SET @key_len = 1024;

-- Create private key
SET @priv = CREATEASYMMETRICPRIVKEY(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = CREATEASYMMETRICPUBKEY(@algo, @priv);
```

Now you can use the key pair to encrypt and decrypt data, sign and verify data, or generate symmetric keys.

## Use the private key to encrypt data and the public key to decrypt it

This requires that the members of the key pair be RSA keys.

```
SET @ciphertext = ASYMMETRICENCRYPT(@algo, 'My secret text', @priv);
SET @cleartext = ASYMMETRICDECRYPT(@algo, @ciphertext, @pub);
```

Conversely, you can encrypt using the public key and decrypt using the private key.

```
SET @ciphertext = ASYMMETRICENCRYPT(@algo, 'My secret text', @pub);
SET @cleartext = ASYMMETRICDECRYPT(@algo, @ciphertext, @priv);
```

In either case, the algorithm specified for the encryption and decryption functions must match that used to generate the keys.

## Generate a digest from a string

```
-- Digest type; can be 'SHA256', 'SHA384', or 'SHA512' instead
SET @dig_type = 'SHA224';

-- Generate digest string
SET @dig = CREATEDIGEST(@dig_type, 'My text to digest');
```

## Use the digest with a key pair

The key pair can be used to sign data, then verify that the signature matches the digest.

```
-- Encryption algorithm; could be 'DSA' instead; keys must
-- have been created using same algorithm
SET @algo = 'RSA';

-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRICSIGN(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = ASYMMETRICVERIFY(@algo, @dig, @sig, @pub, @dig_type);
```

## Create a symmetric key

This requires DH private/public keys as inputs, created using a shared symmetric secret. Create the secret by passing the key length to [CREATE\\_DH\\_PARAMETERS\(\)](#), then pass the secret as the “key length” to [CREATEASYMMETRICPRIVKEY\(\)](#).

```
-- Generate DH shared symmetric secret
```

```

SET @dhp = CREATE_DH_PARAMETERS(1024);
-- Generate DH key pairs
SET @algo = 'DH';
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub1 = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv1);
SET @priv2 = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub2 = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv2);

-- Generate symmetric key using public key of first party,
-- private key of second party
SET @sym1 = ASYMMETRIC_DERIVE(@pub1, @priv2);

-- Or use public key of second party, private key of first party
SET @sym2 = ASYMMETRIC_DERIVE(@pub2, @priv1);

```

Key string values can be created at runtime and stored into a variable or table using [SET](#), [SELECT](#), or [INSERT](#):

```

SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SELECT CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024) INTO @priv2;
INSERT INTO t (key_col) VALUES(CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024));

```

Key string values stored in files can be read using the [LOAD\\_FILE\(\)](#) function by users who have the [FILE](#) privilege.

Digest and signature strings can be handled similarly.

## Limit CPU usage by key-generation operations

The [CREATE\\_ASYMMETRIC\\_PRIV\\_KEY\(\)](#) and [CREATE\\_DH\\_PARAMETERS\(\)](#) encryption functions take a key-length parameter, and the amount of CPU resources required by these functions increases as the key length increases. For some installations, this might result in unacceptable CPU usage if applications frequently generate excessively long keys.

OpenSSL imposes a minimum key length of 1,024 bits for all keys. OpenSSL also imposes a maximum key length of 10,000 bits and 16,384 bits for DSA and RSA keys, respectively, for [CREATE\\_ASYMMETRIC\\_PRIV\\_KEY\(\)](#), and a maximum key length of 10,000 bits for [CREATE\\_DH\\_PARAMETERS\(\)](#). If those maximum values are too high, three environment variables are available as of MySQL 5.7.17 to enable MySQL server administrators to set lower maximum lengths for key generation, and thereby to limit CPU usage:

- [MYSQL\\_OPENSSL\\_UDF\\_DSA\\_BITS\\_THRESHOLD](#): Maximum DSA key length in bits for [CREATE\\_ASYMMETRIC\\_PRIV\\_KEY\(\)](#). The minimum and maximum values for this variable are 1,024 and 10,000.
- [MYSQL\\_OPENSSL\\_UDF\\_RSA\\_BITS\\_THRESHOLD](#): Maximum RSA key length in bits for [CREATE\\_ASYMMETRIC\\_PRIV\\_KEY\(\)](#). The minimum and maximum values for this variable are 1,024 and 16,384.
- [MYSQL\\_OPENSSL\\_UDF\\_DH\\_BITS\\_THRESHOLD](#): Maximum key length in bits for [CREATE\\_DH\\_PARAMETERS\(\)](#). The minimum and maximum values for this variable are 1,024 and 10,000.

To use any of these environment variables, set them in the environment of the process that starts the server. If set, their values take precedence over the maximum key lengths imposed by OpenSSL. For example, to set a maximum key length of 4,096 bits for DSA and RSA keys for [CREATE\\_ASYMMETRIC\\_PRIV\\_KEY\(\)](#), set these variables:

```

export MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD=4096
export MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD=4096

```

The example uses Bourne shell syntax. The syntax for other shells may differ.

### 13.18.3 Enterprise Encryption Function Reference

**Table 13.23 MySQL Enterprise Encryption Functions**

| Name   | Description                                    |
|--|--|
| <a href="#">ASYMMETRIC_DECRYPT()</a>         | Decrypt ciphertext using private or public key |
| <a href="#">ASYMMETRIC_DERIVE()</a>          | Derive symmetric key from asymmetric keys      |
| <a href="#">ASYMMETRIC_ENCRYPT()</a>         | Encrypt cleartext using private or public key  |
| <a href="#">ASYMMETRIC_SIGN()</a>            | Generate signature from digest                 |
| <a href="#">ASYMMETRIC_VERIFY()</a>          | Verify that signature matches digest           |
| <a href="#">CREATE_ASYMMETRIC_PRIV_KEY()</a> | Create private key                             |

| <a href="#">CREATE_DH_PARAMETERS()</a>       | Generate shared DH secret                      |
| <a href="#">CREATE_DIGEST()</a>              | Generate digest from string                    |

### 13.18.4 Enterprise Encryption Function Descriptions

Enterprise Encryption functions have these general characteristics:

- For arguments of the wrong type or an incorrect number of arguments, each function returns an error.
- If the arguments are not suitable to permit a function to perform the requested operation, it returns [NULL](#) or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key. (OpenSSL imposes its own key-length limits, and server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 13.18.2, “Enterprise Encryption Usage and Examples”](#).)
- The underlying SSL library takes care of randomness initialization.

Several of the functions take an encryption algorithm argument. The following table summarizes the supported algorithms by function.

**Table 13.24 Supported Algorithms by Function**

| Function                                     | Supported Algorithms |
|--|----------------------|
| <a href="#">ASYMMETRIC_DECRYPT()</a>         | RSA                  |
| <a href="#">ASYMMETRIC_DERIVE()</a>          | DH                   |
| <a href="#">ASYMMETRIC_ENCRYPT()</a>         | RSA                  |
| <a href="#">ASYMMETRIC_SIGN()</a>            | RSA, DSA             |
| <a href="#">ASYMMETRIC_VERIFY()</a>          | RSA, DSA             |
| <a href="#">CREATE_ASYMMETRIC_PRIV_KEY()</a> | RSA, DSA, DH         |
| <a href="#">CREATE_ASYMMETRIC_PUB_KEY()</a>  | RSA, DSA, DH         |
| <a href="#">CREATE_DH_PARAMETERS()</a>       | DH                   |

#### Note

Although you can create keys using any of the RSA, DSA, or DH encryption algorithms, other functions that take key arguments might accept only certain types of keys. For example, [ASYMMETRIC\\_ENCRYPT\(\)](#) and [ASYMMETRIC\\_DECRYPT\(\)](#) accept only RSA keys.

The following descriptions describe the calling sequences for Enterprise Encryption functions. For additional examples and discussion, see [Section 13.18.2, “Enterprise Encryption Usage and Examples”](#).

- `ASYMMETRIC_DECRYPT(algorithm, crypt_str, key_str)`

Decrypts an encrypted string using the given algorithm and key string, and returns the resulting cleartext as a binary string. If decryption fails, the result is `NULL`.

*key\_str* must be a valid key string in PEM format. For successful decryption, it must be the public or private key string corresponding to the private or public key string used with `ASYMMETRIC_ENCRYPT()` to produce the encrypted string. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: `'RSA'`

For a usage example, see the description of `ASYMMETRIC_ENCRYPT()`.

- `ASYMMETRIC_DERIVE(pub_key_str, priv_key_str)`

Derives a symmetric key using the private key of one party and the public key of another, and returns the resulting key as a binary string. If key derivation fails, the result is `NULL`.

*pub\_key\_str* and *priv\_key\_str* must be valid key strings in PEM format. They must be created using the DH algorithm.

Suppose that you have two pairs of public and private keys:

```
SET @dhp = CREATE_DH_PARAMETERS(1024);
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub1 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv1);
SET @priv2 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub2 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv2);
```

Suppose further that you use the private key from one pair and the public key from the other pair to create a symmetric key string. Then this symmetric key identity relationship holds:

```
ASYMMETRIC_DERIVE(@pub1, @priv2) = ASYMMETRIC_DERIVE(@pub2, @priv1)
```

- `ASYMMETRIC_ENCRYPT(algorithm, str, key_str)`

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is `NULL`.

The *str* length cannot be greater than the *key\_str* length – 11, in bytes

*key\_str* must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: `'RSA'`

To encrypt a string, pass a private or public key string to `ASYMMETRIC_ENCRYPT()`. To recover the original unencrypted string, pass the encrypted string to `ASYMMETRIC_DECRYPT()`, along with the public or private key string corresponding to the private or public key string used for encryption.

```
-- Generate private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('RSA', @priv);

-- Encrypt using private key, decrypt using public key
SET @ciphertext = ASYMMETRIC_ENCRYPT('RSA', 'The quick brown fox', @priv);
SET @cleartext = ASYMMETRIC_DECRYPT('RSA', @ciphertext, @pub);
```

```
-- Encrypt using public key, decrypt using private key
SET @ciphertext = ASYMMETRIC_ENCRYPT('RSA', 'The quick brown fox', @pub);
SET @cleartext = ASYMMETRIC_DECRYPT('RSA', @ciphertext, @priv);
```

Suppose that:

```
SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format
```

Then these identity relationships hold:

```
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @priv), @pub) = @s
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @pub), @priv) = @s
```

- `ASYMMETRIC_SIGN(algorithm, digest_str, priv_key_str, digest_type)`

Signs a digest string using a private key string, and returns the signature as a binary string. If signing fails, the result is `NULL`.

*digest\_str* is the digest string. It can be generated by calling `CREATE_DIGEST()`. *digest\_type* indicates the digest algorithm used to generate the digest string.

*priv\_key\_str* is the private key string to use for signing the digest string. It must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA', 'DSA'

Supported *digest\_type* values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

For a usage example, see the description of `ASYMMETRIC_VERIFY()`.

- `ASYMMETRIC_VERIFY(algorithm, digest_str, sig_str, pub_key_str, digest_type)`

Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed.

*digest\_str* is the digest string. It can be generated by calling `CREATE_DIGEST()`. *digest\_type* indicates the digest algorithm used to generate the digest string.

*sig\_str* is the signature string. It can be generated by calling `ASYMMETRIC_SIGN()`.

*pub\_key\_str* is the public key string of the signer. It corresponds to the private key passed to `ASYMMETRIC_SIGN()` to generate the signature string and must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA', 'DSA'

Supported *digest\_type* values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
-- Set the encryption algorithm and digest type
SET @algo = 'RSA';
SET @dig_type = 'SHA224';

-- Create private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY(@algo, 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv);

-- Generate digest from string
SET @dig = CREATE_DIGEST(@dig_type, 'The quick brown fox');
```

```
-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRIC_SIGN(@algo, @dig, @priv, @dig_type);
SET @verf = ASYMMETRIC_VERIFY(@algo, @dig, @sig, @pub, @dig_type);
```

- `CREATE_ASYMMETRIC_PRIV_KEY(algorithm, {key_len|dh_secret})`

Creates a private key using the given algorithm and key length or DH secret, and returns the key as a binary string in PEM format. If key generation fails, the result is `NULL`.

Supported *algorithm* values: 'RSA', 'DSA', 'DH'

Supported *key\_len* values: The minimum key length in bits is 1,024. The maximum key length depends on the algorithm: 16,384 for RSA and 10,000 for DSA. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 13.18.2, “Enterprise Encryption Usage and Examples”](#).

For DH keys, pass a shared DH secret instead of a key length. To create the secret, pass the key length to `CREATE_DH_PARAMETERS()`.

This example creates a 2,048-bit DSA private key, then derives a public key from the private key:

```
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('DSA', 2048);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('DSA', @priv);
```

For an example showing DH key generation, see the description of `ASYMMETRIC_DERIVE()`.

Some general considerations in choosing key lengths and encryption algorithms:

- The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.
- Generation of DH keys takes much longer than RSA or RSA keys.
- Asymmetric encryption functions are slower than symmetric functions. If performance is an important factor and the functions are to be used very frequently, you are better off using symmetric encryption. For example, consider using `AES_ENCRYPT()` and `AES_DECRYPT()`.
- `CREATE_ASYMMETRIC_PUB_KEY(algorithm, priv_key_str)`

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. If key derivation fails, the result is `NULL`.

*priv\_key\_str* must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA', 'DSA', 'DH'

For a usage example, see the description of `CREATE_ASYMMETRIC_PRIV_KEY()`.

- `CREATE_DH_PARAMETERS(key_len)`

Creates a shared secret for generating a DH private/public key pair and returns a binary string that can be passed to `CREATE_ASYMMETRIC_PRIV_KEY()`. If secret generation fails, the result is null.

Supported *key\_len* values: The minimum and maximum key lengths in bits are 1,024 and 10,000. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See [Section 13.18.2, “Enterprise Encryption Usage and Examples”](#).

For an example showing how to use the return value for generating symmetric keys, see the description of `ASYMMETRIC_DERIVE()`.

```
SET @dhp = CREATE_DH_PARAMETERS(1024);
```

- `CREATE_DIGEST(digest_type, str)`

Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is `NULL`.

Supported *digest\_type* values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
SET @dig = CREATE_DIGEST('SHA512', 'The quick brown fox');
```

The resulting digest string is suitable for use with `ASYMMETRIC_SIGN()` and `ASYMMETRIC_VERIFY()`.

## 13.19 Aggregate (GROUP BY) Functions

### 13.19.1 Aggregate (GROUP BY) Function Descriptions

Table 13.25 Aggregate (GROUP BY) Functions

| Name                         | Description                                      |
|------------------------------|--|
| <code>AVG()</code>           | Return the average value of the argument         |
| <code>BIT_AND()</code>       | Return bitwise AND                               |
| <code>BIT_OR()</code>        | Return bitwise OR                                |
| <code>BIT_XOR()</code>       | Return bitwise XOR                               |
| <code>COUNT()</code>         | Return a count of the number of rows returned    |
| <code>COUNT(DISTINCT)</code> | Return the count of a number of different values |
| <code>GROUP_CONCAT()</code>  | Return a concatenated string                     |
| <code>MAX()</code>           | Return the maximum value                         |
| <code>MIN()</code>           | Return the minimum value                         |
| <code>STD()</code>           | Return the population standard deviation         |
| <code>STDDEV()</code>        | Return the population standard deviation         |
| <code>STDDEV_POP()</code>    | Return the population standard deviation         |
| <code>STDDEV_SAMP()</code>   | Return the sample standard deviation             |
| <code>SUM()</code>           | Return the sum                                   |
| <code>VAR_POP()</code>       | Return the population standard variance          |
| <code>VAR_SAMP()</code>      | Return the sample variance                       |
| <code>VARIANCE()</code>      | Return the population standard variance          |

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore `NULL` values.

If you use a group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows. For more information, see [Section 13.19.3, “MySQL Handling of GROUP BY”](#).

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The `SUM()` and `AVG()` functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem,

convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;  
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions perform bit operations. They require `BIGINT` (64-bit integer) arguments and return `BIGINT` values. Arguments of other types are converted to `BIGINT` and truncation might occur. For information about a change in MySQL 8.0 that permits bit operations to take binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types), see [Section 13.12, “Bit Functions and Operators”](#).

- `AVG([DISTINCT] expr)`

Returns the average value of *expr*. The `DISTINCT` option can be used to return the average of the distinct values of *expr*.

If there are no matching rows, `AVG()` returns `NULL`.

```
mysql> SELECT student_name, AVG(test_score)  
->      FROM student  
->      GROUP BY student_name;
```

- `BIT_AND(expr)`

Returns the bitwise `AND` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

If there are no matching rows, `BIT_AND()` returns a neutral value (all bits set to 1).

- `BIT_OR(expr)`

Returns the bitwise `OR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

If there are no matching rows, `BIT_OR()` returns a neutral value (all bits set to 0).

- `BIT_XOR(expr)`

Returns the bitwise `XOR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

If there are no matching rows, `BIT_XOR()` returns a neutral value (all bits set to 0).

- `COUNT(expr)`

Returns a count of the number of non-`NULL` values of *expr* in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

If there are no matching rows, `COUNT()` returns 0.

```
mysql> SELECT student.student_name, COUNT(*)  
->      FROM student, course  
->      WHERE student.student_id=course.student_id  
->      GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

For [MyISAM](#) tables, `COUNT( *)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to [MyISAM](#) tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as `NOT NULL`.

For transactional storage engines such as [InnoDB](#), storing an exact row count is problematic because multiple transactions may be occurring, each of which may affect the count. For more information about how [InnoDB](#) handles `COUNT( *)` operations, see [Section 15.8.8, “Limits on InnoDB Tables”](#).

- `COUNT(DISTINCT expr, [expr...])`

Returns a count of the number of rows with different non-`NULL` *expr* values.

If there are no matching rows, `COUNT(DISTINCT)` returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

This function returns a string result with the concatenated non-`NULL` values from a group. It returns `NULL` if there are no non-`NULL` values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
               [ASC | DESC] [,col_name ...])
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
->        GROUP_CONCAT(test_score)
->        FROM student
->        GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
->        GROUP_CONCAT(DISTINCT test_score
->                      ORDER BY test_score DESC SEPARATOR ' ')
->        FROM student
->        GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the `DISTINCT` clause. To sort values in the result, use the `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use `SEPARATOR` followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify `SEPARATOR ''`.

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective

maximum length of the return value is constrained by the value of `max_allowed_packet`. The syntax to change the value of `group_concat_max_len` at runtime is as follows, where `val` is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

See also `CONCAT ( )` and `CONCAT_WS ( )`: [Section 13.5, “String Functions”](#).

- `MAX([DISTINCT] expr)`

Returns the maximum value of *expr*. `MAX ( )` may take a string argument; in such cases, it returns the maximum string value. See [Section 9.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MAX ( )` returns `NULL`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
->      FROM student
->      GROUP BY student_name;
```

For `MAX ( )`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `MIN([DISTINCT] expr)`

Returns the minimum value of *expr*. `MIN ( )` may take a string argument; in such cases, it returns the minimum string value. See [Section 9.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MIN ( )` returns `NULL`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
->      FROM student
->      GROUP BY student_name;
```

For `MIN ( )`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `STD(expr)`

Returns the population standard deviation of *expr*. This is an extension to standard SQL. The standard SQL function `STDDEV_POP ( )` can be used instead.

If there are no matching rows, `STD ( )` returns `NULL`.

- `STDDEV(expr)`

Returns the population standard deviation of *expr*. This function is provided for compatibility with Oracle. The standard SQL function `STDDEV_POP ( )` can be used instead.

If there are no matching rows, `STDDEV ( )` returns `NULL`.

- `STDDEV_POP(expr)`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

If there are no matching rows, `STDDEV_POP()` returns `NULL`.

- `STDDEV_SAMP(expr)`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`).

If there are no matching rows, `STDDEV_SAMP()` returns `NULL`.

- `SUM([DISTINCT] expr)`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of *expr*.

If there are no matching rows, `SUM()` returns `NULL`.

- `VAR_POP(expr)`

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

If there are no matching rows, `VAR_POP()` returns `NULL`.

- `VAR_SAMP(expr)`

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

If there are no matching rows, `VAR_SAMP()` returns `NULL`.

- `VARIANCE(expr)`

Returns the population standard variance of *expr*. This is an extension to standard SQL. The standard SQL function `VAR_POP()` can be used instead.

If there are no matching rows, `VARIANCE()` returns `NULL`.

## 13.19.2 GROUP BY Modifiers

The `GROUP BY` clause permits a `WITH ROLLUP` modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. `ROLLUP` thus enables you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a table named `sales` has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
  year      INT NOT NULL,
  country   VARCHAR(20) NOT NULL,
  product   VARCHAR(32) NOT NULL,
  profit    INT
);
```

The table's contents can be summarized per year with a simple `GROUP BY` like this:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
+-----+-----+
| year | SUM(profit) |
```

|      |      |
|------|------|
| 2000 | 4525 |
| 2001 | 3010 |

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
```

| year | SUM(profit) |
|------|-------------|
| 2000 | 4525        |
| 2001 | 3010        |
| NULL | 7535        |

The grand total super-aggregate line is identified by the value `NULL` in the `year` column.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a “break” (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary on the `sales` table based on `year`, `country`, and `product` might look like this:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product;
```

| year | country | product    | SUM(profit) |
|------|---------|------------|-------------|
| 2000 | Finland | Computer   | 1500        |
| 2000 | Finland | Phone      | 100         |
| 2000 | India   | Calculator | 150         |
| 2000 | India   | Computer   | 1200        |
| 2000 | USA     | Calculator | 75          |
| 2000 | USA     | Computer   | 1500        |
| 2001 | Finland | Phone      | 10          |
| 2001 | USA     | Calculator | 50          |
| 2001 | USA     | Computer   | 2700        |
| 2001 | USA     | TV         | 250         |

The output indicates summary values only at the year/country/product level of analysis. When `ROLLUP` is added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP;
```

| year | country | product    | SUM(profit) |
|------|---------|------------|-------------|
| 2000 | Finland | Computer   | 1500        |
| 2000 | Finland | Phone      | 100         |
| 2000 | Finland | NULL       | 1600        |
| 2000 | India   | Calculator | 150         |
| 2000 | India   | Computer   | 1200        |
| 2000 | India   | NULL       | 1350        |
| 2000 | USA     | Calculator | 75          |
| 2000 | USA     | Computer   | 1500        |
| 2000 | USA     | NULL       | 1575        |
| 2000 | NULL    | NULL       | 4525        |

|      |         |            |      |
|------|---------|------------|------|
| 2001 | Finland | Phone      | 10   |
| 2001 | Finland | NULL       | 10   |
| 2001 | USA     | Calculator | 50   |
| 2001 | USA     | Computer   | 2700 |
| 2001 | USA     | TV         | 250  |
| 2001 | USA     | NULL       | 3000 |
| 2001 | NULL    | NULL       | 3010 |
| NULL | NULL    | NULL       | 7535 |

For this query, adding `ROLLUP` causes the output to include summary information at four levels of analysis, not just one. Here is how to interpret the `ROLLUP` output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.
- Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

## Other Considerations When using ROLLUP

The following items list some behaviors specific to the MySQL implementation of `ROLLUP`.

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive. However, you still have some control over sort order. `GROUP BY` in MySQL implicitly sorts results, and you can use explicit `ASC` and `DESC` keywords with columns named in the `GROUP BY` list to specify sort order for individual columns. (The higher-level summary rows added by `ROLLUP` still appear after the rows from which they are calculated, regardless of the sort order.)

Implicit `GROUP BY` sorting in MySQL 5.7 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. You can work around the restriction that prevents using `ROLLUP` with `ORDER BY` by placing the `ROLLUP` clause within a subquery. For example:

```
mysql> SELECT * FROM (SELECT year, country, SUM(profit) FROM sales GROUP BY year WITH ROLLUP)
-> derived_t1 ORDER BY year;
```

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP
-> LIMIT 5;
```

|      |         |            |      |
|------|---------|------------|------|
| 2000 | Finland | Computer   | 1500 |
| 2000 | Finland | Phone      | 100  |
| 2000 | Finland | NULL       | 1600 |
| 2000 | India   | Calculator | 150  |
| 2000 | India   | Computer   | 1200 |

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has

changed value. For any column in the result set with a name that matches any of those names, its value is set to `NULL`. (If you specify grouping columns by column number, the server identifies which columns to set to `NULL` by number.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as `NULL` values within the query itself. For example, you cannot add `HAVING product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface.

MySQL permits a column that does not appear in the `GROUP BY` list to be named in the select list. In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are indeterminate:

```
mysql> SELECT year, country, SUM(profit)
      -> FROM sales GROUP BY year WITH ROLLUP;
```

| year | country | SUM(profit) |
|------|---------|-------------|
| 2000 | India   | 4525        |
| 2001 | USA     | 3010        |
| NULL | USA     | 7535        |

This behavior occurs if the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. For more information about nonaggregated columns and `GROUP BY`, see [Section 13.19.3, “MySQL Handling of GROUP BY”](#).

### 13.19.3 MySQL Handling of GROUP BY

SQL92 and earlier does not permit queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on (uniquely determined by) `GROUP BY` columns. For example, this query is illegal in standard SQL92 because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
  FROM orders AS o, customers AS c
 WHERE o.custid = c.custid
  GROUP BY o.custid;
```

For the query to be legal in SQL92, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

SQL99 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on `GROUP BY` columns: If such a relationship exists between `name` and `custid`, the query is legal. This would be the case, for example, were `custid` a primary key of `customers`.

MySQL 5.7.5 and up implements detection of functional dependence. If the `ONLY_FULL_GROUP_BY` SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on them. (Before 5.7.5, MySQL does not detect functional dependency and `ONLY_FULL_GROUP_BY` is not enabled by default. For a description of pre-5.7.5 behavior, see the [MySQL 5.6 Reference Manual](#).)

If `ONLY_FULL_GROUP_BY` is disabled, a MySQL extension to the standard SQL use of `GROUP BY` permits the select list, `HAVING` condition, or `ORDER BY` list to refer to nonaggregated columns even if

the columns are not functionally dependent on `GROUP BY` columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are indeterminate, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an `ORDER BY` clause. Result set sorting occurs after values have been chosen, and `ORDER BY` does not affect which value within each group the server chooses. Disabling `ONLY_FULL_GROUP_BY` is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the `GROUP BY` are the same for each group.

You can achieve the same effect without disabling `ONLY_FULL_GROUP_BY` by using `ANY_VALUE()` to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with `ONLY_FULL_GROUP_BY` enabled because the nonaggregated `address` column in the select list is not named in the `GROUP BY` clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if `name` is a primary key of `t` or is a unique `NOT NULL` column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if `name` is a primary key, its value determines the value of `address` because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of `address` value in a group and no need to reject the query.

The query is invalid if `name` is not a primary key of `t` or a unique `NOT NULL` column. In this case, no functional dependency can be inferred and an error occurs:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

If you know that, *for a given data set*, each `name` value in fact uniquely determines the `address` value, `address` is effectively functionally dependent on `name`. To tell MySQL to accept the query, you can use the `ANY_VALUE()` function:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable `ONLY_FULL_GROUP_BY`.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see [Section 13.19.4, “Detection of Functional Dependence”](#).

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, `HAVING` condition, or `ORDER BY` list with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is indeterminate which `name` value to choose for the group. Here, too, `ANY_VALUE()` can be used, if it is immaterial which `name` value MySQL chooses:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

In MySQL 5.7.5 and higher, `ONLY_FULL_GROUP_BY` also affects handling of queries that use `DISTINCT` and `ORDER BY`. Consider the case of a table `t` with three columns `c1`, `c2`, and `c3` that contains these rows:

```
c1 c2 c3
1  2  A
3  4  B
1  2  C
```

Suppose that we execute the following query, expecting the results to be ordered by `c3`:

```
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of `c3`, which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has `DISTINCT` and `ORDER BY` is rejected as invalid if any `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query's selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. For example, the following query returns `name` values that occur only once in table `orders`:

```
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

#### Note

Before MySQL 5.7.5, enabling `ONLY_FULL_GROUP_BY` disables this extension, thus requiring the `HAVING` clause to be written using unaliased expressions.

Standard SQL does not permit expressions in `GROUP BY` clauses, so a statement such as this is invalid:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

### 13.19.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

```
{X} -> {Y}
```

Understand this as “*X* uniquely determines *Y*,” which also means that *Y* is functionally dependent on *X*.

The examples use the [world](#) database, which can be downloaded from the [MySQL Documentation page](#). You can find details on how to install the database on the same page.

#### Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

```
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
WHERE cl.CountryCode = co.Code
GROUP BY co.Code;
```

`co.Code` is a primary key of `co`, so all columns of `co` are functionally dependent on it, as expressed using this notation:

```
{co.Code} -> {co.*}
```

Thus, `co.name` is functionally dependent on `GROUP BY` columns and the query is valid.

A **UNIQUE** index over a **NOT NULL** column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a **UNIQUE** index that permits **NULL** values because it permits multiple **NULL** values and in that case uniqueness is lost.)

#### Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
WHERE cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

The pair (`cl.CountryCode`, `cl.Language`) is a two-column composite primary key of `cl`, so that column pair uniquely determines all columns of `cl`:

```
{cl.CountryCode, cl.Language} -> {cl.*}
```

Moreover, because of the equality in the `WHERE` clause:

```
{cl.CountryCode} -> {co.Code}
```

And, because `co.Code` is primary key of `co`:

```
{co.Code} -> {co.*}
```

“Uniquely determines” relationships are transitive, therefore:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

As a result, the query is valid.

As with the previous example, a `UNIQUE` key over `NOT NULL` columns could be used instead of a primary key.

An `INNER JOIN` condition can be used instead of `WHERE`. The same functional dependencies apply:

```
SELECT co.Name, cl.Language,
       cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl INNER JOIN country co
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

## Functional Dependency Special Cases

Whereas an equality test in a `WHERE` condition or `INNER JOIN` condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `countrylanguage` without a corresponding row in `country`. Consider the same query as in the previous example, but with a `LEFT JOIN`:

```
SELECT co.Name, cl.Language,
       cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl LEFT JOIN country co
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is `NULL`-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

```
{cl.CountryCode} -> {co.Code}
```

`cl.CountryCode` is itself functionally dependent on `{cl.CountryCode, cl.Language}` which is a primary key.

If in the join result `co.Code` is `NULL`-complemented, `co.Name` is as well. If `co.Code` is not `NULL`-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

```
{co.Code} -> {co.Name}
```

Which yields:

```
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```
SELECT co.Name, cl.Language,
       cl.Percentage * co.Population/100.0 AS SpokenBy
FROM country co LEFT JOIN countrylanguage cl
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does *not* apply:

```
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

Indeed, all `NULL`-complemented rows made for `cl` will be put into a single group (they have both `GROUP BY` columns equal to `NULL`), and inside this group the value of `co.Name` can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the `LEFT JOIN`. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

## Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```
CREATE VIEW country2 AS
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
ON cl.CountryCode = co.Code
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;
```

This definition is valid because:

```
{co.Code} -> {co.*}
```

In the view result, the first selected column is `co.Code`, which is also the group column and thus determines all other selected expressions:

```
{country2.Code} -> {country2.*}
```

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the `city` table:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM country2 AS co2 JOIN city ci
ON ci.CountryCode = co2.Code
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

```
{co2.Code} -> {co2.*}
```

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if `country2` were a derived table, as in:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
(
  SELECT co.Code, UPPER(co.Name) AS UpperName,
  COUNT(cl.Language) AS OfficialLanguages
  FROM country AS co JOIN countrylanguage AS cl
  ON cl.CountryCode=co.Code
  WHERE cl.isOfficial='T'
  GROUP BY co.Code
) AS co2
JOIN City ci ON ci.CountryCode = co2.Code
GROUP BY co2.Code;
```

## Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

## 13.20 Miscellaneous Functions

Table 13.26 Miscellaneous Functions

| Name                             | Description   |
|----------------------------------|---|
| <code>ANY_VALUE()</code>         | Suppress <code>ONLY_FULL_GROUP_BY</code> value rejection                            |
| <code>DEFAULT()</code>           | Return the default value for a table column   |
| <code>GET_LOCK()</code>          | Get a named lock  |
| <code>INET_ATON()</code>         | Return the numeric value of an IP address   |
| <code>INET_NTOA()</code>         | Return the IP address from a numeric value  |
| <code>INET6_ATON()</code>        | Return the numeric value of an IPv6 address   |
| <code>INET6_NTOA()</code>        | Return the IPv6 address from a numeric value  |
| <code>IS_FREE_LOCK()</code>      | Whether the named lock is free  |
| <code>IS_IPV4()</code>           | Whether argument is an IPv4 address   |
| <code>IS_IPV4_COMPAT()</code>    | Whether argument is an IPv4-compatible address                                      |
| <code>IS_IPV4_MAPPED()</code>    | Whether argument is an IPv4-mapped address  |
| <code>IS_IPV6()</code>           | Whether argument is an IPv6 address   |
| <code>IS_USED_LOCK()</code>      | Whether the named lock is in use; return connection identifier if true              |
| <code>MASTER_POS_WAIT()</code>   | Block until the slave has read and applied all updates up to the specified position |
| <code>NAME_CONST()</code>        | Causes the column to have the given name  |
| <code>RAND()</code>              | Return a random floating-point value  |
| <code>RELEASE_ALL_LOCKS()</code> | Releases all current named locks  |
| <code>RELEASE_LOCK()</code>      | Releases the named lock   |
| <code>SLEEP()</code>             | Sleep for a number of seconds   |
| <code>UUID()</code>              | Return a Universal Unique Identifier (UUID)   |
| <code>UUID_SHORT()</code>        | Return an integer-valued universal identifier                                       |
| <code>VALUES()</code>            | Defines the values to be used during an INSERT                                      |

- `ANY_VALUE(arg)`

This function is useful for `GROUP BY` queries when the `ONLY_FULL_GROUP_BY` SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the `ONLY_FULL_GROUP_BY` SQL mode.

For example, if `name` is a nonindexed column, the following query fails with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

The failure occurs because `address` is a nonaggregated column that is neither named among `GROUP BY` columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique `NOT NULL` column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if `NULL` must be permitted as a valid `name` value.)
- Use `ANY_VALUE()` to refer to `address`:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

- Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

```
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is indeterminate which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see [Section 13.19.3, “MySQL Handling of GROUP BY”](#).

- `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X,D)`

Formats the number *x* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 13.5, “String Functions”](#).

- `GET_LOCK(str,timeout)`

Tries to obtain a lock with a name given by the string *str*, using a timeout of *timeout* seconds. A negative *timeout* value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Lock release may also occur with another call to `GET_LOCK()`:

- Before 5.7.5, only a single simultaneous lock can be acquired and `GET_LOCK()` releases any existing lock.
- In MySQL 5.7.5, `GET_LOCK()` was reimplemented using the metadata locking (MDL) subsystem and its capabilities were extended. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

As a result of the MDL reimplementation, locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER_LEVEL_LOCK` and the `OBJECT_NAME` column indicates the lock name. Also, the capability of acquiring multiple locks introduces the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

The difference in lock acquisition behavior as of MySQL 5.7.5 can be seen by the following example. Suppose that you execute these statements:

```
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

In MySQL 5.7.5 or later, the second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return `1` (success). Before MySQL 5.7.5, the second `GET_LOCK()` releases the first lock ('lock1') and the second `RELEASE_LOCK()` returns `NULL` (failure) because there is no 'lock1' to release.

MySQL 5.7.5 and later enforces a maximum length on lock names of 64 characters. Previously, no limit was enforced.

Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

### Caution

With the capability of acquiring multiple named locks in MySQL 5.7.5, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure will still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent will not be satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of user-defined functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see [Section 27.3.1](#), “The Locking Service”.

- `INET_ATON(expr)`

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as  $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$ .

`INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as `'127.1'` as a representation of `'127.0.0.1'`). Because of this, `INET_ATON()` should not be used for such addresses.

### Note

To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 12.2.6](#), “Out-of-Range and Overflow Handling”.

- `INET_NTOA(expr)`

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a nonbinary string in the connection character set. `INET_NTOA()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- `INET6_ATON(expr)`

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the `VARBINARY` data type: `VARBINARY(16)` for IPv6 addresses and `VARBINARY(4)` for IPv4 addresses. If the argument is not a valid address, `INET6_ATON()` returns `NULL`.

The following examples use `HEX()` to display the `INET6_ATON()` result in printable form:

```
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE0000000000005A55CAFFFEFA9089'
mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

`INET6_ATON()` observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `192.168.1.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `192.168.1` are rejected. A trailing port number is not permitted, as in `192.168.1.2:8080`. Hexadecimal numbers in address components are not permitted, as in `192.0xa0.1.2`. Octal numbers are not supported: `192.168.010.1` is treated as `192.168.10.1`, not `192.168.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address *expr* represented in numeric form as an `INT` value to an IPv6 address represented in numeric form as a `VARBINARY` value, use this expression:

```
INET6_ATON( INET_NTOA(expr) )
```

For example:

```
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

- `INET6_NTOA(expr)`

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a nonbinary string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` returns `NULL`.

`INET6_NTOA()` has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
```

- The return string uses lowercase letters for IPv6 addresses.

```
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:feffa:9089'));
-> 'fdfe::5a55:caff:feffa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'

mysql> SELECT INET6_NTOA(UNHEX('FDFE0000000000005A55CAFFFEFFA9089'));
-> 'fdfe::5a55:caff:feffa:9089'
mysql> SELECT INET6_NTOA(UNHEX('0A000509'));
-> '10.0.5.9'
```

- `IS_FREE_LOCK(str)`

Checks whether the lock named *str* is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_IPV4(expr)`

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

```
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if `IS_IPV4()` returns 1, `INET_ATON()` (and `INET6_ATON()`) will return non-`NULL`. The converse statement is not true: In some cases, `INET_ATON()` returns non-`NULL` when `IS_IPV4()` returns 0.

As implied by the preceding remarks, `IS_IPV4()` is more strict than `INET_ATON()` about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` to convert IPv4 addresses to internal form and check for a `NULL` result (which indicates an invalid address). `INET6_ATON()` is equally strong as `IS_IPV4()` about checking IPv4 addresses.

- `IS_IPV4_COMPAT(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form `::ipv4_address`.

```
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, `192.168.0.1` has this raw hexadecimal value:

```
mysql> SELECT HEX(INET6_ATON('192.168.0.1'));
-> 'C0A80001'
```

Expressed in IPv4-compatible form, `::192.168.0.1` is equivalent to `::c0a8:0001` or (without leading zeros) `::c0a8:1`

```
mysql> SELECT
```

```
-> IS_IPV4_COMPAT(INET6_ATON('::192.168.0.1')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV4_MAPPED(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form `::ffff:ipv4_address`.

```
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```
mysql> SELECT
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:192.168.0.1')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV6(expr)`

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-NULL.

- `IS_USED_LOCK(str)`

Checks whether the lock named *str* is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns NULL.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `MASTER_POS_WAIT(log_name, log_pos[, timeout][, channel_name])`

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns NULL if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns NULL. If the slave is past the specified position, the function returns immediately.

If a *timeout* value is specified, `MASTER_POS_WAIT()` stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout.

The optional *channel* added in MySQL 5.7.6 enables you to choose which replication channel the function applies to. See [Section 18.2.3, “Replication Channels”](#) for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 22.7, “Binary Logging of Stored Programs”](#). You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+-----+
| myname |
+-----+
|      14 |
+-----+
1 row in set (0.00 sec)
```

See [Section 14.2.9, “SELECT Syntax”](#), for more information about column aliases.

- `RELEASE_ALL_LOCKS()`

Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

This function was added in MySQL 5.7.5.

- `RELEASE_LOCK(str)`

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 14.2.3, “DO Syntax”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

When sleep returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
```

```
+-----+
|          0 |
+-----+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|          1 |
+-----+
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|          1 |
+-----+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
ERROR 3024 (HY000): Query execution was interrupted, maximum statement
execution time exceeded
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique Identifier (UUID) URN Namespace” (<http://www.ietf.org/rfc/rfc4122.txt>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

### Warning

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaa-bbbb-cccc-dddd-eeeeeeeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.

- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

#### Note

`UUID()` does not work with statement-based replication.

- `UUID_SHORT()`

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and have different uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` value of the current server is between 0 and 255 and is unique among your set of master and slave servers
- You do not set back the system time for your server host between `mysqld` restarts
- You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

#### Note

`UUID_SHORT()` does not work with statement-based replication.

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See [Section 14.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
```

```
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

## 13.21 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree of control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND( )` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see [Section 6.1.8, “Server SQL Modes”](#).

### 13.21.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and `DECIMAL` types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

### 13.21.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of `DECIMAL` columns

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments are as follows:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65.
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 65 for *M* means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before.

Values for `DECIMAL` columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

| Leftover Digits | Number of Bytes |
|-----------------|-----------------|
| 0               | 0               |
| 1–2             | 1               |
| 3–4             | 2               |
| 5–6             | 3               |
| 7–9             | 4               |

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

`DECIMAL` columns do not store a leading `+` character or `-` character or leading 0 digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored.

`DECIMAL` columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits at most *M* - *D* digits to the left of the decimal point.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* *M* digits. For `DECIMAL(M,D)`, the standard requires a precision of at least *M* digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly *M* digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

### 13.21.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its

exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 6.1.8, “Server SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in [Section 13.21.4, “Rounding Behavior”](#).

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.

- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

| sql_mode Value                                  | Result   |
|---|--|
| ' ' (Default)                                   | No warning, no error; <code>i</code> is set to <code>NULL</code> . |
| strict  | No warning, no error; <code>i</code> is set to <code>NULL</code> . |
| <code>ERROR_FOR_DIVISION_BY_ZERO</code>         | Warning, no error; <code>i</code> is set to <code>NULL</code> .    |
| strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code> | Error condition; no row is inserted.                               |

### 13.21.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d    |
+-----+
| 3    |
| 3    |
+-----+
```

## 13.21.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in [Section 13.21.3, “Expression Handling”](#), and [Section 13.21.4, “Rounding Behavior”](#).

**Example 1.** Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+-----+
| (.1 + .2) = .3 |
+-----+
|                |
+-----+
|                |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
+-----+
| (.1E0 + .2E0) = .3E0 |
+-----+
|                      |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+-----+-----+
| d      | f      |
+-----+-----+
| 1.0000 | 0.999999999999991 |
+-----+-----+
```

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers `x1` and `x2` that have scale `s1` and `s2`, the scale of the result is `s1 + s2`:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+
```

**Example 3.** Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3          | -3          |
+-----+-----+
```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
| 2            | -2            |
+-----+-----+
```

**Example 4.** In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127   |
+-----+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5:** In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i      |
+-----+
| NULL   |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6.** Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as [DECIMAL](#):

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double              | NO   |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

**Example 7.** If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| avg(i) | decimal(4,0)         | NO   |     |         |       |
| avg(d) | decimal(4,0)         | NO   |     |         |       |
| avg(f) | double               | NO   |     |         |       |
+-----+-----+-----+-----+-----+-----+
```

## Precision Math Examples

---

|                                       |        |  |               |  |     |  |  |  |      |  |  |  |
|---------------------------------------|--------|--|---------------|--|-----|--|--|--|------|--|--|--|
|                                       | AVG(i) |  | decimal(14,4) |  | YES |  |  |  | NULL |  |  |  |
|                                       | AVG(d) |  | decimal(14,4) |  | YES |  |  |  | NULL |  |  |  |
|                                       | AVG(f) |  | double        |  | YES |  |  |  | NULL |  |  |  |
| +-----+-----+-----+-----+-----+-----+ |        |  |               |  |     |  |  |  |      |  |  |  |

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

---

This chapter describes the syntax for the [SQL](#) statements supported by MySQL.

## 14.1 Data Definition Statements

### 14.1.1 ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

[ALTER DATABASE](#) enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use [ALTER DATABASE](#), you need the [ALTER](#) privilege on the database. [ALTER SCHEMA](#) is a synonym for [ALTER DATABASE](#).

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

### National Language Characteristics

The [CHARACTER SET](#) clause changes the default database character set. The [COLLATE](#) clause changes the default database collation. [Section 11.1, “Character Set Support”](#), discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) statements. See [Section 14.7.5.3, “SHOW CHARACTER SET Syntax”](#), and [Section 14.7.5.4, “SHOW COLLATION Syntax”](#), for more information.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 14.1.16, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)

## Upgrading from Versions Older than MySQL 5.1

The syntax that includes the [UPGRADE DATA DIRECTORY NAME](#) clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see [Section 10.2.3, “Mapping of Identifiers to File Names”](#)). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the `-` (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql50#a-b-c`, and you must refer to the name using the `#mysql50#` prefix. Use [UPGRADE DATA DIRECTORY NAME](#) in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql50#` prefix.

### Note

The [UPGRADE DATA DIRECTORY NAME](#) clause is deprecated in MySQL 5.7.6 and will be removed in a future version of MySQL. If it is necessary to convert MySQL 5.0 database or table names, a workaround is to upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

## 14.1.2 ALTER EVENT Syntax

```
ALTER
  [DEFINER = { user | CURRENT_USER }]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  [DO event_body]
```

The [ALTER EVENT](#) statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the [DEFINER](#), [ON SCHEDULE](#), [ON](#)

COMPLETION, COMMENT, ENABLE / DISABLE, and DO clauses is exactly the same as when used with CREATE EVENT. (See [Section 14.1.12, "CREATE EVENT Syntax"](#).)

Any user can alter an event defined on a database for which that user has the [EVENT](#) privilege. When a user executes a successful ALTER EVENT statement, that user becomes the definer for the affected event.

ALTER EVENT works only with an existing event:

```
mysql> ALTER EVENT no_such_event
>     ON SCHEDULE
>     EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
  EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
  EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this ALTER EVENT statement is run.

```
ALTER EVENT myevent
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
  TRUNCATE TABLE myschema.mytable;
```

Specify the options in an ALTER EVENT statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for CREATE EVENT such as [ENABLE](#).

To disable `myevent`, use this ALTER EVENT statement:

```
ALTER EVENT myevent
DISABLE;
```

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the [timestamp](#) or [interval](#) values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use [SELECT FROM DUAL](#). This is true for both ALTER EVENT and CREATE EVENT statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an ALTER EVENT statement that contains another ALTER EVENT statement in its DO clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
  RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
  RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

#### Note

There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replication slave instead of `ENABLE` or `DISABLE` to indicate an event that was created on the master and replicated to the slave, but that is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 18.4.1.12, “Replication of Invoked Features”](#), for more information.

### 14.1.3 ALTER FUNCTION Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  COMMENT 'string'
| LANGUAGE SQL
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

### 14.1.4 ALTER INSTANCE Syntax

```
ALTER INSTANCE ROTATE INNODB MASTER KEY
```

`ALTER INSTANCE`, introduced in MySQL 5.7.11, defines actions applicable to a MySQL server instance. Using `ALTER INSTANCE` requires the `SUPER` privilege.

The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is used to rotate the master encryption key used for `InnoDB` tablespace encryption. A keyring plugin must be loaded to use this statement. For information about keyring plugins, see [Section 7.5.4, “The MySQL Keyring”](#).

`ALTER INSTANCE ROTATE INNODB MASTER KEY` supports concurrent DML. However, it cannot be run concurrently with `CREATE TABLE ... ENCRYPTION` or `ALTER TABLE ... ENCRYPTION` operations, and locks are taken to prevent conflicts that could arise from concurrent execution of

these statements. If one of the conflicting statements is running, it must complete before another can proceed.

`ALTER INSTANCE` actions are written to the binary log so that they can be executed on replicated servers.

For additional `ALTER INSTANCE ROTATE INNODB MASTER KEY` usage information, see [Section 15.7.10, “InnoDB Tablespace Encryption”](#). For information about keyring plugins, see [Section 7.5.4, “The MySQL Keyring”](#).

## 14.1.5 ALTER LOGFILE GROUP Syntax

```
ALTER LOGFILE GROUP logfile_group
  ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
  ENGINE [=] engine_name
```

This statement adds an `UNDO` file named '*file\_name*' to an existing log file group *logfile\_group*. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is currently supported.

### Note

All MySQL Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional `INITIAL_SIZE` parameter sets the `UNDO` file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB). (Bug #29574)

### Note

`WAIT` is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The `ENGINE` parameter (required) determines the storage engine which is used by this log file group, with *engine\_name* being the name of the storage engine. Currently, the only accepted values for *engine\_name* are “`NDBCLUSTER`” and “`NDB`”. The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see [Section 14.1.15, “CREATE LOGFILE GROUP Syntax”](#)):

```
ALTER LOGFILE GROUP lg_3
  ADD UNDOFILE 'undo_10.dat'
  INITIAL_SIZE=32M
  ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an `UNDO` log file is created on each MySQL Cluster data node. You can verify that the `UNDO`

files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg_3';
```

| FILE_NAME   | LOGFILE_GROUP_NUMBER | EXTRA          |
|-------------|----------------------|----------------|
| newdata.dat | 0                    | CLUSTER_NODE=3 |
| newdata.dat | 0                    | CLUSTER_NODE=4 |
| undo_10.dat | 11                   | CLUSTER_NODE=3 |
| undo_10.dat | 11                   | CLUSTER_NODE=4 |

```
4 rows in set (0.01 sec)
```

(See [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

`ALTER LOGFILE GROUP` is useful only with Disk Data storage for MySQL Cluster. For more information, see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#).

## 14.1.6 ALTER PROCEDURE Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
    COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 22.2.2, “Stored Routines and MySQL Privileges”](#).

## 14.1.7 ALTER SERVER Syntax

```
ALTER SERVER server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for *server\_name*, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` does not cause an automatic commit.

In MySQL 5.7, `ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

## 14.1.8 ALTER TABLE Syntax

```
ALTER [IGNORE] TABLE tbl_name
    [alter_specification [, alter_specification] ...]
    [partition_options]

alter_specification:
    table_options
| ADD [COLUMN] col_name column_definition
    [FIRST | AFTER col_name ]
| ADD [COLUMN] (col_name column_definition,...)
| ADD {INDEX|KEY} [index_name]
    [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]] PRIMARY KEY
    [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
    UNIQUE [INDEX|KEY] [index_name]
    [index_type] (index_col_name,...) [index_option] ...
| ADD FULLTEXT [INDEX|KEY] [index_name]
    (index_col_name,...) [index_option] ...
| ADD SPATIAL [INDEX|KEY] [index_name]
    (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
    FOREIGN KEY [index_name] (index_col_name,...)
    reference_definition
| ALGORITHM [=] {DEFAULT|INPLACE|COPY}
| ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
| CHANGE [COLUMN] old_col_name new_col_name column_definition
    [FIRST|AFTER col_name]
| LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
| MODIFY [COLUMN] col_name column_definition
    [FIRST | AFTER col_name]
| DROP [COLUMN] col_name
| DROP PRIMARY KEY
| DROP {INDEX|KEY} index_name
| DROP FOREIGN KEY fk_symbol
| DISABLE KEYS
| ENABLE KEYS
| RENAME [TO|AS] new_tbl_name
| RENAME {INDEX|KEY} old_index_name TO new_index_name
| ORDER BY col_name [, col_name] ...
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
| DISCARD TABLESPACE
| IMPORT TABLESPACE
| FORCE
| {WITHOUT|WITH} VALIDATION
| ADD PARTITION (partition_definition)
| DROP PARTITION partition_names
| DISCARD PARTITION {partition_names | ALL} TABLESPACE
| IMPORT PARTITION {partition_names | ALL} TABLESPACE
| TRUNCATE PARTITION {partition_names | ALL}
| COALESCE PARTITION number
| REORGANIZE PARTITION partition_names INTO (partition_definitions)
| EXCHANGE PARTITION partition_name WITH TABLE tbl_name [{WITH|WITHOUT} VALIDATION]
| ANALYZE PARTITION {partition_names | ALL}
| CHECK PARTITION {partition_names | ALL}
| OPTIMIZE PARTITION {partition_names | ALL}
| REBUILD PARTITION {partition_names | ALL}
| REPAIR PARTITION {partition_names | ALL}
| REMOVE PARTITIONING
| UPGRADE PARTITIONING

index_col_name:
```

```
col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option:
    KEY_BLOCK_SIZE [=] value
    | index_type
    | WITH PARSER parser_name
    | COMMENT 'string'

table_options:
    table_option [[,] table_option] ... (see CREATE TABLE options)

partition_options:
    (see CREATE TABLE options)
```

**ALTER TABLE** changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.

The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. See [Section 14.1.18, “CREATE TABLE Syntax”](#), for more information.

*table\_options* signifies table options of the kind that can be used in the **CREATE TABLE** statement, such as **ENGINE**, **AUTO\_INCREMENT**, **AVG\_ROW\_LENGTH**, **MAX\_ROWS**, **ROW\_FORMAT**, or **TABLESPACE**. For a list of all table options and a description of each, see [Section 14.1.18, “CREATE TABLE Syntax”](#). However, **ALTER TABLE** ignores the **DATA DIRECTORY** and **INDEX DIRECTORY** table options.

Use of table options with **ALTER TABLE** provides a convenient way of altering single table characteristics. For example, if *t1* is currently not an **InnoDB** table, this statement changes its storage engine to **InnoDB**:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

To change the **InnoDB** table to use compressed row-storage format:

```
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
```

If the **InnoDB** tablespace encryption feature is enabled (see [Section 15.7.10, “InnoDB Tablespace Encryption”](#)), encryption for *t1* can be enabled or disabled like this:

```
ALTER TABLE t1 ENCRYPTION='Y';
ALTER TABLE t1 ENCRYPTION='N';
```

To disable encryption for an **InnoDB** table, set **ENCRYPTION='N'** using **ALTER TABLE**.

To reset the current auto-increment value:

```
ALTER TABLE t1 AUTO_INCREMENT = 13;
```

To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

**NDB\_TABLE options in table comments.** MySQL Cluster NDB 7.5.2 and later supports setting [NDB\\_TABLE](#) options for controlling a table's partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination of these, as part of the table comment for an [ALTER TABLE](#) statement in the same manner as for [CREATE TABLE](#), as shown in this example:

```
mysql> ALTER TABLE t1
> COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (1.73 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

To verify that the table options were changed as you intend, use [SHOW CREATE TABLE](#), or query [INFORMATION\\_SCHEMA.TABLES](#). Bear in mind that [ALTER TABLE ... COMMENT ...](#) discards any existing comment for the table. See [Setting NDB\\_TABLE options](#), for additional information and examples.

[partition\\_options](#) signifies options that can be used with partitioned tables for repartitioning, for adding, dropping, discarding, importing, merging, and splitting partitions, and for performing partitioning maintenance. It is possible for an [ALTER TABLE](#) statement to contain a [PARTITION BY](#) or [REMOVE PARTITIONING](#) clause in an addition to other alter specifications, but the [PARTITION BY](#) or [REMOVE PARTITIONING](#) clause must be specified last after any other specifications. The [ADD PARTITION](#), [DROP PARTITION](#), [DISCARD PARTITION](#), [IMPORT PARTITION](#), [COALESCE PARTITION](#), [REORGANIZE PARTITION](#), [EXCHANGE PARTITION](#), [ANALYZE PARTITION](#), [CHECK PARTITION](#), and [REPAIR PARTITION](#) options cannot be combined with other alter specifications in a single [ALTER TABLE](#), since the options just listed act on individual partitions. For more information about partition options, see [Section 14.1.18, “CREATE TABLE Syntax”](#), and [Section 14.1.8.1, “ALTER TABLE Partition Operations”](#). For information about and examples of [ALTER TABLE ... EXCHANGE PARTITION](#) statements, see [Section 21.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

Prior to MySQL 5.7.6, partitioned [InnoDB](#) tables used the generic [ha\\_partition](#) partitioning handler employed by [MyISAM](#) and other storage engines not supplying their own partitioning handlers; in MySQL 5.7.6 and later, such tables are created using the [InnoDB](#) storage engine's own (or “native”) partitioning handler. Beginning with MySQL 5.7.9, you can upgrade an [InnoDB](#) table that was created in MySQL 5.7.6 or earlier (that is, created using [ha\\_partition](#)) to the [InnoDB](#) native partition handler using [ALTER TABLE ... UPGRADE PARTITIONING](#). (Bug #76734, Bug #20727344) This version of [ALTER TABLE](#) does not accept any other options and can be used only on a single table at a time.

#### Note

You can also use [mysql\\_upgrade](#) in MySQL 5.7.9 or later to upgrade older partitioned [InnoDB](#) tables to the native partitioning handler.

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with [SHOW WARNINGS](#). See [Section 14.7.5.40, “SHOW WARNINGS Syntax”](#).

For information on troubleshooting [ALTER TABLE](#), see [Section B.5.6.1, “Problems with ALTER TABLE”](#).

## Storage, Performance, and Concurrency Considerations

In most cases, [ALTER TABLE](#) makes a temporary copy of the original table. MySQL waits for other operations that are modifying the table, then proceeds. It incorporates the alteration into the copy, deletes the original table, and renames the new one. While [ALTER TABLE](#) is executing, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table that begin after the [ALTER TABLE](#) operation begins are stalled until the new table is ready, then are

automatically redirected to the new table without any failed updates. The temporary copy of the original table is created in the database directory of the new table. This can differ from the database directory of the original table for `ALTER TABLE` operations that rename the table to a different database.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to install a new version of the table `.frm` file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads (and writes).

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

For some operations, an in-place `ALTER TABLE` is possible that does not require a temporary table:

- For `ALTER TABLE tbl_name RENAME TO new_tbl_name` without any other options, MySQL simply renames any files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See [Section 14.1.33, “RENAME TABLE Syntax”](#).) Any privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- Alterations that modify only table metadata and not table data are immediate because the server only needs to alter the table `.frm` file, not touch table contents. The following changes are fast alterations that can be made this way:
  - Renaming a column.
  - Changing the default value of a column (except for `NDB` tables).
  - Changing the definition of an `ENUM` or `SET` column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a `SET` column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this will require a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
- `ALTER TABLE` with `DISCARD ... PARTITION ... TABLESPACE` or `IMPORT ... PARTITION ... TABLESPACE` do not create any temporary tables or temporary partition files.

`ALTER TABLE` with `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REBUILD PARTITION`, or `REORGANIZE PARTITION` does not create any temporary tables (except when used with `NDB` tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

- Renaming an index.
- Adding or dropping an index, for `InnoDB` and `NDB`.

You can force an `ALTER TABLE` operation that would otherwise not require a table copy to use the temporary table method (as supported in MySQL 5.0) by setting the `old_alter_table` system variable to `ON`, or specifying `ALGORITHM=COPY` as one of the *alter\_specification* clauses. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence. (`ALGORITHM = DEFAULT` is the same as specifying no `ALGORITHM` clause at all.)

Specifying `ALGORITHM=INPLACE` makes the operation use the in-place technique for clauses and storage engines that support it, and fail with an error otherwise, thus avoiding a lengthy table copy

if you try altering a table that uses a different storage engine than you expect. See [Section 15.13, “InnoDB and Online DDL”](#) for information about online DDL for [InnoDB](#) tables.

For [InnoDB](#) tables, a table-copying [ALTER TABLE](#) operation on table that resides in a shared tablespace such as a [general tablespace](#) or the [system tablespace](#) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table that resides in a shared tablespace, the additional space used during a table-copying [ALTER TABLE](#) operation is not released back to the operating system as it is for a table that resides in a [file-per-table](#) tablespace.

As of MySQL 5.7.4, [ALTER TABLE](#) upgrades MySQL 5.5 temporal columns to 5.6 format for [ADD COLUMN](#), [CHANGE COLUMN](#), [MODIFY COLUMN](#), [ADD INDEX](#), and [FORCE](#) operations. This conversion cannot be done using the [INPLACE](#) algorithm because the table must be rebuilt, so specifying [ALGORITHM=INPLACE](#) in these cases results in an error. Specify [ALGORITHM=COPY](#) if necessary.

Starting with MySQL 5.7.6, an [ALTER TABLE](#) operation on a multicolumn index used to partition a table by [KEY](#) cannot be performed online when the operation would change the order of the columns. In such cases, you must use a copying [ALTER TABLE](#) instead. (Bug #17896265)

MySQL Cluster formerly supported online [ALTER TABLE](#) operations using the [ONLINE](#) and [OFFLINE](#) keywords. These keywords are no longer supported; their use causes a syntax error. MySQL Cluster NDB 7.5 (and later) supports online operations using the same [ALGORITHM=INPLACE](#) syntax used with the standard MySQL Server. See [Section 14.1.8.2, “ALTER TABLE Online Operations in MySQL Cluster”](#), for more information.

You can control the level of concurrent reading and writing of the table while it is being altered, using the [LOCK](#) clause. Specifying a non-default value for this clause lets you require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the [LOCK](#) clause are:

- [LOCK = DEFAULT](#)

Maximum level of concurrency for the given [ALGORITHM](#) clause (if any) and [ALTER TABLE](#) operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- [LOCK = NONE](#)

If supported, permit concurrent reads and writes. Otherwise, return an error message.

- [LOCK = SHARED](#)

If supported, permit concurrent reads but block writes. Note that writes will be blocked even if concurrent writes are supported by the storage engine for the given [ALGORITHM](#) clause (if any) and [ALTER TABLE](#) operation. If concurrent reads are not supported, return an error message.

- [LOCK = EXCLUSIVE](#)

Enforce exclusive access. This will be done even if concurrent reads/writes are supported by the storage engine for the given [ALGORITHM](#) clause (if any) and [ALTER TABLE](#) operation.

The [WITHOUT VALIDATION](#) and [WITH VALIDATION](#) clauses affect whether [ALTER TABLE](#) performs an in-place operation for [generated virtual column](#) modifications. See [Section 14.1.8.3, “ALTER TABLE and Generated Columns”](#).

You can also use [ALTER TABLE tbl\\_name FORCE](#) to perform a “null” alter operation that rebuilds the table. Previously the [FORCE](#) option was recognized but ignored. As of MySQL 5.7.4, [online DDL](#) support is provided for the [FORCE](#) option. For more information, see [Section 15.13.1, “Overview of Online DDL”](#).

For [NDB](#) tables, operations that add and drop indexes on variable-width columns occur online, without any table copying and without blocking concurrent DML actions for most of their duration. See [Section 14.1.8.2, “ALTER TABLE Online Operations in MySQL Cluster”](#).

## Usage Notes

- To use [ALTER TABLE](#), you need [ALTER](#), [CREATE](#), and [INSERT](#) privileges for the table. Renaming a table requires [ALTER](#) and [DROP](#) on the old table, [ALTER](#), [CREATE](#), and [INSERT](#) on the new table.
- [IGNORE](#) is a MySQL extension to standard SQL. It controls how [ALTER TABLE](#) works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If [IGNORE](#) is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If [IGNORE](#) is specified, only one row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.

As of MySQL 5.7.4, the [IGNORE](#) clause for [ALTER TABLE](#) is removed and its use produces an error.

- [table\\_option](#) signifies a table option of the kind that can be used in the [CREATE TABLE](#) statement, such as [ENGINE](#), [AUTO\\_INCREMENT](#), [AVG\\_ROW\\_LENGTH](#), [MAX\\_ROWS](#), [ROW\\_FORMAT](#), or [TABLESPACE](#). For a list of all table options and a description of each, see [Section 14.1.18, “CREATE TABLE Syntax”](#). However, [ALTER TABLE](#) ignores the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options.
- For example, to convert a table to be an [InnoDB](#) table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

See [Section 15.8.5, “Converting Tables from MyISAM to InnoDB”](#) for considerations when switching tables to the [InnoDB](#) storage engine.

When you specify an [ENGINE](#) clause, [ALTER TABLE](#) rebuilds the table. This is true even if the table already has the specified storage engine.

Running [ALTER TABLE tbl\\_name ENGINE=INNODB](#) on an existing [InnoDB](#) table performs a “null” [ALTER TABLE](#) operation, which can be used to defragment an [InnoDB](#) table, as described in [Section 15.12.4, “Defragmenting a Table”](#). Running [ALTER TABLE tbl\\_name FORCE](#) on an [InnoDB](#) table performs the same function.

As of MySQL 5.7.4, both [ALTER TABLE tbl\\_name ENGINE=INNODB](#) and [ALTER TABLE tbl\\_name FORCE](#) use [online DDL \(ALGORITHM=INPLACE\)](#). For more information, see [Section 15.13.1, “Overview of Online DDL”](#).

The outcome of attempting to change a table's storage engine is affected by whether the desired storage engine is available and the setting of the [NO\\_ENGINE\\_SUBSTITUTION](#) SQL mode, as described in [Section 6.1.8, “Server SQL Modes”](#).

To prevent inadvertent loss of data, [ALTER TABLE](#) cannot be used to change the storage engine of a table to [MERGE](#) or [BLACKHOLE](#).

- To change the value of the [AUTO\\_INCREMENT](#) counter to be used for new rows, do this:

```
ALTER TABLE t2 AUTO_INCREMENT = value;
```

You cannot reset the counter to a value less than or equal to the value that is currently in use. For both [InnoDB](#) and [MyISAM](#), if the value is less than or equal to the maximum value currently in the [AUTO\\_INCREMENT](#) column, the value is reset to the current maximum [AUTO\\_INCREMENT](#) column value plus one.

- As of MySQL 5.7.6, you can use [ALTER TABLE](#) with the [TABLESPACE](#) option to move non-partitioned [InnoDB](#) tables between existing [general tablespaces](#), [file-per-table](#) tablespaces, and

the [system tablespace](#). See [Moving Non-Partitioned Tables Between Tablespaces Using ALTER TABLE](#).

For partitioned tables, `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` only modifies the table's default tablespace. It does not move partitions from one tablespace to another. To move table partitions, you must move each partition using an `ALTER TABLE tbl_name REORGANIZE PARTITION` statement. See [Moving Table Partitions Between Tablespaces Using ALTER TABLE](#).

`ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

`ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

For more information about the capabilities and limitations of the `TABLESPACE` option, see [CREATE TABLE](#).

- You can issue multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- `CHANGE col_name`, `DROP col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.
- The word `COLUMN` is optional and can be omitted.
- `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. See [Section 14.1.18, "CREATE TABLE Syntax"](#).
- For information about generated columns, see [Section 14.1.8.3, "ALTER TABLE and Generated Columns"](#).
- You can rename a column using a `CHANGE old_col_name new_col_name column_definition` clause. To do so, specify the old and new column names and the definition that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

To change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

`MODIFY` is an extension to `ALTER TABLE` for Oracle compatibility.

When you use `CHANGE` or `MODIFY`, `column_definition` must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not

carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

The resulting column will be defined as `BIGINT`, but will not include the attributes `UNSIGNED DEFAULT 1 COMMENT 'my column'`. To retain them, the statement should be:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

- When you change a data type using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

### Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see [Section 6.1.8, “Server SQL Modes”](#)).

- To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last. You can also use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations to reorder columns within a table.
- `ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in [Section 12.7, “Data Type Default Values”](#).
- `DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 14.1.25, “DROP INDEX Syntax”](#). If you are unsure of the index name, use `SHOW INDEX FROM tbl_name`.
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.
- `DROP PRIMARY KEY` drops the [primary key](#). If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for [InnoDB](#) tables, see [Section 9.3.2, “Using Primary Keys”](#).

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

- Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see [Section 14.1.14, “CREATE INDEX Syntax”](#). The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about permissible `index_option` values, see [Section 14.1.14, “CREATE INDEX Syntax”](#).

- `RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. `old_index_name` must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE`

statement. `new_index_name` is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`.

- After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See [Section 14.7.5.22, “SHOW INDEX Syntax”](#).
- `ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

**Note**

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for `InnoDB` tables because `InnoDB` always orders table rows according to the [clustered index](#).

**Note**

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

- If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

- In MySQL 5.7, the server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. It also prohibits changes to the data type of such columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.
- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` and `NDB` storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See [Section 1.8.3.2, “FOREIGN KEY Constraints”](#); for information specific to `InnoDB`, see [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 14.1.18, “CREATE TABLE Syntax”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.8.2, “MySQL Differences from Standard SQL”](#).

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (....) ...
```

### Important

The inline `REFERENCES` specifications where the references are defined as part of the column specification are silently ignored. MySQL only accepts `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

### Note

Partitioned `InnoDB` tables do not support foreign keys. This restriction does not apply to `NDB` tables, including those explicitly partitioned by `[LINEAR] KEY`. See [Section 21.6.2, “Partitioning Limitations Relating to Storage Engines”](#), for more information.

- MySQL Server and MySQL Cluster both support the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

For more information, see [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

- Prior to MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Separate statements should be used for each operation. As of MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but remains unsupported for `ALTER TABLE ... ALGORITHM=COPY`.
- An `InnoDB` table created in its own `file-per-table` tablespace can be discarded and imported using the `DISCARD TABLESPACE` and `IMPORT TABLESPACE` options. These options can be used to import a file-per-table tablespace from a backup or to copy a file-per-table tablespace from one database server to another. See [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#).
- To change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` will change the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of  $3 \times 65,535 = 196,605$  bytes. That length will not fit in a `TEXT` column's length bytes, so MySQL will convert the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

If `charset_name` is `DEFAULT`, the database character set is used.

### Warning

The `CONVERT TO` operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See [Section 26.8.7.36, “mysql\\_info\(\)](#)”.

## 14.1.8.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, for adding, dropping, discarding, importing, merging, and splitting partitions, and for performing partitioning maintenance.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (see [Section 14.1.18, “CREATE TABLE Syntax”](#),

for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by [HASH](#), using the [id](#) column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
  PARTITION BY HASH(id)
  PARTITIONS 8;
```

MySQL 5.7.1 and later supports an [ALGORITHM](#) option with [\[SUB\]PARTITION BY \[LINEAR\] KEY](#). [ALGORITHM=1](#) causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; [ALGORITHM=2](#) means that the server employs the key-hashing functions implemented and used by default for new [KEY](#) partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using [ALGORITHM=2](#). This option is intended for use chiefly when upgrading or downgrading [\[LINEAR\] KEY](#) partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by [KEY](#) or [LINEAR KEY](#) on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a [KEY](#) partitioned table that was created in MySQL 5.1, first execute [SHOW CREATE TABLE](#) and note the exact columns and number of partitions shown. Now execute an [ALTER TABLE](#) statement using exactly the same column list and number of partitions as in the [CREATE TABLE](#) statement, while adding [ALGORITHM=2](#) immediately following the [PARTITION BY](#) keywords. (You should also include the [LINEAR](#) keyword if it was used for the original table definition.) An example from a session in the [mysql](#) client is shown here:

```
mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)

mysql> ALTER TABLE p PARTITION BY LINEAR KEY ALGORITHM=2 (id) PARTITIONS 32;
Query OK, 0 rows affected (5.34 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use [ALGORITHM=1](#) to force

the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved [KEY](#) hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

#### Note

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 21.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 14.1.18, “CREATE TABLE Syntax”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`ADD PARTITION` can also be used with the `TABLESPACE` clause to add a new partition to an existing general tablespace, to a file-per-table tablespace, or to the system tablespace.

```
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `ts1`);
```

```
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `innodb_file_per_table`);
```

```
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `innodb_system`);
```

#### Note

If the `TABLESPACE = tablespace_name` option is not defined, the `ALTER TABLE ... ADD PARTITION` operation adds the partition to the table's default tablespace, which can be specified at the table level during `CREATE TABLE` or `ALTER TABLE`.

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

#### Note

`DROP PARTITION` does not work with tables that use the `NDB` storage engine. See [Section 21.3.1, “Management of RANGE and LIST Partitions”](#), and [Section 20.1.6, “Known Limitations of NDB Cluster”](#).

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

In MySQL 5.7.4, `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` options extend the [Transportable Tablespace](#) feature to individual `InnoDB` table partitions. Each `InnoDB` table partition has its own tablespace file (`.idb` file). The [Transportable Tablespace](#) feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

```
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

As of MySQL 5.7.4, the [Transportable Tablespace](#) feature also supports copying or restoring partitioned `InnoDB` tables (all partitions at once). For additional information about the [Transportable Tablespace](#) feature, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#). For usage examples, see [Section 15.7.6.1, “Transportable Tablespace Examples”](#).

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation makes a copy of the partition's data..

In MySQL 5.7, it is possible to delete rows from selected partitions using the `TRUNCATE PARTITION` option. This option takes a comma-separated list of one or more partition names. For example, consider the table `t1` as defined here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2003),
  PARTITION p4 VALUES LESS THAN (2007)
);
```

To delete all rows from partition `p0`, you can use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex [WHERE](#) conditions if done with [DELETE](#) statements. For example, this statement deletes all rows from partitions [p1](#) and [p3](#):

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent [DELETE](#) statement is shown here:

```
DELETE FROM t1 WHERE
  (year_col >= 1991 AND year_col < 1995)
  OR
  (year_col >= 2003 AND year_col < 2007);
```

You can also use the [ALL](#) keyword in place of the list of partition names; in this case, the statement acts on all partitions in the table.

[TRUNCATE PARTITION](#) merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

**Note**

Prior to MySQL 5.7.2, [TRUNCATE PARTITION](#) did not work with subpartitions (Bug #14028340, Bug #65184).

You can verify that the rows were dropped by checking the [INFORMATION\\_SCHEMA.PARTITIONS](#) table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
  FROM INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_NAME = 't1';
```

[TRUNCATE PARTITION](#) is supported only for partitioned tables that use the [MyISAM](#), [InnoDB](#), or [MEMORY](#) storage engine. It also works on [BLACKHOLE](#) tables (but has no effect). It is not supported for [ARCHIVE](#) tables.

[COALESCE PARTITION](#) can be used with a table that is partitioned by [HASH](#) or [KEY](#) to reduce the number of partitions by *number*. Suppose that you have created table [t2](#) using the following definition:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

You can reduce the number of partitions used by [t2](#) from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use [REORGANIZE PARTITION](#). This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the `partition_names` list and supplying a single definition for `partition_definition`.
- To split an existing partition into several partitions. You can accomplish this by naming a single partition for `partition_names` and providing multiple `partition_definitions`.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.
- To move a partition from one tablespace to another. For an example, see [Moving Table Partitions Between Tablespaces Using ALTER TABLE](#).
- This statement may also be used without the `partition_names INTO (partition_definitions)` option on tables that are automatically partitioned using `HASH` partitioning to force redistribution of data. (Currently, only `NDB` tables are automatically partitioned in this way.) This is useful in MySQL Cluster where, after you have added new MySQL Cluster data nodes online to an existing MySQL Cluster, you wish to redistribute existing MySQL Cluster table data to the new data nodes. In such cases, you should invoke the statement with the `ALGORITHM=INPLACE` option; in other words, as shown here:

```
ALTER TABLE table ALGORITHM=INPLACE REORGANIZE PARTITION;
```

You cannot perform other DDL concurrently with online table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... ALGORITHM=INPLACE REORGANIZE PARTITION` statement is executing. For more information about adding MySQL Cluster data nodes online, see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#).

`ALTER TABLE ... ALGORITHM=INPLACE REORGANIZE PARTITION` does not work with tables which were created using the `MAX_ROWS` option, because it uses the constant `MAX_ROWS` value specified in the original `CREATE TABLE` statement to determine the number of partitions required, so no new partitions are created. Instead, you can use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=rows` to increase the maximum number of rows for such a table; in this case, `ALTER TABLE ... ALGORITHM=INPLACE REORGANIZE PARTITION` is not needed (and causes an error if executed). The value of `rows` must be greater than the value specified for `MAX_ROWS` in the original `CREATE TABLE` statement for this to work.

Attempting to use `REORGANIZE PARTITION` without the `partition_names INTO (partition_definitions)` option on explicitly partitioned tables results in the error `REORGANIZE PARTITION without parameters can only be used on auto-partitioned tables using HASH partitioning`.

#### Note

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 21.3.1, “Management of RANGE and LIST Partitions”](#).

- In MySQL 5.7, it is possible to exchange a table partition or subpartition with a table using the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see [Section 21.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

- Several additional options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; see [Section 14.7.2, “Table Maintenance Statements”](#) for more information). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a *partition\_names* clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the `ALL` keyword in place of *partition\_names*, in which case the statement acts on all partitions in the table. For more information and examples, see [Section 21.3.4, “Maintenance of Partitions”](#).

Some MySQL storage engines, such as `InnoDB`, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not permitted for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.
- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

In MySQL 5.7, when `ALTER TABLE ... EXCHANGE PARTITION` or `ALTER TABLE ... TRUNCATE PARTITION` is run against a partitioned table that uses `MyISAM` (or another storage engine that makes use of table-level locking), only those partitions that are actually read from are locked. (This does not apply to partitioned tables using a storage engine that employs row-level locking, such as `InnoDB`.) See [Section 21.6.4, “Partitioning and Locking”](#).

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 14.1.8.1, “ALTER TABLE Partition Operations”](#).

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform [ANALYZE](#) and [CHECK](#) operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;  
ALTER TABLE t1 CHECK PARTITION p2;
```

Prior to MySQL 5.7.2, [ANALYZE](#), [CHECK](#), [OPTIMIZE](#), [REPAIR](#), and [TRUNCATE](#) operations were not supported for subpartitions. (Bug #14028340, Bug #65184)

[REBUILD](#) operations are currently unsupported for subpartitions. In MySQL 5.7.2, 5.7.3, and 5.7.4, the [REBUILD](#) keyword was accepted with subpartition names as valid syntax in [ALTER TABLE](#) statements, even though it had no effect. In MySQL 5.7.5, [REBUILD](#) is expressly disallowed with subpartitions, and causes [ALTER TABLE](#) to fail with an error if so used. (Bug #19075411, Bug #73130)

[CHECK PARTITION](#) and [REPAIR PARTITION](#) operations fail when the partition to be checked or repaired contains any duplicate key errors.

MySQL 5.7.2 and 5.7.3 allowed alternative behavior that could be invoked using [ALTER IGNORE TABLE](#) with the corresponding options (Bug #16900947), which caused the statement to behave as follows:

- [ALTER IGNORE TABLE ... REPAIR PARTITION](#) removed from the partition all rows that could not be moved due to the presence of duplicate keys.
- [ALTER IGNORE TABLE ... CHECK PARTITION](#) wrote out the contents of all columns in the partitioning expression for each row in the partition in which a duplicate key violation was found.

This is no longer possible in MySQL 5.7.4 and later, where the [IGNORE](#) keyword is no longer allowed (see [ALTER IGNORE TABLE](#)).

For more information about these statements, see [Section 21.3.4, “Maintenance of Partitions”](#).

#### 14.1.8.2 ALTER TABLE Online Operations in MySQL Cluster

MySQL Cluster 7.5 supports online table schema changes using the standard [ALTER TABLE](#) syntax employed by the MySQL Server ([ALGORITHM=DEFAULT](#) | [INPLACE](#) | [COPY](#)), and described elsewhere.

Some older releases of MySQL Cluster used a syntax specific to [NDB](#) for online [ALTER TABLE](#) operations. That syntax has since been removed.

#### 14.1.8.3 ALTER TABLE and Generated Columns

[ALTER TABLE](#) operations permitted for generated columns are [ADD](#), [MODIFY](#), and [CHANGE](#).

- Generated columns can be added.
- The data type and expression of generated columns can be modified.
- Generated columns can be renamed or dropped, if no other column refers to them.
- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.
- Nongenerated columns can be altered to stored but not virtual generated columns.
- Stored but not generated virtual columns can be altered to nongenerated columns. The generated stored values become the values of the nongenerated column.
- [ADD COLUMN](#) is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.

- For non-partitioned tables, `ADD COLUMN` and `DROP COLUMN` are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in-place in combination with other `ALTER TABLE` operations.

For partitioned tables, `ADD COLUMN` and `DROP COLUMN` are not in-place operations for virtual columns.

- As of MySQL 5.7.8, `InnoDB` supports secondary indexes on generated virtual columns. Adding or dropping a secondary index on a generated virtual column is an in-place operation. For more information, see [Section 14.1.18.8, “Secondary Indexes and Generated Columns”](#).
- When a `VIRTUAL` generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression will not be out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. As of MySQL 5.7.9, to permit control over whether validation occurs for such columns, `ALTER TABLE` supports `WITHOUT VALIDATION` and `WITH VALIDATION` clauses:
  - With `WITHOUT VALIDATION` (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.
  - With `WITH VALIDATION`, `ALTER TABLE` copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

`WITHOUT VALIDATION` and `WITH VALIDATION` are permitted only with `ADD COLUMN`, `CHANGE COLUMN`, and `MODIFY COLUMN` operations. An `ER_WRONG_USAGE` error occurs otherwise.

- As of MySQL 5.7.10, if expression evaluation causes truncation or provides incorrect input to a function, the `ALTER TABLE` statement terminates with an error and the DDL operation is rejected.
- An `ALTER TABLE` statement that changes the default value of a column `col_name` may also change the value of a generated column expression that refers to the column using `DEFAULT(col_name)`. For this reason, as of MySQL 5.7.13, `ALTER TABLE` operations that change the definition of a column now cause a table rebuild if any generated column expression uses `DEFAULT()`.

#### 14.1.8.4 ALTER TABLE Examples

Begin with a table `t1` that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

For `NDB` tables, it is also possible to change the storage type used for a table or column. For example, consider an `NDB` table created as shown here:

```
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;  
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;  
Query OK, 0 rows affected (2.99 sec)  
Records: 0 Duplicates: 0 Warnings: 0  
  
mysql> SHOW CREATE TABLE t1\G  
***** 1. row *****  
Table: t1  
Create Table: CREATE TABLE `t1` (  
  `c1` int(11) DEFAULT NULL  
) /*!50100 TABLESPACE ts_1 STORAGE DISK */  
ENGINE=ndbcluster DEFAULT CHARSET=latin1  
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;  
Query OK, 0 rows affected (1.00 sec)  
  
mysql> ALTER TABLE t2 STORAGE DISK;  
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)  
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;  
Query OK, 0 rows affected (3.42 sec)  
Records: 0 Duplicates: 0 Warnings: 0  
mysql> SHOW CREATE TABLE t2\G  
***** 1. row *****  
Table: t1  
Create Table: CREATE TABLE `t2` (  
  `c1` int(11) DEFAULT NULL  
) /*!50100 TABLESPACE ts_1 STORAGE DISK */  
ENGINE=ndbcluster DEFAULT CHARSET=latin1  
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create a MySQL Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```
mysql> CREATE TABLE t3 (c1 INT, c2 INT)  
-> TABLESPACE ts_1 STORAGE DISK ENGINE NDB;  
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE t3\G
***** 1. row *****
      Table: t3
Create Table: CREATE TABLE `t3` (
  `c1` int(11) DEFAULT NULL,
  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See [Section 6.1.5, “Server System Variables”](#).

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

## 14.1.9 ALTER TABLESPACE Syntax

```
ALTER TABLESPACE tablespace_name
  {ADD|DROP} DATAFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

This statement can be used either to add a new data file, or to drop a data file from a tablespace.

The **ADD DATAFILE** variant enables you to specify an initial size using an **INITIAL\_SIZE** clause, where *size* is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in *my.cnf*. Generally, this is one of the letters **M** (megabytes) or **G** (gigabytes).

#### Note

All MySQL Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an data file with the same name, or an undo log file and a tablespace with the same name.

On 32-bit systems, the maximum supported value for **INITIAL\_SIZE** is 4294967296 (4 GB). (Bug #29186)

**INITIAL\_SIZE** is rounded, explicitly, as for **CREATE TABLESPACE**.

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional **ALTER TABLESPACE ... ADD DATAFILE** statements.

Using **DROP DATAFILE** with **ALTER TABLESPACE** drops the data file '*file\_name*' from the tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See [Section 20.5.13.1, “NDB Cluster Disk Data Objects”](#). In addition, any data file to be dropped must previously have been added to the tablespace with **CREATE TABLESPACE** or **ALTER TABLESPACE**.

Both **ALTER TABLESPACE ... ADD DATAFILE** and **ALTER TABLESPACE ... DROP DATAFILE** require an **ENGINE** clause which specifies the storage engine used by the tablespace. Currently, the only accepted values for *engine\_name* are **NDB** and **NDBCLUSTER**.

**WAIT** is parsed but otherwise ignored, and so has no effect in MySQL 5.7. It is intended for future expansion.

When **ALTER TABLESPACE ... ADD DATAFILE** is used with **ENGINE = NDB**, a data file is created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the **INFORMATION\_SCHEMA.FILES** table. For example, the following query shows all data files belonging to the tablespace named *newts*:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

| LOGFILE_GROUP_NAME | FILE_NAME    | EXTRA          |
|--------------------|--------------|----------------|
| lg_3               | newdata.dat  | CLUSTER_NODE=3 |
| lg_3               | newdata.dat  | CLUSTER_NODE=4 |
| lg_3               | newdata2.dat | CLUSTER_NODE=3 |
| lg_3               | newdata2.dat | CLUSTER_NODE=4 |

```
2 rows in set (0.03 sec)
```

See [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

**ALTER TABLESPACE** is useful only with Disk Data storage for MySQL Cluster. See [Section 20.5.13, “NDB Cluster Disk Data Tables”](#).

## 14.1.10 ALTER VIEW Syntax

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for [CREATE VIEW](#) and the effect is the same as for [CREATE OR REPLACE VIEW](#). See [Section 14.1.21, “CREATE VIEW Syntax”](#). This statement requires the [CREATE VIEW](#) and [DROP](#) privileges for the view, and some privilege for each column referred to in the [SELECT](#) statement. [ALTER VIEW](#) is permitted only to the definer or users with the [SUPER](#) privilege.

## 14.1.11 CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_specification] ...

create_specification:
  [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
```

[CREATE DATABASE](#) creates a database with the given name. To use this statement, you need the [CREATE](#) privilege for the database. [CREATE SCHEMA](#) is a synonym for [CREATE DATABASE](#).

An error occurs if the database exists and you did not specify [IF NOT EXISTS](#).

In MySQL 5.7, [CREATE DATABASE](#) is not permitted within a session that has an active [LOCK TABLES](#) statement.

[create\\_specification](#) options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The [CHARACTER SET](#) clause specifies the default database character set. The [COLLATE](#) clause specifies the default database collation. [Section 11.1, “Character Set Support”](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the [CREATE DATABASE](#) statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for permissible database names are given in [Section 10.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 10.2.3, “Mapping of Identifiers to File Names”](#).

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of [SHOW DATABASES](#).

You can also use the `mysqladmin` program to create databases. See [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

## 14.1.12 CREATE EVENT Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  DO event_body;
```

```

schedule:
    AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]

interval:
    quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
               WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
               DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}

```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see [Section 22.4.2, “Event Scheduler Configuration”](#).

**CREATE EVENT** requires the **EVENT** privilege for the schema in which the event is to be created. It might also require the **SUPER** privilege, depending on the **DEFINER** value, as described later in this section.

The minimum requirements for a valid **CREATE EVENT** statement are as follows:

- The keywords **CREATE EVENT** plus an event name, which uniquely identifies the event in a database schema.
- An **ON SCHEDULE** clause, which determines when and how often the event executes.
- A **DO** clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal **CREATE EVENT** statement:

```

CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;

```

The previous statement creates an event named **myevent**. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the **myschema.mytable** table's **mycol** column by 1.

The **event\_name** must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case sensitive, so you cannot have two events named **myevent** and **MyEvent** in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 10.2, “Schema Object Names”](#).

An event is associated with a schema. If no schema is indicated as part of **event\_name**, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using **schema\_name.event\_name** syntax.

The **DEFINER** clause specifies the MySQL account to be used when checking access privileges at event execution time. If a **user** value is given, it should be a MySQL account specified as **'user\_name'@'host\_name'**, **CURRENT\_USER**, or **CURRENT\_USER()**. The default **DEFINER** value is the user who executes the **CREATE EVENT** statement. This is the same as specifying **DEFINER = CURRENT\_USER** explicitly.

If you specify the **DEFINER** clause, these rules determine the valid **DEFINER** user values:

- If you do not have the **SUPER** privilege, the only permitted **user** value is your own account, either specified literally or by using **CURRENT\_USER**. You cannot set the definer to some other account.
- If you have the **SUPER** privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create an event with a nonexistent **DEFINER** account, an error occurs at event execution time if the account does not exist.

For more information about event security, see [Section 22.6, “Access Control for Stored Programs and Views”](#).

Within an event, the `CURRENT_USER()` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 7.3.11, “SQL-Based MySQL Account Activity Auditing”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named *event\_name* already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the *event\_body* defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by *timestamp*, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
->     ON SCHEDULE AT '2006-02-10 23:59:00'
->     DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` function (see [Section 13.7, “Date and Time Functions”](#)). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an *interval* as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a *timestamp* value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see [Section 22.4.4, “Event Metadata”](#). See also [Section 14.7.5.18, “SHOW EVENTS Syntax”](#), and [Section 23.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 14.1.2, “ALTER EVENT Syntax”](#)).

A third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See [Section 18.4.1.12, “Replication of Invoked Features”](#).

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section C.1, “Restrictions on Stored Programs”](#).) For example,

the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
  EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
  DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, *regardless of the current server SQL mode when the event begins executing*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

#### Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |

CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
  BEGIN
    INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END |

delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See [Section 22.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |

CREATE EVENT e
ON SCHEDULE
  EVERY 5 SECOND
DO
  BEGIN
    DECLARE v INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

    SET v = 0;
```

```

        WHILE v < 5 DO
            INSERT INTO t1 VALUES (0);
            UPDATE t2 SET s1 = s1 + 1;
            SET v = v + 1;
        END WHILE;
    END |
delimiter ;

```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```

CREATE EVENT e_call_myproc
ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);

```

If an event's definer has the [SUPER](#) privilege, the event can read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see [Section 22.2.1, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

### 14.1.13 CREATE FUNCTION Syntax

The [CREATE FUNCTION](#) statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 14.1.16, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).
- For information about creating user-defined functions, see [Section 14.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”](#).

### 14.1.14 CREATE INDEX Syntax

```

CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (index_col_name,...)
    [index_option]
    [algorithm_option | lock_option] ...

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option:
    KEY_BLOCK_SIZE [=] value
    | index_type
    | WITH PARSER parser_name
    | COMMENT 'string'

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY}

lock_option:
    LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}

```

[CREATE INDEX](#) is mapped to an [ALTER TABLE](#) statement to create indexes. See [Section 14.1.8, “ALTER TABLE Syntax”](#). [CREATE INDEX](#) cannot be used to create a [PRIMARY KEY](#); use [ALTER TABLE](#) instead. For more information about indexes, see [Section 9.3.1, “How MySQL Uses Indexes”](#).

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 14.1.18, “CREATE TABLE Syntax”](#). This guideline is especially important for `InnoDB` tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index key values are formed by concatenating the values of the given columns.

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` column indexes.
- Prefixes *must* be specified for `BLOB` and `TEXT` column indexes.
- Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.
- For spatial columns, prefix values cannot be given, as described later in this section.

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for `InnoDB` tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For `MyISAM` tables, the prefix limit is 1000 bytes. The `NDB` storage engine does not support prefixes (see [Section 20.1.6.6, “Unsupported or Missing Features in NDB Cluster”](#)).

MySQL Cluster formerly supported online `CREATE INDEX` operations using an alternative syntax that is no longer supported. MySQL Cluster now supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See [Section 14.1.8.2, “ALTER TABLE Online Operations in MySQL Cluster”](#), for more information.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix.

`FULLTEXT` indexes are supported only for `InnoDB` and `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 13.9, “Full-Text Search Functions”](#), for details of operation.

The `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` storage engines support spatial columns such as (`POINT` and `GEOMETRY`). ([Section 12.5, “Extensions for Spatial Data”](#), describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes are available according to the following rules.

Spatial indexes (created using `SPATIAL INDEX`) have these characteristics:

- Available only for `MyISAM` and (as of MySQL 5.7.5) `InnoDB` tables. Specifying `SPATIAL INDEX` for other storage engines results in an error.

- Indexed columns must be `NOT NULL`.
- Column prefix lengths are prohibited. The full width of each column is indexed.

Characteristics of nonspatial indexes (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`):

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.
- You can add an index on a column that can have `NULL` values only for `InnoDB`, `MyISAM`, and `MEMORY` tables.
- You can add an index on a `BLOB` or `TEXT` column only for using the `InnoDB` and `MyISAM` tables.
- When the `innodb_stats_persistent` setting is enabled, run the `ANALYZE TABLE` statement for an `InnoDB` table after creating an index on that table.

As of MySQL 5.7.8, `InnoDB` supports secondary indexes on virtual columns. For more information, see [Section 14.1.18.8, “Secondary Indexes and Generated Columns”](#).

An `index_col_name` specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

Following the index column list, index options can be given. An `index_option` value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value.

`KEY_BLOCK_SIZE` is not supported at the index level for `InnoDB` tables. See [Section 14.1.18, “CREATE TABLE Syntax”](#).

- `index_type`

Some storage engines permit you to specify an index type when creating an index. [Table 14.1, “Index Types Per Storage Engine”](#) shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an `index_type` clause in index definitions.

**Table 14.1 Index Types Per Storage Engine**

| Storage Engine           | Permissible Index Types                                   |
|--------------------------|---|
| <code>InnoDB</code>      | <code>BTREE</code>  |
| <code>MyISAM</code>      | <code>BTREE</code>  |
| <code>MEMORY/HEAP</code> | <code>HASH</code> , <code>BTREE</code>                    |
| <code>NDB</code>         | <code>HASH</code> , <code>BTREE</code> (see note in text) |

Example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

The *index\_type* clause cannot be used for `FULLTEXT INDEX` or `SPATIAL INDEX` specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

`BTREE` indexes are implemented by the `NDB` storage engine as T-tree indexes.

#### Note

For indexes on `NDB` table columns, the `USING` option can be specified only for a unique index or primary key. `USING HASH` prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an `NDB` table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more `NULL` columns of an `NDB` table, the hash index can be used only to look up literal values, which means that `IS [NOT] NULL` conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more `NULL` columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing `USING HASH` when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `RTREE` as a type name, but currently this cannot be specified for any storage engine.

#### Note

Use of the *index\_type* option before the `ON tbl_name` clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an *index\_type* option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

For the storage engines that support an *index\_type* option, [Table 14.2, “Storage Engine Index Characteristics”](#) shows some characteristics of index use.

**Table 14.2 Storage Engine Index Characteristics**

| Storage Engine | Index Type   | Index Class | Stores NULL Values | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|----------------|--------------|-------------|--------------------|------------------------------|-------------------|-----------------------|
| InnoDB         | BTREE        | Primary key | No                 | No                           | N/A               | N/A                   |
|                |              | Unique      | Yes                | Yes                          | Index             | Index                 |
|                |              | Key         | Yes                | Yes                          | Index             | Index                 |
|                | Inapplicable | FULLTEXT    | Yes                | Yes                          | Table             | Table                 |
|                | Inapplicable | SPATIAL     | No                 | No                           | N/A               | N/A                   |
| MyISAM         | BTREE        | Primary key | No                 | No                           | N/A               | N/A                   |

| Storage Engine | Index Type            | Index Class                           | Stores NULL Values | Permits Multiple NULL Values | IS NULL Scan Type  | IS NOT NULL Scan Type |
|----------------|-----------------------|---------------------------------------|--------------------|------------------------------|--------------------|-----------------------|
|                |                       | Unique                                | Yes                | Yes                          | Index              | Index                 |
|                |                       | Key                                   | Yes                | Yes                          | Index              | Index                 |
|                |                       | Inapplicable <a href="#">FULLTEXT</a> | Yes                | Yes                          | Table              | Table                 |
|                |                       | Inapplicable <a href="#">SPATIAL</a>  | No                 | No                           | N/A                | N/A                   |
| MEMORY         | <a href="#">HASH</a>  | Primary key                           | No                 | No                           | N/A                | N/A                   |
|                |                       | Unique                                | Yes                | Yes                          | Index              | Index                 |
|                |                       | Key                                   | Yes                | Yes                          | Index              | Index                 |
|                | <a href="#">BTREE</a> | Primary                               | No                 | No                           | N/A                | N/A                   |
|                |                       | Unique                                | Yes                | Yes                          | Index              | Index                 |
|                |                       | Key                                   | Yes                | Yes                          | Index              | Index                 |
| NDB            | <a href="#">BTREE</a> | Primary key                           | No                 | No                           | Index              | Index                 |
|                |                       | Unique                                | Yes                | Yes                          | Index              | Index                 |
|                |                       | Key                                   | Yes                | Yes                          | Index              | Index                 |
|                | <a href="#">HASH</a>  | Primary                               | No                 | No                           | Table (see note 1) | Table (see note 1)    |
|                |                       | Unique                                | Yes                | Yes                          | Table (see note 1) | Table (see note 1)    |
|                |                       | Key                                   | Yes                | Yes                          | Table (see note 1) | Table (see note 1)    |

Table note:

1. If [USING HASH](#) is specified that prevents creation of an implicit ordered index.

- [WITH\\_PARSER parser\\_name](#)

This option can be used only with [FULLTEXT](#) indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. As of MySQL 5.7.3, [InnoDB](#) and [MyISAM](#) support full-text parser plugins. Prior to MySQL 5.7.3, only [MyISAM](#) supported full-text parser plugins. See [Full-Text Parser Plugins](#) and [Section 27.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.

- [COMMENT 'string'](#)

Index definitions can include an optional comment of up to 1024 characters.

As of MySQL 5.7.6, the [MERGE\\_THRESHOLD](#) for index pages can be configured for individual indexes using the [index\\_option COMMENT](#) clause of the [CREATE INDEX](#) statement. For example:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the [MERGE\\_THRESHOLD](#) value when a row is deleted or when a row is shortened by an update operation, [InnoDB](#) attempts to merge the index page with a neighboring index page. The default [MERGE\\_THRESHOLD](#) value is 50, which is the previously hardcoded value.

[MERGE\\_THRESHOLD](#) can also be defined at the index level and table level using [CREATE TABLE](#) and [ALTER TABLE](#) statements. For more information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 14.1.8, “ALTER TABLE Syntax”](#)

### 14.1.15 CREATE LOGFILE GROUP Syntax

```
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] comment_text]
  [ENGINE [=] engine_name]
```

This statement creates a new log file group named *logfile\_group* having a single UNDO file named '*undo\_file*'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see [Section 10.2, “Schema Object Names”](#).

#### Note

All MySQL Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per MySQL Cluster instance at any given time.

The optional `INITIAL_SIZE` parameter sets the UNDO file's initial size; if not specified, it defaults to **128M** (128 megabytes). The optional `UNDO_BUFFER_SIZE` parameter sets the size used by the UNDO buffer for the log file group; The default value for `UNDO_BUFFER_SIZE` is **8M** (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters **M** (for megabytes) or **G** (for gigabytes).

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileSize` data node configuration parameter.

The maximum permitted for `UNDO_BUFFER_SIZE` is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB).

The `ENGINE` option determines the storage engine to be used by this log file group, with *engine\_name* being the name of the storage engine. In MySQL 5.7, this must be `NDB` (or `NDBCLUSTER`). If `ENGINE` is not set, MySQL tries to use the engine specified by the `default_storage_engine` server system variable (formerly `storage_engine`). In any case, if the engine is not specified as `NDB` or `NDBCLUSTER`, the `CREATE LOGFILE GROUP` statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
->     ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
->     ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the `CREATE LOGFILE GROUP` statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of MySQL Cluster.

`REDO_BUFFER_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so have no effect in MySQL 5.7. These options are intended for future expansion.

When used with `ENGINE [=] NDB`, a log file group and associated `UNDO` log file are created on each Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'undo_10.dat';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA |
+-----+-----+-----+
| lg_3              | 11                   | CLUSTER_NODE=3 |
| lg_3              | 11                   | CLUSTER_NODE=4 |
+-----+-----+-----+
2 rows in set (0.06 sec)
```

`CREATE LOGFILE GROUP` is useful only with Disk Data storage for MySQL Cluster. See [Section 20.5.13, “NDB Cluster Disk Data Tables”](#).

## 14.1.16 CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  PROCEDURE sp_name ([proc_parameter[,...]] )
  [characteristic ...] routine_body

CREATE
  [DEFINER = { user | CURRENT_USER }]
  FUNCTION sp_name ([func_parameter[,...]] )
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
```

```
| SQL SECURITY { DEFINER | INVOKER }  
  
routine_body:  
    Valid SQL routine statement
```

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 27.4, “Adding New Functions to MySQL”](#). A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See [Section 10.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 14.2.1, “CALL Syntax”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. They might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 22.2.2, “Stored Routines and MySQL Privileges”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

#### Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

Routine parameters cannot be referenced in statements prepared within the routine; see [Section C.1, “Restrictions on Stored Programs”](#).

The following example shows a simple stored procedure that uses an `OUT` parameter:

```
mysql> delimiter //
```

```
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END//
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> delimiter ;
```

```
mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 22.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by the `CHARACTER SET` attribute.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 14.6, “Compound-Statement Syntax”](#).

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see [Section C.1, “Restrictions on Stored Programs”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 14.2.1, “CALL Syntax”](#).

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, *regardless of the current server SQL mode when the routine begins executing*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 22.7, “Binary Logging of Stored Programs”](#).

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK( 'abc' )`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a routine with a nonexistent `DEFINER` account, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about stored routine security, see [Section 22.6, “Access Control for Stored Programs and Views”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 7.3.11, “SQL-Based MySQL Account Activity Auditing”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()  
BEGIN  
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;  
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if there is a `CHARACTER SET` attribute in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

If `CHARACTER SET` and `COLLATE` attributes are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide explicit `CHARACTER SET` and `COLLATE` attributes for character data parameters.

If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see [Section 11.1.3.3, “Database Character Set and Collation”](#).

## 14.1.17 CREATE SERVER Syntax

```
CREATE SERVER server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)

option:
{ HOST character-literal
| DATABASE character-literal
| USER character-literal
| PASSWORD character-literal
| SOCKET character-literal
| OWNER character-literal
| PORT numeric-literal }
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` should be `mysql`, and may be quoted with single quotation marks. Other values for `wrapper_name` are not currently supported.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals

are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

#### Note

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 16.8, “The FEDERATED Storage Engine”](#).

`CREATE SERVER` causes an automatic commit.

In MySQL 5.7, `CREATE SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

## 14.1.18 CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name

  SELECT ... (Some valid select or union statement)
```

**CREATE TABLE** creates a table with the given name. You must have the **CREATE** privilege for the table.

By default, tables are created in the default database, using the **InnoDB** storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

For information about the physical representation of a table, see [Section 14.1.18.2, “Files Created by CREATE TABLE”](#).

The original **CREATE TABLE** statement, including all specifications and table options are stored by MySQL when the table is created. For more information, see [Section 14.1.18.1, “CREATE TABLE Statement Retention”](#).

There are several aspects to the **CREATE TABLE** statement, described under the following topics in this section:

- [Temporary Tables](#)
- [Table Name](#)
- [Cloning or Copying a Table](#)
- [Column Data Types and Attributes](#)
- [Indexes and Foreign Keys](#)
- [Table Options](#)
- [Creating Partitioned Tables](#)

## Temporary Tables

You can use the **TEMPORARY** keyword when creating a table. A **TEMPORARY** table is visible only to the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-**TEMPORARY** table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the **CREATE TEMPORARY TABLES** privilege.

**CREATE TABLE** does not automatically commit the current active transaction if you use the **TEMPORARY** keyword.

**TEMPORARY** tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any **TEMPORARY** tables created within that database. Also, you can create a **TEMPORARY** table in a nonexistent database if you qualify the table name with the database name in the **CREATE TABLE** statement. In this case, all subsequent references to the table must be qualified with the database name.

## Table Name

- *tbl\_name*

The table name can be specified as *db\_name.tbl\_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

Rules for permissible table names are given in [Section 10.2, “Schema Object Names”](#).

- **IF NOT EXISTS**

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

## Cloning or Copying a Table

- `LIKE`

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see [Section 14.1.18.3, “CREATE TABLE ... LIKE Syntax”](#).

- `[AS] query_expression`

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see [Section 14.1.18.4, “CREATE TABLE ... SELECT Syntax”](#).

- `IGNORE|REPLACE`

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see [Section 14.1.18.4, “CREATE TABLE ... SELECT Syntax”](#).

## Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- `data_type`

`data_type` represents the data type in a column definition. `spatial_type` represents a spatial data type. The data type syntax shown is representative only. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see [Chapter 12, Data Types](#), and [Section 12.5, “Extensions for Spatial Data”](#). Beginning with MySQL 5.7.8, a `JSON` data type is also supported for table columns; see [Section 12.6, “The JSON Data Type”](#), for more information.

- Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. `DEFAULT` does not apply to the `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` types.
- Character data types (`CHAR`, `VARCHAR`, `TEXT`) can include `CHARACTER SET` and `COLLATE` attributes to specify the character set and collation for the column. For details, see [Section 11.1, “Character Set Support”](#). `CHARSET` is a synonym for `CHARACTER SET`. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.7 interprets length specifications in character column definitions in characters. Lengths for `BINARY` and `VARBINARY` are in bytes.

- For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length.

`BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first *length* bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see [Section 14.1.14, “CREATE INDEX Syntax”](#).

Only the `InnoDB` and `MyISAM` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

- `JSON` columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the `JSON` column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

- `NOT NULL` | `NULL`

If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.

In MySQL 5.7, only the `InnoDB`, `MyISAM`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.

- `DEFAULT`

Specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` or `DATETIME` column. See [Section 12.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as described in [Section 12.7, “Data Type Default Values”](#).

`BLOB`, `TEXT`, and `JSON` columns cannot be assigned a default value.

If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled and a date-valued default is not correct according to that mode, `CREATE TABLE` produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with `NO_ZERO_IN_DATE` enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

- `AUTO_INCREMENT`

An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is *value*+1, where *value* is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with 1.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See [Section 13.14, “Information Functions”](#), and [Section 26.8.7.38, “mysql\\_insert\\_id\(\)”](#).

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store 0 in `AUTO_INCREMENT` columns as 0 without generating a new sequence value. See [Section 6.1.8, “Server SQL Modes”](#).

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to

avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains 0.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See [Section 4.6.9, “Using AUTO\\_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to 0. See [Section 6.1.5, “Server System Variables”](#).

For information about `InnoDB` and `AUTO_INCREMENT`, see [Section 15.8.6, “AUTO\\_INCREMENT Handling in InnoDB”](#). For information about `AUTO_INCREMENT` and MySQL Replication, see [Section 18.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `COMMENT`

A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.

- `COLUMN_FORMAT`

In MySQL Cluster, it is also possible to specify a data storage format for individual columns of `NDB` tables using `COLUMN_FORMAT`. Permissible column formats are `FIXED`, `DYNAMIC`, and `DEFAULT`. `FIXED` is used to specify fixed-width storage, `DYNAMIC` permits the column to be variable-width, and `DEFAULT` causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a `ROW_FORMAT` specifier).

Beginning with MySQL Cluster NDB 7.5.4, for `NDB` tables, the default value for `COLUMN_FORMAT` is `FIXED`. (The default had been switched to `DYNAMIC` in MySQL Cluster NDB 7.5.1, but this change was reverted to maintain backwards compatibility with existing GA release series.) (Bug #24487363)

`COLUMN_FORMAT` currently has no effect on columns of tables using storage engines other than `NDB`. In MySQL 5.7 and later, `COLUMN_FORMAT` is silently ignored.

- `STORAGE`

For `NDB` tables, it is possible to specify whether the column is stored on disk or in memory by using a `STORAGE` clause. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. The `CREATE TABLE` statement used must still include a `TABLESPACE` clause:

```
mysql> CREATE TABLE t1 (  
->     c1 INT STORAGE DISK,  
->     c2 INT STORAGE MEMORY  
-> ) ENGINE NDB;  
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)  
  
mysql> CREATE TABLE t1 (  
->     c1 INT STORAGE DISK,  
->     c2 INT STORAGE MEMORY  
-> ) TABLESPACE ts_1 ENGINE NDB;  
Query OK, 0 rows affected (1.06 sec)
```

For `NDB` tables, `STORAGE DEFAULT` is equivalent to `STORAGE MEMORY`.

The `STORAGE` clause has no effect on tables using storage engines other than `NDB`. The `STORAGE` keyword is supported only in the build of `mysqld` that is supplied with MySQL Cluster; it is not

recognized in any other version of MySQL, where any attempt to use the `STORAGE` keyword causes a syntax error.

- `GENERATED ALWAYS`

Used to specify a generated column expression. For information about [generated columns](#), see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#).

[Generated stored columns](#) can be indexed. As of MySQL 5.7.8, `InnoDB` supports secondary indexes on [generated virtual columns](#). See [Section 14.1.18.8, “Secondary Indexes and Generated Columns”](#).

## Indexes and Foreign Keys

- `CONSTRAINT symbol`

If the `CONSTRAINT symbol` clause is given, the *symbol* value, if used, must be unique in the database. A duplicate *symbol* results in an error. If the clause is not given, or a *symbol* is not included following the `CONSTRAINT` keyword, a name for the constraint is created automatically.

- `PRIMARY KEY`

A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. The name of a `PRIMARY KEY` is always `PRIMARY`, which thus cannot be used as the name for any other kind of index.

If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, keep the `PRIMARY KEY` short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See [Section 15.8.9, “Clustered and Secondary Indexes”](#).)

In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(index_col_name, ...)` clause.

If a `PRIMARY KEY` consists of only one column that has an integer type, you can also refer to the column as `_rowid` in `SELECT` statements.

In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 14.7.5.22, “SHOW INDEX Syntax”](#).

- `KEY | INDEX`

`KEY` is normally a synonym for `INDEX`. The key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.

- `UNIQUE`

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`.

If a [UNIQUE](#) index consists of only one column that has an integer type, you can also refer to the column as `_rowid` in [SELECT](#) statements.

- [FULLTEXT](#)

A [FULLTEXT](#) index is a special type of index used for full-text searches. Only the [InnoDB](#) and [MyISAM](#) storage engines support [FULLTEXT](#) indexes. They can be created only from [CHAR](#), [VARCHAR](#), and [TEXT](#) columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 13.9, “Full-Text Search Functions”](#), for details of operation. A [WITH PARSER](#) clause can be specified as an [index\\_option](#) value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for [FULLTEXT](#) indexes. Prior to MySQL 5.7.3, only [MyISAM](#) supported full-text parser plugins. As of MySQL 5.7.3, both [InnoDB](#) and [MyISAM](#) support full-text parser plugins. See [Full-Text Parser Plugins](#) and [Section 27.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.

- [SPATIAL](#)

You can create [SPATIAL](#) indexes on spatial data types. Spatial types are supported only for [MyISAM](#) and (as of MySQL 5.7.5) [InnoDB](#) tables, and indexed columns must be declared as [NOT NULL](#). See [Section 12.5, “Extensions for Spatial Data”](#).

- [FOREIGN KEY](#)

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see [reference\\_definition](#), and [reference\\_option](#).

Partitioned tables employing the [InnoDB](#) storage engine do not support foreign keys. See [Section 21.6, “Restrictions and Limitations on Partitioning”](#), for more information.

- [CHECK](#)

The [CHECK](#) clause is parsed but ignored by all storage engines. See [Section 1.8.2.3, “Foreign Key Differences”](#).

- [index\\_col\\_name](#)

- An [index\\_col\\_name](#) specification can end with [ASC](#) or [DESC](#). These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- Prefixes, defined by the [length](#) attribute, can be up to 767 bytes long for [InnoDB](#) tables or 3072 bytes if the [innodb\\_large\\_prefix](#) option is enabled. For [MyISAM](#) tables, the prefix limit is 1000 bytes.

Prefix limits are measured in bytes, whereas the prefix length in [CREATE TABLE](#), [ALTER TABLE](#), and [CREATE INDEX](#) statements is interpreted as number of characters for nonbinary string types ([CHAR](#), [VARCHAR](#), [TEXT](#)) and number of bytes for binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- [index\\_type](#)

Some storage engines permit you to specify an index type when creating an index. The syntax for the [index\\_type](#) specifier is [USING type\\_name](#).

Example:

```
CREATE TABLE lookup
```

```
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

- *index\_option*

*index\_option* values specify additional options for an index.

- `KEY_BLOCK_SIZE`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

For information about the table-level `KEY_BLOCK_SIZE` attribute, see [Table Options](#).

- `WITH PARSER`

The `WITH PARSER` option can only be used with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. Prior to MySQL 5.7.3, only `MyISAM` supported full-text parser plugins. As of MySQL 5.7.3, both `InnoDB` and `MyISAM` support full-text parser plugins. If you have a `MyISAM` table with an associated full-text parser plugin, you can convert the table to `InnoDB` using `ALTER TABLE`.

- `COMMENT`

In MySQL 5.7, index definitions can include an optional comment of up to 1024 characters.

You can set the `InnoDB MERGE_THRESHOLD` value for an individual index using the *index\_option* `COMMENT` clause. See [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

For more information about permissible *index\_option* values, see [Section 14.1.14, “CREATE INDEX Syntax”](#). For more information about indexes, see [Section 9.3.1, “How MySQL Uses Indexes”](#).

- *reference\_definition*

For *reference\_definition* syntax details and examples, see [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in `InnoDB`, see [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

`InnoDB` and `NDB` tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys are supported. For more detailed information and examples, see [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in `InnoDB`, see [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. See [Section 1.8.2.3, “Foreign Key Differences”](#).

#### Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON`

`UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, `InnoDB` does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only keys that are both `UNIQUE` (or `PRIMARY`) and `NOT NULL`.

MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification.

- *reference\_option*

For information about the `RESTRICT`, `CASCADE`, `SET NULL`, and `NO ACTION` options, see [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#).

## Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `ENGINE`

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name `'DEFAULT'` is recognized but ignored.

| Storage Engine       | Description  |
|----------------------|--|
| <code>InnoDB</code>  | Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See <a href="#">Chapter 15, The InnoDB Storage Engine</a> , and in particular <a href="#">Section 15.1, “Introduction to InnoDB”</a> if you have MySQL experience but are new to <code>InnoDB</code> . |
| <code>MyISAM</code>  | The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See <a href="#">Section 16.2, “The MyISAM Storage Engine”</a> .  |
| <code>MEMORY</code>  | The data for this storage engine is stored only in memory. See <a href="#">Section 16.3, “The MEMORY Storage Engine”</a> .   |
| <code>CSV</code>     | Tables that store rows in comma-separated values format. See <a href="#">Section 16.4, “The CSV Storage Engine”</a> .  |
| <code>ARCHIVE</code> | The archiving storage engine. See <a href="#">Section 16.5, “The ARCHIVE Storage Engine”</a> .   |
| <code>EXAMPLE</code> | An example engine. See <a href="#">Section 16.9, “The EXAMPLE Storage Engine”</a> .  |

| Storage Engine            | Description  |
|---------------------------|--|
| <a href="#">FEDERATED</a> | Storage engine that accesses remote tables. See <a href="#">Section 16.8, “The FEDERATED Storage Engine”</a> .   |
| <a href="#">HEAP</a>      | This is a synonym for <a href="#">MEMORY</a> .   |
| <a href="#">MERGE</a>     | A collection of <a href="#">MyISAM</a> tables used as one table. Also known as <a href="#">MRG_MyISAM</a> . See <a href="#">Section 16.7, “The MERGE Storage Engine”</a> .                   |
| <a href="#">NDB</a>       | Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as <a href="#">NDBCLUSTER</a> . See <a href="#">Chapter 20, MySQL NDB Cluster 7.5</a> . |

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing [NO\\_ENGINE\\_SUBSTITUTION](#) from the server SQL mode (see [Section 6.1.8, “Server SQL Modes”](#)) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is [InnoDB](#), which is the default value for the [default\\_storage\\_engine](#) system variable. When [NO\\_ENGINE\\_SUBSTITUTION](#) is disabled, a warning occurs if the storage engine specification is not honored.

- [AUTO\\_INCREMENT](#)

The initial [AUTO\\_INCREMENT](#) value for the table. In MySQL 5.7, this works for [MyISAM](#), [MEMORY](#), [InnoDB](#), and [ARCHIVE](#) tables. To set the first auto-increment value for engines that do not support the [AUTO\\_INCREMENT](#) table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the [AUTO\\_INCREMENT](#) table option in [CREATE TABLE](#) statements, you can also use [ALTER TABLE tbl\\_name AUTO\\_INCREMENT = N](#) to reset the [AUTO\\_INCREMENT](#) value. The value cannot be set lower than the maximum value currently in the column.

- [AVG\\_ROW\\_LENGTH](#)

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a [MyISAM](#) table, MySQL uses the product of the [MAX\\_ROWS](#) and [AVG\\_ROW\\_LENGTH](#) options to decide how big the resulting table is. If you don't specify either option, the maximum size for [MyISAM](#) data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the [myisam\\_data\\_pointer\\_size](#) system variable. (See [Section 6.1.5, “Server System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- [\[DEFAULT\] CHARACTER SET](#)

Specifies a default character set for the table. [CHARSET](#) is a synonym for [CHARACTER SET](#). If the character set name is [DEFAULT](#), the database character set is used.

- [CHECKSUM](#)

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The [CHECKSUM TABLE](#) statement reports the checksum. ([MyISAM](#) only.)

- [\[DEFAULT\] COLLATE](#)

Specifies a default collation for the table.

- **COMMENT**

A comment for the table, up to 2048 characters long.

You can set the `InnoDB MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause. See [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

**Setting NDB\_TABLE options.** In MySQL Cluster NDB 7.5.2 and later, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify one to four of the `NDB_TABLE` options `NOLOGGING`, `READ_BACKUP`, `PARTITION_BALANCE`, or `FULLY_REPLICATED` as a set of name-value pairs, separated by commas if need be, immediately following the string `NDB_TABLE=` that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

```
CREATE TABLE t1 (
  c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c2 VARCHAR(100),
  c3 VARCHAR(100) )
ENGINE=NDB
COMMENT="NDB_TABLE=READ_BACKUP=0 ,PARTITION_BALANCE=FOR_RP_BY_NODE" ;
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available as the `TABLE_COMMENT` column of the MySQL Information Schema `TABLES` table.

This comment syntax is also supported with `ALTER TABLE` statements for `NDB` tables. Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have had previously.

Setting the `MERGE_THRESHOLD` option in table comments is not supported for `NDB` tables (it is ignored).

For complete syntax information and examples, see [Section 14.1.18.9, “Setting NDB\\_TABLE Options in Table Comments”](#).

- **COMPRESSION**

The compression algorithm used for page level compression for `InnoDB` tables. Supported values include `Zlib`, `LZ4`, and `None`. The `COMPRESSION` attribute was introduced with the transparent page compression feature in MySQL 5.7.8. Page compression is only supported with `InnoDB` tables that reside in `file-per-table` tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- **CONNECTION**

The connection string for a `FEDERATED` table.

**Note**

Older versions of MySQL used a `COMMENT` option for the connection string.

- **DATA DIRECTORY, INDEX DIRECTORY**

For `InnoDB`, the `DATA DIRECTORY='directory'` option allows you to create `InnoDB` file-per-table tablespaces outside the MySQL data directory. Within the directory that you specify, MySQL creates a subdirectory corresponding to the database name, and within that a `.ibd` file for the table. The `innodb_file_per_table` configuration option must be enabled to use the `DATA DIRECTORY` option with `InnoDB`. The full directory path must be specified. See [Section 15.7.5, “Creating a File-Per-Table Tablespace Outside the Data Directory”](#) for more information.

When creating `MyISAM` tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a `MyISAM` table's data file and index file, respectively. Unlike `InnoDB` tables, MySQL does not create subdirectories that correspond to the database name when creating a `MyISAM` table with a `DATA DIRECTORY` or `INDEX DIRECTORY` option. Files are created in the directory that is specified.

**Important**

Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See [Section 9.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”](#), for more complete information.

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case `MyISAM` will not overwrite existing files and returns an error instead.

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

**Important**

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- `DELAY_KEY_WRITE`

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in [Section 6.1.5, “Server System Variables”](#). (`MyISAM` only.)

- `ENCRYPTION`

Set the `ENCRYPTION` option to `'Y'` to enable page-level data encryption for an `InnoDB` table created in a `file-per-table` tablespace. Option values are not case sensitive. The `ENCRYPTION` option was introduced with the `InnoDB` tablespace encryption feature; see [Section 15.7.10, “InnoDB Tablespace Encryption”](#). The `keyring_file` plugin must be loaded to use the `ENCRYPTION` option.

- `INSERT_METHOD`

If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See [Section 16.7, “The MERGE Storage Engine”](#).

- `KEY_BLOCK_SIZE`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

For `InnoDB` tables, `KEY_BLOCK_SIZE` optionally specifies the `page` size (in kilobytes) to use for `compressed` `InnoDB` tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size

could be used by `InnoDB` if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See [Section 15.9.1, “InnoDB Table Compression”](#) for more information.

Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for `InnoDB` tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

`InnoDB` only supports `KEY_BLOCK_SIZE` at the table level.

`KEY_BLOCK_SIZE` is not supported with 32k and 64k `innodb_page_size` values. `InnoDB` table compression does not support these pages sizes.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

The `NDB` storage engine treats this value as a maximum. If you plan to create very large MySQL Cluster tables (containing millions of rows), you should use this option to insure that `NDB` allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting `MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

Takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- `ROW_FORMAT`

Defines the physical format in which the rows are stored.

When executing a `CREATE TABLE` statement, if you specify a row format that is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The information reported in this column in response to `SHOW TABLE STATUS` is the actual row format used. This may differ from the value in the `Create_options` column because the original `CREATE TABLE` definition is retained during creation.

Row format choices differ depending on the storage engine used for the table.

For `InnoDB` tables:

- In MySQL 5.7.8 and earlier, rows are stored in `COMPACT` format by default. As of MySQL 5.7.9, the default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by `innodb_default_row_format`. For more information, see [Section 15.11.2, “Specifying the Row Format for a Table”](#).

- For more efficient `InnoDB` storage of data types, especially `BLOB` types, use the `DYNAMIC`. See [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#) for requirements associated with the `DYNAMIC` row format.
- To enable compression for `InnoDB` tables, specify `ROW_FORMAT=COMPRESSED`. See [Section 15.9, “InnoDB Table and Page Compression”](#) for requirements associated with the `COMPRESSED` row format.
- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.
- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.
- `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, `InnoDB` issues a warning and assumes `ROW_FORMAT=DYNAMIC`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default as of MySQL 5.7.7, `InnoDB` returns an error.
- For additional information about `InnoDB` row formats, see [Section 15.11, “InnoDB Row Storage and Row Formats”](#).

For `MyISAM` tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 16.2.3, “MyISAM Table Storage Formats”](#).

For `NDB` tables, the default `ROW_FORMAT` in MySQL Cluster NDB 7.5.1 and later is `DYNAMIC`. (Previously, it was `FIXED`.)

- `STATS_AUTO_RECALC`

Specifies whether to automatically recalculate [persistent statistics](#) for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the

`innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_PERSISTENT`

Specifies whether to enable [persistent statistics](#) for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_SAMPLE_PAGES`

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `TABLESPACE`

The `TABLESPACE` option, added in MySQL 5.7.6 with the introduction of `InnoDB general tablespaces`, is used to create a table in an `InnoDB` general tablespace.

```
CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
```

The general tablespace that you specify must exist prior to using the `TABLESPACE` option. For information about general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

The `tablespace_name` is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with “`innodb_`” are reserved for special use.

The `TABLESPACE` option may be used to assign `InnoDB` table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. `TABLESPACE` option support for table partitions and subpartitions was added in MySQL 5.7.8. All partitions must belong to the same storage engine.

A tablespace specified at the table level becomes the default tablespace for new partitions and subpartitions. The default tablespace may be overridden by specifying a tablespace at the partition or subpartition level in a `CREATE TABLE` or `ALTER TABLE` statement. The following example shows tablespaces defined at the table level and partition level.

```
mysql> CREATE TABLE t1 ( a INT NOT NULL, PRIMARY KEY (a))
-> ENGINE=InnoDB TABLESPACE ts1
-> PARTITION BY RANGE (a) PARTITIONS 3 (
-> PARTITION P1 VALUES LESS THAN (2),
-> PARTITION P2 VALUES LESS THAN (4) TABLESPACE ts2,
-> PARTITION P3 VALUES LESS THAN (6) TABLESPACE ts3);
```

For more information about the `TABLESPACE` option and partitioning, see [Section 15.7.9, “InnoDB General Tablespaces”](#)

To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
```

Using the `TABLESPACE [=] innodb_system` option, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For

example, you can add a table with `ROW_FORMAT=DYNAMIC` to the system tablespace using the `TABLESPACE [=] innodb_system` option.

To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

#### Note

If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when `innodb_file_per_table` is enabled.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` option.

The `TABLESPACE` option is supported with `ALTER TABLE` and `ALTER TABLE ... REORGANIZE PARTITION` statements, which can be used to move tables and partitions from one tablespace to another, respectively. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

The `STORAGE` table option is employed only with NDB tables. `STORAGE` determines the type of storage used (disk or memory), and can be one of `DISK`, `MEMORY`, or `DEFAULT`.

`TABLESPACE ... STORAGE DISK` assigns a table to a MySQL Cluster Disk Data tablespace. The tablespace must already have been created using `CREATE TABLESPACE`. See [Section 20.5.13, “NDB Cluster Disk Data Tables”](#), for more information.

#### Important

A `STORAGE` clause cannot be used in a `CREATE TABLE` statement without a `TABLESPACE` clause.

- `UNION`

Used to access a collection of identical MyISAM tables as one. This works only with `MERGE` tables. See [Section 16.7, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table.

#### Note

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

## Creating Partitioned Tables

`partition_options` can be used to control partitioning of the table created with `CREATE TABLE`.

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 21, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 14.1.8, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 21.3, “Partition Management”](#).

- `PARTITION BY`

If used, a *partition\_options* clause begins with **PARTITION BY**. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to *num*, where *num* is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

#### Note

The expression (*expr*) used in a **PARTITION BY** clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

- **HASH(*expr*)**

Hashes one or more columns to create a key for placing and locating rows. *expr* is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid **CREATE TABLE** statements using **PARTITION BY HASH**:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
  PARTITION BY HASH ( YEAR(col3) );
```

You may not use either **VALUES LESS THAN** or **VALUES IN** clauses with **PARTITION BY HASH**.

**PARTITION BY HASH** uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 21.2.4, “HASH Partitioning”](#).

The **LINEAR** keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical **AND** operations. For discussion and examples of linear hashing, see [Section 21.2.4.1, “LINEAR HASH Partitioning”](#).

- **KEY(*column\_list*)**

This is similar to **HASH**, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column\_list* argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY KEY(col3)
  PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the **LINEAR** keyword. This has the same effect as with tables that are partitioned by **HASH**. That is, the partition number is found using the **&** operator rather than the modulus (see [Section 21.2.4.1, “LINEAR HASH Partitioning”](#), and [Section 21.2.5, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY LINEAR KEY(col3)
  PARTITIONS 5;
```

The **ALGORITHM={1|2}** option is supported with **[SUB]PARTITION BY [LINEAR] KEY** beginning with MySQL 5.7.1. **ALGORITHM=1** causes the server to use the same key-hashing functions as MySQL 5.1; **ALGORITHM=2** means that the server employs the key-hashing functions implemented and used by default for new **KEY** partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a

MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see [Section 14.1.8.1, “ALTER TABLE Partition Operations”](#).

`mysqldump` in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 1 */ /*!50100 (
PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by `KEY` into a MySQL 5.6 server previous to version 5.6.11, be sure to consult [Changes Affecting Upgrades to MySQL 5.6](#), before proceeding. (The information found there also applies if you are loading a dump containing `KEY` partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE(expr)`

In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

#### Note

For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 5.7, you can overcome this limitation in a table that is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

| Partition Number: | Years Range:     |
|-------------------|------------------|
| 0                 | 1990 and earlier |
| 1                 | 1991 to 1994     |
| 2                 | 1995 to 1998     |
| 3                 | 1999 to 2002     |
| 4                 | 2003 to 2005     |
| 5                 | 2006 and later   |

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
```

```

        some_data INT
    )
    PARTITION BY RANGE (year_col) (
        PARTITION p0 VALUES LESS THAN (1991),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (1999),
        PARTITION p3 VALUES LESS THAN (2002),
        PARTITION p4 VALUES LESS THAN (2006),
        PARTITION p5 VALUES LESS THAN MAXVALUE
    );

```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- `RANGE COLUMNS(column_list)`

This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```

CREATE TABLE rc (
    a INT NOT NULL,
    b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
    PARTITION p0 VALUES LESS THAN (10,5),
    PARTITION p1 VALUES LESS THAN (20,10),
    PARTITION p2 VALUES LESS THAN (MAXVALUE,15),
    PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 21.2.1, “RANGE Partitioning”](#), and [Section 21.4, “Partition Pruning”](#).

- `LIST(expr)`

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to [RANGE](#), except that only `VALUES IN` may be used to specify permissible values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

#### Note

For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 5.7, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

- `LIST COLUMNS(column_list)`

This variant on `LIST` facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the `COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- **PARTITIONS** *num*

The number of partitions may optionally be specified with a **PARTITIONS** *num* clause, where *num* is the number of partitions. If both this clause *and* any **PARTITION** clauses are used, *num* must be equal to the total number of any partitions that are declared using **PARTITION** clauses.

#### Note

Whether or not you use a **PARTITIONS** clause in creating a table that is partitioned by **RANGE** or **LIST**, you must still include at least one **PARTITION VALUES** clause in the table definition (see below).

- **SUBPARTITION BY**

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional **SUBPARTITION BY** clause. Subpartitioning may be done by **HASH** or **KEY**. Either of these may be **LINEAR**. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by **LIST** or **RANGE**.)

The number of subpartitions can be indicated using the **SUBPARTITIONS** keyword followed by an integer value.

- Rigorous checking of the value used in **PARTITIONS** or **SUBPARTITIONS** clauses is applied and this value must adhere to the following rules:
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, **PARTITIONS 0.2E+01** is not permitted, even though **0.2E+01** evaluates to **2**. (Bug #15890)
- *partition\_definition*

Each partition may be individually defined using a *partition\_definition* clause. The individual parts making up this clause are as follows:

- **PARTITION** *partition\_name*

Specifies a logical name for the partition.

- **VALUES**

For range partitioning, each partition must include a **VALUES LESS THAN** clause; for list partitioning, you must specify a **VALUES IN** clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 21, Partitioning](#), for syntax examples.

- **[STORAGE] ENGINE**

The partitioning handler accepts a **[STORAGE] ENGINE** option for both **PARTITION** and **SUBPARTITION**. Currently, the only way in which this can be used is to set all partitions or all

subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL`. We expect to lift this restriction on partitioning in a future MySQL release.

- **COMMENT**

An optional **COMMENT** clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

- **DATA DIRECTORY** and **INDEX DIRECTORY**

**DATA DIRECTORY** and **INDEX DIRECTORY** may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data\_dir* and the *index\_dir* must be absolute system path names. Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2002 VALUES IN (1998, 2002, 2006)
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

**DATA DIRECTORY** and **INDEX DIRECTORY** behave in the same way as in the **CREATE TABLE** statement's *table\_option* clause as used for **MyISAM** tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the **DATA DIRECTORY** and **INDEX DIRECTORY** options are not supported for individual partitions or subpartitions of **MyISAM** tables, and the **INDEX DIRECTORY** option is not supported for individual partitions or subpartitions of **InnoDB** tables. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

#### Note

The **DATA DIRECTORY** and **INDEX DIRECTORY** options are ignored for creating partitioned tables if **NO\_DIR\_IN\_CREATE** is in effect. (Bug #24633)

- **MAX\_ROWS** and **MIN\_ROWS**

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for *max\_number\_of\_rows* and *min\_number\_of\_rows* must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- **TABLESPACE**

May be used to assign [InnoDB](#) table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. [TABLESPACE](#) option support for table partitions and subpartitions was added in MySQL 5.7.8; see [Section 15.7.9, “InnoDB General Tablespaces”](#). It is also supported by MySQL Cluster. All partitions must belong to the same storage engine.

- [subpartition\\_definition](#)

The partition definition may optionally contain one or more [subpartition\\_definition](#) clauses. Each of these consists at a minimum of the [SUBPARTITION name](#), where *name* is an identifier for the subpartition. Except for the replacement of the [PARTITION](#) keyword with [SUBPARTITION](#), the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by [HASH](#) or [KEY](#), and can be done only on [RANGE](#) or [LIST](#) partitions. See [Section 21.2.6, “Subpartitioning”](#).

### Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```
CREATE TABLE t1 (  
  s1 INT,  
  s2 INT AS (EXP(s1)) STORED  
)  
PARTITION BY LIST (s2) (  
  PARTITION p1 VALUES IN (1)  
);
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see [Section 21.6.3, “Partitioning Limitations Relating to Functions”](#)). The preceding example demonstrates this technique: [EXP\(\)](#) cannot be used directly in the [PARTITION BY](#) clause, but a generated column defined using [EXP\(\)](#) is permitted.

#### 14.1.18.1 CREATE TABLE Statement Retention

The original [CREATE TABLE](#) statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an [ALTER TABLE](#) statement, the original table options specified are retained. This enables you to change between [InnoDB](#) and [MyISAM](#) table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the [ROW\\_FORMAT](#)), the active table definition (accessible through [DESCRIBE](#) or with [SHOW TABLE STATUS](#)) and the table creation string (accessible through [SHOW CREATE TABLE](#)) will report different values.

#### 14.1.18.2 Files Created by CREATE TABLE

MySQL represents each table by an [.frm](#) table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For an [InnoDB](#) table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in an [ibd file](#) in the database directory. When an [InnoDB](#) table is created in the system tablespace, table data and indexes are stored in the [ibdata\\* files](#) that represent the system tablespace. The [innodb\\_file\\_per\\_table](#) option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The [TABLESPACE](#) option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the [innodb\\_file\\_per\\_table](#) setting.

For [MyISAM](#) tables, the storage engine creates data and index files. Thus, for each [MyISAM](#) table *tbl\_name*, there are three disk files.

| File                      | Purpose                        |
|---------------------------|--------------------------------|
| <code>tbl_name.frm</code> | Table format (definition) file |
| <code>tbl_name.MYD</code> | Data file                      |
| <code>tbl_name.MYI</code> | Index file                     |

Chapter 16, *Alternative Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 10.2.3, “Mapping of Identifiers to File Names”](#).

### 14.1.18.3 CREATE TABLE ... LIKE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

#### Important

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

### 14.1.18.4 CREATE TABLE ... SELECT Syntax

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
->     PRIMARY KEY (a), KEY(b))
->     ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n |
+----+
| 1 |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m      | n |
+-----+-----+
| NULL   | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. See also [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
  FROM artist LEFT JOIN work ON artist.id = work.artist_id
  GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails.

#### 14.1.18.5 Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and [foreign key constraints](#), which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a `CREATE TABLE` or `ALTER TABLE` statement looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION
```

*index\_name* represents a foreign key ID. The *index\_name* value is ignored if there is already an explicitly defined index on the child table that can support the foreign key. Otherwise, MySQL implicitly creates a foreign key index that is named according to the following rules:

- If defined, the `CONSTRAINT symbol` value is used. Otherwise, the `FOREIGN KEY index_name` value is used.
- If neither a `CONSTRAINT symbol` or `FOREIGN KEY index_name` is defined, the foreign key index name is generated using the name of the referencing foreign key column.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a [parent table](#) that holds the central data values, and a [child table](#) with identical values pointing back to its parent. The `FOREIGN KEY` clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be [TEMPORARY](#) tables.

In MySQL 5.7, creation of a foreign key constraint requires the `REFERENCES` privilege for the parent table as of 5.7.6.

- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is described in [Section 14.1.8, “ALTER TABLE Syntax”](#).

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. *index\_name*, if given, is used as described previously.
- **InnoDB** permits a foreign key to reference any column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.

**NDB** requires an explicit unique key (or primary key) on any column referenced as a foreign key.

- Index prefixes on foreign key columns are not supported. One consequence of this is that **BLOB** and **TEXT** columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- If the **CONSTRAINT** *symbol* clause is given, the *symbol* value, if used, must be unique in the database. A duplicate *symbol* will result in an error similar to: `ERROR 1022 (2300): Can't write; duplicate key in table '#sql- 464_1'`. If the clause is not given, or a *symbol* is not included following the **CONSTRAINT** keyword, a name for the constraint is created automatically.
- **InnoDB** does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

This restriction does not apply for **NDB** tables that are partitioned by **KEY** or **LINEAR KEY** (the only user partitioning types supported by the **NDB** storage engine); these may have foreign key references or be the targets of such references.

- For **NDB** tables, **ON UPDATE CASCADE** is not supported where the reference is to the parent table's primary key.

## Referential Actions

This section describes how foreign keys help guarantee [referential integrity](#).

For storage engines supporting foreign keys, MySQL rejects any **INSERT** or **UPDATE** operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an **UPDATE** or **DELETE** operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified using **ON UPDATE** and **ON DELETE** subclauses of the **FOREIGN KEY** clause. MySQL supports five options regarding the action to be taken, listed here:

- **CASCADE**: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both **ON DELETE CASCADE** and **ON UPDATE CASCADE** are supported. Between two tables, do not define several **ON UPDATE CASCADE** clauses that act on the same column in the parent table or in the child table.

### Note

Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to **NULL**. Both **ON DELETE SET NULL** and **ON UPDATE SET NULL** clauses are supported.

If you specify a **SET NULL** action, *make sure that you have not declared the columns in the child table as **NOT NULL***.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying **RESTRICT** (or **NO ACTION**) is the same as omitting the **ON DELETE** or **ON UPDATE** clause.
- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to **RESTRICT**. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and **NO ACTION** is a deferred check. In MySQL, foreign key constraints are checked immediately, so **NO ACTION** is the same as **RESTRICT**.
- **SET DEFAULT**: This action is recognized by the MySQL parser, but both **InnoDB** and **NDB** reject table definitions containing **ON DELETE SET DEFAULT** or **ON UPDATE SET DEFAULT** clauses.

For an **ON DELETE** or **ON UPDATE** that is not specified, the default action is always **RESTRICT**.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

A foreign key constraint on a generated stored column cannot use **ON UPDATE CASCADE**, **ON DELETE SET NULL**, **ON UPDATE SET NULL**, **ON DELETE SET DEFAULT**, or **ON UPDATE SET DEFAULT**.

A foreign key constraint cannot reference a generated virtual column.

For **InnoDB** restrictions related to foreign keys and generated columns, see [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

## Examples of Foreign Key Clauses

Here is a simple example that relates **parent** and **child** tables through a single-column foreign key:

```
CREATE TABLE parent (  
    id INT NOT NULL,  
    PRIMARY KEY (id)  
) ENGINE=INNODB;  
  
CREATE TABLE child (  
    id INT,  
    parent_id INT,  
    INDEX par_ind (parent_id),  
    FOREIGN KEY (parent_id)  
        REFERENCES parent(id)  
        ON DELETE CASCADE  
) ENGINE=INNODB;
```

A more complex example in which a **product\_order** table has foreign keys for two other tables. One foreign key references a two-column index in the **product** table. The other references a single-column index in the **customer** table:

```
CREATE TABLE product (  
    category INT NOT NULL, id INT NOT NULL,  
    price DECIMAL,  
    PRIMARY KEY(category, id)  
) ENGINE=INNODB;  
  
CREATE TABLE customer (  
    id INT NOT NULL,  
    PRIMARY KEY (id)  
) ENGINE=INNODB;  
  
CREATE TABLE product_order (  
    no INT NOT NULL AUTO_INCREMENT,  
    product_category INT NOT NULL,  
    product_id INT NOT NULL,
```

```

customer_id INT NOT NULL,

PRIMARY KEY(no),
INDEX (product_category, product_id),
INDEX (customer_id),

FOREIGN KEY (product_category, product_id)
REFERENCES product(category, id)
ON UPDATE CASCADE ON DELETE RESTRICT,

FOREIGN KEY (customer_id)
REFERENCES customer(id)
) ENGINE=INNODB;

```

## Adding foreign keys

You can add a new foreign key constraint to an existing table by using `ALTER TABLE`. The syntax relating to foreign keys for this statement is shown here:

```

ALTER TABLE tbl_name
ADD [CONSTRAINT [symbol]] FOREIGN KEY
[index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name,...)
[ON DELETE reference_option]
[ON UPDATE reference_option]

```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, *remember to create the required indexes first*.

## Dropping Foreign Keys

You can also use `ALTER TABLE` to drop foreign keys, using the syntax shown here:

```

ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;

```

If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the *fk\_symbol* value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a `SHOW CREATE TABLE` statement, as shown here:

```

mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;

```

Prior to MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Separate statements should be used for

each operation. As of MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but remains unsupported for `ALTER TABLE ... ALGORITHM=COPY`.

In MySQL 5.7, the server prohibits changes to foreign key columns with the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.

## Foreign Keys and Other MySQL Statements

Table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause can be quoted within backticks (```). Alternatively, double quotation marks (`"`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The setting of the `lower_case_table_names` system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table.

You can find information about foreign keys used by `InnoDB` tables in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, also in the `INFORMATION_SCHEMA` database.

`mysqldump` produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `foreign_key_checks` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;
```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `foreign_key_checks` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `foreign_key_checks = 0`, MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, `ALTER TABLE` cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue `DROP TABLE` for a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET foreign_key_checks = 0`. When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.

For `InnoDB` tables, you can obtain a detailed explanation of the most recent `InnoDB` foreign key error in the MySQL Server, by checking the output of `SHOW ENGINE INNODB STATUS`.

**Important**

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including [InnoDB](#), recognizes or enforces the [MATCH](#) clause used in referential-integrity constraint definitions. Use of an explicit [MATCH](#) clause will not have the specified effect, and also causes [ON DELETE](#) and [ON UPDATE](#) clauses to be ignored. For these reasons, specifying [MATCH](#) should be avoided.

The [MATCH](#) clause in the SQL standard controls how [NULL](#) values in a composite (multiple-column) foreign key are handled when comparing to a primary key. MySQL essentially implements the semantics defined by [MATCH SIMPLE](#), which permit a foreign key to be all or partially [NULL](#). In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that the referenced columns be [UNIQUE](#) or be declared [NOT NULL](#). The handling of foreign key references to nonunique keys or keys that contain [NULL](#) values is not well defined for operations such as [UPDATE](#) or [DELETE CASCADE](#). You are advised to use foreign keys that reference only [UNIQUE](#) (including [PRIMARY](#)) and [NOT NULL](#) keys.

Furthermore, MySQL parses but ignores “inline [REFERENCES](#) specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts [REFERENCES](#) clauses only when specified as part of a separate [FOREIGN KEY](#) specification. For storage engines that do not support foreign keys (such as [MyISAM](#)), MySQL Server parses and ignores foreign key specifications.

#### 14.1.18.6 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- Columns that are part of a [PRIMARY KEY](#) are made [NOT NULL](#) even if not declared that way.
- Trailing spaces are automatically deleted from [ENUM](#) and [SET](#) member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 12.10, “Using Data Types from Other Database Engines”](#).
- If you include a [USING](#) clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a [VARCHAR](#) column with a length specification greater than 65535 is converted to [TEXT](#), and a [VARBINARY](#) column with a length specification greater than 65535 is converted to [BLOB](#). Otherwise, an error occurs in either of these cases.
- Specifying the [CHARACTER SET binary](#) attribute for a character data type causes the column to be created as the corresponding binary data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a [DESCRIBE](#) or [SHOW CREATE TABLE](#) statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using [myisampack](#). See [Section 16.2.3.3, “Compressed Table Characteristics”](#).

### 14.1.18.7 CREATE TABLE and Generated Columns

As of MySQL 5.7.6, [CREATE TABLE](#) supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

Generated columns are supported by the [NDB](#) storage engine beginning with MySQL Cluster NDB 7.5.3.

The following simple example shows a table that stores the lengths of the sides of right triangles in the [sidea](#) and [sideb](#) columns, and computes the length of the hypotenuse in [sidec](#) (the square root of the sums of the squares of the other sides):

```
CREATE TABLE triangle (
  sidea DOUBLE,
  sideb DOUBLE,
  sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mysql> SELECT * FROM triangle;
+-----+-----+-----+
| sidea | sideb | sidec |
+-----+-----+-----+
| 1     | 1     | 1.4142135623730951 |
| 3     | 4     | 5 |
| 6     | 8     | 10 |
+-----+-----+-----+
```

Any application that uses the [triangle](#) table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```
col_name data_type [GENERATED ALWAYS] AS (expression)
[VIRTUAL | STORED] [UNIQUE [KEY]] [COMMENT comment]
[[NOT] NULL] [[PRIMARY] KEY]
```

**AS** (*expression*) indicates that the column is generated and defines the expression used to compute column values. **AS** may be preceded by **GENERATED ALWAYS** to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The **VIRTUAL** or **STORED** keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any **BEFORE** triggers. A virtual column takes no storage.

Prior to MySQL 5.7.8, virtual columns cannot be indexed. As of MySQL 5.7.8, **InnoDB** supports secondary indexes on virtual columns. See [Section 14.1.18.8, “Secondary Indexes and Generated Columns”](#).

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is **VIRTUAL** if neither keyword is specified.

It is permitted to mix **VIRTUAL** and **STORED** columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be **NULL**, or provide a comment. (Note that the order of these attributes differs from their order in nongenerated column definitions.)

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that fail this definition: **CONNECTION\_ID()**, **CURRENT\_USER()**, **NOW()**.
- Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.
- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.
- The **AUTO\_INCREMENT** attribute cannot be used in a generated column definition.
- An **AUTO\_INCREMENT** column cannot be used as a base column in a generated column definition.
- As of MySQL 5.7.10, if expression evaluation causes truncation or provides incorrect input to a function, the **CREATE TABLE** statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 13.2, “Type Conversion in Expression Evaluation”](#).

**Note**

If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For **CREATE TABLE ... LIKE**, the destination table preserves generated column information from the original table.

For **CREATE TABLE ... SELECT**, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The **SELECT** part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See [Creating Partitioned Tables](#).

A foreign key constraint on a generated stored column cannot use `ON UPDATE CASCADE`, `ON DELETE SET NULL`, `ON UPDATE SET NULL`, `ON DELETE SET DEFAULT`, or `ON UPDATE SET DEFAULT`.

A foreign key constraint cannot reference a generated virtual column.

For `InnoDB` restrictions related to foreign keys and generated columns, see [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns.

For `INSERT`, `REPLACE`, and `UPDATE`, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is `DEFAULT`.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.
- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.
- Generated columns can simulate functional indexes: Use a stored column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as `JSON` columns; see [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

The disadvantage of such an approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see [Section 9.3.9, “Optimizer Use of Generated Column Indexes”](#).

Example:

Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:

```
SELECT CONCAT(first_name, ' ', last_name) AS full_name FROM t1;
```

One way to avoid writing out the expression is to create a view `v1` on `t1`, which simplifies applications by enabling them to select `full_name` directly without using an expression:

```
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name, ' ', last_name) AS full_name FROM t1;

SELECT full_name FROM v1;
```

A generated column also enables applications to select `full_name` directly without the need to define a view:

```
CREATE TABLE t1 (
```

```

first_name VARCHAR(10),
last_name VARCHAR(10),
full_name VARCHAR(255) AS (CONCAT(first_name, ' ', last_name))
);

SELECT full_name FROM t1;

```

### 14.1.18.8 Secondary Indexes and Generated Columns

[InnoDB](#) supports secondary indexes on generated virtual columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or generated stored columns. Secondary indexes that include virtual columns may be defined as [UNIQUE](#).

When a secondary index is created on a generated virtual column, generated column values are materialized in the records of the index. If the index is a [covering index](#) (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during [INSERT](#) and [UPDATE](#) operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated *stored* columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for [COMPACT](#) and [REDUNDANT](#) row formats, and 3072 bytes for [DYNAMIC](#) and [COMPRESSED](#) row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

Prior to 5.7.16, a foreign key constraint cannot reference a secondary index defined on a generated virtual column.

In MySQL 5.7.13 and earlier, [InnoDB](#) does not permit defining a foreign key constraint with a cascading referential action on the base column of an indexed generated virtual column. This restriction is lifted in MySQL 5.7.14.

### Indexing a Generated Column to Provide a JSON Column Index

As noted elsewhere, [JSON](#) columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```

mysql> CREATE TABLE jemp (
->   c JSON,
->   g INT GENERATED ALWAYS AS (c->"$.id"),
->   INDEX i (g)
-> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES
->   ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),
->   ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

```

```
mysql> SELECT c->>"$.name" AS name
> FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| Barney |
| Betty |
+-----+
2 rows in set (0.00 sec)

mysql> EXPLAIN SELECT c->>"$.name" AS name
> FROM jemp WHERE g > 2\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: jemp
    partitions: NULL
         type: range
possible_keys: i
         key: i
        key_len: 5
         ref: NULL
         rows: 2
    filtered: 100.00
      Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`, '$.name'))
AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

(We have wrapped the output from the last statement in this example to fit the viewing area.)

The `->` operator is supported in MySQL 5.7.9 and later. The `->>` operator is supported beginning with MySQL 5.7.13.

When you use `EXPLAIN` on a `SELECT` or other SQL statement containing one or more expressions that use the `->` or `->>` operator, these expressions are translated into their equivalents using `JSON_EXTRACT()` and (if needed) `JSON_UNQUOTE()` instead, as shown here in the output from `SHOW WARNINGS` immediately following this `EXPLAIN` statement:

```
mysql> EXPLAIN SELECT c->>"$.name"
> FROM jemp WHERE g > 2 ORDER BY c->>"$.name"\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: jemp
    partitions: NULL
         type: range
possible_keys: i
         key: i
        key_len: 5
         ref: NULL
         rows: 2
    filtered: 100.00
      Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`, '$.name')) AS
`c->>"$.name"` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by
json_extract(`test`.`jemp`.`c`, '$.name')
1 row in set (0.00 sec)
```

See the descriptions of the `->` and `->>` operators, as well as those of the `JSON_EXTRACT()` and `JSON_UNQUOTE()` functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as `GEOMETRY` columns.

### JSON columns and indirect indexing in MySQL Cluster

It is also possible to use indirect indexing of JSON columns in MySQL Cluster NDB 7.5.3 and later, subject to the following conditions:

1. `NDB` handles a `JSON` column value internally as a `BLOB`. This means that any `NDB` table having one or more JSON columns must have a primary key, else it cannot be recorded in the binary log.
2. The `NDB` storage engine does not support indexing of virtual columns. Since the default for generated columns is `VIRTUAL`, you must specify explicitly the generated column to which to apply the indirect index as `STORED`.

The `CREATE TABLE` statement used to create the table `jempn` shown here is a version of the `jemp` table shown previously, with modifications making it compatible with `NDB`:

```
CREATE TABLE jempn (
  a BIGINT(20) NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c JSON DEFAULT NULL,
  g INT GENERATED ALWAYS AS (c->"$.name") STORED,
  INDEX i (g)
) ENGINE=NDB;
```

We can populate this table using the following `INSERT` statement:

```
INSERT INTO jempn (a, c) VALUES
(NULL, '{"id": "1", "name": "Fred"}'),
(NULL, '{"id": "2", "name": "Wilma"}'),
(NULL, '{"id": "3", "name": "Barney"}'),
(NULL, '{"id": "4", "name": "Betty"}');
```

Now `NDB` can use index `i`, as shown here:

```
mysql> EXPLAIN SELECT c->>"$.name" AS name
      FROM jempn WHERE g > 2\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: jempn
   partitions: p0,p1
         type: range
possible_keys: i
          key: i
       key_len: 5
         ref: NULL
        rows: 3
   filtered: 100.00
      Extra: Using where with pushed condition (`test`.`jempn`.`g` > 2)
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
       Code: 1003
  Message: /* select#1 */ select
json_unquote(json_extract(`test`.`jempn`.`c`,'$.name')) AS `name` from
`test`.`jempn` where (`test`.`jempn`.`g` > 2)
1 row in set (0.00 sec)
```

You should keep in mind that a stored generated column uses `DataMemory`, and that an index on such a column uses `IndexMemory`.

### 14.1.18.9 Setting NDB\_TABLE Options in Table Comments

In MySQL Cluster NDB 7.5.2 and later, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_TABLE` option, which consists of one or more name-value pairs, separated by commas if need be, following the string `NDB_TABLE=`. Complete syntax for names and values syntax is shown here:

```
COMMENT="NDB_TABLE=ndb_table_option[,ndb_table_option[,...]]"

ndb_table_option:
    NOLOGGING={1|0}
    | READ_BACKUP={1|0}
    | PARTITION_BALANCE={FOR_RP_BY_NODE|FOR_RA_BY_NODE|FOR_RP_BY_LDM|FOR_RA_BY_LDM}
    | FULLY_REPLICATED={1|0}
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The four `NDB` table options that can be set as part of a comment in this way are described in more detail in the next few paragraphs.

**NOLOGGING:** Using 1 corresponds to having `ndb_table_no_logging` enabled, but has no actual effect. Provided as a placeholder, mostly for completeness of `ALTER TABLE` statements.

**READ\_BACKUP:** Setting this option to 1 has the same effect as though `ndb_read_backup` were enabled; enables reading from any replica. Starting with MySQL Cluster NDB 7.5.3, you can set `READ_BACKUP` for an existing table online (Bug #80858, Bug #23001617), using an `ALTER TABLE` statement similar to one of those shown here:

```
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1";

ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=0";
```

Prior to MySQL Cluster NDB 7.5.4, setting `READ_BACKUP` to 1 also caused `FRAGMENT_COUNT_TYPE` to be set to `ONE_PER_LDM_PER_NODE_GROUP`.

For more information about the `ALGORITHM` option for `ALTER TABLE`, see [Section 14.1.8.2, “ALTER TABLE Online Operations in MySQL Cluster”](#).

**PARTITION\_BALANCE:** Provides additional control over assignment and placement of partitions. The following four schemes are supported:

1. **FOR\_RP\_BY\_NODE:** One partition per node.

Only one LDM on each node stores a primary partition. Each partition is stored in the same LDM (same ID) on all nodes.

2. **FOR\_RA\_BY\_NODE:** One partition per node group.

Each node stores a single partition, which can be either a primary replica or a backup replica. Each partition is stored in the same LDM on all nodes.

3. **FOR\_RP\_BY\_LDM:** One partition for each LDM on each node; the default.

This is the same behavior as prior to MySQL Cluster NDB 7.5.2, except for a slightly different mapping of partitions to LDMs, starting with LDM 0 and placing one partition per node group, then moving on to the next LDM.

In MySQL Cluster NDB 7.5.4 and later, this is the setting used if `READ_BACKUP` is set to 1. (Bug #82634, Bug #24482114)

4. **FOR\_RA\_BY\_LDM:** One partition per LDM in each node group.

These partitions can be primary or backup partitions.

Prior to MySQL Cluster NDB 7.5.4, this is the setting used if `READ_BACKUP` is set to 1.

Prior to MySQL Cluster NDB 7.5.4, `PARTITION_BALANCE` was named `FRAGMENT_COUNT_TYPE`, and accepted as its value one of (in the same order as that of the listing just shown) `ONE_PER_NODE`, `ONE_PER_NODE_GROUP`, `ONE_PER_LDM_PER_NODE`, or `ONE_PER_LDM_PER_NODE_GROUP`. (Bug #81761, Bug #23547525)

`FULLY_REPLICATED` controls whether the table is fully replicated, that is, whether each data node has a complete copy of the table. To enable full replication of the table, use `FULLY_REPLICATED=1`. You must also set (or have already set) the table's `PARTITION_BALANCE` to either one of `FOR_RA_BY_NODE` or `FOR_RA_BY_LDM` in order for this to work.

This setting can also be controlled using the `ndb_fully_replicated` system variable. Setting it to `ON` enables the option by default for all new `NDB` tables; the default is `OFF`, which maintains the previous behavior (as in MySQL Cluster NDB 7.5.1 and earlier, before support for fully replicated tables was introduced). The `ndb_data_node_neighbour` system variable is also used for fully replicated tables, to ensure that when a fully replicated table is accessed, we access the data node which is local to this MySQL Server.

An example of a `CREATE TABLE` statement using such a comment when creating an `NDB` table is shown here:

```
mysql> CREATE TABLE t1 (
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
>   c2 VARCHAR(100),
>   c3 VARCHAR(100) )
> ENGINE=NDB
>
COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
```

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available from querying the MySQL Information Schema `TABLES` table, as in this example:

```
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
```

| TABLE_NAME | TABLE_SCHEMA | TABLE_COMMENT  |
|------------|--------------|--|
| t1         | c            | NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE |
| t1         | d            |  |

```
2 rows in set (0.00 sec)
```

This comment syntax is also supported with `ALTER TABLE` statements for `NDB` tables. Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have.

```
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
```

| TABLE_NAME | TABLE_SCHEMA | TABLE_COMMENT                              |
|------------|--------------|--|
| t1         | c            | NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE |
| t1         | d            |  |

```
2 rows in set (0.01 sec)
```

You can also see the value of the `PARTITION_BALANCE` option in the output of `ndb_desc`. `ndb_desc` also shows whether the `READ_BACKUP` and `FULLY_REPLICATED` options are set for the table. See the description of this program for more information.

Because the `READ_BACKUP` value was not carried over to the new comment set by the `ALTER TABLE` statement, there is no longer a way using SQL to retrieve the value previously set for it. To keep this from happening, it is suggested that you preserve any such values from the existing comment string, like this:

```
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
+-----+-----+-----+
| TABLE_NAME | TABLE_SCHEMA | TABLE_COMMENT |
+-----+-----+-----+
| t1          | c             | NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE |
| t1          | d             |                  |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

```
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (1.56 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
+-----+-----+-----+
| TABLE_NAME | TABLE_SCHEMA | TABLE_COMMENT |
+-----+-----+-----+
| t1          | c             | NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE |
| t1          | d             |                  |
+-----+-----+-----+
2 rows in set (0.01 sec)
```

## 14.1.19 CREATE TABLESPACE Syntax

```
CREATE TABLESPACE tablespace_name

InnoDB and NDB:
    ADD DATAFILE 'file_name'

InnoDB only:
    [FILE_BLOCK_SIZE = value]

NDB only:
    USE LOGFILE GROUP logfile_group
    [EXTENT_SIZE [=] extent_size]
    [INITIAL_SIZE [=] initial_size]
    [AUTOEXTEND_SIZE [=] autoextend_size]
    [MAX_SIZE [=] max_size]
    [NODEGROUP [=] nodegroup_id]
    [WAIT]
    [COMMENT [=] comment_text]

InnoDB and NDB:
    [ENGINE [=] engine_name]
```

This statement is used to create a tablespace. The precise syntax and semantics depend on the storage engine used. In standard MySQL 5.7 releases, this is always an `InnoDB` tablespace. MySQL Cluster NDB 7.5 also supports tablespaces using the `NDB` storage engine in addition to those using `InnoDB`.

### Considerations for InnoDB

An `InnoDB` tablespace created using `CREATE TABLESPACE` is referred to as a *general tablespace*. This is a shared tablespace, similar to the system tablespace. It can hold multiple tables, and supports

all table row formats. General tablespaces can be created in a location relative to or independent of the MySQL data directory.

After creating an InnoDB general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace.

For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

`CREATE TABLESPACE` is supported with InnoDB as of MySQL 5.7.6.

## Considerations for MySQL Cluster (NDB)

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for MySQL Cluster Disk Data tables (see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#)). One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the `ALTER TABLESPACE` statement (see [Section 14.1.9, “ALTER TABLESPACE Syntax”](#)).

### Note

All MySQL Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the `USE LOGFILE GROUP` clause. *logfile\_group* must be an existing log file group created with `CREATE LOGFILE GROUP` (see [Section 14.1.15, “CREATE LOGFILE GROUP Syntax”](#)). Multiple tablespaces may use the same log file group for UNDO logging.

When setting `EXTENT_SIZE` or `INITIAL_SIZE`, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

`INITIAL_SIZE` and `EXTENT_SIZE` are subject to rounding as follows:

- `EXTENT_SIZE` is rounded up to the nearest whole multiple of 32K.
- `INITIAL_SIZE` is rounded *down* to the nearest whole multiple of 32K; this result is rounded up to the nearest whole multiple of `EXTENT_SIZE` (after any rounding).

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating `INFORMATION_SCHEMA.FILES` column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

When `CREATE TABLESPACE` is used with `ENGINE [=] NDB`, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. (See the example later in this section.)

(See [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).)

## Options

- `ADD DATAFILE`: Defines the name of a tablespace data file; this option is always required. An InnoDB tablespace supports only a single data file, whose name must include a `.ibd` extension. A MySQL Cluster tablespace supports multiple data files which can have any legal file names; more

data files can be added to a MySQL Cluster tablespace following its creation by using an [ALTER TABLESPACE](#) statement.

**Note**

[ALTER TABLESPACE](#) is not supported by [InnoDB](#).

To place the data file in a location outside of the MySQL data directory ([datadir](#)), include an absolute directory path or a path relative to the MySQL data directory. If you do not specify a path, the tablespace is created in the MySQL data directory. As of MySQL 5.7.8, an [isl](#) file is created in the MySQL data directory when an [InnoDB](#) tablespace is created outside of the MySQL data directory.

To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist prior to creating the tablespace.

The *file\_name*, including the path (optional), must be quoted with single or double quotation marks. File names (not counting any “.ibd” extension for [InnoDB](#) files) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

- [FILE\\_BLOCK\\_SIZE](#): This option—which is specific to [InnoDB](#), and is ignored by [NDB](#)—defines the block size for the tablespace data file. If you do not specify this option, [FILE\\_BLOCK\\_SIZE](#) defaults to [innodb\\_page\\_size](#). [FILE\\_BLOCK\\_SIZE](#) is required when you intend to use the tablespace for storing compressed [InnoDB](#) tables ([ROW\\_FORMAT=COMPRESSED](#)).

If [FILE\\_BLOCK\\_SIZE](#) is equal [innodb\\_page\\_size](#), the tablespace can contain only tables having an uncompressed row format ([COMPACT](#), [REDUNDANT](#), or [DYNAMIC](#)). The physical page size for tables using [COMPRESSED](#) differs from that of uncompressed tables; this means that compressed tables and uncompressed tables cannot coexist in the same tablespace.

For a general tablespace to contain compressed tables, [FILE\\_BLOCK\\_SIZE](#) must be specified, and the [FILE\\_BLOCK\\_SIZE](#) value must be a valid compressed page size in relation to the [innodb\\_page\\_size](#) value. Also, the physical page size of the compressed table ([KEY\\_BLOCK\\_SIZE](#)) must be equal to [FILE\\_BLOCK\\_SIZE](#)/1024. For example, if [innodb\\_page\\_size](#)=16K, and [FILE\\_BLOCK\\_SIZE](#)=8K, the [KEY\\_BLOCK\\_SIZE](#) of the table must be 8. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- [USE LOGFILE GROUP](#): Required for [NDB](#), this is the name of a log file group previously created using [CREATE LOGFILE GROUP](#). Not supported for [InnoDB](#), where it fails with an error.
- [EXTENT\\_SIZE](#): This option is specific to [NDB](#), and is not supported by [InnoDB](#), where it fails with an error. [EXTENT\\_SIZE](#) sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An *extent* is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may be used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example, that a tablespace having a single datafile whose [INITIAL\\_SIZE](#) (described in the following item) is 256 MB and whose [EXTENT\\_SIZE](#) is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the [INFORMATION\\_SCHEMA.FILES](#) table, and so derive an estimate for how much space remains free

in the file. For further discussion and examples, see [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

- **INITIAL\_SIZE**: This option is specific to **NDB**, and is not supported by **InnoDB**, where it fails with an error.

The **INITIAL\_SIZE** parameter sets the total size in bytes of the data file that was specific using **ADD DATAFILE**. Once this file has been created, its size cannot be changed; however, you can add more data files to the tablespace using **ALTER TABLESPACE ... ADD DATAFILE**.

**INITIAL\_SIZE** is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for **INITIAL\_SIZE** is 4294967296 (4 GB).

- **AUTOEXTEND\_SIZE**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 5.7 or MySQL Cluster NDB 7.5, regardless of the storage engine used.
- **MAX\_SIZE**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 5.7 or MySQL Cluster NDB 7.5, regardless of the storage engine used.
- **NODEGROUP**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 5.7 or MySQL Cluster NDB 7.5, regardless of the storage engine used.
- **WAIT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 5.7 or MySQL Cluster NDB 7.5, regardless of the storage engine used.
- **COMMENT**: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of MySQL 5.7 or MySQL Cluster NDB 7.5, regardless of the storage engine used.
- **ENGINE**: Defines the storage engine which uses the tablespace, where *engine\_name* is the name of the storage engine. Currently, only the **InnoDB** storage engine is supported by standard MySQL 5.7 releases. MySQL Cluster NDB 7.5 supports both **NDB** and **InnoDB** tablespaces. The value of the **default\_storage\_engine** system variable is used for **ENGINE** if the option is not specified.

## Notes

- For the rules covering the naming of MySQL tablespaces, see [Section 10.2, “Schema Object Names”](#). In addition to these rules, the slash character (“/”) is not permitted, nor can you use names beginning with **innodb\_**, as this prefix is reserved for system use.
- Tablespaces do not support temporary tables.
- As of MySQL 5.7.8, the **TABLESPACE** option may be used with **CREATE TABLE** or **ALTER TABLE** to assign **InnoDB** table partitions or subpartitions to a **general tablespace**, a separate file-per-table tablespace, or the system tablespace. **TABLESPACE** option support for table partitions and subpartitions was added in MySQL 5.7.8. All partitions must belong to the same storage engine. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).
- **innodb\_file\_per\_table**, **innodb\_file\_format**, and **innodb\_file\_format\_max** settings have no influence on **CREATE TABLESPACE** operations. **innodb\_file\_per\_table** does not need to be enabled. General tablespaces support all table row formats regardless of file format settings. Likewise, general tablespaces support the addition of tables of any row format using **CREATE TABLE ... TABLESPACE**, regardless of file format settings.
- **innodb\_strict\_mode** is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of **innodb\_strict\_mode**. If **CREATE TABLESPACE** parameters are incorrect or incompatible, the operation fails regardless of the **innodb\_strict\_mode** setting. When a table is added to a general tablespace using **CREATE TABLE ... TABLESPACE** or **ALTER TABLE ... TABLESPACE**, **innodb\_strict\_mode** is ignored but the statement is evaluated as if **innodb\_strict\_mode** is enabled.
- Use **DROP TABLESPACE** to remove a tablespace. All tables must be dropped from a tablespace using **DROP TABLE** prior to dropping the tablespace. Before dropping a MySQL Cluster tablespace

you must also remove all its data files using one or more `ALTER TABLESPACE ... DROP DATATFILE` statements. See [Section 20.5.13.1, “NDB Cluster Disk Data Objects”](#).

- All parts of an [InnoDB](#) table added to an [InnoDB](#) general tablespace reside in the general tablespace, including indexes and [BLOB](#) pages.

For an [NDB](#) table assigned to a tablespace, only those columns which are not indexed are stored on disk, and actually use the tablespace data files. Indexes and indexed columns for all [NDB](#) tables are always kept in memory.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace [.ibd data file](#) which can only be used for new [InnoDB](#) data. Space is not released back to the operating system as it is for file-per-table tablespaces.
- A general tablespace is not associated with any database or schema.
- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.
- A generated or existing tablespace cannot be changed to a general tablespace.
- Tables stored in a general tablespace can only be opened in MySQL 5.7.6 or later due to the addition of new table flags.
- There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.
- General tablespaces created on Windows using a relative data file path cannot be opened on Unix-like systems. This limitation is removed in MySQL 5.7.8 (Bug #20555168).
- In MySQL 5.7.6 and MySQL 5.7.7, tables stored in general tablespaces may not open (due to a missing general tablespace file) after moving the MySQL data directory to a new location. This limitation is addressed in MySQL 5.7.8 with the introduction of [isl](#) files for general tablespaces created outside of the MySQL data directory (Bug #20563954).

## InnoDB Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```
mysql> CREATE TABLESPACE `ts1`
->     ADD DATAFILE 'ts1.ibd'
->     ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY)
->     TABLESPACE ts1
->     ROW_FORMAT=REDUNDANT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY)
->     TABLESPACE ts1
->     ROW_FORMAT=COMPACT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY)
->     TABLESPACE ts1
```

```
-> ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.00 sec)
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2`
-> ADD DATAFILE 'ts2.ibd'
-> FILE_BLOCK_SIZE = 8192
-> ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY)
-> TABLESPACE ts2
-> ROW_FORMAT=COMPRESSED
-> KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

## NDB Example

Suppose that you wish to create a MySQL Cluster Disk Data tablespace named `myts` using a datafile named `mydata-1.dat`. An NDB tablespace always requires the use of a log file group consisting of one or more undo log files. For this example, we first create a log file group named `mylg` that contains one undo log file named `myundo-1.dat`, using the `CREATE LOGFILE GROUP` statement shown here:

```
mysql> CREATE LOGFILE GROUP mylg
-> ADD UNDOFILE 'myundo-1.dat'
-> ENGINE=NDB;
Query OK, 0 rows affected (3.29 sec)
```

Now you can create the tablespace previously described using the following statement:

```
mysql> CREATE TABLESPACE myts
-> ADD DATAFILE 'mydata-1.dat'
-> USE LOGFILE GROUP mylg
-> ENGINE=NDB;
Query OK, 0 rows affected (2.98 sec)
```

You can now create a Disk Data table using a `CREATE TABLE` statement with the `TABLESPACE` and `STORAGE DISK` options, similar to what is shown here:

```
mysql> CREATE TABLE mytable (
-> id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> lname VARCHAR(50) NOT NULL,
-> fname VARCHAR(50) NOT NULL,
-> dob DATE NOT NULL,
-> joined DATE NOT NULL,
-> INDEX(last_name, first_name)
-> )
-> TABLESPACE myts STORAGE DISK
-> ENGINE=NDB;
Query OK, 0 rows affected (1.41 sec)
```

It is important to note that only the `dob` and `joined` columns from `mytable` are actually stored on disk, due to the fact that the `id`, `lname`, and `fname` columns are all indexed.

As mentioned previously, when `CREATE TABLESPACE` is used with `ENGINE [=] NDB`, a tablespace and associated data file are created on each MySQL Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table, as shown here:

```
mysql> SELECT FILE_NAME, FILE_TYPE, LOGFILE_GROUP_NAME, STATUS, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE TABLESPACE_NAME = 'myts';
```

| file_name    | file_type  | logfile_group_name | status | extra          |
|--------------|------------|--------------------|--------|----------------|
| mydata-1.dat | DATAFILE   | mylg               | NORMAL | CLUSTER_NODE=5 |
| mydata-1.dat | DATAFILE   | mylg               | NORMAL | CLUSTER_NODE=6 |
| NULL         | TABLESPACE | mylg               | NORMAL | NULL           |

3 rows in set (0.01 sec)

For additional information and examples, see [Section 20.5.13.1, “NDB Cluster Disk Data Objects”](#).

## 14.1.20 CREATE TRIGGER Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  TRIGGER trigger_name
  trigger_time trigger_event
  ON tbl_name FOR EACH ROW
  [trigger_order]
  trigger_body

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }

trigger_order: { FOLLOWS | PRECEDES } other_trigger_name
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named *tbl\_name*, which must refer to a permanent table. You cannot associate a trigger with a **TEMPORARY** table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes **CREATE TRIGGER** syntax. For additional discussion, see [Section 22.3.1, “Trigger Syntax and Examples”](#).

**CREATE TRIGGER** requires the **TRIGGER** privilege for the table associated with the trigger. The statement might also require the **SUPER** privilege, depending on the **DEFINER** value, as described later in this section. If binary logging is enabled, **CREATE TRIGGER** might require the **SUPER** privilege, as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

The **DEFINER** clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

*trigger\_time* is the trigger action time. It can be **BEFORE** or **AFTER** to indicate that the trigger activates before or after each row to be modified.

*trigger\_event* indicates the kind of operation that activates the trigger. These *trigger\_event* values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table; for example, through **INSERT**, **LOAD DATA**, and **REPLACE** statements.
- **UPDATE**: The trigger activates whenever a row is modified; for example, through **UPDATE** statements.
- **DELETE**: The trigger activates whenever a row is deleted from the table; for example, through **DELETE** and **REPLACE** statements. **DROP TABLE** and **TRUNCATE TABLE** statements on the table

do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The *trigger\_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

**Note**

Cascaded foreign key actions do not activate triggers.

As of MySQL 5.7.2, it is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a *trigger\_order* clause that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

Before MySQL 5.7.2, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

*trigger\_body* is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See [Section 14.6.1, “BEGIN ... END Compound-Statement Syntax”](#). Some statements are not permitted in triggers; see [Section C.1, “Restrictions on Stored Programs”](#).

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns. For information about generated columns, see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#).

MySQL stores the *sql\_mode* system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, *regardless of the current server SQL mode when the trigger begins executing*.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a *user* value is given, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted *user* value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.

- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `TRIGGER` privilege for the subject table.
  - The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
- Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see [Section 22.6, “Access Control for Stored Programs and Views”](#).

Within a trigger body, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 7.3.11, “SQL-Based MySQL Account Activity Auditing”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [Section 14.3.5.2, “LOCK TABLES and Triggers”](#).

For additional discussion of trigger use, see [Section 22.3.1, “Trigger Syntax and Examples”](#).

## 14.1.21 CREATE VIEW Syntax

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

For information about restrictions on view use, see [Section C.5, “Restrictions on Views”](#).

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation

time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. `CREATE VIEW` might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- Before MySQL 5.7.7, the `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.

- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If the `DEFINER` clause is present, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only valid `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.

- If you have the [SUPER](#) privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a view with a nonexistent [DEFINER](#) account, an error occurs when the view is referenced if the [SQL SECURITY](#) value is [DEFINER](#) but the definer account does not exist.

For more information about view security, see [Section 22.6, “Access Control for Stored Programs and Views”](#).

Within a view definition, [CURRENT\\_USER](#) returns the view's [DEFINER](#) value by default. For views defined with the [SQL SECURITY INVOKER](#) characteristic, [CURRENT\\_USER](#) returns the account for the view's invoker. For information about user auditing within views, see [Section 7.3.11, “SQL-Based MySQL Account Activity Auditing”](#).

Within a stored routine that is defined with the [SQL SECURITY DEFINER](#) characteristic, [CURRENT\\_USER](#) returns the routine's [DEFINER](#) value. This also affects a view defined within such a routine, if the view definition contains a [DEFINER](#) value of [CURRENT\\_USER](#).

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the [SELECT](#) privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.
- The user who references a view must have appropriate privileges to access it ([SELECT](#) to select from it, [INSERT](#) to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view [DEFINER](#) account or invoker, depending on whether the [SQL SECURITY](#) characteristic is [DEFINER](#) or [INVOKER](#), respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function [SQL SECURITY](#) characteristic is [DEFINER](#) or [INVOKER](#). If the security characteristic is [DEFINER](#), the function runs with the privileges of the [DEFINER](#) account. If the characteristic is [INVOKER](#), the function runs with the privileges determined by the view's [SQL SECURITY](#) characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function [f\(\)](#):

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that [f\(\)](#) contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within [f\(\)](#) need to be checked when [f\(\)](#) executes. This might mean that privileges are needed for [p1\(\)](#) or [p2\(\)](#), depending on the execution path within [f\(\)](#). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the [SQL SECURITY](#) values of the view [v](#) and the function [f\(\)](#).

The [DEFINER](#) and [SQL SECURITY](#) clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for [SQL SECURITY DEFINER](#). The standard says that the

definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, [SELECT](#)) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The [DEFINER](#) clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default [DEFINER](#) value is the account of the view creator.

The optional [ALGORITHM](#) clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. [ALGORITHM](#) takes three values: [MERGE](#), [TEMPTABLE](#), or [UNDEFINED](#). For more information, see [Section 22.5.2, “View Processing Algorithms”](#), as well as [Optimizing Derived Tables and View References](#).

Some views are updatable. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#).

The [WITH CHECK OPTION](#) clause can be given for an updatable view to prevent inserts or updates to rows except those for which the [WHERE](#) clause in the *select\_statement* is true.

In a [WITH CHECK OPTION](#) clause for an updatable view, the [LOCAL](#) and [CASCADED](#) keywords determine the scope of check testing when the view is defined in terms of another view. The [LOCAL](#) keyword restricts the [CHECK OPTION](#) only to the view being defined. [CASCADED](#) causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is [CASCADED](#).

For more information about updatable views and the [WITH CHECK OPTION](#) clause, see [Section 22.5.3, “Updatable and Insertable Views”](#), and [Section 22.5.4, “The View WITH CHECK OPTION Clause”](#).

Views created before MySQL 5.7.3 containing [ORDER BY integer](#) can result in errors at view evaluation time. Consider these view definitions, which use [ORDER BY](#) with an ordinal number:

```
CREATE VIEW v1 AS SELECT x, y, z FROM t ORDER BY 2;
CREATE VIEW v2 AS SELECT x, 1, z FROM t ORDER BY 2;
```

In the first case, [ORDER BY 2](#) refers to a named column *y*. In the second case, it refers to a constant 1. For queries that select from either view fewer than 2 columns (the number named in the [ORDER BY](#) clause), an error occurs if the server evaluates the view using the [MERGE](#) algorithm. Examples:

```
mysql> SELECT x FROM v1;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
mysql> SELECT x FROM v2;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
```

As of MySQL 5.7.3, to handle view definitions like this, the server writes them differently into the *.frm* file that stores the view definition. This difference is visible with [SHOW CREATE VIEW](#). Previously, the *.frm* file contained this for the [ORDER BY 2](#) clause:

```
For v1: ORDER BY 2
For v2: ORDER BY 2
```

As of 5.7.3, the *.frm* file contains this:

```
For v1: ORDER BY `t`.`y`
For v2: ORDER BY ''
```

That is, for `v1`, 2 is replaced by a reference to the name of the column referred to. For `v2`, 2 is replaced by a constant string expression (ordering by a constant has no effect, so ordering by any constant will do).

If you experience view-evaluation errors such as just described, drop and recreate the view so that the `.frm` file contains the updated view representation. Alternatively, for views like `v2` that order by a constant value, drop and recreate the view with no `ORDER BY` clause.

## 14.1.22 DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

### Important

When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 14.7.1.4, “GRANT Syntax”](#).

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions.

|                   |                   |                   |                   |
|-------------------|-------------------|-------------------|-------------------|
| <code>.BAK</code> | <code>.DAT</code> | <code>.HSH</code> | <code>.MRG</code> |
| <code>.MYD</code> | <code>.MYI</code> | <code>.TRG</code> | <code>.TRN</code> |
| <code>.cfg</code> | <code>.db</code>  | <code>.frm</code> | <code>.ibd</code> |
| <code>.ndb</code> | <code>.par</code> |                   |                   |

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See [Temporary Tables](#).

You can also drop databases with `mysqladmin`. See [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

## 14.1.23 DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named *event\_name*. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

## 14.1.24 DROP FUNCTION Syntax

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see [Section 14.1.27, “DROP PROCEDURE and DROP FUNCTION Syntax”](#).
- For information about dropping user-defined functions, see [Section 14.7.3.2, “DROP FUNCTION Syntax”](#).

## 14.1.25 DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
    [algorithm_option | lock_option] ...

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY}

lock_option:
    LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

`DROP INDEX` drops the index named *index\_name* from the table *tbl\_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 14.1.8, “ALTER TABLE Syntax”](#).

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

Indexes on variable-width columns of `NDB` tables are dropped online; that is, without any table copying. The table is not locked against access from other MySQL Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

`ALGORITHM` and `LOCK` clauses may be given. These influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 14.1.8, “ALTER TABLE Syntax”](#).

MySQL Cluster formerly supported online `DROP INDEX` operations using the `ONLINE` and `OFFLINE` keywords. These keywords are no longer supported in MySQL Cluster NDB 7.5 and later, and their use causes a syntax error. Instead, MySQL Cluster NDB 7.5 and later support online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See [Section 14.1.8.2, “ALTER TABLE Online Operations in MySQL Cluster”](#), for more information.

## 14.1.26 DROP LOGFILE GROUP Syntax

```
DROP LOGFILE GROUP logfile_group
ENGINE [=] engine_name
```

This statement drops the log file group named *logfile\_group*. The log file group must already exist or an error results. (For information on creating log file groups, see [Section 14.1.15, “CREATE LOGFILE GROUP Syntax”](#).)

#### Important

Before dropping a log file group, you must drop all tablespaces that use that log file group for [UNDO](#) logging.

The required [ENGINE](#) clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for *engine\_name* are [NDB](#) and [NDBCLUSTER](#).

[DROP LOGFILE GROUP](#) is useful only with Disk Data storage for MySQL Cluster. See [Section 20.5.13, “NDB Cluster Disk Data Tables”](#).

## 14.1.27 DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the [ALTER ROUTINE](#) privilege for the routine. (If the [automatic\\_sp\\_privileges](#) system variable is enabled, that privilege and [EXECUTE](#) are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See [Section 22.2.2, “Stored Routines and MySQL Privileges”](#).)

The [IF EXISTS](#) clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with [SHOW WARNINGS](#).

[DROP FUNCTION](#) is also used to drop user-defined functions (see [Section 14.7.3.2, “DROP FUNCTION Syntax”](#)).

## 14.1.28 DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server\_name*. The corresponding row in the [mysql.servers](#) table is deleted. This statement requires the [SUPER](#) privilege.

Dropping a server for a table does not affect any [FEDERATED](#) tables that used this connection information when they were created. See [Section 14.1.17, “CREATE SERVER Syntax”](#).

[DROP SERVER](#) does not cause an automatic commit.

In MySQL 5.7, [DROP SERVER](#) is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.7.1, [gtid\\_next](#) must be set to [AUTOMATIC](#) before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

## 14.1.29 DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
tbl_name [, tbl_name] ...
```

[RESTRICT | CASCADE]

**DROP TABLE** removes one or more tables. You must have the **DROP** privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent tables it was unable to drop, but it also drops all of the tables in the list that do exist.

### Important

When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 14.7.1.4, “GRANT Syntax”](#).

For a partitioned table, **DROP TABLE** permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes partition definitions associated with the dropped table.

### Note

Prior to MySQL 5.7.6, **DROP TABLE** removes partition definitions (`.par`) files associated with the dropped table. As of MySQL 5.7.6, partition definition (`.par`) files are no longer created. Instead, partition definitions are stored in the internal data dictionary.

Use **IF EXISTS** to prevent an error from occurring for tables that do not exist. A **NOTE** is generated for each nonexistent table when using **IF EXISTS**. See [Section 14.7.5.40, “SHOW WARNINGS Syntax”](#).

**RESTRICT** and **CASCADE** are permitted to make porting easier. In MySQL 5.7, they do nothing.

### Note

**DROP TABLE** automatically commits the current active transaction, unless you use the **TEMPORARY** keyword.

The **TEMPORARY** keyword has the following effects:

- The statement drops only **TEMPORARY** tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A **TEMPORARY** table is visible only to the session that created it, so no check is necessary.)

Using **TEMPORARY** is a good way to ensure that you do not accidentally drop a non-**TEMPORARY** table.

## 14.1.30 DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace_name
[ENGINE [=] engine_name]
```

This statement drops a tablespace that was previously created using **CREATE TABLESPACE**. It is supported with all MySQL Cluster NDB 7.5 releases, and with **InnoDB** in the standard MySQL Server as well, beginning with MySQL 5.7.6.

**ENGINE** sets the storage engine that uses the tablespace, where *engine\_name* is the name of the storage engine. Currently, the values **InnoDB** and **NDB** are supported. If not set, the value of `default_storage_engine` is used. If it is not the same as the storage engine used to create the tablespace, the **DROP TABLESPACE** statement fails.

For an **InnoDB** tablespace, all tables must be dropped from the tablespace prior to a **DROP TABLESPACE** operation. If the tablespace is not empty, **DROP TABLESPACE** returns an error.

As with the [InnoDB](#) system tablespace, truncating or dropping [InnoDB](#) tables stored in a general tablespace creates free space in the tablespace [.ibd data file](#), which can only be used for new [InnoDB](#) data. Space is not released back to the operating system by such operations as it is for file-per-table tablespaces.

An [NDB](#) tablespace to be dropped must not contain any data files; in other words, before you can drop an [NDB](#) tablespace, you must first drop each of its data files using `ALTER TABLESPACE ... DROP DATAFILE`.

## Notes

- Tablespaces are not deleted automatically. A tablespace must be dropped explicitly using `DROP TABLESPACE`. `DROP DATABASE` has no effect in this regard, even if the operation drops all tables belonging to the tablespace.
- A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace [.ibd data file](#) which can only be used for new [InnoDB](#) data. Space is not released back to the operating system as it is for file-per-table tablespaces.

## InnoDB Example

This example demonstrates how to drop an [InnoDB](#) general tablespace. The general tablespace `ts1` is created with a single table. Before dropping the tablespace, the table must be dropped.

```
mysql> CREATE TABLESPACE `ts1`
->     ADD DATAFILE 'ts1.ibd'
->     ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY)
->     TABLESPACE ts10
->     ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)

mysql> DROP TABLE t1;
Query OK, 0 rows affected (0.01 sec)

mysql> DROP TABLESPACE ts1;
Query OK, 0 rows affected (0.01 sec)
```

## NDB Example

This example shows how to drop an [NDB](#) tablespace `myts` having a data file named `mydata-1.dat` after first creating the tablespace, and assumes the existence of a log file group named `mylg` (see [Section 14.1.15, “CREATE LOGFILE GROUP Syntax”](#)).

```
mysql> CREATE TABLESPACE myts
->     ADD DATAFILE 'mydata-1.dat'
->     USE LOGFILE GROUP mylg
->     ENGINE=NDB;
```

You must remove all data files from the tablespace using `ALTER TABLESPACE`, as shown here, before it can be dropped:

```
mysql> ALTER TABLESPACE myts
->     DROP DATAFILE 'mydata-1.dat'
```

```
-> ENGINE=NDB;  
mysql> DROP TABLESPACE myts;
```

### 14.1.31 DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See [Section 14.7.5.40, “SHOW WARNINGS Syntax”](#).

Triggers for a table are also dropped if you drop the table.

### 14.1.32 DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]  
  view_name [, view_name] ...  
  [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See [Section 14.7.5.40, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

### 14.1.33 RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name  
  [, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables. The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running.

For example, a table named `old_table` can be renamed to `new_table` as shown here:

```
RENAME TABLE old_table TO new_table;
```

This statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,  
             new_table TO old_table,
```

```
tmp_table TO new_table;
```

MySQL checks the destination table name before checking whether the source table exists. For example, if `new_table` already exists and `old_table` does not, the following statement fails as shown here:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_mydb |
+-----+
| table_a        |
+-----+
1 row in set (0.00 sec)

mysql> RENAME TABLE table_b TO table_a;
ERROR 1050 (42S01): Table 'table_a' already exists
```

As long as two databases are on the same file system, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

You can use this method to move all tables from one database to a different one, in effect renaming the database. (MySQL has no single statement to perform this task.)

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `Trigger in wrong schema`.

Foreign keys that point to the renamed table are not automatically updated. In such cases, you must drop and re-create the foreign keys in order for them to function properly.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME TABLE`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

You cannot use `RENAME TABLE` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` with temporary tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used to perform the rename, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move the table files.

### 14.1.34 TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege.

Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements. To achieve high performance, it bypasses the DML

method of deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for `InnoDB` tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways in MySQL 5.7:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back.
- Truncation operations cannot be performed if the session holds an active table lock.
- `TRUNCATE TABLE` fails for an `InnoDB` table or `NDB` table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.

**Note**

As of MySQL 5.7.6, partition definition (`.par`) files are no longer created. Instead, partition definitions are stored in the internal data dictionary.

- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using `InnoDB` and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using `InnoDB` in the manner described previously.

On a system with a large `InnoDB` buffer pool and `innodb_adaptive_hash_index` enabled, `TRUNCATE TABLE` operations may cause a temporary drop in system performance due to an LRU scan that occurs when removing an `InnoDB` table's adaptive hash index entries. The problem was addressed for `DROP TABLE` in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for `TRUNCATE TABLE` (Bug #68184).

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See [Section 24.10.15, “Performance Schema Summary Tables”](#).

## 14.2 Data Manipulation Statements

### 14.2.1 CALL Syntax

---

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version      | @increment |
+-----+-----+
| 5.5.3-m3-log  |          11 |
+-----+-----+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholders can be used for `IN` parameters. For `OUT` and `INOUT` parameters, placeholder support is available as of MySQL 5.5.3. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+-----+-----+
| @version      | @increment |
+-----+-----+
| 5.5.3-m3-log  |          11 |
+-----+-----+
```

Before MySQL 5.5.3, placeholder support is not available for `OUT` or `INOUT` parameters. To work around this limitation for `OUT` and `INOUT` parameters, forego the use of placeholders; instead, refer to user variables in the `CALL` statement itself and do not specify them in the `EXECUTE` statement:

```
mysql> SET @increment = 10;
```

```
mysql> PREPARE s FROM 'CALL p(@version, @increment)';
mysql> EXECUTE s;
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.0-m2-log | 11 |
+-----+-----+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 5.7, `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

For programs written in a language that provides a MySQL interface, there is no native method prior to MySQL 5.5.3 for directly retrieving the results of `OUT` or `INOUT` parameters from `CALL` statements. To get the parameter values, pass user-defined variables to the procedure in the `CALL` statement and then execute a `SELECT` statement to produce a result set containing the variable values. To handle an `INOUT` parameter, execute a statement prior to the `CALL` that sets the corresponding user variable to the value to be passed to the procedure.

The following example illustrates the technique (without error checking) for the stored procedure `p` described earlier that has an `OUT` parameter and an `INOUT` parameter:

```
mysql_query(mysql, "SET @increment = 10");
mysql_query(mysql, "CALL p(@version, @increment)");
mysql_query(mysql, "SELECT @version, @increment");
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@version` and `@increment`, respectively.

In MySQL 5.7, C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see [Section 26.8.20, “C API Support for Prepared CALL Statements”](#). Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

In MySQL 5.7, metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## 14.2.2 DELETE Syntax

`DELETE` is a DML statement that removes rows from a table.

## Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
  [PARTITION (partition_name,...)]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

The **DELETE** statement deletes rows from *tbl\_name* and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` function described in [Section 13.14, “Information Functions”](#).

## Main Clauses

The conditions in the optional **WHERE** clause identify which rows to delete. With no **WHERE** clause, all rows are deleted.

*where\_condition* is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 14.2.9, “SELECT Syntax”](#).

If the **ORDER BY** clause is specified, the rows are deleted in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

## Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name['.*'] [, tbl_name['.*']] ...
FROM table_references
[WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name['.*'] [, tbl_name['.*']] ...
  USING table_references
  [WHERE where_condition]
```

## Privileges

You need the **DELETE** privilege on a table to delete rows from it. You need only the **SELECT** privilege for any columns that are only read, such as those named in the **WHERE** clause.

## Performance

When you do not need to know the number of deleted rows, the **TRUNCATE TABLE** statement is a faster way to empty a table than a **DELETE** statement with no **WHERE** clause. Unlike **DELETE**, **TRUNCATE TABLE** cannot be used within a transaction or if you have a lock on the table. See [Section 14.1.34, “TRUNCATE TABLE Syntax”](#) and [Section 14.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

The speed of delete operations may also be affected by factors discussed in [Section 9.2.2.3, “Speed of DELETE Statements”](#).

To ensure that a given **DELETE** statement does not take too much time, the MySQL-specific **LIMIT row\_count** clause for **DELETE** specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the **DELETE** statement until the number of affected rows is less than the **LIMIT** value.

## Subqueries

You cannot delete from a table and select from the same table in a subquery.

## Partitioned Tables

`DELETE` supports explicit partition selection using the `PARTITION` option, which takes a comma-separated list of the names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0)`; in both cases, all rows in partition `p0` are dropped.

`PARTITION` can be used along with a `WHERE` condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the `DELETE`.

The `PARTITION` option can also be used in multiple-table `DELETE` statements. You can use up to one such option per table named in the `FROM` option.

See [Section 21.5, “Partition Selection”](#), for more information and examples.

## Auto-Increment Columns

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 15.8.6, “AUTO\\_INCREMENT Handling in InnoDB”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 4.6.9, “Using AUTO\\_INCREMENT”](#).

## Modifiers

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- For `MyISAM` tables, if you use the `QUICK` keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` keyword causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

## Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
```

```
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` also helps to delete rows in an order required to avoid referential integrity violations.

## InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an [InnoDB](#) table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See [Section 14.1.33, “RENAME TABLE Syntax”](#).

## MyISAM Tables

In [MyISAM](#) tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier to use, but `myisamchk` is faster. See [Section 14.7.2.4, “OPTIMIZE TABLE Syntax”](#), and [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The `QUICK` modifier affects whether index leaves are merged for delete operations. `DELETE QUICK` is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

`DELETE QUICK` is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of `QUICK` can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed `AUTO_INCREMENT` column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using `DELETE QUICK`.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of `QUICK`. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use `DELETE` without `QUICK`, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use `OPTIMIZE TABLE`.

If you are going to delete many rows from a table, it might be faster to use `DELETE QUICK` followed by `OPTIMIZE TABLE`. This rebuilds the index rather than performing many index block merge operations.

## Multi-Table Deletes

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the condition in the `WHERE` clause. You cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The *table\_references* clause lists the tables involved in the join, as described in [Section 14.2.9.2, “JOIN Syntax”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use `INNER JOIN`, but multiple-table `DELETE` statements can use other types of join permitted in `SELECT` statements, such as `LEFT JOIN`. For example, to delete rows that exist in `t1` that have no match in `t2`, use a `LEFT JOIN`:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `.*` after each *tbl\_name* for compatibility with *Access*.

If you use a multiple-table `DELETE` statement involving *InnoDB* tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that *InnoDB* provides to cause the other tables to be modified accordingly.

### Note

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table `DELETE` should be declared only in the *table\_references* part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
```

```
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

### 14.2.3 DO Syntax

```
DO expr [, expr] ...
```

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT *expr*, ...**, but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as **RELEASE\_LOCK()**.

Example: This **SELECT** statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+-----+
| SLEEP(5) |
+-----+
|         0 |
+-----+
1 row in set (5.02 sec)
```

**DO**, on the other hand, pauses without producing a result set.:

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

**DO** only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.

As of MySQL 5.7.8, **DO** statement errors that previously were converted to warnings are returned as errors.

### 14.2.4 HANDLER Syntax

```
HANDLER tbl_name OPEN [ [AS] alias ]

HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]

HANDLER tbl_name CLOSE
```

The **HANDLER** statement provides direct access to table storage engine interfaces. It is available for **InnoDB** and **MyISAM** tables.

The **HANDLER ... OPEN** statement opens a table, making it accessible using subsequent **HANDLER ... READ** statements. This table object is not shared by other sessions and is not closed until the session calls **HANDLER ... CLOSE** or the session terminates.

If you open the table using an alias, further references to the open table with other **HANDLER** statements must use the alias rather than the table name. If you do not use an alias, but open the table

using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 14.2.9, “SELECT Syntax”](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
  - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
  - The handler interface does not have to provide a consistent look of the data (for example, [dirty reads](#) are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
- `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface. (See [Section 15.20, “InnoDB memcached Plugin”](#) for an alternative way to adapt applications that use the key-value store paradigm.)
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current

session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

In previous versions of MySQL, `HANDLER` was not supported with partitioned tables. This limitation is removed beginning with MySQL 5.7.1.

## 14.2.5 INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in [Section 14.2.5.1, “INSERT ... SELECT Syntax”](#).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` option takes a comma-separated list of the names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given `INSERT` statement do not match one of the partitions listed, the `INSERT` statement fails with the error `Found a row not matching the given partition set`. See [Section 21.5, “Partition Selection”](#), for more information and examples.

In MySQL 5.7, the `DELAYED` keyword is accepted but ignored by the server. See [Section 14.2.5.2, “INSERT DELAYED Syntax”](#), for the reasons for this.

You can use [REPLACE](#) instead of [INSERT](#) to overwrite old rows. [REPLACE](#) is the counterpart to [INSERT IGNORE](#) in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 14.2.8, “REPLACE Syntax”](#).

*tbl\_name* is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the [VALUES](#) list or the [SELECT](#) statement.
- If you do not specify a list of column names for [INSERT ... VALUES](#) or [INSERT ... SELECT](#), values for every column in the table must be provided by the [VALUES](#) list or the [SELECT](#) statement. If you do not know the order of the columns in the table, use [DESCRIBE tbl\\_name](#) to find out.
- The [SET](#) clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 12.7, “Data Type Default Values”](#). See also [Section 1.8.3.3, “Constraints on Invalid Data”](#).

If you want an [INSERT](#) statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 6.1.8, “Server SQL Modes”](#).

- Use the keyword [DEFAULT](#) to set a column explicitly to its default value. This makes it easier to write [INSERT](#) statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete [VALUES](#) list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the [VALUES](#) list.

You can also use [DEFAULT\(col\\_name\)](#) as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the [VALUES](#) list are empty, [INSERT](#) creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression *expr* to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an [INT](#), [FLOAT](#), [DECIMAL\(10,6\)](#), or [YEAR](#) column results in the values `1999`, `19.9921`, `19.992100`, and `1999` being inserted, respectively. The reason the value stored in the [INT](#) and [YEAR](#) columns is `1999` is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression *expr* can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, and either may be used whether there is a single values list or multiple lists.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` function (see [Section 13.14, “Information Functions”](#)), or the `mysql_affected_rows()` C API function (see [Section 26.8.7.1, “mysql\\_affected\\_rows\(\)”](#)).

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

**Records** indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because **Duplicates** can be nonzero.) **Duplicates** indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. **Warnings** indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ( `' '` ) for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as `'10.34 a'` to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If a generated column is inserted into explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#).

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 26.8.7.36, “mysql\\_info\(\)”](#).

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 13.14, “Information Functions”](#), and [Section 26.8.7.38, “mysql\\_insert\\_id\(\)”](#).

The `INSERT` statement supports the following modifiers:

- `INSERT DELAYED` was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 5.7, the `DELAYED` keyword is accepted but ignored. Use `INSERT` (without `DELAYED`) instead. See [Section 14.2.5.2, “INSERT DELAYED Syntax”](#).
- If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time.

**Note**

`LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 9.11.3, “Concurrent Inserts”](#).

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 9.11.3, “Concurrent Inserts”](#).

`LOW_PRIORITY` and `HIGH_PRIORITY` affect only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` keyword, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors generate warnings instead.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error; however, when `INSERT IGNORE` is used, the insert operation fails silently for the row containing the unmatched value, but any rows that are matched are inserted. For an example, see [Section 21.2.2, “LIST Partitioning”](#).

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See [Section 14.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Inserting into a table requires the [INSERT](#) privilege for the table. If the [ON DUPLICATE KEY UPDATE](#) clause is used and a duplicate key causes an [UPDATE](#) to be performed instead, the statement requires the [UPDATE](#) privilege for the columns to be updated. For columns that are read but not modified you need only the [SELECT](#) privilege (such as for a column referenced only on the right hand side of an [col\\_name=expr](#) assignment in an [ON DUPLICATE KEY UPDATE](#) clause).

In MySQL 5.7, an [INSERT](#) statement affecting a partitioned table using a storage engine such as [MyISAM](#) that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as [InnoDB](#) that employ row-level locking, no locking of partitions takes place.) For more information, see [Section 21.6.4, “Partitioning and Locking”](#).

### 14.2.5.1 INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name,...)]
    [(col_name,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With [INSERT ... SELECT](#), you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
    SELECT tbl_temp1.fld_order_id
    FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a [INSERT ... SELECT](#) statements:

- Specify [IGNORE](#) to ignore rows that would cause duplicate-key violations.
- The target table of the [INSERT](#) statement may appear in the [FROM](#) clause of the [SELECT](#) part of the query. (This was not possible in some older versions of MySQL.) However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into a table at the same time, MySQL creates a temporary table to hold the rows from the [SELECT](#) and then inserts those rows into the target table. However, it remains true that you cannot use [INSERT INTO t ... SELECT ... FROM t](#) when [t](#) is a [TEMPORARY](#) table, because [TEMPORARY](#) tables cannot be referred to twice in the same statement (see [Section B.5.6.2, “TEMPORARY Table Problems”](#)).

- [AUTO\\_INCREMENT](#) columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for [INSERT ... SELECT](#) statements (see [Section 9.11.3, “Concurrent Inserts”](#)).
- To avoid ambiguous column reference problems when the [SELECT](#) and the [INSERT](#) refer to the same table, provide a unique alias for each table used in the [SELECT](#) part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a [PARTITION](#) option following the name of the table. When [PARTITION](#) is used with the name of the source table in the [SELECT](#) portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When [PARTITION](#) is used with the name of the target table for the [INSERT](#) portion of the statement, then it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option, else the [INSERT ... SELECT](#) statement fails. For more information and examples, see [Section 21.5, “Partition Selection”](#).

In the values part of [ON DUPLICATE KEY UPDATE](#), you can refer to columns in other tables, as long as you do not use [GROUP BY](#) in the [SELECT](#) part. One side effect is that you must qualify nonunique column names in the values part.

The order in which rows are returned by a `SELECT` statement with no `ORDER BY` clause is not determined. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave; this can lead to inconsistencies between them. To prevent this from occurring, you should always write `INSERT ... SELECT` statements that are to be replicated as `INSERT ... SELECT ... ORDER BY column`. The choice of `column` does not matter as long as the same order for returning the rows is enforced on both the master and the slave. See also [Section 18.4.1.17, “Replication and LIMIT”](#).

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

In MySQL 5.7, an `INSERT ... SELECT` statement that acted on partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) See [Section 21.6.4, “Partitioning and Locking”](#), for more information.

### 14.2.5.2 INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as `MyISAM`), such that when a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6.6. In MySQL 5.7, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning (“INSERT DELAYED is no longer supported. The statement was converted to INSERT”). The `DELAYED` keyword is scheduled for removal in a future release.

### 14.2.5.3 INSERT ... ON DUPLICATE KEY UPDATE Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, MySQL performs an `UPDATE` of the old row. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
  ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements for the master and the slave to diverge. Thus, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. In addition, an `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637) See also [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

In MySQL 5.7, an `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) See [Section 21.6.4, “Partitioning and Locking”](#), for more information.

## 14.2.6 LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
```

```

]
[ IGNORE number { LINES | ROWS } ]
[ ( col_name_or_user_var, ... ) ]
[ SET col_name = expr, ... ]

```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. `LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 14.2.9.1, “SELECT ... INTO Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 5.5.5, “mysqlimport — A Data Import Program”](#).

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 9.2.2.1, “Speed of INSERT Statements”](#).

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name.

`LOAD DATA` supports explicit partition selection using the `PARTITION` option with a comma-separated list of one or more names of partitions, subpartitions, or both. When this option is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information, see [Section 21.5, “Partition Selection”](#).

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Section 21.6.4, “Partitioning and Locking”](#).

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

#### Note

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD`

`DATA` is executing. This option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

With row-based replication, `CONCURRENT` is replicated regardless of MySQL version. With statement-based replication `CONCURRENT` is not replicated prior to MySQL 5.5.1 (see Bug #34628). For more information, see [Section 18.4.1.18, “Replication and LOAD DATA INFILE”](#).

The `LOCAL` keyword affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with `--local-infile=0`, `LOCAL` does not work. See [Section 7.1.6, “Security Issues with LOAD DATA LOCAL”](#).

The `LOCAL` keyword affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the server's temporary directory. This is *not* the directory determined by the value of `tmpdir` or `slave_load_tmpdir`, but rather the operating system's temporary directory, and is not configurable in the MySQL Server. (Typically the system temporary directory is `/tmp` on Linux systems and `C:\WINDOWS\TEMP` on Windows.) Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
  - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by the user account used to run the server. Also, to use `LOAD DATA INFILE` on server files, you must have the `FILE` privilege. See [Section 7.2.1, “Privileges Provided by MySQL”](#). For non-`LOCAL` load operations, if the `secure_file_priv` system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

`LOCAL` also affects error handling:

- With `LOAD DATA INFILE`, data-interpretation and duplicate-key errors terminate the operation.
- With `LOAD DATA LOCAL INFILE`, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if `IGNORE` is specified. `IGNORE` is explained further later in this section.

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 14.2.8, “REPLACE Syntax”](#).
- If you specify `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).
- If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

To ignore foreign key constraints during the load operation, issue a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 9.2.2.1, “Speed of INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

(Backslash is the MySQL escape character within strings in SQL statements, so to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.)

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character `\` as escape sequences. For example, `\t`, `\n`, and `\\` signify tab, newline, and backslash, respectively. See the discussion of `FIELDS ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `\` to escape instances of tab, newline, or `\` that occur within field values.

- Write newlines at the ends of lines.

#### Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be (`"abc",1`) and (`"def",2`). The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use **OPTIONALLY** before the **ENCLOSED BY** keywords.

Any of the field- or line-handling options can specify an empty string (' '). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY '\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of **%%**, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

**FIELDS [OPTIONALLY] ENCLOSED BY** controls quoting of fields. For output (**SELECT ... INTO OUTFILE**), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"
```

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as **CHAR**, **BINARY**, **TEXT**, or **ENUM**):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also note that if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA INFILE**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are

interpreted as a single instance of the character. For example, if `ENCLOSED BY '''` is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss      -> The "BIG" boss
The ""BIG"" boss    -> The ""BIG"" boss
```

`FIELDS ESCAPED BY` controls how to read or write special characters:

- For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using `\` for the escape character). The rules for `NULL` handling are described later in this section.

| Character       | Escape Sequence                               |
|-----------------|---|
| <code>\0</code> | An ASCII NUL ( <code>x'00'</code> ) character |
| <code>\b</code> | A backspace character                         |
| <code>\n</code> | A newline (linefeed) character                |
| <code>\r</code> | A carriage return character                   |
| <code>\t</code> | A tab character.                              |
| <code>\z</code> | ASCII 26 (Control+Z)                          |
| <code>\N</code> | NULL  |

For more information about `\`-escape syntax, see [Section 10.1.1, “String Literals”](#).

If the `FIELDS ESCAPED BY` character is empty, escape-sequence interpretation does not occur.

- For output, if the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:
  - The `FIELDS ESCAPED BY` character
  - The `FIELDS [OPTIONALLY] ENCLOSED BY` character
  - The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (`''`), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `''`. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

#### Note

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 12.7, “Data Type Default Values”](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY ' ' ENCLOSED BY ' '
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 12.7, “Data Type Default Values”](#).

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 12.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded using binary notation (for example, `b'011010'`). To work around this, specify the values as regular integers and use the `SET` clause to convert them so that MySQL performs a numeric type conversion and loads them into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
-> INTO TABLE bit_test (@var1) SET b = CAST(@var1 AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| bin(b+0) |
+-----+
| 10       |
| 1111111  |
+-----+
2 rows in set (0.00 sec)
```

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see [Section 14.2.5, "INSERT Syntax"](#)), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 14.7.5.40, "SHOW WARNINGS Syntax"](#).

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 26.8.7.36, "mysql\\_info\(\)"](#).

## 14.2.7 LOAD XML Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE [db_name.]tbl_name
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<tagname>']
[IGNORE number {LINES | ROWS}]
[(field_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
shell> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use `LOAD XML INFILE`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

Prior to MySQL 5.7.9, `LOAD XML` did not handle empty XML elements in the form `<element/>` correctly. (Bug #67542, Bug #16171518)

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`

- CHARACTER SET
- SET

See [Section 14.2.6, “LOAD DATA INFILE Syntax”](#), for more information about these clauses.

(*field\_name\_or\_user\_var*, ...) is a comma-separated list of one or more XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with @. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first *number* rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```
USE test;

CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
    <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field></person>
  <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';

Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
```

| person_id | fname  | lname      | created             |
|-----------|--------|------------|---------------------|
| 1         | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
| 2         | Sajon  | Rondela    | 2007-07-13 16:18:47 |
| 3         | Likame | Örrtmons   | 2007-07-13 16:18:47 |
| 4         | Slar   | Manlanth   | 2007-07-13 16:18:47 |
| 5         | Stoma  | Nilu       | 2007-07-13 16:18:47 |
| 6         | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
| 7         | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
| 8         | Sreraf | Encmelt    | 2007-07-13 16:18:47 |

```
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read in using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>

  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>

  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>

  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>

  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>

  <row>
    <field name="person_id">6</field>
    <field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field>
  </row>

  <row>
    <field name="person_id">7</field>
    <field name="fname">Sungam</field>
    <field name="lname">Dulbåd</field>
  </row>

  <row>
```

```
<field name="person_id">8</field>
<field name="fname">Sreraf</field>
<field name="lname">Encmelt</field>
</row>
</resultset>
```

**Note**

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See [Section 5.5.1, “mysql — The MySQL Command-Line Tool”](#).

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```
mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
```

| person_id | fname  | lname      | created             |
|-----------|--------|------------|---------------------|
| 1         | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
| 2         | Sajon  | Rondela    | 2007-07-13 16:18:47 |
| 3         | Likema | Örrtmons   | 2007-07-13 16:18:47 |
| 4         | Slar   | Manlanth   | 2007-07-13 16:18:47 |
| 5         | Stoma  | Nilu       | 2007-07-13 16:18:47 |
| 6         | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
| 7         | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
| 8         | Sreraf | Encmelt    | 2007-07-13 16:18:47 |

```
8 rows in set (0.00 sec)
```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```
mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
***** 1. row *****
      Table: person2
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  PRIMARY KEY (`person_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

```
mysql> SELECT * FROM person2;
```

| person_id | fname  | lname      |
|-----------|--------|------------|
| 1         | Kapek  | Sainnouine |
| 2         | Sajon  | Rondela    |
| 3         | Likema | Örrtmons   |
| 4         | Slar   | Manlanth   |
| 5         | Stoma  | Nilu       |
| 6         | Nirtam | Sklöd      |
| 7         | Sungam | Dulbåd     |
| 8         | Sreraf | Encmelt    |

```
8 rows in set (0.00 sec)
```

The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```
mysql> CREATE TABLE individual (
->     individual_id INT NOT NULL PRIMARY KEY,
->     name1 VARCHAR(40) NULL,
->     name2 VARCHAR(40) NULL,
->     made TIMESTAMP
-> );
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml'
->     INTO TABLE test.individual (@person_id, @fname, @lname, @created)
->     SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

```
mysql> SELECT * FROM individual;
```

| individual_id | name1  | name2      | made                |
|---------------|--------|------------|---------------------|
| 1             | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
| 2             | Sajon  | Rondela    | 2007-07-13 16:18:47 |
| 3             | Likema | Örrtmons   | 2007-07-13 16:18:47 |
| 4             | Slar   | Manlanth   | 2007-07-13 16:18:47 |
| 5             | Stoma  | Nilu       | 2007-07-13 16:18:47 |
| 6             | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
| 7             | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
| 8             | Sreraf | Encmelt    | 2007-07-13 16:18:47 |

```
8 rows in set (0.00 sec)
```

The names of the user variables *must* match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```
<?xml version="1.0"?>

<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
</list>
```

You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person\G
***** 1. row *****
      Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
```

| person_id | fname  | lname | created             |
|-----------|--------|-------|---------------------|
| 1         | Robert | Jones | 2007-07-24 17:37:06 |
| 2         | Mary   | Smith | 2007-07-24 17:37:06 |

```
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE address
-> ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
```

| address_id | person_id | street          | zip   | city         | created             |
|------------|-----------|-----------------|-------|--------------|---------------------|
| 1          | 1         | Mill Creek Road | 45365 | Sidney       | 2007-07-24 17:37:37 |
| 2          | 1         | Main Street     | 28681 | Taylorsville | 2007-07-24 17:37:37 |
| 3          | 2         | River Road      | 80239 | Denver       | 2007-07-24 17:37:37 |

```
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

### Important

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML INFILE` statement (as well as the `LOAD_FILE()` function; it does *not* prevent the user from executing `LOAD XML LOCAL INFILE`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the [FILE](#) privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as [MyISAM](#), any locks caused by [LOAD XML](#) perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as [InnoDB](#). For more information, see [Section 21.6.4, “Partitioning and Locking”](#).

## 14.2.8 REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
```

[REPLACE](#) works exactly like [INSERT](#), except that if an old row in the table has the same value as a new row for a [PRIMARY KEY](#) or a [UNIQUE](#) index, the old row is deleted before the new row is inserted. See [Section 14.2.5, “INSERT Syntax”](#).

[REPLACE](#) is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see [Section 14.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

[DELAYED](#) inserts and replaces were deprecated in MySQL 5.6.6. In MySQL 5.7, [DELAYED](#) is not supported. The server recognizes but ignores the [DELAYED](#) keyword, handles the replace as a nondelayed replace, and generates an [ER\\_WARN\\_LEGACY\\_SYNTAX\\_CONVERTED](#) warning. (“REPLACE DELAYED is no longer supported. The statement was converted to REPLACE.”) The [DELAYED](#) keyword will be removed in a future release.

### Note

[REPLACE](#) makes sense only if a table has a [PRIMARY KEY](#) or [UNIQUE](#) index. Otherwise, it becomes equivalent to [INSERT](#), because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the [REPLACE](#) statement. Any missing columns are set to their default values, just as happens for [INSERT](#). You cannot refer to values from the current row and use them in the new row. If you use an assignment such as [SET \*col\\_name\* = \*col\\_name\* + 1](#), the reference to the column name on the right hand side is treated as [DEFAULT\(\*col\\_name\*\)](#), so the assignment is equivalent to [SET \*col\\_name\* = DEFAULT\(\*col\\_name\*\) + 1](#).

If a generated column is replaced explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#).

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

`REPLACE` supports explicit partition selection using the `PARTITION` keyword with a comma-separated list of names of partitions, subpartitions, or both. As with `INSERT`, if it is not possible to insert the new row into any of these partitions or subpartitions, the `REPLACE` statement fails with the error `Found a row not matching the given partition set`. See [Section 21.5, “Partition Selection”](#), for more information.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
  - a. Delete from the table the conflicting row that has the duplicate key value
  - b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using the `STATEMENT` binary logging mode, and are logged using the row-based format when using `MIXED` mode. See also [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see [Section 21.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```
CREATE TABLE test (  
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,  
  data VARCHAR(64) DEFAULT NULL,  
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
  PRIMARY KEY (id)  
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
```

```
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+-----+-----+
| id | data | ts      |
+----+-----+-----+
| 1  | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```
CREATE TABLE test2 (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+-----+-----+
| id | data | ts      |
+----+-----+-----+
| 1  | Old  | 2014-08-20 18:47:00 |
| 1  | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

In MySQL 5.7, a `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement's `WHERE` clause, as long as none of the table's partitioning columns are updated; otherwise the entire table is locked. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Section 21.6.4, "Partitioning and Locking"](#).

## 14.2.9 SELECT Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [MAX_STATEMENT_TIME = N]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references
  [PARTITION partition_list]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
```

```
[HAVING where_condition]
[ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
[PROCEDURE procedure_name(argument_list)]
[INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name]]
[FOR UPDATE | LOCK IN SHARE MODE]]
```

**SELECT** is used to retrieve rows selected from one or more tables, and can include **UNION** statements and subqueries. See [Section 14.2.9.3, “UNION Syntax”](#), and [Section 14.2.10, “Subquery Syntax”](#).

The most commonly used clauses of **SELECT** statements are these:

- Each *select\_expr* indicates a column that you want to retrieve. There must be at least one *select\_expr*.
- *table\_references* indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 14.2.9.2, “JOIN Syntax”](#).
- **SELECT** supports explicit partition selection using the **PARTITION** with a list of partitions or subpartitions (or both) following the name of the table in a *table\_reference* (see [Section 14.2.9.2, “JOIN Syntax”](#)). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see [Section 21.5, “Partition Selection”](#).

**SELECT ... PARTITION** from tables using storage engines such as **MyISAM** that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the **PARTITION** option.

See [Section 21.6.4, “Partitioning and Locking”](#), for more information.

- The **WHERE** clause, if given, indicates the condition or conditions that rows must satisfy to be selected. *where\_condition* is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no **WHERE** clause.

In the **WHERE** expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Section 10.5, “Expression Syntax”](#), and [Chapter 13, Functions and Operators](#).

**SELECT** can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

**DUAL** is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The exception is that the **INTO** clause can appear either as shown in the syntax description or

immediately following the *select\_expr* list. For more information about `INTO`, see [Section 14.2.9.1, “SELECT ... INTO Syntax”](#).

The list of *select\_expr* terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `*`-shorthand:

- A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- *tbl\_name*.`*` can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified *tbl\_name*.`*` reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A *select\_expr* can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name, ', ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a *select\_expr* with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ', ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two *select\_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section B.5.4.4, “Problems with Column Aliases”](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 14.2.9.2, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 9.9.4, “Index Hints”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 6.1.5, “Server System Variables”](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 10.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a subquery and also is applied in the outer query, the outermost `ORDER BY` takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

Relying on implicit `GROUP BY` sorting in MySQL 5.7 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

- When you use `ORDER BY` or `GROUP BY` on a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.
- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in [Section 13.19, “Aggregate \(GROUP BY\) Functions”](#).
- `GROUP BY` permits a `WITH ROLLUP` modifier. See [Section 13.19.2, “GROUP BY Modifiers”](#).
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)
- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
  - Within prepared statements, `LIMIT` parameters can be specified using `?` placeholder markers.

- Within stored programs, `LIMIT` parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5;      # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 9.4.2.4, “Using PROCEDURE ANALYSE”](#), which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see [Section 14.2.9.1, “SELECT ... INTO Syntax”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See [Section 15.5.2.4, “Locking Reads”](#).

In addition, you cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...` (If you attempt to do so, the statement

is rejected with the error `Can't update table 'old_table' while 'new_table' is being created`.) This is a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

Following the `SELECT` keyword, you can use a number of options that affect the operation of the statement. `HIGH_PRIORITY`, `MAX_STATEMENT_TIME`, `STRAIGHT_JOIN`, and options beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` options specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both options. `DISTINCTROW` is a synonym for `DISTINCT`.
- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `MAX_STATEMENT_TIME = N` sets a statement execution timeout of `N` milliseconds. If this option is absent or `N` is 0, the statement timeout established by the `max_statement_time` system variable applies.

**Note**

This option was added in MySQL 5.7.4. It was removed in MySQL 5.7.8 in preference to the `MAX_EXECUTION_TIME()` optimizer hint. See [Section 9.9.3, “Optimizer Hints”](#)

The `MAX_STATEMENT_TIME` option is applicable as follows:

- For statements with multiple `SELECT` keywords, such as unions or statements with subqueries, `MAX_STATEMENT_TIME` applies to the entire statement and must appear after the first `SELECT`.
- It applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- It does not apply to `SELECT` statements in stored programs; an error occurs.
- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 14.2.9.2, “JOIN Syntax”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 9.8.1, “Optimizing Queries with EXPLAIN”](#). This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This option can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 13.14, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` options affect caching of query results in the query cache (see [Section 9.10.3, “The MySQL Query Cache”](#)). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is `2` or `DEMAND`. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

These two options are mutually exclusive and an error occurs if they are both specified. Also, these options are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

In MySQL 5.7, a `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `SELECT` statement's `WHERE` clause. (This does not occur with storage engines such as `InnoDB` that employ row-level locking.) For more information, see [Section 21.6.4, “Partitioning and Locking”](#).

### 14.2.9.1 SELECT ... INTO Syntax

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.
- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.
- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

The `SELECT` syntax description (see [Section 14.2.9, “SELECT Syntax”](#)) shows the `INTO` clause near the end of the statement. It is also possible to use `INTO` immediately following the `select_expr` list.

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context.

The `INTO` clause can name a list of one or more variables, which can be user-defined variables, stored procedure or function parameters, or stored program local variables. (Within a prepared `SELECT ... INTO OUTFILE` statement, only user-defined variables are permitted; see [Section 14.6.4.2, “Local Variable Scope and Resolution”](#).)

The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 10.4, “User-Defined Variables”](#).

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some other host than the server host, you normally cannot use `SELECT ... INTO OUTFILE` since there is no way to write a path to the file relative to the server host's file system.

However, if the MySQL client software is installed on the remote machine, you can instead use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

It is also possible to create the resulting file on a different host other than the server host, if the location of the file on the remote host can be accessed using a network-mapped path on the server's file system. In this case, the presence of `mysql` (or some other MySQL client program) is not required on the target host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 14.2.6, "LOAD DATA INFILE Syntax"](#), for information about the `FIELDS` and `LINES` clauses, including their default values and permissible values.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

#### Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 22.4.5, “Event Scheduler Status”](#).

### 14.2.9.2 JOIN Syntax

MySQL supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
    escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
    table_reference
  | { OJ table_reference }

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [PARTITION (partition_names)]
      [[AS] alias] [index_hint_list]
  | table_subquery [AS] alias
  | ( table_references )

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | IGNORE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
  | FORCE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
    index_name [, index_name] ...
```

A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a [PARTITION](#) option, including a comma-separated list of partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions—in other words, any partitions or subpartitions not named in the list are ignored. For more information, see [Section 21.5, “Partition Selection”](#).

The syntax of *table\_factor* is extended in comparison with the SQL Standard. The latter accepts only *table\_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of *table\_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, [JOIN](#), [CROSS JOIN](#), and [INNER JOIN](#) are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. [INNER JOIN](#) is used with an [ON](#) clause, [CROSS JOIN](#) is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins (see [Section 9.2.1.11, “Nested Join Optimization”](#)).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 9.9.4, “Index Hints”](#).

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using *tbl\_name AS alias\_name* or *tbl\_name alias\_name*:

```
SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A *table\_subquery* is also known as a subquery in the [FROM](#) clause. Such subqueries *must* include an alias to give the subquery result a table name. A trivial example follows; see also [Section 14.2.10.8, “Subqueries in the FROM Clause”](#).

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- [INNER JOIN](#) and [,](#) (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of [INNER JOIN](#), [CROSS JOIN](#), [LEFT JOIN](#), and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The *conditional\_expr* used with [ON](#) is any conditional expression of the form that can be used in a [WHERE](#) clause. Generally, you should use the [ON](#) clause for conditions that specify how to join tables, and the [WHERE](#) clause to restrict which rows you want in the result set.

- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See [Section 9.2.1.9, “LEFT JOIN and RIGHT JOIN Optimization”](#).

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- `STRAIGHT_JOIN` is similar to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```
SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;

SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
LEFT JOIN table3 ON table2.id=table3.id;
```

### Join Processing Changes in MySQL 5.0.12

#### Note

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to `NATURAL JOIN` and `JOIN ... USING` according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to

work correctly in older versions (prior to 5.0.12) must be rewritten to comply with the standard.

These changes have five main aspects:

- The way that MySQL determines the result columns of `NATURAL` or `USING` join operations (and thus the result of the entire `FROM` clause).
- Expansion of `SELECT *` and `SELECT tbl_name.*` into a list of selected columns.
- Resolution of column names in `NATURAL` or `USING` joins.
- Transformation of `NATURAL` or `USING` joins into `JOIN ... ON`.
- Resolution of column names in the `ON` condition of a `JOIN ... ON`.

The following list provides more detail about several effects of current join processing versus join processing in older versions. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a `NATURAL` join or a `USING` join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for `SELECT *` expansion may be different from before.

Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

Previously, the statements produced this output:

```
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
| 1     | 1     | 1     | 1     |
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
| 1     | 1     | 1     | 1     |
+-----+-----+-----+-----+
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

```
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
```

The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN V1 IS NOT NULL THEN V1 ELSE V2 END)
```

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a `JOIN`. Suppose that the tables `t1(a,b)` and `t2(a,c)` have the following contents:

| t1  | t2  |
|-----|-----|
| 1 x | 2 z |
| 2 y | 3 w |

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

Here column `a` contains the values of `t1.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
| 2     | z     | y     |
| 3     | w     | NULL  |
+-----+-----+-----+
```

Here column `a` contains the values of `t2.a`.

Compare these results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 1     | x     | NULL  | NULL  |
| 2     | y     | 2     | z     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
```

| a    | b    | a | c |
|------|------|---|---|
| 2    | y    | 2 | z |
| NULL | NULL | 3 | w |

- Previously, a `USING` clause could be rewritten as an `ON` clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

- With respect to determining which rows satisfy the join condition, both joins remain semantically identical.
- With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the preceding `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1,b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column will be omitted from the result.

- The evaluation of multi-way natural joins differs in a very important way that affects the result of `NATURAL` or `USING` joins and that can require query rewriting. Suppose that you have three tables `t1(a,b)`, `t2(c,b)`, and `t3(a,c)` that each have one row: `t1(1,2)`, `t2(10,2)`, and `t3(7,10)`. Suppose also that you have this `NATURAL JOIN` on the three tables:

```
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be `t2`, whereas it should be the nested join `(t1 NATURAL JOIN t2)`. As a result, the columns of `t3` are checked for common columns only in `t2`, and, if `t3` has common columns with `t1`, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```

That join is missing one more equi-join predicate `(t1.a = t3.a)`. As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator (,) and `JOIN` both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now `JOIN` has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an `ON` clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the `SELECT` was legal due to the implicit grouping of `t1,t2` as `(t1,t2)`. Now the `JOIN` takes precedence, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1,t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which now have higher precedence than the comma operator.

- Previously, the `ON` clause could refer to columns in tables named to its right. Now an `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

Previously, the `SELECT` statement was legal. Now the statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. The statement should be rewritten as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- Resolution of column names in `NATURAL` or `USING` joins is different than previously. For column names that are outside the `FROM` clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of `NATURAL` or `USING` joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

```
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
```

Previously, this query would produce an error `ERROR 1052 (23000): Column 'b' in where clause is ambiguous`. Now the query produces the correct result:

```
+-----+-----+-----+
| b      | c      | y      |
+-----+-----+-----+
| 4      | 2      | 3      |
+-----+-----+-----+
```

One extension of MySQL compared to the SQL:2003 standard is that MySQL enables you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins (just as previously), while the standard disallows that.

### 14.2.9.3 UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` is used to combine the result from multiple `SELECT` statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all of the `SELECT` statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a              |
| bbbbbbbbbbb   |
+-----+
```

The `SELECT` statements are normal select statements, but with the following restrictions:

- Only the last `SELECT` statement can use `INTO OUTFILE`. (However, the entire `UNION` result is written to the file.)
- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

**Note**

Previous versions of MySQL may permit such statements without parentheses. In MySQL 5.7, the requirement for parentheses is enforced.

Use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, colla;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

As of MySQL 5.7.5, `UNION` queries with an aggregate function in an `ORDER BY` clause are rejected with an `ERAggregateOrderForUnion` error. Example:

```
SELECT 1 AS foo UNION SELECT 2 ORDER BY MAX(1);
```

## 14.2.10 Subquery Syntax

A subquery is a [SELECT](#) statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, [SELECT \\* FROM t1 ...](#) is the *outer query* (or *outer statement*), and [\(SELECT column1 FROM t2\)](#) is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
   WHERE NOT EXISTS
    (SELECT * FROM t3
     WHERE ROW(5*t2.s1,77)=
      (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
       (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary [SELECT](#) can contain: [DISTINCT](#), [GROUP BY](#), [ORDER BY](#), [LIMIT](#), joins, index hints, [UNION](#) constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: [SELECT](#), [INSERT](#), [UPDATE](#), [DELETE](#), [SET](#), or [DO](#).

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as [DELETE](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and (because subqueries can be used in the [SET](#) clause) [LOAD DATA INFILE](#).

For information about how the optimizer handles subqueries, see [Section 9.2.1.18, “Subquery Optimization”](#). For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see [Section C.4, “Restrictions on Subqueries”](#).

### 14.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you

can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value ('abcde') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (`SELECT column1 FROM t1`), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 14.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 14.2.10.5, “Row Subqueries”](#).

### 14.2.10.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> !=
```

The `ANY` keyword, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ANY` of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21,14,7)` because there is a value `7` in `t2` that is less than `10`. The expression is `FALSE` if table `t2` contains `(20,10)`, or if table `t2` is empty. The expression is *unknown* (that is, `NULL`) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word `IN` is an alias for `= ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See [Section 13.3.2, “Comparison Functions and Operators”](#).

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See [Section 14.2.10.4, “Subqueries with ALL”](#).

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word `SOME` is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is

meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using `<>` `SOME` instead helps ensure that everyone understands the true meaning of the query.

#### 14.2.10.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word `ALL`, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ALL` of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(-5, 0, +5)` because `10` is greater than all three values in `t2`. The expression is `FALSE` if table `t2` contains `(12, 6, NULL, -100)` because there is a single value `12` in table `t2` that is greater than `10`. The expression is *unknown* (that is, `NULL`) if table `t2` contains `(0, NULL, 1)`.

Finally, the expression is `TRUE` if table `t2` is empty. So, the following expression is `TRUE` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing `NULL` values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

`NOT IN` is an alias for `<> ALL`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

#### 14.2.10.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1
  WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
  WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table `t2` contains a single row with `id = 10`, the subquery returns a single row. If this row has `col3` and `col4` values equal to the `col1` and `col2` values of any rows in `t1`, the `WHERE` expression is `TRUE` and each query returns those `t1` rows. If the `t2` row `col3` and `col4` values

are not equal the `col1` and `col2` values of any `t1` row, the expression is `FALSE` and the query returns an empty result set. The expression is *unknown* (that is, `NULL`) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see [Section 13.3.2, “Comparison Functions and Operators”](#).

The expressions `(1,2)` and `ROW(1,2)` are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
  FROM t1
 WHERE (column1,column2,column3) IN
       (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see [Section 9.2.1.20, “Row Constructor Expression Optimization”](#)

## 14.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
 WHERE EXISTS (SELECT * FROM cities_stores
               WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
```

```
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in *Stores*”? But it is easier to say that a nested `NOT EXISTS` answers the question “is *x* `TRUE` for all *y*?”

#### 14.2.10.7 Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
                    WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the expression as a whole is `FALSE`.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
                  WHERE x.column1 = (SELECT column1 FROM t3
                                    WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

#### 14.2.10.8 Subqueries in the FROM Clause

Subqueries are legal in a `SELECT` statement's `FROM` clause. The actual syntax is:

```
SELECT ... FROM (subquery) [AS] name ...
```

The [`AS`] *name* clause is mandatory, because every table in a `FROM` clause must have a name. Any columns in the *subquery* select list must have unique names.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
  FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
 WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
  FROM (SELECT SUM(column1) AS sum_column1
        FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

Subqueries in the `FROM` clause can return a scalar, column, row, or table. Subqueries in the `FROM` clause cannot be correlated subqueries, unless used within the `ON` clause of a `JOIN` operation.

In MySQL 5.7, the optimizer determines information about derived tables in such a way that materialization of them does not occur for `EXPLAIN`. See [Optimizing Derived Tables and View References](#).

It is possible under certain circumstances to modify table data using `EXPLAIN SELECT`. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, created as shown here:

```
mysql> CREATE DATABASE d1;
Query OK, 1 row affected (0.00 sec)

mysql> USE d1;
Database changed

mysql> CREATE TABLE t1 (c1 INT);
Query OK, 0 rows affected (0.15 sec)

mysql> CREATE TABLE t2 (c1 INT);
Query OK, 0 rows affected (0.08 sec)
```

Now we create a stored function `f1` which modifies `t2`:

```
mysql> DELIMITER //
mysql> CREATE FUNCTION f1(p1 INT) RETURNS INT
mysql> BEGIN
mysql>     INSERT INTO t2 VALUES (p1);
mysql>     RETURN p1;
mysql> END //
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;
```

Referencing the function directly in an `EXPLAIN SELECT` does not have any effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.00 sec)

mysql> EXPLAIN SELECT f1(5);
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | NULL | NULL | NULL | NULL | NULL | NULL | NULL | No tables used |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2;
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | PRIMARY | NULL | NULL | NULL | NULL | NULL | NULL | NULL | No tables used |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note | 1249 | Select 2 was reduced during optimization |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2;
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | PRIMARY | a1 | system | NULL | NULL | NULL | NULL | 0 | const row not changed |
| 1 | PRIMARY | <derived2> | system | NULL | NULL | NULL | NULL | 1 | |
| 2 | DERIVED | NULL | NULL | NULL | NULL | NULL | NULL | NULL | No tables used |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+----+
| c1 |
+----+
| 5 |
+----+
```

```
+-----+
1 row in set (0.00 sec)
```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

### 14.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that MySQL does not support statements of the following form:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See [Section 14.2.10.5, “Row Subqueries”](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an [UPDATE](#) statement because subqueries are legal in [UPDATE](#) and [DELETE](#) statements as well as in [SELECT](#) statements. However, you cannot use the same table (in this case, table [t1](#)) for both the subquery [FROM](#) clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

#### 14.2.10.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with:

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
  SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 14.2.10.11, “Rewriting Subqueries as Joins”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1
WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1
WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 13.14, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also [MySQL Internals: How MySQL Transforms Subqueries](#).

### 14.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
  FROM table1 LEFT JOIN table2 ON table1.id=table2.id
 WHERE table2.id IS NULL;
```

A `LEFT [OUTER] JOIN` can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table `DELETE` statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table `UPDATE` statements are also supported. See [Section 14.2.2, “DELETE Syntax”](#), and [Section 14.2.11, “UPDATE Syntax”](#).

## 14.2.11 UPDATE Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
  SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
  SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
  [WHERE where_condition]
```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in *table\_references* that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, `ORDER BY` and `LIMIT` cannot be used.

For partitioned tables, both the single-table and multiple-table forms of this statement support the use of a `PARTITION` option as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the *where\_condition* or not.

#### Note

Unlike the case when using `PARTITION` with an `INSERT` or `REPLACE` statement, an otherwise valid `UPDATE ... PARTITION` statement is considered successful even if no rows in the listed partitions (or subpartitions) match the *where\_condition*.

See [Section 21.5, “Partition Selection”](#), for more information and examples.

*where\_condition* is an expression that evaluates to true for each row to be updated. For expression syntax, see [Section 10.5, “Expression Syntax”](#).

*table\_references* and *where\_condition* are specified as described in [Section 14.2.9, “SELECT Syntax”](#).

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` keyword, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- With the `IGNORE` keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

`UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439) See [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#), for more information.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is `0` for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. See [Section 12.7, “Data Type Default Values”](#).

If a generated column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#).

`UPDATE` returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the `UPDATE`.

You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The `table_references` clause lists the tables involved in the join. Its syntax is described in [Section 14.2.9.2, “JOIN Syntax”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join permitted in `SELECT` statements, such as `LEFT JOIN`.

If you use a multiple-table `UPDATE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly. See [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

You cannot update a table and select from the same table in a subquery.

In MySQL 5.7, an `UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `UPDATE` statement's `WHERE` clause, as long as none of the table's partitioning columns are updated. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Section 21.6.4, “Partitioning and Locking”](#).

## 14.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 14.3.1, “START](#)

[TRANSACTION, COMMIT, and ROLLBACK Syntax](#)". XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 14.3.7, "XA Transactions"](#).

### 14.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION
    [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic:
    WITH CONSISTENT SNAPSHOT
    | READ WRITE
    | READ ONLY

BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of [transactions](#):

- [START TRANSACTION](#) or [BEGIN](#) start a new transaction.
- [COMMIT](#) commits the current transaction, making its changes permanent.
- [ROLLBACK](#) rolls back the current transaction, canceling its changes.
- [SET autocommit](#) disables or enables the default autocommit mode for the current session.

By default, MySQL runs with [autocommit](#) mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk to make it permanent. The change cannot be rolled back.

To disable autocommit mode implicitly for a single series of statements, use the [START TRANSACTION](#) statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With [START TRANSACTION](#), autocommit remains disabled until you end the transaction with [COMMIT](#) or [ROLLBACK](#). The autocommit mode then reverts to its previous state.

[START TRANSACTION](#) permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The [WITH CONSISTENT SNAPSHOT](#) modifier starts a [consistent read](#) for storage engines that are capable of it. This applies only to [InnoDB](#). The effect is the same as issuing a [START TRANSACTION](#) followed by a [SELECT](#) from any [InnoDB](#) table. See [Section 15.5.2.3, "Consistent Nonlocking Reads"](#). The [WITH CONSISTENT SNAPSHOT](#) modifier does not change the current transaction [isolation level](#), so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is [REPEATABLE READ](#). For all other isolation levels, the [WITH CONSISTENT SNAPSHOT](#) clause is ignored. As of MySQL 5.7.2, a warning is generated when the [WITH CONSISTENT SNAPSHOT](#) clause is ignored.
- The [READ WRITE](#) and [READ ONLY](#) modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The [READ ONLY](#) restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on [InnoDB](#) tables when the transaction is known to be read-only. Specifying [READ ONLY](#) ensures these optimizations are applied in cases where the

read-only status cannot be determined automatically. See [Section 9.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see [Section 14.3.6, “SET TRANSACTION Syntax”](#).

If the `read_only` system variable is enabled, explicitly starting a transaction with `START TRANSACTION READ WRITE` requires the `SUPER` privilege.

#### Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See [Chapter 26, Connectors and APIs](#), or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for `InnoDB` or `NDB`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at [Section 6.1.5, “Server System Variables”](#).

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that `BEGIN` does not.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See [Section 14.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

#### Note

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 6.1.5, “Server System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See [Section 14.3.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See [Section 6.4.4, “The Binary Log”](#).

You can change the isolation level or access mode for transactions with the `SET TRANSACTION` statement. See [Section 14.3.6, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

**Note**

In MySQL 5.7, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

## 14.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

## 14.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. Transaction-

control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER SERVER`, `ALTER TABLE`, `ALTER VIEW`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE SERVER`, `CREATE TABLE`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP DATABASE`, `DROP EVENT`, `DROP INDEX`, `DROP PROCEDURE`, `DROP SERVER`, `DROP TABLE`, `DROP TRIGGER`, `DROP VIEW`, `INSTALL PLUGIN` (as of MySQL 5.7.6), `RENAME TABLE`, `TRUNCATE TABLE`, `UNINSTALL PLUGIN` (as of MySQL 5.7.6).

`ALTER FUNCTION`, `CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with user-defined functions. (`ALTER FUNCTION` can only be used with stored functions.)

`CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

`CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.) This is to prevent an issue during replication where the table could be created on the master after a rollback, but fail to be recorded in the binary log, and therefore not replicated to the slave.

- **Statements that implicitly use or modify tables in the `mysql` database.** `ALTER USER`, `CREATE USER`, `DROP USER`, `GRANT`, `RENAME USER`, `REVOKE`, `SET PASSWORD`.
- **Transaction-control and locking statements.** `BEGIN`, `LOCK TABLES`, `SET autocommit = 1` (if the value is not already 1), `START TRANSACTION`, `UNLOCK TABLES`.

`UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES` to acquire nontransactional table locks. A commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See [Section 14.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

- **Data loading statements.** `LOAD DATA INFILE`. `LOAD DATA INFILE` causes an implicit commit only for tables using the `NDB` storage engine.
- **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `FLUSH`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`, `RESET`.
- **Replication control statements.** `START SLAVE`, `STOP SLAVE`, `RESET SLAVE`, `CHANGE MASTER TO`.

### 14.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 14.3.5 LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
  tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...

lock_type:
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE

UNLOCK TABLES
```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail later in this section.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [Section 14.3.5.2, “LOCK TABLES and Triggers”](#).

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See [Section 14.7.6.3, “FLUSH Syntax”](#). (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

For information about other conditions on the use of `LOCK TABLES` and statements that cannot be used while `LOCK TABLES` is in effect, see [Section 14.3.5.3, “Table-Locking Restrictions and Conditions”](#)

### Rules for Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement. The following lock types are available:

`READ [LOCAL]` lock:

- The session that holds the lock can read the table (but not write it).
- Multiple sessions can acquire a `READ` lock for the table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.
- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See [Section 9.11.3, “Concurrent Inserts”](#).) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:

- The session that holds the lock can read and write the table.
- Only the session that holds the lock can access the table. No other session can access it until the lock is released.
- Lock requests for the table by other sessions block while the `WRITE` lock is held.
- The `LOW_PRIORITY` modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use `WRITE` without `LOW_PRIORITY` instead.

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables.

For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+-----+
| COUNT(*) |
+-----+
|          3 |
+-----+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it.

`LOCK TABLES` acquires locks as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the session gets all locks.

This policy ensures that table locking is deadlock free.

#### Note

`LOCK TABLES` or `UNLOCK TABLES`, when applied to a partitioned table, always locks or unlocks the entire table; these statements do not support partition lock pruning. See [Section 21.6.4, “Partitioning and Locking”](#).

## Rules for Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with `UNLOCK TABLES`.
- If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with `START TRANSACTION`), an implicit `UNLOCK TABLES` is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see [Section 14.3.5.1, “Interaction of Table Locking and Transactions”](#).)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See [Section 26.8.16, “Controlling Automatic Reconnection Behavior”](#).

### Note

If you use `ALTER TABLE` on a locked table, it may become unlocked. For example, if you attempt a second `ALTER TABLE` operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

## 14.3.5.1 Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.
- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See [Section 14.7.6.3, “FLUSH Syntax”](#).
- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).
- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`)

followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then InnoDB releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

### 14.3.5.2 LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken at the same time as those acquired explicitly with the `LOCK TABLES` statement.
- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.
- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for writing because it might be updated within the trigger.

### 14.3.5.3 Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See [Section 14.7.6.4, "KILL Syntax"](#).

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a `WRITE` lock on any of those tables with a `LOCK TABLES` statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of `MyISAM` tables, it is much faster to lock the tables you are going to use. Locking `MyISAM` tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a `READ`-locked table (including the one holding the lock) and no session can access a `WRITE`-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use `LOCK TABLES` if you want to ensure that no other session modifies the tables between a `SELECT` and an `UPDATE`. The example shown here requires `LOCK TABLES` to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without `LOCK TABLES`, it is possible that another session might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See [Section 13.20, “Miscellaneous Functions”](#).

See [Section 9.11.1, “Internal Locking Methods”](#), for more information on locking policy.

## 14.3.6 SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_characteristic [, transaction_characteristic] ...

transaction_characteristic:
    ISOLATION LEVEL level
    | READ WRITE
    | READ ONLY

level:
    REPEATABLE READ
    | READ COMMITTED
    | READ UNCOMMITTED
    | SERIALIZABLE
```

This statement specifies [transaction](#) characteristics. It takes a list of one or more characteristic values separated by commas. These characteristics set the transaction [isolation level](#) or access mode. The isolation level is used for operations on [InnoDB](#) tables. The access mode may be specified as to whether transactions operate in read/write or read-only mode.

In addition, `SET TRANSACTION` can include an optional `GLOBAL` or `SESSION` keyword to indicate the scope of the statement.

### Scope of Transaction Characteristics

You can set transaction characteristics globally, for the current session, or for the next transaction:

- With the `GLOBAL` keyword, the statement applies globally for all subsequent sessions. Existing sessions are unaffected.
- With the `SESSION` keyword, the statement applies to all subsequent transactions performed within the current session.
- Without any `SESSION` or `GLOBAL` keyword, the statement applies to the next (not started) transaction performed within the current session. Subsequent transactions revert to using the `SESSION` isolation level.

A global change to transaction characteristics requires the `SUPER` privilege. Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction.

`SET TRANSACTION` without `GLOBAL` or `SESSION` is not permitted while there is an active transaction:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed
while a transaction is in progress
```

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option to `mysqld` on the command line or in an option file. Values of *level* for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the `[mysqld]` section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
```

It is possible to check or set the global and session transaction isolation levels at runtime by using the `tx_isolation` system variable:

```
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
SET GLOBAL tx_isolation='REPEATABLE-READ';
SET SESSION tx_isolation='SERIALIZABLE';
```

Similarly, to set the transaction access mode at server startup or at runtime, use the `--transaction-read-only` option or `tx_read_only` system variable. By default, these are `OFF` (the mode is read/write) but can be set to `ON` for a default mode of read only.

Setting the global or session value of `tx_isolation` or `tx_read_only` is equivalent to setting the isolation level or access mode with `SET GLOBAL TRANSACTION` or `SET SESSION TRANSACTION`.

## Transaction Isolation Levels

For information about transaction isolation levels, see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

## Transaction Access Mode

The transaction access mode may be specified with `SET TRANSACTION`. By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

## 14.3.7 XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section C.6, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, `SERIALIZABLE`

may be preferred if your applications are sensitive to read phenomena. `REPEATABLE READ` may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

#### 14.3.7.1 XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```

XA {START|BEGIN} xid [JOIN|RESUME]

XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid

XA RECOVER [CONVERT XID]

```

For **XA START**, the **JOIN** and **RESUME** clauses are not supported.

For **XA END** the **SUSPEND [FOR MIGRATE]** clause is not supported.

Each XA statement begins with the **XA** keyword, and most of them require an *xid* value. An *xid* is an XA transaction identifier. It indicates which transaction the statement applies to. *xid* values are supplied by the client, or generated by the MySQL server. An *xid* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

*gtrid* is a global transaction identifier, *bqual* is a branch qualifier, and *formatID* is a number that identifies the format used by the *gtrid* and *bqual* values. As indicated by the syntax, *bqual* and *formatID* are optional. The default *bqual* value is '' if not given. The default *formatID* value is 1 if not given.

*gtrid* and *bqual* must be string literals, each up to 64 bytes (not characters) long. *gtrid* and *bqual* can be specified in several ways. You can use a quoted string ('*ab*'), hex string (X'6162', 0x6162), or bit value (b'*nnnn*').

*formatID* is an unsigned integer.

The *gtrid* and *bqual* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *gtrid* and *bqual* as hex strings.

*xid* values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *xid* values in a list of values returned by the **XA RECOVER** statement.

For **XA START** *xid* starts an XA transaction with the given *xid* value. Each XA transaction must have a unique *xid* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *gtrid* and *bqual* values. All following XA statements for the XA transaction must be specified using the same *xid* value as that given in the **XA START** statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The **XA RECOVER** statement returns information for those XA transactions on the MySQL server that are in the **PREPARED** state. (See [Section 14.3.7.2, “XA Transaction States”](#).) The output includes a row for each such XA transaction on the server, regardless of which client started it.

**XA RECOVER** output rows look like this (for an example *xid* value consisting of the parts '*abc*', '*def*', and 7):

```
mysql> XA RECOVER;
```

| formatID | gtrid_length | bqual_length | data   |
|----------|--------------|--------------|--------|
| 7        | 3            | 3            | abcdef |

The output columns have the following meanings:

- `formatID` is the `formatID` part of the transaction `xid`
- `gtrid_length` is the length in bytes of the `gtrid` part of the `xid`
- `bqual_length` is the length in bytes of the `bqual` part of the `xid`
- `data` is the concatenation of the `gtrid` and `bqual` parts of the `xid`

XID values may contain nonprintable characters. As of MySQL 5.7.5, `XA RECOVER` permits an optional `CONVERT XID` clause so that clients can request XID values in hexadecimal.

### 14.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
  - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's `xid` value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
  - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The `xid` value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the [ACTIVE](#) state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).

## 14.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls master servers, a group which controls slave servers, and a group which can be applied to any replication servers.

### 14.4.1 SQL Statements for Controlling Master Servers

This section discusses statements for managing master replication servers. [Section 14.4.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

In addition to the statements described here, the following [SHOW](#) statements are used with master servers in replication. For information about these statements, see [Section 14.7.5, “SHOW Syntax”](#).

- [SHOW BINARY LOGS](#)
- [SHOW BINLOG EVENTS](#)
- [SHOW MASTER STATUS](#)
- [SHOW SLAVE HOSTS](#)

#### 14.4.1.1 PURGE BINARY LOGS Syntax

```
PURGE { BINARY | MASTER } LOGS
      { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see [Section 6.4.4, “The Binary Log”](#)).

The [PURGE BINARY LOGS](#) statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. [BINARY](#) and [MASTER](#) are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the [--log-bin](#) option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2008-04-02 22:46:26';
```

The [BEFORE](#) variant's *datetime\_expr* argument should evaluate to a [DATETIME](#) value (a value in '[YYYY-MM-DD hh:mm:ss](#)' format).

This statement is safe to run while slaves are replicating. You need not stop them. If you have an active slave that currently is reading one of the log files you are trying to delete, this statement does nothing. In MySQL 5.7.2 and later, it fails with an error in such cases. (Bug #13727933) However, if a slave is

not connected and you happen to purge one of the log files it has yet to read, the slave will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the slaves. This is the target file. If all the slaves are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 6.1.5, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

### 14.4.1.2 RESET MASTER Syntax

#### RESET MASTER

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

`RESET MASTER` also clears the values of the `gtid_purged` system variable as well as the global value of the `gtid_executed` system variable (but not its session value); that is, executing this statement sets each of these values to an empty string ( `' '` ). In MySQL 5.7.5 and later, this statement also clears the `mysql.gtid_executed` table (see [mysql.gtid\\_executed Table](#)).

This statement is intended to be used only when the master is started for the first time.

#### Important

The effects of `RESET MASTER` differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes *all* binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replication slaves are running.

See also [Section 14.4.1.1, “PURGE BINARY LOGS Syntax”](#).

`RESET MASTER` can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#)).
2. Execute a few test queries on the master.
3. Check that the queries were replicated to the slave.
4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the slave, then verify that any unwanted data no longer exists on the slave.
5. Issue `RESET MASTER` on the master to clean up the test queries.

After verifying the setup and getting rid of any unwanted and log files generated by testing, you can start the slave and begin replicating.

### 14.4.1.3 SET sql\_log\_bin Syntax

```
SET sql_log_bin = {0|1}
```

The `sql_log_bin` variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` privilege to set this variable. Set this variable to 0 for a session to temporarily disable binary logging while making changes to the master which you do not want to replicate to the slave.

As of MySQL 5.5, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

#### Warning

Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are *still* being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

In MySQL 5.7, it is not possible to set `@@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

## 14.4.2 SQL Statements for Controlling Slave Servers

This section discusses statements for managing slave replication servers. [Section 14.4.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replication slaves. For information about these statements, see [Section 14.7.5.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 14.7.5.32, “SHOW RELAYLOG EVENTS Syntax”](#).

### 14.4.2.1 CHANGE MASTER TO Syntax

```
CHANGE MASTER TO option [, option] ... [ channel_option ]
```

*option*:

```
MASTER_BIND = 'interface_name'
MASTER_HOST = 'host_name'
MASTER_USER = 'user_name'
MASTER_PASSWORD = 'password'
MASTER_PORT = port_num
MASTER_CONNECT_RETRY = interval
MASTER_RETRY_COUNT = count
MASTER_DELAY = interval
```

```

MASTER_HEARTBEAT_PERIOD = interval
MASTER_LOG_FILE = 'master_log_name'
MASTER_LOG_POS = master_log_pos
MASTER_AUTO_POSITION = {0|1}
RELAY_LOG_FILE = 'relay_log_name'
RELAY_LOG_POS = relay_log_pos
MASTER_SSL = {0|1}
MASTER_SSL_CA = 'ca_file_name'
MASTER_SSL_CAPATH = 'ca_directory_name'
MASTER_SSL_CERT = 'cert_file_name'
MASTER_SSL_CRL = 'crl_file_name'
MASTER_SSL_CRLPATH = 'crl_directory_name'
MASTER_SSL_KEY = 'key_file_name'
MASTER_SSL_CIPHER = 'cipher_list'
MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
MASTER_TLS_VERSION = 'protocol_list'
IGNORE_SERVER_IDS = (server_id_list)

channel_option:
    FOR CHANNEL channel

server_id_list:
    [server_id [, server_id] ... ]

```

**CHANGE MASTER TO** changes the parameters that the slave server uses for connecting to the master server, for reading the master binary log, and reading the slave relay log. It also updates the contents of the master info and relay log info repositories (see [Section 18.2.4, “Replication Relay and Status Logs”](#)).

Prior to MySQL 5.7.4, the slave replication threads must be stopped, using **STOP SLAVE** if necessary, before issuing this statement. In MySQL 5.7.4 and later, you can issue **CHANGE MASTER TO** statements on a running slave without doing this, depending on the states of the slave SQL thread and slave I/O thread. The rules governing such use are provided later in this section.

When using a multi-threaded slave (in other words `slave_parallel_workers` is greater than 0), stopping the slave can cause “gaps” in the sequence of transactions that have been executed from the relay log, regardless of whether the slave was stopped intentionally or otherwise. When such gaps exist, issuing **CHANGE MASTER TO** fails. The solution in this situation is to issue **START SLAVE UNTIL SQL\_AFTER\_MTS\_GAPS** which ensures that the gaps are closed.

The optional **FOR CHANNEL *channel*** clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a **FOR CHANNEL *channel*** clause applies the **CHANGE MASTER TO** statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called `channel2`:

```
CHANGE MASTER TO MASTER_NAME=host1, MASTER_PORT=3002 FOR CHANNEL channel2
```

When using multiple replication channels, if a **CHANGE MASTER TO** statement does not have a channel defined using a **FOR CHANNEL *channel*** clause an error is generated. See [Section 18.2.3, “Replication Channels”](#) for more information.

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your MySQL master has changed, issue this statement to tell the slave about the new password:

```
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
```

`MASTER_HOST`, `MASTER_USER`, `MASTER_PASSWORD`, and `MASTER_PORT` provide information to the slave about how to connect to its master:

- `MASTER_HOST` and `MASTER_PORT` are the host name (or IP address) of the master host and its TCP/IP port.

**Note**

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify the `MASTER_HOST` or `MASTER_PORT` option, the slave assumes that the master server is different from before (even if the option value is the same as its current value.) In this case, the old values for the master binary log file name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE= ''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST= ''` (that is, setting its value explicitly to an empty string) is *not* the same as not setting `MASTER_HOST` at all. Beginning with MySQL 5.5, trying to set `MASTER_HOST` to an empty string fails with an error. Previously, setting `MASTER_HOST` to an empty string caused `START SLAVE` subsequently to fail. (Bug #28796)

Values used for `MASTER_HOST` and other `CHANGE MASTER TO` options are checked for linefeed (`\n` or `0x0A`) characters; the presence of such characters in these values causes the statement to fail with `ER_MASTER_INFO`. (Bug #11758581, Bug #50801)

- `MASTER_USER` and `MASTER_PASSWORD` are the user name and password of the account to use for connecting to the master.

`MASTER_USER` cannot be made empty; setting `MASTER_USER = ''` or leaving it unset when setting a value for `MASTER_PASSWORD` causes an error (Bug #13427949).

The password used for a MySQL Replication slave account in a `CHANGE MASTER TO` statement is limited to 32 characters in length; prior to MySQL 5.7.5, if the password was longer, the statement succeeded, but any excess characters were silently truncated. In MySQL 5.7.5 and later, trying to use a password of more than 32 characters causes `CHANGE MASTER TO` to fail. (Bug #11752299, Bug #43439)

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement. (The complete text of a `START SLAVE` statement is also visible to `SHOW PROCESSLIST`.)

The `MASTER_SSL_XXX` options provide information about using SSL for the connection. They correspond to the `--ssl-xxx` options described in [Section 7.4.5, “Command Options for Secure Connections”](#), and [Section 18.3.8, “Setting Up Replication to Use Secure Connections”](#). These options can be changed even on slaves that are compiled without SSL support. They are saved to the master info repository, but are ignored if the slave does not have SSL support enabled.

As of MySQL 5.7.3, the `MASTER_SSL=1` is prescriptive, not advisory. When given, the slave connection to the master must use SSL or the connection attempt fails. Before 5.7.3, an SSL connection is permitted but not required. This is analogous to the client-side meaning of the `--ssl` command-line option; see [Section 7.4.5, “Command Options for Secure Connections”](#).

The `MASTER_TLS_VERSION` option specifies the encryption protocols permitted by the master for slave connections. The value is like that for the `tls_version` system variable: A comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#). This option was added in MySQL 5.7.10.

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60.

`MASTER_RETRY_COUNT` limits the *number* of reconnection attempts and updates the value of the `Master_Retry_Count` column in the output of `SHOW SLAVE STATUS`. The default value is `24 * 3600 = 86400`. `MASTER_RETRY_COUNT` is intended to replace the older `--master-retry-count` server option, and is now the preferred method for setting this limit. You are encouraged

not to rely on `--master-retry-count` in new applications and, when upgrading to MySQL 5.7, to update any existing applications that rely on it, so that they use `CHANGE MASTER TO ... MASTER_RETRY_COUNT` instead.

`MASTER_DELAY` specifies how many seconds behind the master the slave must lag. An event received from the master is not executed until at least `interval` seconds later than its execution on the master. The default is 0. An error occurs if `interval` is not a nonnegative integer in the range from 0 to  $2^{31}-1$ . For more information, see [Section 18.3.10, “Delayed Replication”](#).

In MySQL 5.7.4 and later, a `CHANGE MASTER TO` statement employing the `MASTER_DELAY` option can be executed on a running slave when the slave SQL thread is stopped.

`MASTER_BIND` is for use on replication slaves having multiple network interfaces, and determines which of the slave's network interfaces is chosen for connecting to the master.

The address configured with this option, if any, can be seen in the `Master_Bind` column of the output from `SHOW SLAVE STATUS`. If you are using slave status log tables (server started with `--master-info-repository=TABLE`), the value can also be seen as the `Master_bind` column of the `mysql.slave_master_info` table.

The ability to bind a replication slave to a specific network interface is also supported by MySQL Cluster.

`MASTER_HEARTBEAT_PERIOD` sets the interval in seconds between replication heartbeats. Whenever the master's binary log is updated with an event, the waiting period for the next heartbeat is reset. `interval` is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binary log file for a period longer than `interval`.

Prior to MySQL 5.7.4, not including `MASTER_HEARTBEAT_PERIOD` caused `CHANGE MASTER TO` to reset the heartbeat period (`Slave_heartbeat_period`) to the default, and `Slave_received_heartbeats` to 0. (Bug #18185490)

If you are logging master connection information to tables, `MASTER_HEARTBEAT_PERIOD` can be seen as the value of the `Heartbeat` column of the `mysql.slave_master_info` table.

Setting `interval` to 0 disables heartbeats altogether. The default value for `interval` is equal to the value of `slave_net_timeout` divided by 2.

Setting `@@global.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the slave SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you also cannot specify `MASTER_AUTO_POSITION = 1` (described later in this section). If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

In MySQL 5.7.4 and later, a `CHANGE MASTER TO` statement employing `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or both options can be executed on a running slave when the slave SQL thread is stopped.

If `MASTER_AUTO_POSITION = 1` is used with `CHANGE MASTER TO`, the slave attempts to connect to the master using the GTID-based replication protocol. In MySQL 5.7.4 and later, this option can be employed by `CHANGE MASTER TO` only if both the slave SQL and slave I/O threads are stopped.

When using GTIDs, the slave tells the master which transactions it has already received, executed, or both. To compute this set, it reads the global value of `gtid_executed` and the value of the `Retrieved_gtid_set` column from `SHOW SLAVE STATUS`. The GTID of the last transmitted transaction is included in `Retrieved_gtid_set` only when the full transaction is received. The slave computes the following set:

```
UNION(@@global.gtid_executed, Retrieved_gtid_set)
```

Prior to MySQL 5.7.5, the GTID of the last transmitted transaction was included in `Retrieved_gtid_set` *even if* the transaction was only partially transmitted, and the last received GTID was subtracted from this set. (Bug #17943188) Thus, the slave computed the following set:

```
UNION(@@global.gtid_executed, Retrieved_gtid_set - last_received_GTID)
```

This set is sent to the master as part of the initial handshake, and the master sends back all transactions that it has executed which are not part of the set. If any of these transactions have been already purged from the master's binary log, the master sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the slave, and replication does not start.

When GTID-based replication is employed, the coordinates represented by `MASTER_LOG_FILE` and `MASTER_LOG_POS` are not used, and global transaction identifiers are used instead. Thus the use of either or both of these options together with `MASTER_AUTO_POSITION` causes an error.

Beginning with MySQL 5.7.1, you can see whether replication is running with autopositioning enabled by checking the output of `SHOW SLAVE STATUS`. (Bug #15992220)

`gtid_mode` must also be enabled before issuing `CHANGE MASTER TO ... MASTER_AUTO_POSITION = 1`. Otherwise, the statement fails with an error.

To revert to the older file-based replication protocol after using GTIDs, you can issue a new `CHANGE MASTER TO` statement that specifies `MASTER_AUTO_POSITION = 0`, as well as at least one of `MASTER_LOG_FILE` or `MASTER_LOG_POS`.

Prior to MySQL 5.7.4, `CHANGE MASTER TO` deletes all relay log files and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay log files are kept; the `relay_log_purge` global variable is set silently to 0. In MySQL 5.7.4 and later, relay logs are preserved when neither the slave SQL thread nor the slave I/O thread is stopped; if both threads are stopped, all relay log files are deleted unless you at least one of `RELAY_LOG_FILE` or `RELAY_LOG_POS` is specified.

`RELAY_LOG_FILE` can use either an absolute or relative path, and uses the same base name as `MASTER_LOG_FILE`. (Bug #12190)

`IGNORE_SERVER_IDS` takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its master instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ( );
```

Prior to MySQL 5.7.5, `RESET SLAVE ALL` has no effect on the server ID list. In MySQL 5.7.5 and later, `RESET SLAVE ALL` clears `IGNORE_SERVER_IDS`. (Bug #18816897)

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

In MySQL 5.7, the master info repository and the output of `SHOW SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see [Section 18.2.4.2, “Slave Status Logs”](#), and [Section 14.7.5.34, “SHOW SLAVE STATUS Syntax”](#).

In MySQL 5.7, invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the slave's state prior to execution.

In MySQL 5.7, `CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).

In MySQL 5.7.4 and later, the strict requirement to execute `STOP SLAVE` prior to issuing any `CHANGE MASTER TO` statement (and `START SLAVE` afterward) is removed. Instead of depending on whether the slave is stopped, the behavior of `CHANGE MASTER TO` depends (in MySQL 5.7.4 and later) on the states of the slave SQL thread and slave I/O threads; which of these threads is stopped or running now determines the options that can or cannot be used with a `CHANGE MASTER TO` statement at a given point in time. The rules for making this determination are listed here:

- If the SQL thread is stopped, you can execute `CHANGE MASTER TO` using any combination that is otherwise allowed of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `MASTER_DELAY` options, even if the slave I/O thread is running. No other options may be used with this statement when the I/O thread is running.
- If the I/O thread is stopped, you can execute `CHANGE MASTER TO` using any of the options for this statement (in any allowed combination) *except* `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or `MASTER_DELAY`, even when the SQL thread is running. These three options may not be used when the I/O thread is running.
- Both the SQL thread and the I/O thread must be stopped before issuing a `CHANGE MASTER TO` statement that employs `MASTER_AUTO_POSITION = 1`.

You can check the current state of the slave SQL and I/O threads using `SHOW SLAVE STATUS`.

For more information, see [Section 18.3.7, “Switching Masters During Failover”](#).

If you are using statement-based replication and temporary tables, it is possible for a `CHANGE MASTER TO` statement following a `STOP SLAVE` statement to leave behind temporary tables on the slave. In MySQL 5.7.4 and later, a warning (`ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO`) is now issued whenever this occurs. You can avoid this in such cases by making sure that the value of the `Slave_open_temp_tables` system status variable is equal to 0 prior to executing such a `CHANGE MASTER TO` statement.

`CHANGE MASTER TO` is useful for setting up a slave when you have the snapshot of the master and have recorded the master binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the slave to synchronize it with the master, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the slave to specify the coordinates at which the slave should begin reading the master binary log.

The following example changes the master server the slave uses and establishes the master binary log coordinates from which the slave begins reading. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
```

```
MASTER_PASSWORD='big3cret',
MASTER_PORT=3306,
MASTER_LOG_FILE='master2-bin.001',
MASTER_LOG_POS=4,
MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay log files that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a nonreplication setup with a standalone, nonslave server for recovery following a crash. Suppose that your server has crashed and you have restored it from a backup. You want to replay the server's own binary log files (not relay log files, but regular binary log files), named (for example) `myhost-bin.*`. First, make a backup copy of these binary log files in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary log. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option. Instead, use the `--replicate-same-server-id`, `--relay-log=myhost-bin` (to make the server believe that these regular binary log files are relay log files) and `--skip-slave-start` options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary log files, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, clear the master info and relay log info repositories, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

The following table shows the maximum permissible length for the string-valued options.

| Option                          | Maximum Length |
|---------------------------------|----------------|
| <code>MASTER_HOST</code>        | 60             |
| <code>MASTER_USER</code>        | 16             |
| <code>MASTER_PASSWORD</code>    | 32             |
| <code>MASTER_LOG_FILE</code>    | 255            |
| <code>RELAY_LOG_FILE</code>     | 255            |
| <code>MASTER_SSL_CA</code>      | 255            |
| <code>MASTER_SSL_CAPATH</code>  | 255            |
| <code>MASTER_SSL_CERT</code>    | 255            |
| <code>MASTER_SSL_CRL</code>     | 255            |
| <code>MASTER_SSL_CRLPATH</code> | 255            |
| <code>MASTER_SSL_KEY</code>     | 255            |
| <code>MASTER_SSL_CIPHER</code>  | 511            |

#### 14.4.2.2 CHANGE REPLICATION FILTER Syntax

```

CHANGE REPLICATION FILTER filter[, filter][, ...]

filter:
    REPLICATE_DO_DB = (db_list)
    | REPLICATE_IGNORE_DB = (db_list)
    | REPLICATE_DO_TABLE = (tbl_list)
    | REPLICATE_IGNORE_TABLE = (tbl_list)
    | REPLICATE_WILD_DO_TABLE = (wild_tbl_list)
    | REPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
    | REPLICATE_REWRITE_DB = (db_pair_list)

db_list:
    db_name[, db_name][, ...]

tbl_list:
    db_name.table_name[, db_table_name][, ...]

wild_tbl_list:
    'db_pattern.table_pattern'[, 'db_pattern.table_pattern'][, ...]

db_pair_list:
    (db_pair)[, (db_pair)][, ...]

db_pair:
    from_db, to_db

```

In MySQL 5.7.3 and later, `CHANGE REPLICATION FILTER` sets one or more replication filtering rules on the slave in the same way as starting the slave `mysqld` with replication filtering options such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Unlike the case with the server options, this statement does not require restarting the server to take effect, only that the slave SQL thread be stopped using `STOP SLAVE SQL_THREAD` first (and restarted with `START SLAVE SQL_THREAD` afterwards).

The following list shows the `CHANGE REPLICATION FILTER` options and how they relate to `--replicate-*` server options:

- `REPLICATE_DO_DB`: Include updates based on database name. Equivalent to `--replicate-do-db`.
- `REPLICATE_IGNORE_DB`: Exclude updates based on database name. Equivalent to `--replicate-ignore-db`.
- `REPLICATE_DO_TABLE`: Include updates based on table name. Equivalent to `--replicate-do-table`.
- `REPLICATE_IGNORE_TABLE`: Exclude updates based on table name. Equivalent to `--replicate-ignore-table`.
- `REPLICATE_WILD_DO_TABLE`: Include updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-do-table`.
- `REPLICATE_WILD_IGNORE_TABLE`: Exclude updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-ignore-table`.
- `REPLICATE_REWRITE_DB`: Perform updates on slave after substituting new name on slave for specified database on master. Equivalent to `--replicate-rewrite-db`.

The precise effects of `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` filters are dependent on whether statement-based or row-based replication is in effect. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

Multiple replication filtering rules can be created in a single `CHANGE REPLICATION FILTER` statement by separating the rules with commas, as shown here:

```

CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (d1), REPLICATE_IGNORE_DB = (d2);

```

Issuing the statement just shown is equivalent to starting the slave `mysqld` with the options `--replicate-do-db=db1 --replicate-ignore-db=db2`.

If the same filtering rule is specified multiple times, only the *last* such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first `REPLICATE_DO_DB` rule in the first statement is ignored:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);

CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db3, db4);
```

### Caution

This behavior differs from that of the `--replicate-*` filter options where specifying the same option multiple times causes the creation of multiple filter rules.

Names of tables and database not containing any special characters need not be quoted. Values used with `REPLICATION_WILD_TABLE` and `REPLICATION_WILD_IGNORE_TABLE` are string expressions, possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```
CHANGE REPLICATION FILTER
  REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
  REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new%');
```

Values used with `REPLICATE_REWRITE_DB` represent *pairs* of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `dbA` on the master to database `dbB` on the slave:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

This statement leaves any existing replication filtering rules unchanged; to unset all filters of a given type, set the filter's value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ();
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at `mysqld` startup using `--replicate-*` options on the command line or in the configuration file.

Values employed with `REPLICATE_WILD_DO_TABLE` and `REPLICATE_WILD_IGNORE_TABLE` must be in the format `db_name.tbl_name`. Prior to MySQL 5.7.5, this was not strictly enforced, although using nonconforming values with these options could lead to erroneous results (Bug #18095449).

For more information, see [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

### 14.4.2.3 MASTER\_POS\_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout][, channel])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 13.20, “Miscellaneous Functions”](#), for a full description.

### 14.4.2.4 RESET SLAVE Syntax

```
RESET SLAVE [ALL] [channel_option]
```

```
channel_option:  
FOR CHANNEL channel
```

**RESET SLAVE** makes the slave forget its replication position in the master's binary log. This statement is meant to be used for a clean start: It clears the master info and relay log info repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the **MASTER\_DELAY** option to **CHANGE MASTER TO**. **RESET SLAVE** does not change the values of **gtid\_executed** or **gtid\_purged**. To use **RESET SLAVE**, the slave replication threads must be stopped, so on a running slave use **STOP SLAVE** before issuing **RESET SLAVE**.

#### Note

All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a **STOP SLAVE** statement or if the slave is highly loaded.)

The optional **FOR CHANNEL channel** clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a **FOR CHANNEL channel** clause applies the **RESET SLAVE** statement to a specific replication channel. Combining a **FOR CHANNEL channel** clause with the **ALL** option deletes the specified channel. Issuing a **RESET SLAVE ALL** statement without a **FOR CHANNEL channel** clause when multiple replication channels exist deletes *all* replication channels and recreates only the default channel. See [Section 18.2.3, “Replication Channels”](#) for more information.

**RESET SLAVE** does not change any replication connection parameters such as master host, master port, master user, or master password, which are retained in memory. This means that **START SLAVE** can be issued without requiring a **CHANGE MASTER TO** statement following **RESET SLAVE**.

Connection parameters are reset by **RESET SLAVE ALL**. (**RESET SLAVE** followed by a restart of the slave `mysqld` also does this.)

In MySQL 5.7 **RESET SLAVE** causes an implicit commit of an ongoing transaction. See [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).

If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and **RESET SLAVE** is issued, these replicated temporary tables are deleted on the slave.

Prior to MySQL 5.7.5, **RESET SLAVE** also had the effect of resetting both the heartbeat period (**Slave\_heartbeat\_period**) and **SSL\_VERIFY\_SERVER\_CERT**. This issue is fixed in MySQL 5.7.5 and later. (Bug #18777899, Bug #18778485)

Prior to MySQL 5.7.5, **RESET SLAVE ALL** did not clear the **IGNORE\_SERVER\_IDS** list set by **CHANGE MASTER TO**. In MySQL 5.7.5 and later, the statement clears the list. (Bug #18816897)

#### Note

When used on a MySQL Cluster replication slave SQL node, **RESET SLAVE** clears the `mysql.ndb_apply_status` table. You should keep in mind when

using this statement that `ndb_apply_status` uses the `NDB` storage engine and so is shared by all SQL nodes attached to the slave cluster.

You can override this behavior by issuing `SET GLOBAL @@ndb_clear_apply_status=OFF` prior to executing `RESET SLAVE`, which keeps the slave from purging the `ndb_apply_status` table in such cases.

#### 14.4.2.5 SET GLOBAL sql\_slave\_skip\_counter Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next `N` events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

#### Note

A single transaction can contain changes to both transactional and nontransactional tables.

When you use `SET GLOBAL sql_slave_skip_counter` to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

#### 14.4.2.6 START SLAVE Syntax

```
START SLAVE [thread_types] [until_option] [connection_options] [channel_option]

thread_types:
    [thread_type [, thread_type] ... ]

thread_type:
    IO_THREAD | SQL_THREAD

until_option:
    UNTIL { {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set
            | MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
            | RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
            | SQL_AFTER_MTS_GAPS }

connection_options:
    [USER='user_name' ] [PASSWORD='user_pass' ] [DEFAULT_AUTH='plugin_name' ] [PLUGIN_DIR='plugin_dir' ]

channel_option:
    FOR CHANNEL channel

gtid_set:
    uuid_set [, uuid_set] ...
    | ''

uuid_set:
    uuid:interval[:interval]...

uuid:
    hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh
```

```
h:
    [0-9,A-F]

interval:
    n[-n]

    (n >= 1)
```

`START SLAVE` with no `thread_type` options starts both of the slave threads. The I/O thread reads events from the master server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the `SUPER` privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

In MySQL 5.7, `START SLAVE` causes an implicit commit of an ongoing transaction. See [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).

Beginning with MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement (Bug #16062608).

The optional `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `START SLAVE` statement to a specific replication channel. If a `START SLAVE` statement does not have a channel defined when using multiple channels, this statement starts the specified threads for all channels. Beginning with MySQL 5.7.9, this statement is disallowed for the `group_replication_recovery` channel. See [Section 18.2.3, “Replication Channels”](#) for more information.

MySQL 5.7 supports pluggable user-password authentication with `START SLAVE` with the `USER`, `PASSWORD`, `DEFAULT_AUTH` and `PLUGIN_DIR` options, as described in the following list:

- `USER`: User name. Cannot be set to an empty or null string, or left unset if `PASSWORD` is used.
- `PASSWORD`: Password.
- `DEFAULT_AUTH`: Name of plugin; default is MySQL native authentication.
- `PLUGIN_DIR`: Location of plugin.

You cannot use the `SQL_THREAD` option when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

See [Section 7.3.8, “Pluggable Authentication”](#), for more information.

If an insecure connection is used with any these options, the server issues the warning `Sending passwords in plain text without SSL/TLS is extremely insecure`.

`START SLAVE ... UNTIL` supports two additional options for use with global transaction identifiers (GTIDs) (see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#)). Each of these takes a set of one or more global transaction identifiers `gtid_set` as an argument (see [GTID Sets](#), for more information).

When no `thread_type` is specified, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process transactions until it has reached the *first* transaction whose GTID is listed in the `gtid_set`. `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to process all transactions until the *last* transaction in the `gtid_set` has been processed by both threads. In other words, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process all

transactions occurring before the first GTID in the *gtid\_set* is reached, and `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to handle all transactions, including those whose GTIDs are found in *gtid\_set*, until each has encountered a transaction whose GTID is not part of the set. `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` each support the `SQL_THREAD` and `IO_THREAD` options, although using `IO_THREAD` with them currently has no effect.

For example, `START SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the slave SQL thread to process all transactions originating from the master whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562` until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction with sequence number 10 are processed. Executing `START SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56`, on the other hand, would cause the slave SQL thread to obtain all transactions just mentioned from the master, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the slave SQL thread.

Prior to MySQL 5.7.3, `SQL_AFTER_GTIDS` did not stop the slave once the indicated transaction was completed, but waited until another GTID event was received (Bug #14767986).

When using a multi-threaded slave, there is a chance of gaps in the sequence of transactions that have been executed from the relay log in the following cases:

- killing the coordinator thread
- after an error occurs in the worker threads
- `mysqld` shuts down unexpectedly

Use the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement to cause a multi-threaded slave's worker threads to only run until no more gaps are found in the relay log, and then to stop. This statement can take an `SQL_THREAD` option, but the effects of the statement remain unchanged. It has no effect on the slave I/O thread (and cannot be used with the `IO_THREAD` option).

Issuing `START SLAVE` on a multi-threaded slave with gaps in the sequence of transactions executed from the relay log generates a warning. In such a situation, the solution is to use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, then issue `RESET SLAVE` to remove any remaining relay logs. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

To change a failed multi-threaded slave to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;

SET @@GLOBAL.slave_parallel_workers = 0;

START SLAVE SQL_THREAD;
```

#### Note

It is possible to view the entire text of a running `START SLAVE ...` statement, including any `USER` or `PASSWORD` values used, in the output of `SHOW PROCESSLIST`. This is also true for the text of a running `CHANGE MASTER TO` statement, including any values it employs for `MASTER_USER` or `MASTER_PASSWORD`.

`START SLAVE` sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the I/O thread

is running *and connected*). For more information, see [Section 14.7.5.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 18.1.7.1, “Checking Replication Status”](#).

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start. The `SQL_THREAD` option is disallowed when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

An `UNTIL` clause (*until\_option*, in the preceding grammar) may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary log, specified by the `MASTER_LOG_POS` and `MASTER_LOG_FILE` options, or a given point in the slave relay log, indicated with the `RELAY_LOG_POS` and `RELAY_LOG_FILE` options. When the SQL thread reaches the point specified, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued. You cannot use an `UNTIL` clause with the `IO_THREAD` option.

It is also possible with `START SLAVE UNTIL` to specify a stop point relative to a given GTID or set of GTIDs using one of the options `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`, as explained previously in this section. When using one of these options, you can specify `SQL_THREAD`, `IO_THREAD`, both of these, or neither of them. If you specify only `SQL_THREAD`, then only the slave SQL thread is affected by the statement; if only `IO_THREAD` is used, then only the slave I/O is affected. If both `SQL_THREAD` and `IO_THREAD` are used, or if neither of them is used, then both the SQL and I/O threads are affected by the statement.

The `UNTIL` clause is not supported for multi-threaded slaves except when also using `SQL_AFTER_MTS_GAPS`.

For an `UNTIL` clause, you must specify any one of the following:

- *Both* a log file name and a position in that file
- *Either* of `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`
- `SQL_AFTER_MTS_GAPS`

Do not mix master and relay log options. Do not mix log file options with GTID options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

When specifying a log file and position, you can use the `IO_THREAD` option with `START SLAVE ... UNTIL` even though only the SQL thread is affected by this statement. The `IO_THREAD` option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`); the GTID options support both `SQL_THREAD` and `IO_THREAD`, as explained previously in this section.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master binary log or slave relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

Prior to MySQL 5.7.5, the failure of this statement caused the slave heartbeat period to be reset. This issue is fixed in MySQL 5.7.5 and later. (Bug #18791604)

In very old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. In MySQL 5.7, that syntax produces an error.

### 14.4.2.7 STOP SLAVE Syntax

```
STOP SLAVE [thread_types]

thread_types:
    [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD

channel_option:
    FOR CHANNEL channel
```

Stops the slave threads. `STOP SLAVE` requires the `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the slave before stopping the slave server (see [Section 6.1.12](#), “The Server Shutdown Process”, for more information).

*When using the row-based logging format:* You should execute `STOP SLAVE` or `STOP SLAVE SQL_THREAD` on the slave prior to shutting down the slave server if you are replicating any tables that use a nontransactional storage engine (see the *Note* later in this section).

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

In MySQL 5.7, `STOP SLAVE` causes an implicit commit of an ongoing transaction. See [Section 14.3.3](#), “Statements That Cause an Implicit Commit”.

Beginning with MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement (Bug #16062608).

In MySQL 5.7.2 and later, you can control how long `STOP SLAVE` waits before timing out by setting the `rpl_stop_slave_timeout` system variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave. (Bug #16856735)

Prior to MySQL 5.7.4, it was necessary to issue this statement on a running slave prior to executing `CHANGE MASTER TO`. In MySQL 5.7.4 and later, this is no longer always the case; some `CHANGE MASTER TO` statements are now allowed while the slave is running, depending on the states of the slave SQL and I/O threads. However, using `STOP SLAVE` prior to executing `CHANGE MASTER TO` in such cases is still supported. See [Section 14.4.2.1](#), “CHANGE MASTER TO Syntax”, and [Section 18.3.7](#), “Switching Masters During Failover”, for more information.

The optional `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `STOP SLAVE` statement to a specific replication channel. If a `STOP SLAVE` statement does not have a channel defined when using multiple channels, this statement stops the specified threads for all channels. Beginning with MySQL 5.7.9, this statement cannot be used with the `group_replication_recovery` channel. See [Section 18.2.3](#), “Replication Channels” for more information.

*When using statement-based replication:* changing the master while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the slave by checking the value of `Slave_open_temp_tables`; when using statement-based replication, this value should be 0 before executing `CHANGE MASTER TO`. In MySQL 5.7.4 and later, if there are any temporary tables open on the slave, issuing a `CHANGE MASTER TO` statement after issuing a `STOP SLAVE` causes an `ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO` warning.

When using a multi-threaded slave (`slave_parallel_workers` is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the slave is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing `KILL`) while a `STOP SLAVE` statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#), for more information.

**Note**

In MySQL 5.7, `STOP SLAVE` waits until the current replication event group affecting one or more nontransactional tables has finished executing (if there is any such replication group), or until you issue a `KILL QUERY` or `KILL CONNECTION` statement. (Bug #319, Bug #38205)

### 14.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

#### 14.4.3.1 START GROUP\_REPLICATION Syntax

```
START GROUP_REPLICATION
```

Starts group replication. Added in MySQL 5.7.6.

#### 14.4.3.2 STOP GROUP\_REPLICATION Syntax

```
STOP GROUP_REPLICATION
```

Stops group replication. Added in MySQL 5.7.6.

## 14.5 Prepared SQL Statement Syntax

MySQL 5.7 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.
- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

## Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the [MySQL C API client library](#) or [MySQL Connector/C](#) for C programs, [MySQL Connector/J](#) for Java programs, and [MySQL Connector/Net](#) for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 26.8.8, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the [mysql\\_i extension](#), available in PHP 5.0 and later.

## Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.

- You can use it from any program that can send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library, as long as you connect to a server running MySQL 4.1 or higher.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

## PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see [Section 14.5.1, “PREPARE Syntax”](#)).
- `EXECUTE` executes a prepared statement (see [Section 14.5.2, “EXECUTE Syntax”](#)).
- `DEALLOCATE PREPARE` releases a prepared statement (see [Section 14.5.3, “DEALLOCATE PREPARE Syntax”](#)).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
```

```

mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);

mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+-----+
| a     |
+-----+
| 4     |
| 8     |
| 11    |
| 32    |
| 80    |
+-----+

mysql> DEALLOCATE PREPARE stmt3;

```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

## SQL Syntax Allowed in Prepared Statements

The following SQL statements can be used as prepared statements:

```

ALTER TABLE
ALTER USER
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE | QUERY CACHE}
REVOKE
SELECT
SET
SHOW {WARNINGS | ERRORS}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS

```

```
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE
```

As of MySQL 5.7.2, for compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- `SHOW WARNINGS`, `SHOW COUNT(*) WARNINGS`
- `SHOW ERRORS`, `SHOW COUNT(*) ERRORS`
- Statements containing any reference to the `warning_count` or `error_count` system variable.

Other statements are not supported in MySQL 5.7.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in [Section C.1, “Restrictions on Stored Programs”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#).

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 14.2.9, “SELECT Syntax”](#).

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 5.7. See [Section 14.2.1, “CALL Syntax”](#), for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Prepared statements use the query cache under the conditions described in [Section 9.10.3.1, “How the Query Cache Operates”](#).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see [Section 14.2.1, “CALL Syntax”](#).

## 14.5.1 PREPARE Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, `stmt_name`, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see [Section 14.5, “Prepared SQL Statement Syntax”](#).

Statement names are not case sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which has several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See [Section 26.8.16, “Controlling Automatic Reconnection Behavior”](#).
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see [Section 10.4, “User-Defined Variables”](#).

## 14.5.2 EXECUTE Syntax

```
EXECUTE stmt_name
    [USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see [Section 14.5, “Prepared SQL Statement Syntax”](#).

## 14.5.3 DEALLOCATE PREPARE Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the `DEALLOCATE PREPARE` statement or the end of the session, you might encounter the upper limit enforced by the `max_prepared_stmt_count` system variable.

For examples, see [Section 14.5, “Prepared SQL Statement Syntax”](#).

## 14.6 Compound-Statement Syntax

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see [Chapter 22, \*Stored Programs and Views\*](#)).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

### 14.6.1 BEGIN ... END Compound-Statement Syntax

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The `statement_list` itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) permit `;` to be used in a program body. For an example, see [Section 22.1, “Defining Stored Programs”](#).

A `BEGIN ... END` block can be labeled. See [Section 14.6.2, “Statement Label Syntax”](#).

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

#### Note

Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

### 14.6.2 Statement Label Syntax

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]

[begin_label:] LOOP
    statement_list
END LOOP [end_label]

[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

Labels are permitted for `BEGIN ... END` blocks and for the `LOOP`, `REPEAT`, and `WHILE` statements. Label use for those statements follows these rules:

- `begin_label` must be followed by a colon.
- `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.
- `end_label` cannot be given without `begin_label`.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```
CREATE PROCEDURE doitrate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see [Section 14.6.7.2, “DECLARE ... HANDLER Syntax”](#).

### 14.6.3 DECLARE Syntax

The `DECLARE` statement is used to define various items local to a program:

- Local variables. See [Section 14.6.4, “Variables in Stored Programs”](#).
- Conditions and handlers. See [Section 14.6.7, “Condition Handling”](#).
- Cursors. See [Section 14.6.6, “Cursors”](#).

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 14.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the `DECLARE` statement, as described in [Section 14.6.4.1, “Local Variable DECLARE Syntax”](#).
- Variables can be set directly with the `SET` statement. See [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#).
- Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See [Section 14.2.9.1, “SELECT ... INTO Syntax”](#), and [Section 14.6.6, “Cursors”](#).

For information about the scope of local variables and how MySQL resolves ambiguous names, see [Section 14.6.4.2, “Local Variable Scope and Resolution”](#).

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). In MySQL 5.7, this results in a syntax error.

#### 14.6.4.1 Local Variable DECLARE Syntax

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [Section 14.1.16, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in [Section 10.2, “Schema Object Names”](#).

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see [Section 14.6.4.2, “Local Variable Scope and Resolution”](#).

#### 14.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 14.5.1, “PREPARE Syntax”](#).

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE curl CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN curl;
read_loop: LOOP
  FETCH FROM curl INTO newname, xid;
  IF done THEN LEAVE read_loop; END IF;
  SELECT newname;
END LOOP;
CLOSE curl;
END;
```

See also [Section C.1, “Restrictions on Stored Programs”](#).

## 14.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

### 14.6.5.1 CASE Syntax

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

#### Note

There is also a `CASE expression`, which differs from the `CASE statement` described here. See [Section 13.4, “Control Flow Functions”](#). The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

For the first syntax, *case\_value* is an expression. This value is compared to the *when\_value* expression in each `WHEN` clause until one of them is equal. When an equal *when\_value* is found, the

corresponding **THEN** clause *statement\_list* executes. If no *when\_value* is equal, the **ELSE** clause *statement\_list* executes, if there is one.

This syntax cannot be used to test for equality with **NULL** because **NULL = NULL** is false. See [Section 4.3.4.6, “Working with NULL Values”](#).

For the second syntax, each **WHEN** clause *search\_condition* expression is evaluated until one is true, at which point its corresponding **THEN** clause *statement\_list* executes. If no *search\_condition* is equal, the **ELSE** clause *statement\_list* executes, if there is one.

If no *when\_value* or *search\_condition* matches the value tested and the **CASE** statement contains no **ELSE** clause, a **Case not found for CASE statement** error results.

Each *statement\_list* consists of one or more SQL statements; an empty *statement\_list* is not permitted.

To handle situations where no value is matched by any **WHEN** clause, use an **ELSE** containing an empty **BEGIN ... END** block, as shown in this example. (The indentation used here in the **ELSE** clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |

CREATE PROCEDURE p()
BEGIN
    DECLARE v INT DEFAULT 1;

    CASE v
        WHEN 2 THEN SELECT v;
        WHEN 3 THEN SELECT 0;
        ELSE
            BEGIN
            END;
    END CASE;
END;
|
```

### 14.6.5.2 IF Syntax

```
IF search_condition THEN statement_list
    [ELSEIF search_condition THEN statement_list] ...
    [ELSE statement_list]
END IF
```

The **IF** statement for stored programs implements a basic conditional construct.

#### Note

There is also an **IF()** function, which differs from the **IF** statement described here. See [Section 13.4, “Control Flow Functions”](#). The **IF** statement can have **THEN**, **ELSE**, and **ELSEIF** clauses, and it is terminated with **END IF**.

If the *search\_condition* evaluates to true, the corresponding **THEN** or **ELSEIF** clause *statement\_list* executes. If no *search\_condition* matches, the **ELSE** clause *statement\_list* executes.

Each *statement\_list* consists of one or more SQL statements; an empty *statement\_list* is not permitted.

An **IF ... END IF** block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //
```

```
CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)

  BEGIN
    DECLARE s VARCHAR(20);

    IF n > m THEN SET s = '>';
    ELSEIF n = m THEN SET s = '=';
    ELSE SET s = '<';
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m);

    RETURN s;
  END //

DELIMITER ;
```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```
DELIMITER //

CREATE FUNCTION VerboseCompare (n INT, m INT)
  RETURNS VARCHAR(50)

  BEGIN
    DECLARE s VARCHAR(50);

    IF n = m THEN SET s = 'equals';
    ELSE
      IF n > m THEN SET s = 'greater';
      ELSE SET s = 'less';
      END IF;

    SET s = CONCAT('is ', s, ' than');
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m, '.');

    RETURN s;
  END //

DELIMITER ;
```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

### 14.6.5.3 ITERATE Syntax

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means “start the loop again.”

For an example, see [Section 14.6.5.5, “LOOP Syntax”](#).

### 14.6.5.4 LEAVE Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, `LEAVE` exits the program.

`LEAVE` can be used within `BEGIN ... END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

For an example, see [Section 14.6.5.5, “LOOP Syntax”](#).

### 14.6.5.5 LOOP Syntax

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

**LOOP** implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a **LEAVE** statement. Within a stored function, **RETURN** can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A **LOOP** statement can be labeled. For the rules regarding label use, see [Section 14.6.2, “Statement Label Syntax”](#).

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN
            ITERATE label1;
        END IF;
        LEAVE label1;
    END LOOP label1;
    SET @x = p1;
END;
```

### 14.6.5.6 REPEAT Syntax

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a **REPEAT** statement is repeated until the *search\_condition* expression is true. Thus, a **REPEAT** always enters the loop at least once. *statement\_list* consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A **REPEAT** statement can be labeled. For the rules regarding label use, see [Section 14.6.2, “Statement Label Syntax”](#).

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->     SET @x = 0;
->     REPEAT
->         SET @x = @x + 1;
->     UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
```

```
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

### 14.6.5.7 RETURN Syntax

```
RETURN expr
```

The **RETURN** statement terminates execution of a stored function and returns the value *expr* to the function caller. There must be at least one **RETURN** statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The **LEAVE** statement can be used to exit a stored program of those types.

### 14.6.5.8 WHILE Syntax

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

The statement list within a **WHILE** statement is repeated as long as the *search\_condition* expression is true. *statement\_list* consists of one or more SQL statements, each terminated by a semicolon (;) statement delimiter.

A **WHILE** statement can be labeled. For the rules regarding label use, see [Section 14.6.2, "Statement Label Syntax"](#).

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;

    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END;
```

## 14.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
    DECLARE done INT DEFAULT FALSE;
```

```

DECLARE a CHAR(16);
DECLARE b, c INT;
DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

OPEN cur1;
OPEN cur2;

read_loop: LOOP
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF done THEN
        LEAVE read_loop;
    END IF;
    IF b < c THEN
        INSERT INTO test.t3 VALUES (a,b);
    ELSE
        INSERT INTO test.t3 VALUES (a,c);
    END IF;
END LOOP;

CLOSE cur1;
CLOSE cur2;
END;

```

#### 14.6.6.1 Cursor CLOSE Syntax

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see [Section 14.6.6, “Cursors”](#).

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN ... END` block in which it was declared.

#### 14.6.6.2 Cursor DECLARE Syntax

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see [Section 14.6.6, “Cursors”](#).

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

#### 14.6.6.3 Cursor FETCH Syntax

```
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored

in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see [Section 14.6.6, “Cursors”](#).

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

#### 14.6.6.4 Cursor OPEN Syntax

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see [Section 14.6.6, “Cursors”](#).

### 14.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See [Section 14.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 14.6.7.2, “DECLARE ... HANDLER Syntax”](#). For information about how the server chooses handlers when a condition occurs, see [Section 14.6.7.6, “Scope Rules for Handlers”](#).

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See [Section 14.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 14.6.7.2, “DECLARE ... HANDLER Syntax”](#).

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 14.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 14.6.7.7, “The MySQL Diagnostics Area”](#).

#### 14.6.7.1 DECLARE ... CONDITION Syntax

```
DECLARE condition_name CONDITION FOR condition_value

condition_value:
    mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see [Section 14.6.7.2, “DECLARE ... HANDLER Syntax”](#)).

Condition declarations must appear before cursor or handler declarations.

The *condition\_value* for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- *mysql\_error\_code*: An integer literal indicating a MySQL error code.

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- `SQLSTATE [VALUE] sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
    -- body of handler
END;
```

### 14.6.7.2 DECLARE ... HANDLER Syntax

```
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action:
    CONTINUE
    | EXIT
    | UNDO

condition_value:
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value
    | condition_name
    | SQLWARNING
    | NOT FOUND
    | SQLEXCEPTION
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified *statement* executes. *statement* can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see [Section 14.6.1, “BEGIN ... END Compound-Statement Syntax”](#)).

Handler declarations must appear after variable or condition declarations.

The *handler\_action* value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the **BEGIN ... END** compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.

The *condition\_value* for **DECLARE ... HANDLER** indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- *mysql\_error\_code*: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- **SQLSTATE [VALUE] *sqlstate\_value***: A 5-character string literal indicating an SQLSTATE value, such as '42S01' to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
BEGIN
    -- body of handler
END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

- *condition\_name*: A condition name previously specified with **DECLARE ... CONDITION**. A condition name can be associated with a MySQL error code or SQLSTATE value. See [Section 14.6.7.1, “DECLARE ... CONDITION Syntax”](#).
- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

```
DECLARE CONTINUE HANDLER FOR SQLWARNING
BEGIN
    -- body of handler
END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a **NOT FOUND** condition.

```
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
    -- body of handler
END;
```

For another example, see [Section 14.6.6, “Cursors”](#). The **NOT FOUND** condition also occurs for **SELECT ... INTO *var\_list*** statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
```

```
BEGIN
-- body of handler
END;
```

For information about how the server chooses handlers when a condition occurs, see [Section 14.6.7.6, “Scope Rules for Handlers”](#).

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.
- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following example uses a handler for `SQLSTATE '23000'`, which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

Notice that `@x` is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the `DECLARE ... HANDLER` statement had not been present, MySQL would have taken the default action (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

To ignore a condition, declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the `REPEAT` block has a label of `retry`:

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      ITERATE retry;    # illegal
    END;
    IF i < 0 THEN
      LEAVE retry;      # legal
    END IF;
    SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
END;

```

The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```

DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
  block cleanup statements
END;

```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      SET done = TRUE;
    END;
    IF done OR i < 0 THEN
      LEAVE retry;
    END IF;
    SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
END;

```

### 14.6.7.3 GET DIAGNOSTICS Syntax

```
GET [CURRENT | STACKED] DIAGNOSTICS
```

```
{
    statement_information_item
    [, statement_information_item] ...
| CONDITION condition_number
  condition_information_item
  [, condition_information_item] ...
}

statement_information_item:
    target = statement_information_item_name

condition_information_item:
    target = condition_information_item_name

statement_information_item_name:
    NUMBER
    | ROW_COUNT

condition_information_item_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | RETURNED_SQLSTATE
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

condition_number, target:
    (see following discussion)
```

SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
  -> @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-----+-----+
| @p1   | @p2                                     |
+-----+-----+
| 42S02 | Unknown table 'test.no_such_table' |
+-----+-----+
```

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see [Section 14.6.7.7, “The MySQL Diagnostics Area”](#). Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

`GET DIAGNOSTICS` can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of `GET DIAGNOSTICS` assigns the number of available conditions and the rows-affected count to the user variables `@p1` and `@p2`:

```
GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of `GET DIAGNOSTICS` assigns the SQLSTATE value and error message to the user variables `@p3` and `@p4`:

```
GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
```

The retrieval list specifies one or more *target = item\_name* assignments, separated by commas. Each assignment names a target variable and either a *statement\_information\_item\_name* or *condition\_information\_item\_name* designator, depending on whether the statement retrieves statement or condition information.

Valid *target* designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.

Valid *condition\_number* designators can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a *charset* introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by `GET DIAGNOSTICS`. For example:

```
mysql> GET DIAGNOSTICS CONDITION 1
      -> @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
mysql> SELECT @p5, @p6;
+-----+-----+
| @p5   | @p6   |
+-----+-----+
|       |       |
+-----+-----+
```

In standard SQL, if there are multiple conditions, the first condition relates to the [SQLSTATE](#) value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see [Diagnostics Area Information Items](#).

Here is an example that uses [GET DIAGNOSTICS](#) and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses [GET DIAGNOSTICS](#) to get the rows-affected count. This shows that you can use [GET DIAGNOSTICS](#) multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

```
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE rows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
      code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
    END;

  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS rows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',rows);
  ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;
```

Suppose that `t1.int_col` is an integer column that is declared as [NOT NULL](#). The procedure produces these results when invoked to insert non-[NULL](#) and [NULL](#) values, respectively:

```
mysql> CALL do_insert(1);
+-----+
| result |
+-----+
```

```
| insert succeeded, row count = 1 |
+-----+
mysql> CALL do_insert(NULL);
+-----+
| result |
+-----+
| insert failed, error = 23000, message = Column 'int_col' cannot be null |
+-----+
```

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.
- `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current and stacked diagnostics areas.
- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, *as long as you execute no statements within the handler that change its current diagnostics area*.
- However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except `RESIGNAL`. For information about when the current diagnostics area is set and cleared, see [Section 14.6.7.7, “The MySQL Diagnostics Area”](#).

The next example shows how `GET STACKED DIAGNOSTICS` can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a `TEXT NOT NULL` column. The first value is a non-`NULL` string and the second is `NULL`. The column prohibits `NULL` values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert `NULL` into inserts of the empty string:

```
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        -- Here the current DA is nonempty because no prior statements
        -- executing within the handler have cleared it
        GET CURRENT DIAGNOSTICS CONDITION 1
            errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'current DA before mapped insert' AS op, errno, msg;
        GET STACKED DIAGNOSTICS CONDITION 1
            errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'stacked DA before mapped insert' AS op, errno, msg;

        -- Map attempted NULL insert to empty string insert
        INSERT INTO t1 (c1) VALUES('');

        -- Here the current DA should be empty (if the INSERT succeeded),
        -- so check whether there are conditions before attempting to
        -- obtain condition information
```

```

GET CURRENT DIAGNOSTICS errcount = NUMBER;
IF errcount = 0
THEN
  SELECT 'mapped insert succeeded, current DA is empty' AS op;
ELSE
  GET CURRENT DIAGNOSTICS CONDITION 1
  errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
  SELECT 'current DA after mapped insert' AS op, errno, msg;
END IF ;
GET STACKED DIAGNOSTICS CONDITION 1
errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
SELECT 'stacked DA after mapped insert' AS op, errno, msg;
END;
INSERT INTO t1 (c1) VALUES('string 1');
INSERT INTO t1 (c1) VALUES(NULL);
END;
//
delimiter ;
CALL p();
SELECT * FROM t1;

```

When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

```

+-----+-----+-----+
| op                | errno | msg                                |
+-----+-----+-----+
| current DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg                                |
+-----+-----+-----+
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

```

Statements executing after the [GET DIAGNOSTICS](#) statements may reset the current diagnostics area. statements may reset the current diagnostics area. For example, the handler maps the [NULL](#) insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

```

+-----+-----+
| op                |
+-----+-----+
| mapped insert succeeded, current DA is empty |
+-----+-----+

+-----+-----+-----+
| op                | errno | msg                                |
+-----+-----+-----+
| stacked DA after mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

```

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert [NULL](#) that was mapped to an empty-string insert:

```

+-----+
| c1    |
+-----+
| string 1 |
+-----+

```

```
+-----+
```

In the preceding example, the first two `GET DIAGNOSTICS` statements within the condition handler that retrieve information from the current and stacked diagnostics areas return the same values. This will not be the case if statements that reset the current diagnostics area execute earlier within the handler. Suppose that `p()` is rewritten to place the `DECLARE` statements within the handler definition rather than preceding it:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    ...
  
```

In this case, the result is version dependent:

- Before MySQL 5.7.2, `DECLARE` does not change the current diagnostics area, so the first two `GET DIAGNOSTICS` statements return the same result, just as in the original version of `p()`.

In MySQL 5.7.2, work was done to ensure that all nondiagnostic statements populate the diagnostics area, per the SQL standard. `DECLARE` is one of them, so in 5.7.2 and higher, `DECLARE` statements executing at the beginning of the handler clear the current diagnostics area and the `GET DIAGNOSTICS` statements produce different results:

```
+-----+-----+-----+
| op                | errno | msg |
+-----+-----+-----+
| current DA before mapped insert | NULL | NULL |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg |
+-----+-----+-----+
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+
```

To avoid this issue within a condition handler when seeking to obtain information about the condition that activated the handler, be sure to access the stacked diagnostics area, not the current diagnostics area.

#### 14.6.7.4 RESIGNAL Syntax

```
RESIGNAL [condition_value]
  [SET signal_information_item
    [, signal_information_item] ...]

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name:
  CLASS_ORIGIN
```

```

| SUBCLASS_ORIGIN
| MESSAGE_TEXT
| MYSQL_ERRNO
| CONSTRAINT_CATALOG
| CONSTRAINT_SCHEMA
| CONSTRAINT_NAME
| CATALOG_NAME
| SCHEMA_NAME
| TABLE_NAME
| COLUMN_NAME
| CURSOR_NAME

```

*condition\_name, simple\_value\_specification:*  
(see following discussion)

**RESIGNAL** passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. **RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

**RESIGNAL** makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No special privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see [Section 14.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 14.6.7.7, “The MySQL Diagnostics Area”](#).

For *condition\_value* and *signal\_information\_item*, the definitions and rules are the same for **RESIGNAL** as for **SIGNAL**. For example, the *condition\_value* can be an **SQLSTATE** value, and the value can indicate errors, warnings, or “not found.” For additional information, see [Section 14.6.7.5, “SIGNAL Syntax”](#).

The **RESIGNAL** statement takes *condition\_value* and **SET** clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL** alone:

```
RESIGNAL;
```

- **RESIGNAL** with new signal information:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

- **RESIGNAL** with a condition value and possibly new signal information:

```
RESIGNAL condition_value
[SET signal_information_item [, signal_information_item] ...];
```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the **SQLSTATE** value, **MYSQL\_ERRNO**, or **MESSAGE\_TEXT**.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but will be overwritten by the first statement in the handler that changes the current diagnostics area.
- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See [Diagnostics Area-Related System Variables](#).

## RESIGNAL Alone

A simple `RESIGNAL` alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for `RESIGNAL` alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

And that is what the caller sees.

If `@a` is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
```

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

## RESIGNAL with New Signal Information

`RESIGNAL` with a `SET` clause provides new signal information, so the statement means “pass on the error with changes”:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with `RESIGNAL` alone, the idea is to pop the diagnostics area stack so that the original information will go out. Unlike `RESIGNAL` alone, anything specified in the `SET` clause changes.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that `RESIGNAL` alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The `RESIGNAL SET MYSQL_ERRNO = 5` statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The `RESIGNAL` statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

## RESIGNAL with a Condition Value and Optional New Signal Information

`RESIGNAL` with a condition value means “push a condition into the current diagnostics area.” If the `SET` clause is present, it also changes the error information.

```
RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];
```

This form of `RESIGNAL` restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple `RESIGNAL` alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
    END;
    DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;
```

This is similar to the previous example, and the effects are the same, except that if `RESIGNAL` happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The `RESIGNAL` statement includes a condition value (`SQLSTATE '45000'`), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

```
DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
      (condition 1) ERROR 5 (45000) Unknown table 'xx'
```

The result of `CALL p()` and `SHOW ERRORS` for this example is:

```
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+
| Error | 1051 | Unknown table 'xx'                   |
| Error | 5    | Unknown table 'xx'                   |
+-----+-----+-----+
```

## RESIGNAL Requires Condition Handler Context

All forms of `RESIGNAL` require that the current context be a condition handler. Otherwise, `RESIGNAL` is illegal and a `RESIGNAL when handler not active` error occurs. For example:

```
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
```

Here is a more difficult example:

```
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
    RESIGNAL;
```

```

RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
    SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();

```

`RESIGNAL` occurs within the stored function `f()`. Although `f()` itself is invoked within the context of the `EXIT` handler, execution within `f()` has its own context, which is not handler context. Thus, `RESIGNAL` within `f()` results in a “handler not active” error.

### 14.6.7.5 SIGNAL Syntax

```

SIGNAL condition_value
    [SET signal_information_item
    [, signal_information_item] ...]

condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | condition_name

signal_information_item:
    condition_information_item_name = simple_value_specification

condition_information_item_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

condition_name, simple_value_specification:
    (see following discussion)

```

`SIGNAL` is the way to “return” an error. `SIGNAL` provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error’s characteristics (error number, `SQLSTATE` value, message). Without `SIGNAL`, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No special privileges are required to execute the `SIGNAL` statement.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 14.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 14.6.7.7, “The MySQL Diagnostics Area”](#).

The *condition\_value* in a `SIGNAL` statement indicates the error value to be returned. It can be an `SQLSTATE` value (a 5-character string literal) or a *condition\_name* that refers to a named condition previously defined with `DECLARE ... CONDITION` (see [Section 14.6.7.1, “DECLARE ... CONDITION Syntax”](#)).

An `SQLSTATE` value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in [Signal Condition Information Items](#). Some signal values cause statement termination; see [Effect of Signals on Handlers, Cursors, and Statements](#).

The `SQLSTATE` value for a `SIGNAL` statement should not start with `'00'` because such values indicate success and are not valid for signaling an error. This is true whether the `SQLSTATE` value is specified

directly in the `SIGNAL` statement or in a named condition referred to in the statement. If the value is invalid, a `Bad SQLSTATE` error occurs.

To signal a generic `SQLSTATE` value, use `'45000'`, which means “unhandled user-defined exception.”

The `SIGNAL` statement optionally includes a `SET` clause that contains multiple signal items, in a comma-separated list of `condition_information_item_name` = `simple_value_specification` assignments.

Each `condition_information_item_name` may be specified only once in the `SET` clause. Otherwise, a `Duplicate condition information item` error occurs.

Valid `simple_value_specification` designators can be specified using stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer.

For information about permissible `condition_information_item_name` values, see [Signal Condition Information Items](#).

The following procedure signals an error or warning depending on the value of `pval`, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If `pval` is 0, `p()` signals a warning because `SQLSTATE` values that begin with `'01'` are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the `MESSAGE_TEXT` condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the `SQLSTATE` value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```
mysql> SIGNAL SQLSTATE '77777';
mysql> CREATE TRIGGER t_bi BEFORE INSERT ON t
```

```
-> FOR EACH ROW SIGNAL SQLSTATE '77777';
mysql> CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
-> DO SIGNAL SQLSTATE '77777';
```

**SIGNAL** executes according to the following rules:

If the **SIGNAL** statement indicates a particular **SQLSTATE** value, that value is used to signal the condition specified. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the **SIGNAL** statement uses a named condition, the condition must be declared in some scope that applies to the **SIGNAL** statement, and must be defined using an **SQLSTATE** value, not a MySQL error number. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the **SIGNAL** statement, an **Undefined CONDITION** error occurs.

If **SIGNAL** refers to a named condition that is defined with a MySQL error number rather than an **SQLSTATE** value, a **SIGNAL/RESIGNAL can only use a CONDITION defined with SQLSTATE** error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If **divisor** is 0, the first **SIGNAL** statement executes. The innermost **my\_error** condition declaration applies, raising **SQLSTATE '22012'**.

If **divisor** is not 0, the second **SIGNAL** statement executes. The outermost **my\_error** condition declaration applies, raising **SQLSTATE '45000'**.

For information about how the server chooses handlers when a condition occurs, see [Section 14.6.7.6, “Scope Rules for Handlers”](#).

Signals can be raised within exception handlers:

```

CREATE PROCEDURE p ( )
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;

```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error (“no such table”) and makes a new error with `SQLSTATE '99999'` and message `An error occurred`.

## Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see [Section 14.6.7.7, “The MySQL Diagnostics Area”](#).

| Item Name          | Definition        |
|--------------------|-------------------|
| -----              | -----             |
| CLASS_ORIGIN       | VARCHAR(64)       |
| SUBCLASS_ORIGIN    | VARCHAR(64)       |
| CONSTRAINT_CATALOG | VARCHAR(64)       |
| CONSTRAINT_SCHEMA  | VARCHAR(64)       |
| CONSTRAINT_NAME    | VARCHAR(64)       |
| CATALOG_NAME       | VARCHAR(64)       |
| SCHEMA_NAME        | VARCHAR(64)       |
| TABLE_NAME         | VARCHAR(64)       |
| COLUMN_NAME        | VARCHAR(64)       |
| CURSOR_NAME        | VARCHAR(64)       |
| MESSAGE_TEXT       | VARCHAR(128)      |
| MYSQL_ERRNO        | SMALLINT UNSIGNED |

The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

```

MESSAGE_TEXT = 'Unhandled user-defined warning condition';
MYSQL_ERRNO = ER_SIGNAL_WARN

```

- Class = '02' (not found)

```

MESSAGE_TEXT = 'Unhandled user-defined not found condition';
MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND

```

- Class > '02' (exception)

```

MESSAGE_TEXT = 'Unhandled user-defined exception condition';
MYSQL_ERRNO = ER_SIGNAL_EXCEPTION

```

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- `SQLSTATE` value: Call `mysql_sqlstate()`
- `MYSQL_ERRNO` value: Call `mysql_errno()`
- `MESSAGE_TEXT` value: Call `mysql_error()`

From SQL, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 14.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 14.6.7.7, “The MySQL Diagnostics Area”](#).

## Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled `SQLSTATE` value has been defined with `DECLARE ... HANDLER`.

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. `SQLWARNING` handlers catch the signal. If the signal is unhandled in a function, statements do not end.

- Class = '02' (not found)

`NOT FOUND` handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a function, statements end.

- Class > '02' (exception)

`SQLEXCEPTION` handlers catch the signal. If the signal is unhandled in a function, statements end.

- Class = '40'

Treated as an ordinary exception.

Example:

```
mysql> delimiter //
mysql> CREATE FUNCTION f () RETURNS INT
-> BEGIN
```

```

-> SIGNAL SQLSTATE '01234'; -- signal a warning
-> RETURN 5;
-> END//
mysql> delimiter ;
mysql> CREATE TABLE t (s1 INT);
mysql> INSERT INTO t VALUES (f());

```

The result is that a row containing 5 is inserted into table `t`. The warning that is signaled can be viewed with `SHOW WARNINGS`.

#### 14.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a `BEGIN ... END` block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers `H1` and `H2` are in scope for conditions raised by statements `stmt1` and `stmt2`. But neither `H1` nor `H2` are in scope for conditions raised in the body of `H1` or `H2`.

```

BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  DECLARE EXIT HANDLER FOR ...; -- handler H2
  stmt1;
  stmt2;
END;

```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler `H1` is in scope for `stmt1` in the inner block, but not for `stmt2` in the outer block:

```

BEGIN -- outer block
  BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...; -- handler H1
    stmt1;
  END;
  stmt2;
END;

```

- A handler can be specific or general. A specific handler is for a MySQL error code, `SQLSTATE` value, or condition name. A general handler is for a condition in the `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general `SQLWARNING` handler in an inner block. Or there might be handlers for a specific MySQL error code and the general `SQLWARNING` class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current `BEGIN ... END` block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an `SQLSTATE` value handler.
- An `SQLSTATE` value handler takes precedence over general `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` handlers.
- An `SQLEXCEPTION` handler takes precedence over an `SQLWARNING` handler.

- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is indeterminate, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For `SQLException` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.
- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific `SQLSTATE` value ( `'42S02'` ) that occurs for attempts to drop a nonexistent table, and one for the general `SQLException` class:

```
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLException
    SELECT 'SQLException handler was activated' AS msg;

  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, `SQLSTATE` handlers take precedence over `SQLException` handlers, so if the table `t` is nonexistent, the `DROP TABLE` statement raises a condition that activates the `SQLSTATE` handler:

```
mysql> CALL p1();
+-----+
| msg   |
+-----+
| SQLSTATE handler was activated |
+-----+
```

This procedure contains the same two handlers. But this time, the `DROP TABLE` statement and `SQLException` handler are in an inner block relative to the `SQLSTATE` handler:

```
CREATE PROCEDURE p2()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLException
      SELECT 'SQLException handler was activated' AS msg;

    DROP TABLE test.t; -- occurs within inner block
  END;
END;
```

In this case, the handler that is more local to where the condition occurs takes precedence. The `SQLEXCEPTION` handler activates, even though it is more general than the `SQLSTATE` handler:

```
mysql> CALL p2();
+-----+
| msg                                         |
+-----+
| SQLEXCEPTION handler was activated        |
+-----+
```

In this procedure, one of the handlers is declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p3()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
    END;

  DROP TABLE test.t; -- occurs within outer block
END;
```

Only the `SQLEXCEPTION` handler applies because the other one is not in scope for the condition raised by the `DROP TABLE`:

```
mysql> CALL p3();
+-----+
| msg                                         |
+-----+
| SQLEXCEPTION handler was activated        |
+-----+
```

In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p4()
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
    END;

  DROP TABLE test.t; -- occurs within outer block
END;
```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

#### 14.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution. MySQL supports the `STACKED` keyword as of MySQL 5.7. Before that, MySQL does not support `STACKED`; there is a single diagnostics area containing information from the most recent statement that wrote to it.

This section describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

## Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

## Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be [NULL](#). If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- [NUMBER](#): An integer indicating the number of condition areas that have information.
- [ROW\\_COUNT](#): An integer indicating the number of rows affected by the statement. [ROW\\_COUNT](#) has the same value as the [ROW\\_COUNT\( \)](#) function (see [Section 13.14, “Information Functions”](#)).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the [NUMBER](#) statement condition item. If [NUMBER](#) is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except [MYSQL\\_ERRNO](#), which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a [SIGNAL](#) or [RESIGNAL](#) statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- [CLASS\\_ORIGIN](#): A string containing the class of the [RETURNED\\_SQLSTATE](#) value. If the [RETURNED\\_SQLSTATE](#) value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), [CLASS\\_ORIGIN](#) is 'ISO 9075'. Otherwise, [CLASS\\_ORIGIN](#) is 'MySQL'.

- `SUBCLASS_ORIGIN`: A string containing the subclass of the `RETURNED_SQLSTATE` value. If `CLASS_ORIGIN` is `'ISO 9075'` or `RETURNED_SQLSTATE` ends with `'000'`, `SUBCLASS_ORIGIN` is `'ISO 9075'`. Otherwise, `SUBCLASS_ORIGIN` is `'MySQL'`.
- `RETURNED_SQLSTATE`: A string that indicates the `SQLSTATE` value for the condition.
- `MESSAGE_TEXT`: A string that indicates the error message for the condition.
- `MYSQL_ERRNO`: An integer that indicates the MySQL error code for the condition.
- `CONSTRAINT_CATALOG`, `CONSTRAINT_SCHEMA`, `CONSTRAINT_NAME`: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.
- `CATALOG_NAME`, `SCHEMA_NAME`, `TABLE_NAME`, `COLUMN_NAME`: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.
- `CURSOR_NAME`: A string that indicates the cursor name. This is always empty.

For the `RETURNED_SQLSTATE`, `MESSAGE_TEXT`, and `MYSQL_ERRNO` values for particular errors, see [Section B.3, “Server Error Codes and Messages”](#).

If a `SIGNAL` (or `RESIGNAL`) statement populates the diagnostics area, its `SET` clause can assign to any condition information item except `RETURNED_SQLSTATE` any value that is legal for the item data type. `SIGNAL` also sets the `RETURNED_SQLSTATE` value, but not directly in its `SET` clause. That value comes from the `SIGNAL` statement `SQLSTATE` argument.

`SIGNAL` also sets statement information items. It sets `NUMBER` to 1. It sets `ROW_COUNT` to -1 for errors and 0 otherwise.

## How the Diagnostics Area is Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the `SIGNAL` and `RESIGNAL` statements. The diagnostics area can be examined with `GET DIAGNOSTICS` to extract specific items, or with `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. (Before MySQL 5.7.2, the server clears the diagnostics area for nondiagnostic statements that use tables.) Diagnostic statements do not clear the diagnostics area (`SHOW WARNINGS`, `SHOW ERRORS`, `GET DIAGNOSTICS`).
- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
```

```
| Note | 1051 | Unknown table 'test.no_such_table' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

This `SET` statement generates an error, so it clears and populates the diagnostics area:

```
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'x' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'xx' |
| Error | 1753 | Invalid condition number |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @p;
+-----+
| @p |
+-----+
| Invalid condition number |
+-----+
1 row in set (0.01 sec)
```

## How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

- Execution of a stored program

A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.

Any warning or error conditions occurring during stored program execution then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

- Execution of a condition handler within a stored program

When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.

If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- Execution of `RESIGNAL`

The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in [Section 14.6.7.4, "RESIGNAL Syntax"](#).

## Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- `max_error_count` controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)
- `warning_count` indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.
- `error_count` indicates the number of errors that occurred. This value includes "not found" and exception conditions, but excludes warnings and notes. Like `warning_count`, its value can exceed `max_error_count`.
- If the `sql_notes` system variable is set to 0, notes are not stored and do not increment `warning_count`.

Example: If `max_error_count` is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, `NUMBER` is 10, `warning_count` is 20, and `error_count` is 12.

Changes to the value of `max_error_count` have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and `max_error_count` is set to 5, that has no immediate effect on the size or content of the diagnostics area.

## 14.7 Database Administration Statements

### 14.7.1 Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 6, MySQL Server Administration](#), which you should consult for additional details.

### Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To ensure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

When the `read_only` system variable is enabled, account-management statements require the `SUPER` privilege, in addition to any other required privileges. This is because they modify tables in the `mysql` database.

## 14.7.1.1 ALTER USER Syntax

`ALTER USER` syntax for MySQL 5.7.6 and higher:

```
ALTER USER [IF EXISTS]
  user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [password_option | lock_option] ...

ALTER USER [IF EXISTS]
  USER() IDENTIFIED BY 'auth_string'

user:
  (see Section 7.2.3, “Specifying Account Names”)

auth_option: {
  IDENTIFIED BY 'auth_string'
| IDENTIFIED WITH auth_plugin
| IDENTIFIED WITH auth_plugin BY 'auth_string'
| IDENTIFIED WITH auth_plugin AS 'hash_string'
}

tls_option: {
  SSL
| X509
| CIPHER 'cipher'
| ISSUER 'issuer'
| SUBJECT 'subject'
}

resource_option: {
  MAX_QUERIES_PER_HOUR count
| MAX_UPDATES_PER_HOUR count
| MAX_CONNECTIONS_PER_HOUR count
| MAX_USER_CONNECTIONS count
}

password_option: {
  PASSWORD EXPIRE
| PASSWORD EXPIRE DEFAULT
| PASSWORD EXPIRE NEVER
| PASSWORD EXPIRE INTERVAL N DAY
}

lock_option: {
  ACCOUNT LOCK
| ACCOUNT UNLOCK
}
```

`ALTER USER` syntax before MySQL 5.7.6:

```
ALTER USER
  user [password_option] [, user [password_option]] ...
```

```
password_option: {
    PASSWORD EXPIRE
|   PASSWORD EXPIRE DEFAULT
|   PASSWORD EXPIRE NEVER
|   PASSWORD EXPIRE INTERVAL N DAY
}
```

The `ALTER USER` statement modifies MySQL accounts. It provides control over account password expiration. As of MySQL 5.7.6, it also provides control over authentication, SSL/TLS, and resource-limit properties, and account locking and unlocking.

To use `ALTER USER`, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `ALTER USER` additionally requires the `SUPER` privilege.

An error occurs if you try to modify an account that does not exist.

As of MySQL 5.7.8, the `IF EXISTS` clause can be used, which causes the statement to produce a warning for each named account that does not exist, rather than an error.

`ALTER USER` modifies the `mysql.user` table row for each affected account according to the options specified in the statement. Unspecified properties retain their current values.

Example 1: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example 2: Modify an account to use the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED WITH sha256_password BY 'new_password'
    PASSWORD EXPIRE INTERVAL 180 DAY;
```

Example 3: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```

Example 4: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'
    REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```

Because the capabilities of this statement were expanded considerably in MySQL 5.7.6, this section first describes current syntax, and then the more limited pre-5.7.6 syntax.

- [ALTER USER as of MySQL 5.7.6](#)
- [ALTER USER Before MySQL 5.7.6](#)

#### Important

Under some circumstances, `ALTER USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 7.1.2.3, “Passwords and Logging”](#).

For similar information about client-side logging, see [Section 5.5.1.3, “mysql Logging”](#).

## ALTER USER as of MySQL 5.7.6

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

For one syntax only, the account may be specified with the `USER()` function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally.

For `ALTER USER` syntaxes that permit an `auth_option` value to follow a `user` value, `auth_option` begins with `IDENTIFIED` and indicates how the account authenticates by specifying an account authentication plugin, credentials (password), or both. Each `auth_option` value applies *only* to the user named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-expiration, and locking properties. All these options are *global* to the statement and apply to *all* named users.

Example: This statement changes the password for `jeffrey` but leaves that for `jeanne` unchanged. For both accounts, connections are required to use SSL and each account can be used for a maximum of two simultaneous connections:

```
ALTER USER
  'jeffrey'@'localhost' IDENTIFIED BY 'new_password',
  'jeanne'@'localhost'
  REQUIRE SSL WITH MAX_USER_CONNECTIONS 2;
```

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

There are several aspects to the `ALTER USER` statement, described under the following topics in this section:

- [Authentication Options](#)
- [SSL/TLS Options](#)
- [Resource-Limit Options](#)
- [Password-Expiration Options](#)
- [Account-Locking Options](#)

## Authentication Options

An account name may be followed by an authentication option that specifies the account authentication plugin, credentials, or both:

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` table.
- `'auth_string'` or `'hash_string'` specify account credentials, either as cleartext or hashed in the format expected by the authentication plugin, respectively. Credentials are stored in the `authentication_string` column of the `mysql.user` table.

`ALTER USER` permits these `auth_option` syntaxes:

- `IDENTIFIED BY 'auth_string'`

Sets the account authentication plugin to the default plugin, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin`

Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the `mysql.user` account row.

In addition, the password is marked expired. The user must choose a new one when next connecting.

- `IDENTIFIED WITH auth_plugin BY 'auth_string'`

Sets the account authentication plugin to `auth_plugin`, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to `auth_plugin`, takes the hashed `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise. For descriptions of each plugin, see [Section 7.5.1, “Authentication Plugins”](#).

Example 1: Specify the password as cleartext; the default plugin is used:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED BY 'mypass';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH mysql_native_password  
  BY 'mypass';
```

Example 3: Specify the authentication plugin, along with a hashed password value:

```
ALTER USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH mysql_native_password  
  AS '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

## SSL/TLS Options

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 7.4, “Using Secure Connections”](#).

To specify SSL-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

`ALTER USER` permits these `tls_option` values:

- `NONE`

Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if SSL is not available. Before MySQL 5.7.3, the client must specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.

- `SSL`

Tells the server to permit only encrypted connections for the account.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
```

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if SSL is not available. Before MySQL 5.7.3, the client must specify the `--ssl-ca` option to authenticate the server certificate, and may additionally specify the `--ssl-key` and `--ssl-cert` options. If neither the `--ssl-ca` option nor `--ssl-capath` option is specified, the client does not authenticate the server certificate.

- `X509`

Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
```

The client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- `ISSUER 'issuer'`

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

Because `ISSUER` implies the requirements of `X509`, the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
ALTER USER 'jeffrey'@'localhost'  
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/  
  O=MySQL/CN=CA/emailAddress=ca@example.com';
```

- `SUBJECT 'subject'`

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject `subject`. If the client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

Because `SUBJECT` implies the requirements of `X509`, the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the '*subject*' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

#### Note

Regarding *emailAddress*, see the note in the description of [REQUIRE ISSUER](#).

- [CIPHER](#) '*cipher*'

Requests a specific cipher method for connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The [SUBJECT](#), [ISSUER](#), and [CIPHER](#) options can be combined in the [REQUIRE](#) clause:

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The order of the options does not matter, but no option can be specified twice. The [AND](#) keyword is optional between [REQUIRE](#) options.

## Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 7.3.4, "Setting Account Resource Limits"](#). To do so, use a [WITH](#) clause that specifies one or more *resource\_option* values:

[ALTER USER](#) permits these *resource\_option* values:

- [MAX\\_QUERIES\\_PER\\_HOUR](#) *count*, [MAX\\_UPDATES\\_PER\\_HOUR](#) *count*,  
[MAX\\_CONNECTIONS\\_PER\\_HOUR](#) *count*

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the [MAX\\_QUERIES\\_PER\\_HOUR](#) limit.) If *count* is 0 (the default), this means that there is no limitation for the account.

- [MAX\\_USER\\_CONNECTIONS](#) *count*

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero *count* specifies the limit for the account explicitly. If *count* is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the [max\\_user\\_connections](#) system variable. If [max\\_user\\_connections](#) is also zero, there is no limit for the account.

Example:

```
ALTER USER 'jeffrey'@'localhost'  
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

If a given resource limit is specified multiple times, the last instance takes precedence.

## Password-Expiration Options

`ALTER USER` supports several *password\_option* values for password expiration management, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 7.3.6, “Password Expiration Policy”](#)).

The lifetime of a password is assessed from the date and time it was last changed.

`ALTER USER` permits these *password\_option* values:

- `PASSWORD EXPIRE`

Expires the account password.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- `PASSWORD EXPIRE DEFAULT`

Sets the account so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- `PASSWORD EXPIRE NEVER`

Disables password expiration for the account so that its password never expires.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- `PASSWORD EXPIRE INTERVAL N DAY`

Sets the account password lifetime to *N* days. This statement requires the password to be changed every 180 days:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

If multiple password-expiration options are specified, the last one takes precedence.

A client session operates in restricted mode if the account password was expired manually or if the password is considered past its lifetime per the automatic expiration policy. In restricted mode, operations performed within the session result in an error until the user establishes a new account password. See [Section 7.3.6, “Password Expiration Policy”](#).

### Note

It is possible to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password.

## Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see [Section 7.3.10, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

## ALTER USER Before MySQL 5.7.6

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#).

The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

Each *user* value naming an account is followed by a *password\_option* value that specifies the action to take for the account, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 7.3.6, “Password Expiration Policy”](#)).

The *password\_option* values are as described earlier in this section. The `DEFAULT`, `NEVER`, and `INTERVAL` variants of `PASSWORD EXPIRE` are not available before MySQL 5.7.4.

Before MySQL 5.7.3, it was possible to use `ALTER USER` to expire the password for anonymous-user accounts. This is no longer permitted because an anonymous user cannot reset the account password to lift the expiration.

## 14.7.1.2 CREATE USER Syntax

`CREATE USER` syntax for MySQL 5.7.6 and higher:

```
CREATE USER [IF NOT EXISTS]
  user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [password_option | lock_option] ...

user:
  (see Section 7.2.3, “Specifying Account Names”)

auth_option: {
  IDENTIFIED BY 'auth_string'
| IDENTIFIED BY PASSWORD 'hash_string'
| IDENTIFIED WITH auth_plugin
| IDENTIFIED WITH auth_plugin BY 'auth_string'
| IDENTIFIED WITH auth_plugin AS 'hash_string'
}

tls_option: {
  SSL
| X509
| CIPHER 'cipher'
| ISSUER 'issuer'
| SUBJECT 'subject'
}

resource_option: {
  MAX_QUERIES_PER_HOUR count
| MAX_UPDATES_PER_HOUR count
| MAX_CONNECTIONS_PER_HOUR count
| MAX_USER_CONNECTIONS count
}

password_option: {
  PASSWORD EXPIRE
| PASSWORD EXPIRE DEFAULT
| PASSWORD EXPIRE NEVER
| PASSWORD EXPIRE INTERVAL N DAY
}

lock_option: {
  ACCOUNT LOCK
| ACCOUNT UNLOCK
}
```

```
}
```

`CREATE USER` syntax before MySQL 5.7.6:

```
CREATE USER
    user [auth_option] [, user [auth_option]] ...

user:
    (see Section 7.2.3, "Specifying Account Names")

auth_option: {
    IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}
```

The `CREATE USER` statement creates new MySQL accounts. It enables account authentication properties to be established. As of MySQL 5.7.6, it is also possible to establish authentication, SSL/TLS, and resource-limit properties, account password expiration, and account locking and unlocking.

An account when first created has no privileges.

To use `CREATE USER`, you must have the global `CREATE USER` privilege, or the `INSERT` privilege for the `mysql` database. When the `read_only` system variable is enabled, `CREATE USER` additionally requires the `SUPER` privilege.

An error occurs if you try to create an account that already exists.

As of MySQL 5.7.8, the `IF NOT EXISTS` clause can be used, which causes the statement to produce a warning for each named account that already exists, rather than an error.

For each account, `CREATE USER` creates a new row in the `mysql.user` table. The row reflects the properties specified in the statement. Unspecified properties are set to their default values.

Example 1: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example 2: Create an account that uses the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED WITH sha256_password BY 'new_password'
    PASSWORD EXPIRE INTERVAL 180 DAY;
```

Because the capabilities of this statement were expanded considerably in MySQL 5.7.6, this section first describes current syntax, and then the more limited pre-5.7.6 syntax.

- [CREATE USER as of MySQL 5.7.6](#)
- [CREATE USER Before MySQL 5.7.6](#)

#### Important

Under some circumstances, `CREATE USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that

information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 7.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 5.5.1.3, “mysql Logging”](#).

For additional information about setting passwords and authentication plugins, see [Section 7.3.5, “Assigning Account Passwords”](#), and [Section 7.3.8, “Pluggable Authentication”](#).

## CREATE USER as of MySQL 5.7.6

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The host name part of the account name, if omitted, defaults to `'%'`.

Each `user` value naming an account may be followed by an optional `auth_option` value that specifies how the account authenticates. These values enable account authentication plugins and credentials (passwords) to be specified. Each `auth_option` value applies *only* to the user named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-expiration, and locking properties. All these options are *global* to the statement and apply to *all* named users.

Example: This statement creates two accounts, each with the default authentication plugin and named password. For both accounts, connections must be made using a valid X509 certificate and up to 60 queries per hour are permitted. Both accounts are locked initially, so effectively they are placeholders and cannot be used until an administrator unlocks them:

```
CREATE USER
  'jeffrey'@'localhost' IDENTIFIED BY 'new_password1',
  'jeanne'@'localhost' IDENTIFIED BY 'new_password2'
  REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60
  ACCOUNT LOCK;
```

For omitted options, these default values are used:

- Authentication: The authentication plugin defined by the `default_authentication_plugin` system variable, and empty credentials
- SSL/TLS: `NONE`
- Resource limits: Unlimited
- Password expiration: `PASSWORD EXPIRE DEFAULT`
- Account locking: `ACCOUNT UNLOCK`

There are several aspects to the `CREATE USER` statement, described under the following topics in this section:

- [Authentication Options](#)
- [SSL/TLS Options](#)
- [Resource-Limit Options](#)
- [Password-Expiration Options](#)

- [Account-Locking Options](#)

## Authentication Options

An account name may be followed by an authentication option that specifies the account authentication plugin, credentials, or both:

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` table.
- `'auth_string'` or `'hash_string'` specify account credentials, either as cleartext or hashed in the format expected by the authentication plugin, respectively. Credentials are stored in the `authentication_string` column of the `mysql.user` table.

`CREATE USER` permits these `auth_option` syntaxes:

- `IDENTIFIED BY 'auth_string'`

Sets the account authentication plugin to the default plugin, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED BY PASSWORD 'hash_string'`

Sets the account authentication plugin to the default plugin, takes the hashed `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

### Note

This syntax is deprecated and will be removed in a future MySQL release.

- `IDENTIFIED WITH auth_plugin`

Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin BY 'auth_string'`

Sets the account authentication plugin to `auth_plugin`, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to `auth_plugin`, takes the `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise. For descriptions of each plugin, see [Section 7.5.1, “Authentication Plugins”](#).

Example 1: Specify the password as cleartext; the default plugin is used:

```
CREATE USER 'jeffrey'@'localhost'  
  IDENTIFIED BY 'mypass';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
CREATE USER 'jeffrey'@'localhost'  
  IDENTIFIED WITH mysql_native_password BY 'mypass';
```

## SSL/TLS Options

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see [Section 7.4, “Using Secure Connections”](#).

To specify SSL/TLS-related options for a MySQL account, use a [REQUIRE](#) clause that specifies one or more *tls\_option* values:

[CREATE USER](#) permits these *tls\_option* values:

- [NONE](#)

Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if an encrypted connection cannot be established. Before MySQL 5.7.3, the client must specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.

- [SSL](#)

Tells the server to permit only encrypted connections for the account.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
```

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if an encrypted connection cannot be established. Before MySQL 5.7.3, the client must specify the `--ssl-ca` option to authenticate the server certificate, and may additionally specify the `--ssl-key` and `--ssl-cert` options. If neither the `--ssl-ca` option nor `--ssl-capath` option is specified, the client does not authenticate the server certificate.

- [X509](#)

Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the [SSL](#) option is unnecessary in this case.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

The client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for [ISSUER](#) and [SUBJECT](#) as well because those [REQUIRE](#) options imply the requirements of [X509](#).

- [ISSUER](#) *'issuer'*

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA *'issuer'*. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the [SSL](#) option is unnecessary in this case.

Because [ISSUER](#) implies the requirements of [X509](#), the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com';
```

- **SUBJECT** '*subject*'

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject *subject*. If the client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

Because **SUBJECT** implies the requirements of **X509**, the client must specify the **--ssl-key** and **--ssl-cert** options to connect. (It is recommended but not required that **--ssl-ca** also be specified so that the public certificate provided by the server can be verified.)

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the '*subject*' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

#### Note

Regarding *emailAddress*, see the note in the description of **REQUIRE ISSUER**.

- **CIPHER** '*cipher*'

Requests a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The **SUBJECT**, **ISSUER**, and **CIPHER** options can be combined in the **REQUIRE** clause:

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The order of the options does not matter, but no option can be specified twice. The **AND** keyword is optional between **REQUIRE** options.

## Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 7.3.4, "Setting Account Resource Limits"](#). To do so, use a **WITH** clause that specifies one or more *resource\_option* values.

**CREATE USER** permits these *resource\_option* values:

- **MAX\_QUERIES\_PER\_HOUR** *count*, **MAX\_UPDATES\_PER\_HOUR** *count*, **MAX\_CONNECTIONS\_PER\_HOUR** *count*

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query

cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If `count` is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero `count` specifies the limit for the account explicitly. If `count` is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```
CREATE USER 'jeffrey'@'localhost'  
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

If a given resource limit is specified multiple times, the last instance takes precedence.

## Password-Expiration Options

`CREATE USER` supports several `password_option` values for password expiration management, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 7.3.6, "Password Expiration Policy"](#)).

The lifetime of a password is assessed from the date and time it was last changed.

`CREATE USER` permits these `password_option` values:

- `PASSWORD EXPIRE`

Expires the account password.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- `PASSWORD EXPIRE DEFAULT`

Sets the account so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- `PASSWORD EXPIRE NEVER`

Disables password expiration for the account so that its password never expires.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- `PASSWORD EXPIRE INTERVAL N DAY`

Sets the account password lifetime to `N` days. This statement requires the password to be changed every 180 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

If multiple password-expiration options are specified, the last one takes precedence.

A client session operates in restricted mode if the account password was expired manually or if the password is considered past its lifetime per the automatic expiration policy. In restricted mode,

operations performed within the session result in an error until the user establishes a new account password. See [Section 7.3.6, “Password Expiration Policy”](#).

## Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see [Section 7.3.10, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

## CREATE USER Before MySQL 5.7.6

For each account, `CREATE USER` creates a new row in the `mysql.user` table with no privileges and assigns the account an authentication plugin and credentials (such as a password). If the statement specifies no credentials, the empty string is assigned.

Each `user` value naming an account may be followed by an optional `auth_option` value that specifies how authentication occurs for clients that use the account.

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The host name part of the account name, if omitted, defaults to `'%'`.

The server assigns an authentication plugin and password to each account as follows, depending on whether the user specification clause includes `IDENTIFIED WITH` to specify a plugin or `IDENTIFIED BY` to specify a password:

- With `IDENTIFIED WITH`, the server assigns the specified plugin and the account has no password. If the optional `AS 'hash_string'` clause is also given, the string is stored as is in the `authentication_string` column (it is assumed to be already hashed in the format required by the plugin).
- With `IDENTIFIED BY`, the server assigns the plugin implicitly and assigns the specified password.
- With neither `IDENTIFIED WITH` nor `IDENTIFIED BY`, the server assigns the plugin implicitly and the account has no password.

If the account has no password, the credentials in the account's `mysql.user` table row remain empty, which is insecure. To set the password, use `SET PASSWORD`. See [Section 14.7.1.7, “SET PASSWORD Syntax”](#).

For implicit plugin assignment, the default plugin becomes the value of the `plugin` column in the account's `mysql.user` table row. The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise.

For client connections that use a given account, the server invokes the authentication plugin assigned to the account and the client must provide credentials as required by the authentication method that the plugin implements. If the server cannot find the plugin, either at account-creation time or connect time, an error occurs

If an account's `mysql.user` table row has a nonempty `plugin` column:

- The server authenticates client connection attempts using the named plugin.
- Changes to the account password using `SET PASSWORD` with `PASSWORD( )` must be made with the `old_passwords` system variable set to the value required by the authentication plugin, so that `PASSWORD( )` uses the appropriate password hashing method. If the plugin

is `mysql_old_password`, the password can also be changed using `SET PASSWORD` with `OLD_PASSWORD()`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`. (Use of `mysql_old_password` is not recommended. It is deprecated and support for it is removed in MySQL 5.7.5.)

If an account's `mysql.user` table row has an empty `plugin` column:

- As of MySQL 5.7.2, the server disables any account with an empty plugin until the DBA assigns a nonempty one. Before MySQL 5.7.2, the server authenticates client connection attempts using the `mysql_native_password` or `mysql_old_password` authentication plugin, depending on the hash format of the password stored in the `Password` column.
- Changes to the account password using `SET PASSWORD` can be made with `PASSWORD()`, with `old_passwords` set to 0 or 1 for 4.1 or pre-4.1 password hashing, respectively, or with `OLD_PASSWORD()`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`.

`CREATE USER` examples:

- To specify an authentication plugin for an account, use `IDENTIFIED WITH auth_plugin`. The plugin name can be a quoted string literal or an unquoted name. `'auth_string'` is an optional quoted string literal to pass to the plugin. The plugin interprets the meaning of the string, so its format is plugin specific and it is stored in the `authentication_string` column as given. (This value is meaningful only for plugins that use that column.) Consult the documentation for a given plugin for information about the authentication string values it accepts, if any.

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
```

The server assigns the given authentication plugin to the account but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To ensure that an account uses a specific authentication plugin and has a password with the corresponding hash format, specify the plugin explicitly with `IDENTIFIED WITH`, then use `SET PASSWORD` to set the password:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
SET old_passwords = 0;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

Changes to the account password using `SET PASSWORD` with `PASSWORD()` must be made with the `old_passwords` system variable set to the value required by the account's authentication plugin, so that `PASSWORD()` uses the appropriate password hashing method. Therefore, to use the `sha256_password` or `mysql_old_password` plugin instead, name that plugin in the `CREATE USER` statement and set `old_passwords` to 2 or 1, respectively, before using `SET PASSWORD`. (Use of `mysql_old_password` is not recommended. It is deprecated and support for it is removed in MySQL 5.7.5.)

- To specify a password for an account at account-creation time, use `IDENTIFIED BY` with the literal cleartext password value:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. Clients must provide the given password when they connect.

If the implicitly assigned plugin is `mysql_native_password`, the `old_passwords` system variable must be set to 0. Otherwise, `CREATE USER` does not hash the password in the format required by the plugin and an error occurs:

```
mysql> SET old_passwords = 1;
```

```
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
ERROR 1827 (HY000): The password hash doesn't have the expected
format. Check if the correct password algorithm is being used with
the PASSWORD() function.

mysql> SET old_passwords = 0;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
Query OK, 0 rows affected (0.00 sec)
```

- To avoid specifying the cleartext password if you know its hash value (the value that `PASSWORD()` would return for the password), specify the hash value preceded by the keyword `PASSWORD`:

```
CREATE USER 'jeffrey'@'localhost'
IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. The password hash must be in the format required by the assigned plugin. Clients must provide the password when they connect.

- To enable the user to connect with no password, include no `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost';
```

The server assigns an authentication plugin to the account implicitly, as described previously, but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To avoid this, use `SET PASSWORD` to set the account password.

As mentioned previously, implicit plugin assignment depends on the default authentication plugin. Permitted values of `default_authentication_plugin` are `mysql_native_plugin` and `sha256_password`, but not `mysql_old_password`. This means it is not possible to set the default plugin so as to be able to create an account that uses `mysql_old_password` with `CREATE USER ... IDENTIFIED BY` syntax. To create an account that uses `mysql_old_password`, use `CREATE USER ... IDENTIFIED WITH` to name the plugin explicitly, then set the password:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_old_password;
SET old_passwords = 1;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

However, the preceding procedure is not recommended because `mysql_old_password` is deprecated and support for it is removed in MySQL 5.7.5.

### 14.7.1.3 DROP USER Syntax

```
DROP USER [IF EXISTS] user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

To use `DROP USER`, you must have the global `CREATE USER` privilege, or the `DELETE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `DROP USER` additionally requires the `SUPER` privilege.

An error occurs if you try to drop an account that does not exist.

As of MySQL 5.7.8, the `IF EXISTS` clause can be used, which causes the statement to produce a warning for each named account that does not exist, rather than an error.

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

### Important

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 22.6, “Access Control for Stored Programs and Views”](#).)

## 14.7.1.4 GRANT Syntax

```
GRANT
    priv_type [(column_list)]
    [, priv_type [(column_list)]] ...
ON [object_type] priv_level
TO user [auth_option] [, user [auth_option]] ...
[REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
[WITH {GRANT OPTION | resource_option} ...]

GRANT PROXY ON user
TO user [, user] ...
[WITH GRANT OPTION]

object_type: {
    TABLE
  | FUNCTION
  | PROCEDURE
}

priv_level: {
    *
  | *.*
  | db_name.*
  | db_name.tbl_name
  | tbl_name
  | db_name.routine_name
}

user:
    (see Section 7.2.3, “Specifying Account Names”)

auth_option: {      # Before MySQL 5.7.6
    IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

auth_option: {      # As of MySQL 5.7.6
    IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

| MAX_QUERIES_PER_HOUR count
| MAX_UPDATES_PER_HOUR count
| MAX_CONNECTIONS_PER_HOUR count
| MAX_USER_CONNECTIONS count
}

```

The [GRANT](#) statement grants privileges to MySQL user accounts.

To use [GRANT](#), you must have the [GRANT OPTION](#) privilege, and you must have the privileges that you are granting. When the [read\\_only](#) system variable is enabled, [GRANT](#) additionally requires the [SUPER](#) privilege.

The [REVOKE](#) statement is related to [GRANT](#) and enables administrators to remove account privileges. See [Section 14.7.1.6, “REVOKE Syntax”](#).

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
```

The host name part of the account, if omitted, defaults to `'%'`.

Normally, a database administrator first uses [CREATE USER](#) to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses [GRANT](#) to define its privileges. [ALTER USER](#) may be used to change the nonprivilege characteristics of existing accounts. For example:

```

CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;

```

#### Note

Examples shown here include no [IDENTIFIED](#) clause. It is assumed that you establish passwords with [CREATE USER](#) at account-creation time to avoid creating insecure accounts.

#### Note

If an account named in a [GRANT](#) statement does not already exist, [GRANT](#) may create it under the conditions described later in the discussion of the [NO\\_AUTO\\_CREATE\\_USER](#) SQL mode. It is also possible to use [GRANT](#) to specify nonprivilege account characteristics such as whether it uses secure connections and limits on access to server resources.

However, use of [GRANT](#) to create accounts or define nonprivilege characteristics is deprecated as of MySQL 5.7.6. Instead, perform these tasks using [CREATE USER](#) or [ALTER USER](#).

From the `mysql` program, [GRANT](#) responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use [SHOW GRANTS](#). See [Section 14.7.5.21, “SHOW GRANTS Syntax”](#).

There are several aspects to the [GRANT](#) statement, described under the following topics in this section:

- [Object Quoting Guidelines](#)

- [Privileges Supported by MySQL](#)
- [Global Privileges](#)
- [Database Privileges](#)
- [Table Privileges](#)
- [Column Privileges](#)
- [Stored Routine Privileges](#)
- [Proxy User Privileges](#)
- [Account Names and Passwords](#)
- [Implicit Account Creation](#)
- [Other Account Characteristics](#)
- [MySQL and Standard SQL Versions of GRANT](#)

[GRANT](#) supports host names up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. User names can be up to 32 characters (16 characters before MySQL 5.7.8).

#### Warning

*The permissible length for user names cannot be changed by altering the `mysql.user` table. Attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure described in [Section 5.4.7](#), “`mysql_upgrade` — Check and Upgrade MySQL Tables”.*

#### Important

Under some circumstances, [GRANT](#) may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 7.1.2.3](#), “[Passwords and Logging](#)”. For similar information about client-side logging, see [Section 5.5.1.3](#), “[mysql Logging](#)”.

## Object Quoting Guidelines

Several objects within [GRANT](#) statements are subject to quoting, although quoting is optional in many cases: Account, database, table, column, and routine names. For example, if a `user_name` or `host_name` value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a `user_name` string containing special characters (such as `-`), or a `host_name` string containing special characters or wildcard characters (such as `%`); for example, `'test-user'@'%.com'`. Quote the user name and host name separately.

To specify quoted values, quote database, table, column, and routine names as identifiers. Quote user names and host names as identifiers or as strings. Quote passwords as strings. For string-quoting and identifier-quoting guidelines, see [Section 10.1.1](#), “[String Literals](#)”, and [Section 10.2](#), “[Schema Object Names](#)”.

The `_` and `%` wildcards are permitted when specifying database names in [GRANT](#) statements that grant privileges at the database level. This means, for example, that if you want to use a `_` character as part of a database name, you should specify it as `\_` in the [GRANT](#) statement, to prevent the user from

being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo\_bar`.* TO ....`

## Privileges Supported by MySQL

The following table summarizes the permissible *priv\_type* privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about these privileges, see [Section 7.2.1, “Privileges Provided by MySQL”](#).

**Table 14.3 Permissible Privileges for GRANT and REVOKE**

| Privilege                            | Meaning and Grantable Levels   |
|--------------------------------------|--|
| <code>ALL [PRIVILEGES]</code>        | Grant all privileges at specified access level except <code>GRANT OPTION</code>  |
| <code>ALTER</code>                   | Enable use of <code>ALTER TABLE</code> . Levels: Global, database, table.  |
| <code>ALTER ROUTINE</code>           | Enable stored routines to be altered or dropped. Levels: Global, database, procedure.  |
| <code>CREATE</code>                  | Enable database and table creation. Levels: Global, database, table.   |
| <code>CREATE ROUTINE</code>          | Enable stored routine creation. Levels: Global, database.  |
| <code>CREATE TABLESPACE</code>       | Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.  |
| <code>CREATE TEMPORARY TABLES</code> | Enable use of <code>CREATE TEMPORARY TABLE</code> . Levels: Global, database.  |
| <code>CREATE USER</code>             | Enable use of <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code> . Level: Global. |
| <code>CREATE VIEW</code>             | Enable views to be created or altered. Levels: Global, database, table.  |
| <code>DELETE</code>                  | Enable use of <code>DELETE</code> . Level: Global, database, table.  |
| <code>DROP</code>                    | Enable databases, tables, and views to be dropped. Levels: Global, database, table.  |
| <code>EVENT</code>                   | Enable use of events for the Event Scheduler. Levels: Global, database.  |
| <code>EXECUTE</code>                 | Enable the user to execute stored routines. Levels: Global, database, table.   |
| <code>FILE</code>                    | Enable the user to cause the server to read or write files. Level: Global.   |
| <code>GRANT OPTION</code>            | Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, procedure, proxy.                                |
| <code>INDEX</code>                   | Enable indexes to be created or dropped. Levels: Global, database, table.  |
| <code>INSERT</code>                  | Enable use of <code>INSERT</code> . Levels: Global, database, table, column.   |
| <code>LOCK TABLES</code>             | Enable use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege. Levels: Global, database.                     |
| <code>PROCESS</code>                 | Enable the user to see all processes with <code>SHOW PROCESSLIST</code> . Level: Global.   |
| <code>PROXY</code>                   | Enable user proxying. Level: From user to user.  |
| <code>REFERENCES</code>              | Enable foreign key creation. Levels: Global, database, table, column.  |
| <code>RELOAD</code>                  | Enable use of <code>FLUSH</code> operations. Level: Global.  |
| <code>REPLICATION CLIENT</code>      | Enable the user to ask where master or slave servers are. Level: Global.   |
| <code>REPLICATION SLAVE</code>       | Enable replication slaves to read binary log events from the master. Level: Global.  |

| Privilege                      | Meaning and Grantable Levels  |
|--------------------------------|---|
| <a href="#">SELECT</a>         | Enable use of <a href="#">SELECT</a> . Levels: Global, database, table, column.   |
| <a href="#">SHOW DATABASES</a> | Enable <a href="#">SHOW DATABASES</a> to show all databases. Level: Global.   |
| <a href="#">SHOW VIEW</a>      | Enable use of <a href="#">SHOW CREATE VIEW</a> . Levels: Global, database, table.   |
| <a href="#">SHUTDOWN</a>       | Enable use of <a href="#">mysqladmin shutdown</a> . Level: Global.  |
| <a href="#">SUPER</a>          | Enable use of other administrative operations such as <a href="#">CHANGE MASTER TO</a> , <a href="#">KILL</a> , <a href="#">PURGE BINARY LOGS</a> , <a href="#">SET GLOBAL</a> , and <a href="#">mysqladmin debug</a> command. Level: Global. |
| <a href="#">TRIGGER</a>        | Enable trigger operations. Levels: Global, database, table.   |
| <a href="#">UPDATE</a>         | Enable use of <a href="#">UPDATE</a> . Levels: Global, database, table, column.   |
| <a href="#">USAGE</a>          | Synonym for “no privileges”   |

A trigger is associated with a table, so to create or drop a trigger, you must have the [TRIGGER](#) privilege for the table, not the trigger.

In [GRANT](#) statements, the [ALL \[PRIVILEGES\]](#) or [PROXY](#) privilege must be named by itself and cannot be specified along with other privileges. [ALL \[PRIVILEGES\]](#) stands for all privileges available for the level at which privileges are to be granted except for the [GRANT OPTION](#) and [PROXY](#) privileges.

[USAGE](#) can be specified to create a user that has no privileges, or to specify the [REQUIRE](#) or [WITH](#) clauses for an account without changing its existing privileges. (However, use of [GRANT](#) to define nonprivilege characteristics is deprecated as of MySQL 5.7.6. Instead, perform this task using [CREATE USER](#) or [ALTER USER](#).)

MySQL account information is stored in the tables of the [mysql](#) database. For additional details, consult [Section 7.2, “The MySQL Access Privilege System”](#), which discusses the [mysql](#) database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the [lower\\_case\\_table\\_names](#) system variable is set to a nonzero value, [REVOKE](#) cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. ([GRANT](#) will not create such rows when [lower\\_case\\_table\\_names](#) is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the [ON](#) clause. For [REVOKE](#), the same [ON](#) syntax specifies which privileges to remove.

For the global, database, table, and routine levels, [GRANT ALL](#) assigns only the privileges that exist at the level you are granting. For example, [GRANT ALL ON db\\_name.\\*](#) is a database-level statement, so it does not grant any global-only privileges such as [FILE](#). Granting [ALL](#) does not assign the [GRANT OPTION](#) or [PROXY](#) privilege.

The [object\\_type](#) clause, if present, should be specified as [TABLE](#), [FUNCTION](#), or [PROCEDURE](#) when the following object is a table, a stored function, or a stored procedure.

The privileges for a database, table, column, or routine are formed additively as the logical [OR](#) of the privileges at each of the privilege levels. For example, if a user has a global [SELECT](#) privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details of the privilege-checking procedure are presented in [Section 7.2.5, “Access Control, Stage 2: Request Verification”](#).

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the [CREATE](#) privilege. *This behavior is by design*, and is intended

to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

**Important**

*MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.*

## Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The `CREATE TABLESPACE`, `CREATE USER`, `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

MySQL stores global privileges in the `mysql.user` table.

## Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use `ON *` syntax (rather than `ON *.*`) and you have selected a default database, privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The `CREATE`, `DROP`, `EVENT`, `GRANT OPTION`, `LOCK TABLES`, and `REFERENCES` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` table.

## Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `REFERENCES`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

MySQL stores table privileges in the `mysql.tables_priv` table.

## Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1,col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible *priv\_type* values for a column (that is, when you use a *column\_list* clause) are [INSERT](#), [REFERENCES](#), [SELECT](#), and [UPDATE](#).

MySQL stores column privileges in the `mysql.columns_priv` table.

## Stored Routine Privileges

The [ALTER ROUTINE](#), [CREATE ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#) privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for [CREATE ROUTINE](#), these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible *priv\_type* values at the routine level are [ALTER ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#). [CREATE ROUTINE](#) is not a routine-level privilege because you must have this privilege to create a routine in the first place.

MySQL stores routine-level privileges in the `mysql.procs_priv` table.

## Proxy User Privileges

The [PROXY](#) privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user.

```
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When [PROXY](#) is granted, it must be the only privilege named in the [GRANT](#) statement, the [REQUIRE](#) clause cannot be given, and the only permitted [WITH](#) option is [WITH GRANT OPTION](#).

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the [PROXY](#) privilege for the proxied user. For details and examples, see [Section 7.3.9, “Proxy Users”](#).

MySQL stores proxy privileges in the `mysql.proxies_priv` table.

## Account Names and Passwords

A *user* value in a [GRANT](#) statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the *user* value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to *user\_name* for any host in the `example.com` domain, and `'user_name'@'192.168.1.%'` applies to *user\_name* for any host in the `192.168.1` class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%'`.

MySQL *does not support wildcards in user names*. To refer to an anonymous user, specify an account with an empty user name with the [GRANT](#) statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see [Section 7.2.3, “Specifying Account Names”](#).

**Warning**

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as '[user\\_name](#)'@'[localhost](#)'. Otherwise, the anonymous user account for [localhost](#) in the [mysql.user](#) table is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 7.2.4, “Access Control, Stage 1: Connection Verification”](#).

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

For [GRANT](#) syntaxes that permit an [auth\\_option](#) value to follow a [user](#) value, [auth\\_option](#) begins with [IDENTIFIED](#) and indicates how the account authenticates by specifying an account authentication plugin, credentials (password), or both. Syntax of the [auth\\_option](#) clause is the same as for the [CREATE USER](#) statement. For details, see [Section 14.7.1.2, “CREATE USER Syntax”](#).

**Note**

Use of [GRANT](#) to define account authentication characteristics is deprecated as of MySQL 5.7.6. Instead, establish or change authentication characteristics using [CREATE USER](#) or [ALTER USER](#). This [GRANT](#) capability will be removed in a future MySQL release.

When [IDENTIFIED](#) is present and you have the global grant privilege ([GRANT OPTION](#)), any password specified becomes the new password for the account, even if the account exists and already has a password. Without [IDENTIFIED](#), the account password remains unchanged.

**Implicit Account Creation**

If an account named in a [GRANT](#) statement does not exist, the action taken depends on the [NO\\_AUTO\\_CREATE\\_USER](#) SQL mode:

- If [NO\\_AUTO\\_CREATE\\_USER](#) is not enabled, [GRANT](#) creates the account. *This is very insecure* unless you specify a nonempty password using [IDENTIFIED BY](#).
- If [NO\\_AUTO\\_CREATE\\_USER](#) is enabled, [GRANT](#) fails and does not create the account, unless you specify a nonempty password using [IDENTIFIED BY](#) or name an authentication plugin using [IDENTIFIED WITH](#).

As of MySQL 5.7.2, if the account already exists, [IDENTIFIED WITH](#) is prohibited because it is intended only for use when creating new accounts.

**Other Account Characteristics**

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 7.4, “Using Secure Connections”](#).

The optional [REQUIRE](#) clause specifies SSL-related options for a MySQL account. The syntax is the same as for the [CREATE USER](#) statement. For details, see [Section 14.7.1.2, “CREATE USER Syntax”](#).

**Note**

Use of [GRANT](#) to define account SSL characteristics is deprecated as of MySQL 5.7.6. Instead, establish or change SSL characteristics using [CREATE USER](#) or [ALTER USER](#). This [GRANT](#) capability will be removed in a future MySQL release.

The optional [WITH](#) clause is used for these purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user

The [WITH GRANT OPTION](#) clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the [GRANT OPTION](#) privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the [GRANT OPTION](#) privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the [GRANT OPTION](#) privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the [GRANT OPTION](#) privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the [INSERT](#) privilege on a database. If you then grant the [SELECT](#) privilege on the database and specify [WITH GRANT OPTION](#), that user can give to other users not only the [SELECT](#) privilege, but also [INSERT](#). If you then grant the [UPDATE](#) privilege to the user on the database, the user can grant [INSERT](#), [SELECT](#), and [UPDATE](#).

For a nonadministrative user, you should not grant the [ALTER](#) privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see [Section 7.2.1, “Privileges Provided by MySQL”](#).

It is possible to place limits on use of server resources by an account, as discussed in [Section 7.3.4, “Setting Account Resource Limits”](#). To do so, use a [WITH](#) clause that specifies one or more [resource\\_option](#) values. Limits not specified retain their current values. The syntax is the same as for the [CREATE USER](#) statement. For details, see [Section 14.7.1.2, “CREATE USER Syntax”](#).

**Note**

Use of [GRANT](#) to define account resource limits is deprecated as of MySQL 5.7.6. Instead, establish or change resource limits using [CREATE USER](#) or [ALTER USER](#). This [GRANT](#) capability will be removed in a future MySQL release.

## MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of [GRANT](#) are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL [UNDER](#) privilege.
