|                            |  | <code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN, HASH_SCAN</code> ) |

When preparing batches of rows for row-based logging and replication, this option controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or no key at all. This option takes a comma-separated list of any 2 (or possibly 3) values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The list need not be quoted, but must contain no spaces, whether or not quotes are used. Possible combinations (lists) and their effects are shown in the following table:

| Index used / option value | <code>INDEX_SCAN, HASH_SCAN</code><br>or<br><code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code> | <code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code> | <code>TABLE_SCAN, HASH_SCAN</code> |
|---------------------------|--|--|------------------------------------|
| Primary key or unique key | Index scan   | Index scan                                     | Hash scan over index               |
| (Other) Key               | Hash scan over index   | Index scan                                     | Hash scan over index               |
| No index                  | Hash scan  | Table scan                                     | Hash scan                          |

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously). The default value is `TABLE_SCAN, INDEX_SCAN`, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`. To use hashing for any searches that does not use a primary or unique key, set this option to `INDEX_SCAN, HASH_SCAN`. To force hashing for *all* searches, set it to `TABLE_SCAN, HASH_SCAN`.

#### Note

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

|                            |                                       |                                |
|----------------------------|---------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-skip-errors=name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                           | <code>slave_skip_errors</code> |

|                         |                         |                       |
|-------------------------|-------------------------|-----------------------|
|                         | <b>Variable Scope</b>   | Global                |
|                         | <b>Dynamic Variable</b> | No                    |

|                         |                         |                       |
|                         |                         |                       |
|                         | <b>Type</b>             | string                |
|                         | <b>Default</b>          | OFF                   |
| <b>Permitted Values</b> | <b>Valid Values</b>     | OFF                   |
|                         |                         | [list of error codes] |
|                         |                         | all                   |
|                         | <b>Valid Values</b>     | ddl_exist_errors      |
|                         |                         |                       |
| <b>Permitted Values</b> | <b>Valid Values</b>     | ddl_exist_errors      |
|                         |                         |                       |
|                         |                         |                       |
|                         | <b>Type</b>             | string                |
|                         | <b>Default</b>          | OFF                   |
| <b>Permitted Values</b> | <b>Valid Values</b>     | OFF                   |
|                         |                         | [list of error codes] |
|                         |                         | all                   |
|                         | <b>Valid Values</b>     | ddl_exist_errors      |
|                         |                         |                       |

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This option causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

MySQL 5.7 supports an additional shorthand value `ddl_exist_errors`, which is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}`

|                            |  |         |
|----------------------------|--|---------|
| <b>Command-Line Format</b> | <code>--slave-sql-verify-checksum=value</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean |
|                            | <b>Default</b>                                 | 0       |
|                            | <b>Valid Values</b>                            | 0       |
|                            |  | 1       |

When this option is enabled, the slave examines checksums read from the relay log, in the event of a mismatch, the slave stops with an error. Disabled by default.

The following options are used internally by the MySQL test suite for replication testing and debugging. They are not intended for use in a production setting.

- `--abort-slave-event-count`

|                            |  |         |
|----------------------------|--|---------|
| <b>Command-Line Format</b> | <code>--abort-slave-event-count=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer |
|                            | <b>Default</b>                           | 0       |
|                            | <b>Min Value</b>                         | 0       |
|                            |  |         |

When this option is set to some positive integer *value* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *value* log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays *Yes* in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

- `--disconnect-slave-event-count`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--disconnect-slave-event-count=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                   | integer |
|                            | <b>Default</b>                                | 0       |

## Options for Logging Slave Status to Tables

MySQL 5.7 supports logging of replication slave status information to tables rather than files. Writing of the master info log and the relay log info log can be configured separately using the two server options listed here:

- `--master-info-repository={FILE|TABLE}`

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--master-info-repository=FILE TABLE</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                                      | string |
|                            | <b>Default</b>                                   | FILE   |
|                            | <b>Valid Values</b>                              | FILE   |
|                            |  | TABLE  |

This option causes the server to write its master info log to a file or a table. The name of the file defaults to `master.info`; you can change the name of the file using the `--master-info-file` server option.

The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_master_info` table in the `mysql` database.

- `--relay-log-info-repository={FILE|TABLE}`

|                            |   |        |
|----------------------------|---|--------|
| <b>Command-Line Format</b> | <code>--relay-log-info-repository=FILE TABLE</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>   | string |
|                            | <b>Default</b>                                      | FILE   |
|                            | <b>Valid Values</b>                                 | FILE   |
|                            |   | TABLE  |

This option causes the server to log its relay log info to a file or a table. The name of the file defaults to `relay-log.info`; you can change the name of the file using the `--relay-log-info-file` server option.

The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_relay_log_info` table in the `mysql` database.

These options can be used to make replication slaves resilient to unexpected halts. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#), for more information.

The info log tables and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

For more information, see [Section 18.2.4, “Replication Relay and Status Logs”](#).

## System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

|                            |                                |                         |
|----------------------------|--------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--init-slave=name</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                    | <code>init_slave</code> |
|                            | <b>Variable Scope</b>          | Global                  |
|                            | <b>Dynamic Variable</b>        | Yes                     |
|                            | <b>Type</b>                    | string                  |

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START SLAVE` statements.

### Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 14.4.2.6, “START SLAVE Syntax”](#), for more information.

- `log_slow_slave_statements`

|                        |                       |  |
|------------------------|-----------------------|--|
| <b>Introduced</b>      | 5.7.1                 |  |
| <b>System Variable</b> | <b>Name</b>           | <code>log_slow_slave_statements</code> |
|                        | <b>Variable Scope</b> | Global                                 |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave. This variable was added in MySQL 5.7.1. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

- `master_info_repository`

|                            |  |                                     |
|----------------------------|--|-------------------------------------|
| <b>Command-Line Format</b> | <code>--master-info-repository=FILE TABLE</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>master_info_repository</code> |
|                            | <b>Variable Scope</b>                            | Global                              |
|                            | <b>Dynamic Variable</b>                          | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                                      | string                              |
|                            | <b>Default</b>                                   | FILE                                |
|                            | <b>Valid Values</b>                              | FILE<br>TABLE                       |

The setting of this variable determines whether the slave logs master status and connection information to a `FILE` (`master.info`), or to a `TABLE` (`mysql.slave_master_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_master_info` system variable; see that variable's description for further information.

This variable must be set to `TABLE` before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to `FILE`.

- `relay_log`

|                            |                                    |                        |
|----------------------------|------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--relay-log=file_name</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                        | <code>relay_log</code> |
|                            | <b>Variable Scope</b>              | Global                 |
|                            | <b>Dynamic Variable</b>            | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                        | file name              |

The base name of the relay log file, with no paths and no file extension. By default `relay-log`. The file name of individual files for the default replication channel is `relay-log.XXXXXX`, and for additional replication channels is `relay-log-channel.XXXXXX`.

- `relay_log_basename`

|                        |                       |                                 |
|------------------------|-----------------------|---------------------------------|
| <b>System Variable</b> | <b>Name</b>           | <code>relay_log_basename</code> |
|                        | <b>Variable Scope</b> | Global                          |

|                         |                         |  |
|-------------------------|-------------------------|--|
|                         | <b>Dynamic Variable</b> | No   |
| <b>Permitted Values</b> | <b>Type</b>             | file name  |
|                         | <b>Default</b>          | <code>datadir + '/' + hostname + '-relay-bin'</code> |

Holds the name and complete path to the relay log file.

- `relay_log_index`

|                            |                                |  |
|----------------------------|--------------------------------|--|
| <b>Command-Line Format</b> | <code>--relay-log-index</code> |  |
| <b>System Variable</b>     | <b>Name</b>                    | <code>relay_log_index</code>             |
|                            | <b>Variable Scope</b>          | Global                                   |
|                            | <b>Dynamic Variable</b>        | No                                       |
| <b>Permitted Values</b>    | <b>Type</b>                    | file name                                |
|                            | <b>Default</b>                 | <code>*host_name*-relay-bin.index</code> |

The name of the relay log index file for the default replication channel. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

|                            |  |                                  |
|----------------------------|--|----------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-info-file=file_name</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>relay_log_info_file</code> |
|                            | <b>Variable Scope</b>                        | Global                           |
|                            | <b>Dynamic Variable</b>                      | No                               |
| <b>Permitted Values</b>    | <b>Type</b>                                  | file name                        |
|                            | <b>Default</b>                               | <code>relay-log.info</code>      |

The name of the file in which the slave records information about the relay logs, when `relay_log_info_repository=FILE`. If `relay_log_info_repository=TABLE`, it is the file name that would be used in case the repository was changed to `FILE`). The default name is `relay-log.info` in the data directory.

- `relay_log_info_repository`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>relay_log_info_repository</code>  |
|                         | <b>Variable Scope</b>   | Global                                  |
|                         | <b>Dynamic Variable</b> | Yes                                     |
| <b>Permitted Values</b> | <b>Type</b>             | string                                  |
|                         | <b>Default</b>          | <code>FILE</code>                       |
|                         | <b>Valid Values</b>     | <code>FILE</code><br><code>TABLE</code> |

This variable determines whether the slave's position in the relay logs is written to a **FILE** (`relay-log.info`) or to a **TABLE** (`mysql.slave_relay_log_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable; see that variable's description for further information.

This variable must be set to **TABLE** before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to **FILE**.

- `relay_log_recovery`

|                            |                                   |                                 |
|----------------------------|-----------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-recovery</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                       | <code>relay_log_recovery</code> |
|                            | <b>Variable Scope</b>             | Global                          |
|                            | <b>Dynamic Variable</b>           | No                              |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean                         |
|                            | <b>Default</b>                    | <code>FALSE</code>              |

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. In MySQL 5.7, this global variable is read-only; its value can be changed by starting the slave with the `--relay-log-recovery` option, which should be used following an unexpected halt of a replication slave to ensure that no possibly corrupted relay logs are processed. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#) for more information.

This variable also interacts with `relay-log-purge`, which controls purging of logs when they are no longer needed. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency.

When `relay_log_recovery` is enabled and the slave has stopped due to errors encountered while running in multi-threaded mode, you can use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `rpl_stop_slave_timeout`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Introduced</b>          | 5.7.2   |                                     |
| <b>Command-Line Format</b> | <code>--rpl-stop-slave-timeout=seconds</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                   | <code>rpl_stop_slave_timeout</code> |
|                            | <b>Variable Scope</b>                         | Global                              |
|                            | <b>Dynamic Variable</b>                       | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                                   | integer                             |
|                            | <b>Default</b>                                | <code>31536000</code>               |
|                            | <b>Min Value</b>                              | <code>2</code>                      |
|                            | <b>Max Value</b>                              | <code>31536000</code>               |

In MySQL 5.7.2 and later, you can control the length of time (in seconds) that `STOP SLAVE` waits before timing out by setting this variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave. The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP SLAVE` statements. This variable affects only the client that issues a `STOP SLAVE` statement. When the timeout is reached, the issuing client stops waiting for the slave threads to stop, but the slave threads continue to try to stop.

- `slave_checkpoint_group`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-group=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                             | <code>slave_checkpoint_group=#</code> |
|                            | <b>Variable Scope</b>                   | Global                                |
|                            | <b>Dynamic Variable</b>                 | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                               |
|                            | <b>Default</b>                          | 512                                   |
|                            | <b>Min Value</b>                        | 32                                    |
|                            | <b>Max Value</b>                        | 524280                                |
|                            | <b>Block Size</b>                       | 8                                     |

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this variable. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_period`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-period=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_checkpoint_period=#</code> |
|                            | <b>Variable Scope</b>                    | Global                                 |
|                            | <b>Dynamic Variable</b>                  | Yes                                    |

|                         |                  |         |
|-------------------------|------------------|---------|
| <b>Permitted Values</b> | <b>Type</b>      | integer |
|                         | <b>Default</b>   | 300     |
|                         | <b>Min Value</b> | 1       |
|                         | <b>Max Value</b> | 4G      |

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this variable. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `slave_compressed_protocol`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--slave_compressed_protocol</code> |  |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_compressed_protocol</code> |
|                            | <b>Variable Scope</b>                    | Global                                 |
|                            | <b>Dynamic Variable</b>                  | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean                                |
|                            | <b>Default</b>                           | OFF                                    |

Whether to use compression of the slave/master protocol if both the slave and the master support it. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START SLAVE` statement, as well as reconnections made by a running I/O thread (for example after issuing a `CHANGE MASTER TO MASTER_RETRY_COUNT` statement).

- `slave_exec_mode`

|                            |                                     |                              |
|----------------------------|-------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--slave-exec-mode=mode</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                         | <code>slave_exec_mode</code> |
|                            | <b>Variable Scope</b>               | Global                       |
|                            | <b>Dynamic Variable</b>             | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                         | enumeration                  |
|                            | <b>Default</b>                      | STRICT (ALL)                 |
|                            | <b>Default</b>                      | IDEMPOTENT (NDB)             |

|  |                     |                            |
|--|---------------------|----------------------------|
|  | <b>Valid Values</b> | <a href="#">IDEMPOTENT</a> |
|  |                     | <a href="#">STRICT</a>     |

Controls how a slave thread resolves conflicts and errors during replication. [STRICT](#) mode is the default, and is suitable for most cases. [IDEMPOTENT](#) mode causes suppression of duplicate-key and no-key-found errors. This mode should only be used with MySQL Cluster Replication in some special scenarios, such as multi-master replication, and circular replication. (See [Section 20.6.10](#), “NDB Cluster Replication: Multi-Master and Circular Replication”, and [Section 20.6.11](#), “NDB Cluster Replication Conflict Resolution”, for more information.) Setting this variable takes effect for all replication channels immediately, including running channels.

### Warning

The `mysqld` supplied with MySQL Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as [IDEMPOTENT](#).

[IDEMPOTENT](#) mode is supported only by [NDB](#) and is used when replicating [NDB](#) to [InnoDB](#).

- [slave\\_load\\_tmpdir](#)

|                            |   |                                   |
|----------------------------|---|-----------------------------------|
| <b>Command-Line Format</b> | <code>--slave-load-tmpdir=dir_name</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                               | <a href="#">slave_load_tmpdir</a> |
|                            | <b>Variable Scope</b>                     | Global                            |
|                            | <b>Dynamic Variable</b>                   | No                                |
| <b>Permitted Values</b>    | <b>Type</b>                               | directory name                    |
|                            | <b>Default</b>                            | <a href="#">/tmp</a>              |

The name of the directory where the slave creates temporary files for replicating [LOAD DATA INFILE](#) statements. Setting this variable takes effect for all replication channels immediately, including running channels.

- [slave\\_max\\_allowed\\_packet](#)

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">slave_max_allowed_packet</a> |
|                         | <b>Variable Scope</b>   | Global                                   |
|                         | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                  |
|                         | <b>Default</b>          | <a href="#">1073741824</a>               |
|                         | <b>Min Value</b>        | <a href="#">1024</a>                     |
|                         | <b>Max Value</b>        | <a href="#">1073741824</a>               |

This variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded [max\\_allowed\\_packet](#). Setting this variable takes effect for all replication channels immediately, including running channels.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or

used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_net_timeout`

|                                       |                                    |                                |
|---------------------------------------|------------------------------------|--------------------------------|

|                  |      |
|------------------|------|
| <b>Min Value</b> | 0    |
| <b>Max Value</b> | 1024 |

Sets the number of slave applier threads for executing replication transactions in parallel. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier threads. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread. Setting `slave_parallel_workers` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this variable. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

A multi-threaded slave provides parallel execution by using a coordinator thread and the number of applier threads configured by this variable. The way which transactions are distributed among applier threads is configured by `slave_parallel_type`. The transactions that the slave applies in parallel may commit out of order, unless `slave_preserve_commit_order=1`. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the master have been executed on the slave. This has implications for logging and recovery when using a multi-threaded slave. For example, on a multi-threaded slave the `START SLAVE UNTIL` statement only supports using `SQL_AFTER_MTS_GAPS`.

In MySQL 5.7.5 and later, retrying of transactions is supported when multi-threading is enabled on a slave. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multi-threaded slaves.

- `slave_pending_jobs_size_max`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>slave_pending_jobs_size_max</code> |
|                         | <b>Variable Scope</b>   | Global                                   |
|                         | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                  |
|                         | <b>Default</b>          | 16M                                      |
|                         | <b>Min Value</b>        | 1024                                     |
|                         | <b>Max Value</b>        | 18EB                                     |
|                         | <b>Block Size</b>       | 1024                                     |

For multi-threaded slaves, this variable sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The minimum possible value for this variable is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

**Important**

The value of this variable must not be less than the master's value for `max_allowed_packet`; otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `slave_preserve_commit_order`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.5  |  |
| <b>Command-Line Format</b> | <code>--slave-preserve-commit-order=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>slave_preserve_commit_order</code> |
|                            | <b>Variable Scope</b>                            | Global                                   |
|                            | <b>Dynamic Variable</b>                          | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean                                  |
|                            | <b>Default</b>                                   | 0  |
|                            | <b>Valid Values</b>                              | 0  |
|                            |  | 1  |

For multi-threaded slaves, enabling this variable ensures that transactions are externalized on the slave in the same order as they appear in the slave's relay log. Setting this variable has no effect on slaves for which multi-threading is not enabled. All replication threads (for all replication channels if you are using multiple replication channels) must be stopped before changing this variable. `--log-bin` and `--log-slave-updates` must be enabled on the slave. In addition `--slave-parallel-type` must be set to `LOGICAL_CLOCK`.

Once a multi-threaded slave has been started, transactions can begin to execute in parallel. With `slave_preserve_commit_order` enabled, the executing thread waits until all previous transactions are committed before committing. While the slave thread is waiting for other workers to commit their transactions it reports its status as `Waiting for preceding transaction to commit`. (Prior to MySQL 5.7.8, this was shown as `Waiting for its turn to commit`.) Enabling this mode on a multi-threaded slave ensures that it never enters a state that the master was not in. This makes it well suited to using replication for read scale-out. See [Section 18.3.4, “Using Replication for Scale-Out”](#).

When using a multi-threaded slave, if `slave_preserve_commit_order` is not enabled, there is a chance of gaps in the sequence of transactions that have been executed from the slave's relay log. When this option is enabled, there is not this chance of gaps, but `Exec_master_log_pos` may be behind the position up to which has been executed. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `slave_rows_search_algorithms`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>slave_rows_search_algorithms=list</code> |
|                         | <b>Variable Scope</b>   | Global   |
|                         | <b>Dynamic Variable</b> | Yes  |
| <b>Permitted Values</b> | <b>Type</b>             | set  |
|                         | <b>Default</b>          | <code>TABLE_SCAN, INDEX_SCAN</code>            |
|                         | <b>Valid Values</b>     | <code>TABLE_SCAN, INDEX_SCAN</code>            |

|  |   |
|--|---|
|  | <a href="#">INDEX_SCAN</a> , <a href="#">HASH_SCAN</a>  |
|  | <a href="#">TABLE_SCAN</a> , <a href="#">HASH_SCAN</a>  |
|  | <a href="#">TABLE_SCAN</a> , <a href="#">INDEX_SCAN</a> , <a href="#">HASH_SCAN</a> (equivalent to <a href="#">INDEX_SCAN</a> , <a href="#">HASH_SCAN</a> ) |

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, using some other key, or using no key at all. Setting this variable takes effect for all replication channels immediately, including running channels.

This variable takes a comma-separated list of at least 2 values from the list [INDEX\\_SCAN](#), [TABLE\\_SCAN](#), [HASH\\_SCAN](#). The value expected as a string, so the value must be quoted. In addition, the value must not contain any spaces. Possible combinations (lists) and their effects are shown in the following table:

| Index used / option value | <a href="#">INDEX_SCAN</a> , <a href="#">HASH_SCAN</a> or <a href="#">INDEX_SCAN</a> , <a href="#">TABLE_SCAN</a> , <a href="#">HASH_SCAN</a> | <a href="#">INDEX_SCAN</a> , <a href="#">TABLE_SCAN</a> | <a href="#">TABLE_SCAN</a> , <a href="#">HASH_SCAN</a> |
|---------------------------|---|---|--|
| Primary key or unique key | Index scan  | index scan  | Index hash   |
| (Other) Key               | Index hash  | Index scan  | Index hash   |
| No index                  | Table hash  | Table scan  | Table hash   |

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a [SELECT](#) or [SHOW VARIABLES](#) statement, as shown here:

```
mysql> SET GLOBAL slave_rows_search_algorithms = "INDEX_SCAN, TABLE_SCAN";
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE '%algorithms%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_rows_search_algorithms | TABLE_SCAN, INDEX_SCAN |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET GLOBAL slave_rows_search_algorithms = "TABLE_SCAN, INDEX_SCAN";
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE '%algorithms%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_rows_search_algorithms | TABLE_SCAN, INDEX_SCAN |
+-----+-----+
1 row in set (0.00 sec)
```

The default value is [TABLE\\_SCAN](#), [INDEX\\_SCAN](#), which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

Specifying [INDEX\\_SCAN](#), [TABLE\\_SCAN](#), [HASH\\_SCAN](#) has the same effect as specifying [INDEX\\_SCAN](#), [HASH\\_SCAN](#). To use hashing for any searches that does not use a primary or unique key, set this variable to [INDEX\\_SCAN](#), [HASH\\_SCAN](#). To force hashing for *all* searches, set it to [TABLE\\_SCAN](#), [HASH\\_SCAN](#).

- [slave\\_skip\\_errors](#)

|                            |                                       |

|                         |                         | all                            |
| <b>Permitted Values</b> | <b>Valid Values</b>     | ddl_exist_errors               |
|                         |                         |                                |
|                         |                         |                                |
|                         | <b>Type</b>             | string                         |
|                         | <b>Default</b>          | OFF                            |

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This variable causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value. The setting of this variable takes effect immediately, even for running replication threads.

- `slave_sql_verify_checksum`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>slave_sql_verify_checksum</code> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                |
|                         | <b>Default</b>          | 1                                      |
|                         | <b>Valid Values</b>     | 0                                      |
|                         |                         | 1                                      |

Cause the slave SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the slave stops with an error. Setting this variable takes effect for all replication channels immediately, including running channels.

**Note**

The slave I/O thread always reads checksums if possible when accepting events from over the network.

- `slave_transaction_retries`

|  |  |  |
|--|--|--|
| <b>Command-Line Format</b>                 | <code>--slave_transaction_retries=#</code> |  |
| <b>System Variable</b>                     | <b>Name</b>                                | <code>slave_transaction_retries</code> |
|  | <b>Variable Scope</b>                      | Global                                 |
|  | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                                | integer                                |
|  | <b>Default</b>                             | 10                                     |
|  | <b>Min Value</b>                           | 0                                      |
|  | <b>Max Value</b>                           | 4294967295                             |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                                | integer                                |
|  | <b>Default</b>                             | 10                                     |
|  | <b>Min Value</b>                           | 0                                      |
|  | <b>Max Value</b>                           | 18446744073709551615                   |

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's `innodb_lock_wait_timeout` or NDB's `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10. Setting this variable takes effect for all replication channels immediately, including running channels.

As of MySQL 5.7.5, retrying of transactions is supported when multi-threading is enabled on a slave. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multi-threaded slaves.

- `slave_type_conversions`

|                                    |   |                                     |
|------------------------------------|---|-------------------------------------|
| <b>Command-Line Format</b>         | <code>--slave_type_conversions=set</code> |                                     |
| <b>System Variable</b>             | <b>Name</b>                               | <code>slave_type_conversions</code> |
|                                    | <b>Variable Scope</b>                     | Global                              |
|                                    | <b>Dynamic Variable</b>                   | No                                  |
| <b>Permitted Values</b> (<= 5.7.1) | <b>Type</b>                               | set                                 |
|                                    | <b>Default</b>                            |                                     |
|                                    | <b>Valid Values</b>                       | <code>ALL_LOSSY</code>              |
|                                    |   | <code>ALL_NON_LOSSY</code>          |
| <b>Permitted Values</b> (>= 5.7.2) | <b>Type</b>                               | set                                 |

|  |                     |                               |
|--|---------------------|-------------------------------|
|  | <b>Default</b>      |                               |
|  | <b>Valid Values</b> | <a href="#">ALL_LOSSY</a>     |
|  |                     | <a href="#">ALL_NON_LOSSY</a> |
|  |                     | <a href="#">ALL_SIGNED</a>    |
|  |                     | <a href="#">ALL_UNSIGNED</a>  |

Controls the type conversion mode in effect on the slave when using row-based replication. In MySQL 5.7.2 and later, its value is a comma-delimited set of zero or more elements from the list: [ALL\\_LOSSY](#), [ALL\\_NON\\_LOSSY](#), [ALL\\_SIGNED](#), [ALL\\_UNSIGNED](#). Set this variable to an empty string to disallow type conversions between the master and the slave. Setting this variable takes effect for all replication channels immediately, including running channels.

[ALL\\_SIGNED](#) and [ALL\\_UNSIGNED](#) were added in MySQL 5.7.2 (Bug#15831300). For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

- [sql\\_slave\\_skip\\_counter](#)

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">sql_slave_skip_counter</a> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                |

The number of events from the master that a slave server should skip. Setting the option has no immediate effect. The variable applies to the next [START SLAVE](#) statement; the next [START SLAVE](#) statement also changes the value back to 0. When this variable is set to a non-zero value and there are multiple replication channels configured, the [START SLAVE](#) statement can only be used with the [FOR CHANNEL \*channel\*](#) clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when [--gtid-mode=ON](#). In MySQL 5.7.1 and later, trying to do so is specifically disallowed. (Bug #15833516) If you need to skip transactions when employing GTIDs, use [gtid\\_executed](#) from the master instead. See [Injecting empty transactions](#), for information about how to do this.

#### Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 14.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

- [sync\\_master\\_info](#)

|  |                                      |                                  |
|--|--------------------------------------|----------------------------------|
| <b>Command-Line Format</b>                 | <a href="#">--sync-master-info=#</a> |                                  |
| <b>System Variable</b>                     | <b>Name</b>                          | <a href="#">sync_master_info</a> |
|  | <b>Variable Scope</b>                | Global                           |
|  | <b>Dynamic Variable</b>              | Yes                              |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                          | integer                          |
|  | <b>Default</b>                       | <a href="#">10000</a>            |

|  |                  |                      |
|--|------------------|----------------------|
| <b>Permitted Values</b> (64-bit platforms) | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 4294967295           |
|  | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 10000                |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709551615 |

The effects of this variable on a replication slave depend on whether the slave's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

**master\_info\_repository = FILE.** If the value of `sync_master_info` is greater than 0, the slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

**master\_info\_repository = TABLE.** If the value of `sync_master_info` is greater than 0, the slave updates its master info repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

- `sync_relay_log`

|  |                                 |                             |
|--|---------------------------------|-----------------------------|
| <b>Command-Line Format</b>                 | <code>--sync-relay-log=#</code> |                             |
| <b>System Variable</b>                     | <b>Name</b>                     | <code>sync_relay_log</code> |
|  | <b>Variable Scope</b>           | Global                      |
|  | <b>Dynamic Variable</b>         | Yes                         |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                     | integer                     |
|  | <b>Default</b>                  | 10000                       |
|  | <b>Min Value</b>                | 0                           |
|  | <b>Max Value</b>                | 4294967295                  |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                     | integer                     |
|  | <b>Default</b>                  | 10000                       |
|  | <b>Min Value</b>                | 0                           |
|  | <b>Max Value</b>                | 18446744073709551615        |

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

|  |                                      |                                  |
|--|--------------------------------------|----------------------------------|
| <b>Command-Line Format</b>                 | <code>--sync-relay-log-info=#</code> |                                  |
| <b>System Variable</b>                     | <b>Name</b>                          | <code>sync_relay_log_info</code> |
|  | <b>Variable Scope</b>                | Global                           |
|  | <b>Dynamic Variable</b>              | Yes                              |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                          | integer                          |
|  | <b>Default</b>                       | 10000                            |
|  | <b>Min Value</b>                     | 0                                |
|  | <b>Max Value</b>                     | 4294967295                       |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                          | integer                          |
|  | <b>Default</b>                       | 10000                            |
|  | <b>Min Value</b>                     | 0                                |
|  | <b>Max Value</b>                     | 18446744073709551615             |

The effects of this variable on the slave depend on the server's `relay_log_info_repository` setting (`FILE` or `TABLE`), and if this is `TABLE`, additionally on whether the storage engine used by the relay log info table is transactional (such as `InnoDB`) or not (`MyISAM`). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are shown in the following table:

| <code>sync_relay_log_info</code> | <code>relay_log_info_repository</code>  |   |  |
|----------------------------------|---|---|--|
|                                  | <code>FILE</code>   | <code>TABLE</code>  |  |
|                                  |   | Transactional   | Nontransactional                             |
| $N > 0$                          | The slave synchronizes its <code>relay-log.info</code> file to disk (using <code>fdatasync()</code> ) after every $N$ transactions.   | The table is updated after each transaction. ( $N$ is effectively ignored.) | The table is updated after every $N$ events. |
| 0                                | The MySQL server performs no synchronization of the <code>relay-log.info</code> file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file. |   | The table is never updated.                  |

The default value for `sync_relay_log_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

### 18.1.6.4 Binary Logging Options and Variables

#### Startup Options Used with Binary Logging

#### System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 6.4.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 6.1.4, “Server Command Options”](#), and [Section 6.1.5, “Server System Variables”](#).

#### Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

| Command-Line Format                 | <code>--binlog-row-event-max-size=#</code> |                      |
|-------------------------------------|--|----------------------|
| Permitted Values (32-bit platforms) | Type                                       | integer              |
|                                     | Default                                    | 8192                 |
|                                     | Min Value                                  | 256                  |
|                                     | Max Value                                  | 4294967295           |
| Permitted Values (64-bit platforms) | Type                                       | integer              |
|                                     | Default                                    | 8192                 |
|                                     | Min Value                                  | 256                  |
|                                     | Max Value                                  | 18446744073709551615 |

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 8192. See [Section 18.2.1, “Replication Formats”](#).

- `--log-bin[=base_name]`

| Command-Line Format | <code>--log-bin</code> |                      |
|---------------------|------------------------|----------------------|
| System Variable     | Name                   | <code>log_bin</code> |
|                     | Variable Scope         | Global               |
|                     | Dynamic Variable       | No                   |
|                     | Type                   | file name            |
| Permitted Values    | Type                   | file name            |

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 6.4.4, “The Binary Log”](#).

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see [Section B.5.7, “Known Issues in MySQL”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

When the server reads an entry from the index file, it checks whether the entry contains a relative path, and if it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. (In older versions of MySQL, manual intervention was required whenever relocating the binary log or relay log files.) (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. The binary log file name (with path) is available as the `log_bin_basename` system variable.

In MySQL 5.7.3 and later, if you specify this option without also specifying a `--server-id`, the server is not allowed to start. (Bug #11763963, Bug #56739)

- `--log-bin-index[=file_name]`

|                            |  |           |
|----------------------------|--|-----------|
| <b>Command-Line Format</b> | <code>--log-bin-index=file_name</code> |           |
| <b>Permitted Values</b>    | <b>Type</b>                            | file name |

The index file for binary log file names. See [Section 6.4.4, “The Binary Log”](#). If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--log-bin-trust-function-creators</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>log_bin_trust_function_creators</code> |
|                            | <b>Variable Scope</b>                          | Global                                       |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean                                      |
|                            | <b>Default</b>                                 | <code>FALSE</code>                           |

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to `1`. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 22.7, “Binary Logging of Stored Programs”](#).

- `--log-bin-use-v1-row-events[={0|1}]`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--log-bin-use-v1-row-events[={0 1}]</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>log_bin_use_v1_row_events</code> |
|                            | <b>Variable Scope</b>                            | Global                                 |
|                            | <b>Dynamic Variable</b>                          | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean                                |
|                            | <b>Default</b>                                   | <code>0</code>                         |

MySQL 5.7 uses Version 2 binary log row events, which cannot be read by MySQL Server releases prior to MySQL 5.6.6. Setting this option to `1` causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves. Setting `--log-bin-use-v1-row-events` to `0` (the default) causes `mysqld` to use Version 2 binary log events.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 18.1.6.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

|                            |                                  |        |
|----------------------------|----------------------------------|--------|
| <b>Command-Line Format</b> | <code>--binlog-do-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                      | string |

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`,

the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

|                     |                                      |        |
|---------------------|--------------------------------------|--------|
| Command-Line Format | <code>--binlog-ignore-db=name</code> |        |
| Permitted Values    | Type                                 | string |

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-

based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Prior to MySQL 5.7.2, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.7.2 and later, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.** MySQL 5.7 supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

|                            |                                     |                    |
|----------------------------|-------------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--binlog-checksum=type</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                         | string             |
|                            | <b>Default</b>                      | <code>CRC32</code> |
|                            | <b>Valid Values</b>                 | <code>NONE</code>  |
|                            |                                     | <code>CRC32</code> |

Enabling this option causes the master to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported, and CRC32 is the default.

- `--master-verify-checksum={0|1}`

|                            |  |
|----------------------------|--|
| <b>Command-Line Format</b> | <code>--master-verify-checksum=name</code> |
|----------------------------|--|

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | OFF     |

Enabling this option causes the master to verify events from the binary log using checksums, and to stop with an error in the event of a mismatch. Disabled by default.

To control reading of checksums by the slave (from the relay) log, use the `--slave-sql-verify-checksum` option.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--max-binlog-dump-events=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer |
|                            | <b>Default</b>                          | 0       |

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

|                            |  |         |
|----------------------------|--|---------|
| <b>Command-Line Format</b> | <code>--sporadic-binlog-dump-fail</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean |
|                            | <b>Default</b>                           | FALSE   |

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--binlog-rows-query-log-events`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--binlog-rows-query-log-events</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean |
|                            | <b>Default</b>                              | FALSE   |

This option enables `binlog_rows_query_log_events`.

## System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see [Section 6.1.5, “Server System Variables”](#).

- `binlog_cache_size`

|  |                                    |                                |
|--|------------------------------------|--------------------------------|
| <b>Command-Line Format</b>                 | <code>--binlog_cache_size=#</code> |                                |
| <b>System Variable</b>                     | <b>Name</b>                        | <code>binlog_cache_size</code> |
|  | <b>Variable Scope</b>              | Global                         |
|  | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                        | integer                        |
|  | <b>Default</b>                     | 32768                          |
|  | <b>Min Value</b>                   | 4096                           |

|  |                  |                      |
|--|------------------|----------------------|
|  | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 32768                |
|  | <b>Min Value</b> | 4096                 |
|  | <b>Max Value</b> | 18446744073709551615 |

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 6.4.4, “The Binary Log”](#).

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

|                         |                         |                              |
|-------------------------|-------------------------|------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_checksum</code> |
|                         | <b>Variable Scope</b>   | Global                       |
|                         | <b>Dynamic Variable</b> | Yes                          |
| <b>Permitted Values</b> | <b>Type</b>             | string                       |
|                         | <b>Default</b>          | <code>CRC32</code>           |
|                         | <b>Valid Values</b>     | <code>NONE</code>            |
|                         |                         | <code>CRC32</code>           |

When enabled, this variable causes the master to write a checksum for each event in the binary log. `binlog_checksum` supports the values `NONE` (disabled) and `CRC32`. The default is `CRC32`.

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

Setting this variable on the master to a value unrecognized by the slave causes the slave to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older slaves is a concern, you may want to set the value explicitly to `NONE`.

- `binlog_direct_non_transactional_updates`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--binlog_direct_non_transactional_updates[=value]</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>binlog_direct_non_transactional_updates</code> |
|                            | <b>Variable Scope</b>  | Global, Session                                      |
|                            | <b>Dynamic Variable</b>  | Yes  |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | OFF     |

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

*`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.*

#### Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

In MySQL 5.7, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- `binlog_error_action`

|                                       |  |                                  |
|---------------------------------------|--|----------------------------------|
| <b>Introduced</b>                     | 5.7.6                                      |                                  |
| <b>Command-Line Format</b>            | <code>--binlog_error_action[=value]</code> |                                  |
| <b>System Variable</b>                | <b>Name</b>                                | <code>binlog_error_action</code> |
|                                       | <b>Variable Scope</b>                      | Global, Session                  |
|                                       | <b>Dynamic Variable</b>                    | Yes                              |
| <b>Permitted Values</b>               | <b>Type</b>                                | enumeration                      |
|                                       | <b>Default</b>                             | <code>IGNORE_ERROR</code>        |
|                                       | <b>Valid Values</b>                        | <code>IGNORE_ERROR</code>        |
|                                       |  | <code>ABORT_SERVER</code>        |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                                | enumeration                      |
|                                       | <b>Default</b>                             | <code>ABORT_SERVER</code>        |
|                                       | <b>Valid Values</b>                        | <code>IGNORE_ERROR</code>        |
|                                       |  | <code>ABORT_SERVER</code>        |

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the master's log to become inconsistent and replication slaves to lose synchronization.

In MySQL 5.7.7 and later, this variable defaults to `ABORT_SERVER`, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. Upon server restart, all of the previously prepared and binary logged transactions are committed, while any transactions which were prepared but not binary logged due to the error are aborted.

When `binlog_error_action` is set to `IGNORE_ERROR`, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again. This provides backward compatibility with older versions of MySQL.

In previous releases this variable was named `binlogging_impossible_mode`.

- `binlog_format`

|                                       |                                     |                            |
|---------------------------------------|-------------------------------------|----------------------------|
| <b>Command-Line Format</b>            | <code>--binlog-format=format</code> |                            |
| <b>System Variable</b>                | <b>Name</b>                         | <code>binlog_format</code> |
|                                       | <b>Variable Scope</b>               | Global, Session            |
|                                       | <b>Dynamic Variable</b>             | Yes                        |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>                         | enumeration                |
|                                       | <b>Default</b>                      | <code>STATEMENT</code>     |
|                                       | <b>Valid Values</b>                 | <code>ROW</code>           |
|                                       |                                     | <code>STATEMENT</code>     |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Valid Values</b>                 | <code>MIXED</code>         |
|                                       |                                     |                            |
|                                       | <b>Type</b>                         | enumeration                |
|                                       | <b>Default</b>                      | <code>ROW</code>           |
|                                       | <b>Valid Values</b>                 | <code>ROW</code>           |
|                                       |                                     | <code>STATEMENT</code>     |
|                                       | <b>Valid Values</b>                 | <code>MIXED</code>         |
|                                       |                                     |                            |

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See [Section 18.2.1, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

#### Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

Prior to MySQL 5.7.7, the default format was `STATEMENT`. In MySQL 5.7.7 and later the default is `ROW`. *Exception:* In MySQL Cluster, the default is `MIXED`; statement-based replication is not supported for MySQL Cluster.

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#).

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when

statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.
- From within a transaction.

Trying to switch the format in those cases results in an error.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlog_group_commit_sync_delay`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.5   |   |
| <b>Command-Line Format</b> | <code>--binlog-group-commit-sync-delay=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>binlog_group_commit_sync_delay</code> |
|                            | <b>Variable Scope</b>                           | Global                                      |
|                            | <b>Dynamic Variable</b>                         | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                     | integer                                     |
|                            | <b>Default</b>                                  | 0   |
|                            | <b>Min Value</b>                                | 0   |
|                            | <b>Max Value</b>                                | 1000000                                     |

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default `binlog_group_commit_sync_delay` is set to 0, meaning that there is no delay. Setting `binlog_group_commit_sync_delay` to a microsecond delay enables more transactions to be synchronized together to disk at once, reducing the overall time to commit a group of transactions because the larger groups require fewer time units per group. With the correct tuning, this can increase slave performance without compromising the master's throughput.

- `binlog_group_commit_sync_no_delay_count`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.5  |  |
| <b>Command-Line Format</b> | <code>--binlog-group-commit-sync-no-delay-count=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>binlog_group_commit_sync_no_delay_count</code> |
|                            | <b>Variable Scope</b>                                    | Global   |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 0       |
|                         | <b>Min Value</b>        | 0       |
|                         | <b>Max Value</b>        | 1000000 |

The maximum number of transactions to wait for before aborting the current delay as specified by `binlog-group-commit-sync-delay`. If `binlog-group-commit-sync-delay` is set to 0, then this option has no effect.

- `binlogging_impossible_mode`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.5   |   |
| <b>Deprecated</b>          | 5.7.6   |   |
| <b>Command-Line Format</b> | <code>--binlogging_impossible_mode[=value]</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                       | <code>binlogging_impossible_mode</code> |
|                            | <b>Variable Scope</b>                             | Global, Session                         |
|                            | <b>Dynamic Variable</b>                           | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                       | enumeration                             |
|                            | <b>Default</b>                                    | <code>IGNORE_ERROR</code>               |
|                            | <b>Valid Values</b>                               | <code>IGNORE_ERROR</code>               |
|                            |   | <code>ABORT_SERVER</code>               |

This option is deprecated and will be removed in a future MySQL release. Use the renamed `binlog_error_action` to control what happens when the server cannot write to the binary log.

- `binlog_max_flush_queue_time`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>Deprecated</b>       | 5.7.9                   |  |
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_max_flush_queue_time</code> |
|                         | <b>Variable Scope</b>   | Global                                   |
|                         | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                  |
|                         | <b>Default</b>          | 0  |
|                         | <b>Min Value</b>        | 0  |
|                         | <b>Max Value</b>        | 100000                                   |

Formerly, this controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. In MySQL 5.7, this variable no longer has any effect.

`binlog_max_flush_queue_time` is deprecated as of MySQL 5.7.9, and is marked for eventual removal in a future MySQL release.

- `binlog_order_commits`

|                         |                         |                                   |
|-------------------------|-------------------------|-----------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_order_commits</code> |
|                         | <b>Variable Scope</b>   | Global                            |
|                         | <b>Dynamic Variable</b> | Yes                               |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                           |
|                         | <b>Default</b>          | <code>ON</code>                   |

When this variable is enabled on a master (the default), transactions are externalized in the same order as they are written to the binary log. If disabled, transactions may be committed in parallel. In some cases, disabling this variable might produce a performance increment.

- `binlog_row_image`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--binlog-row-image=image_type</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>binlog_row_image=image_type</code>   |
|                            | <b>Variable Scope</b>                      | Global, Session  |
|                            | <b>Dynamic Variable</b>                    | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                | enumeration  |
|                            | <b>Default</b>                             | <code>full</code>  |
|                            | <b>Valid Values</b>                        | <code>full</code> (Log all columns)  |
|                            |  | <code>minimal</code> (Log only changed columns, and columns needed to identify rows) |
|                            |  | <code>noblob</code> (Log all columns, except for unneeded BLOB and TEXT columns)     |

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

#### Note

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are `NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- `full`: Log all columns in both the before image and the after image.
- `minimal`: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image that are actually changed.
- `noblob`: Log all columns (same as `full`), except for `BLOB` and `TEXT` columns that are not required to identify rows, or that have not changed.

#### Note

This variable is not supported by MySQL Cluster; setting it has no effect on the logging of `NDB` tables.

The default value is `full`.

In MySQL 5.5 and earlier, full row images are always used for both before images and after images. If you need to replicate from a newer master to a slave running MySQL 5.5 or earlier, the master should always use this value.

When using `minimal` or `noblob`, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the master and slave silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is `STATEMENT`. When `binlog_format` is `MIXED`, the setting for `binlog_row_image` is applied to changes that are logged using row-based format, but this setting has no effect on changes logged as statements.

Setting `binlog_row_image` on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- `binlog_rows_query_log_events`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_rows_query_log_events</code> |
|                         | <b>Variable Scope</b>   | Global, Session                           |
|                         | <b>Dynamic Variable</b> | Yes                                       |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                   |
|                         | <b>Default</b>          | <code>FALSE</code>                        |

The `binlog_rows_query_log_events` system variable affects row-based logging only. When enabled, it causes the MySQL Server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes; such

as obtaining the original query issued on the master when it cannot be reconstructed from the row updates.

These events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using mysqlbinlog's `--verbose` option twice, either as `"-vv"` or `"--verbose --verbose"`.

- `binlog_stmt_cache_size`

|  |   |                                     |
|--|---|-------------------------------------|
| <b>Command-Line Format</b>                 | <code>--binlog_stmt_cache_size=#</code> |                                     |
| <b>System Variable</b>                     | <b>Name</b>                             | <code>binlog_stmt_cache_size</code> |
|  | <b>Variable Scope</b>                   | Global                              |
|  | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 32768                               |
|  | <b>Min Value</b>                        | 4096                                |
|  | <b>Max Value</b>                        | 4294967295                          |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 32768                               |
|  | <b>Min Value</b>                        | 4096                                |
|  | <b>Max Value</b>                        | 18446744073709551615                |

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. Separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 6.4.4, “The Binary Log”](#).

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `log_bin`

|                        |                         |                      |
|------------------------|-------------------------|----------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>log_bin</code> |
|                        | <b>Variable Scope</b>   | Global               |
|                        | <b>Dynamic Variable</b> | No                   |

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See [Section 6.4.4, “The Binary Log”](#).

- `log_bin_basename`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>log_bin_basename</code>                  |
|                         | <b>Variable Scope</b>   | Global   |
|                         | <b>Dynamic Variable</b> | No   |
| <b>Permitted Values</b> | <b>Type</b>             | file name                                      |
|                         | <b>Default</b>          | <code>datadir + '/' + hostname + '-bin'</code> |

Holds the name and complete path to the binary log file. Unlike the `log_bin` system variable, `log_bin_basename` reflects the name set with the `--log-bin` server option.

- `log_bin_index`

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>log_bin_index</code> |
|                         | <b>Variable Scope</b>   | Global                     |
|                         | <b>Dynamic Variable</b> | No                         |
| <b>Permitted Values</b> | <b>Type</b>             | file name                  |

The index file for binary log file names.

- `log_bin_use_v1_row_events`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--log-bin-use-v1-row-events[={0 1}]</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>log_bin_use_v1_row_events</code> |
|                            | <b>Variable Scope</b>                            | Global                                 |
|                            | <b>Dynamic Variable</b>                          | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean                                |
|                            | <b>Default</b>                                   | 0                                      |

Shows whether Version 2 binary logging is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of MySQL Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB $EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

#### Note

MySQL Cluster NDB 7.5 uses Version 2 binary log row events by default. You should keep this mind when planning upgrades or downgrades, and for setups using MySQL Cluster Replication.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `log_slave_updates`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--log-slave-updates</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>log_slave_updates</code> |
|                            | <b>Variable Scope</b>            | Global                         |
|                            | <b>Dynamic Variable</b>          | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | <code>FALSE</code>             |

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

- `log_statements_unsafe_for_binlog`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>Introduced</b>       | 5.7.11                  |   |
| <b>System Variable</b>  | <b>Name</b>             | <code>log_statements_unsafe_for_binlog</code> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                       |
|                         | <b>Default</b>          | <code>ON</code>                               |

If error 1592 is encountered, controls whether the generated warnings are added to the error log or not.

- `master_verify_checksum`

|                         |                         |                                     |
|-------------------------|-------------------------|-------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>master_verify_checksum</code> |
|                         | <b>Variable Scope</b>   | Global                              |
|                         | <b>Dynamic Variable</b> | Yes                                 |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                             |
|                         | <b>Default</b>          | <code>OFF</code>                    |

Enabling this variable causes the master to examine checksums when reading from the binary log. `master_verify_checksum` is disabled by default; in this case, the master uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- `max_binlog_cache_size`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Command-Line Format</b> | <code>--max_binlog_cache_size=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>max_binlog_cache_size</code> |
|                            | <b>Variable Scope</b>                  | Global                             |
|                            | <b>Dynamic Variable</b>                | Yes                                |
| <b>Permitted Values</b>    | <b>Type</b>                            | integer                            |

|  |                  |                      |
|--|------------------|----------------------|
|  | <b>Default</b>   | 18446744073709551615 |
|  | <b>Min Value</b> | 4096                 |
|  | <b>Max Value</b> | 18446744073709551615 |

If a transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

`max_binlog_cache_size` sets the size for the transaction cache only; the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

In MySQL 5.7, the visibility to sessions of `max_binlog_cache_size` matches that of the `binlog_cache_size` system variable; in other words, changing its value effects only new sessions that are started after the value is changed.

- `max_binlog_size`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--max_binlog_size=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>max_binlog_size</code> |
|                            | <b>Variable Scope</b>            | Global                       |
|                            | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Default</b>                   | 1073741824                   |
|                            | <b>Min Value</b>                 | 4096                         |
|                            | <b>Max Value</b>                 | 1073741824                   |

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--max_binlog_stmt_cache_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>max_binlog_stmt_cache_size</code> |
|                            | <b>Variable Scope</b>                       | Global                                  |
|                            | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                 | integer                                 |

|  |                  |                      |
|--|------------------|----------------------|
|  | <b>Default</b>   | 18446744073709547520 |
|  | <b>Min Value</b> | 4096                 |
|  | <b>Max Value</b> | 18446744073709547520 |

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `sync_binlog`

|  |                              |                          |
|--|------------------------------|--------------------------|
| <b>Command-Line Format</b>                 | <code>--sync-binlog=#</code> |                          |
| <b>System Variable</b>                     | <b>Name</b>                  | <code>sync_binlog</code> |
|  | <b>Variable Scope</b>        | Global                   |
|  | <b>Dynamic Variable</b>      | Yes                      |
| <b>Permitted Values</b> (>= 5.7.7)         | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 1                        |
|  | <b>Min Value</b>             | 0                        |
|  | <b>Max Value</b>             | 4294967295               |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 0                        |
|  | <b>Min Value</b>             | 0                        |
|  | <b>Max Value</b>             | 4294967295               |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                  | integer                  |
|  | <b>Default</b>               | 0                        |
|  | <b>Min Value</b>             | 0                        |
|  | <b>Max Value</b>             | 4294967295               |

Controls the number of binary log commit groups to collect before synchronizing the binary log to disk. When `sync_binlog=0`, the binary log is never synchronized to disk, and when `sync_binlog` is set to a value greater than 0 this number of binary log commit groups is periodically synchronized to disk. When `sync_binlog=1`, all transactions are synchronized to the binary log before they are committed. Therefore, even in the event of an unexpected restart, any transactions that are missing from the binary log are only in prepared state. This causes the server's automatic recovery routine to roll back those transactions. This guarantees that no transaction is lost from the binary log, and is the safest option. However this can have a negative impact on performance because of an increased number of disk writes. Using a higher value improves performance, but with the increased risk of data loss.

When `sync_binlog=0` or `sync_binlog` is greater than 1, transactions are committed without having been synchronized to disk. Therefore, in the event of a power failure or operating system crash, it is possible that the server has committed some transactions that have not been synchronized to the binary log. Therefore it is impossible for the recovery routine to recover these transactions and they will be lost from the binary log.

Prior to MySQL 5.7.7, the default value of `sync_binlog` was 0, which configures no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. MySQL 5.7.7 and later use a default value of 1, which is the safest choice, but as noted above can impact performance.

### 18.1.6.5 Global Transaction ID Options and Variables

#### Startup Options Used with GTID Replication

#### System Variables Used with GTID Replication

The MySQL Server options and system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs).

For additional information, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

#### Startup Options Used with GTID Replication

The following server startup options are used with GTID-based replication:

- `--enforce-gtid-consistency`

| Command-Line Format                | <code>--enforce-gtid-consistency[=value]</code> |                                       |
|------------------------------------|---|---------------------------------------|
| <b>System Variable</b> (<= 5.7.5)  | <b>Name</b>                                     | <code>enforce_gtid_consistency</code> |
|                                    | <b>Variable Scope</b>                           | Global                                |
|                                    | <b>Dynamic Variable</b>                         | No                                    |
| <b>System Variable</b> (>= 5.7.6)  | <b>Name</b>                                     | <code>enforce_gtid_consistency</code> |
|                                    | <b>Variable Scope</b>                           | Global                                |
|                                    | <b>Dynamic Variable</b>                         | Yes                                   |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>                                     | boolean                               |
|                                    | <b>Default</b>                                  | <code>false</code>                    |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>                                     | enumeration                           |
|                                    | <b>Default</b>                                  | <code>OFF</code>                      |
|                                    | <b>Valid Values</b>                             | <code>OFF</code>                      |
|                                    |   | <code>ON</code>                       |
|                                    |   | <code>WARN</code>                     |

When enabled, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this option to `ON` before enabling GTID based replication.

The values that `--enforce-gtid-consistency` can be configured to are:

- `OFF`: all transactions are allowed to violate GTID consistency.

- **ON**: no transaction is allowed to violate GTID consistency.
- **WARN**: all transactions are allowed to violate GTID consistency, but a warning is generated in this case. Added in MySQL 5.7.6.

Setting `--enforce-gtid-consistency` without a value is an alias for `--enforce-gtid-consistency=ON`. This impacts on the behavior of the variable, see `enforce_gtid_consistency`.

Only statements that can be logged using GTID safe statements can be logged when `enforce-gtid-consistency` is set to **ON**, so the operations listed here cannot be used with this option:

- `CREATE TABLE ... SELECT` statements
- `CREATE TEMPORARY TABLE` or `DROP TEMPORARY TABLE` statements inside transactions
- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all *nontransactional* tables are temporary.

For more information, see [Section 18.1.3.4, “Restrictions on Replication with GTIDs”](#).

- `--executed-gtids-compression-period`

|                            |  |            |
|----------------------------|--|------------|
| <b>Introduced</b>          | 5.7.5  |            |
| <b>Deprecated</b>          | 5.7.6  |            |
| <b>Command-Line Format</b> | <code>--executed-gtids-compression-period=#</code> |            |
| <b>Permitted Values</b>    | <b>Type</b>  | integer    |
|                            | <b>Default</b>                                     | 1000       |
|                            | <b>Min Value</b>                                   | 0          |
|                            | <b>Max Value</b>                                   | 4294967295 |

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `--gtid-mode`

|                                    |                               |                        |
|------------------------------------|-------------------------------|------------------------|
| <b>Command-Line Format</b>         | <code>--gtid-mode=MODE</code> |                        |
| <b>System Variable</b> (<= 5.7.5)  | <b>Name</b>                   | <code>gtid_mode</code> |
|                                    | <b>Variable Scope</b>         | Global                 |
|                                    | <b>Dynamic Variable</b>       | No                     |
| <b>System Variable</b> (>= 5.7.6)  | <b>Name</b>                   | <code>gtid_mode</code> |
|                                    | <b>Variable Scope</b>         | Global                 |
|                                    | <b>Dynamic Variable</b>       | Yes                    |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>                   | enumeration            |
|                                    | <b>Default</b>                | OFF                    |

|                                       |                     |                |
|---------------------------------------|---------------------|----------------|
|                                       | <b>Valid Values</b> | OFF            |
|                                       |                     | UPGRADE_STEP_1 |
|                                       |                     | UPGRADE_STEP_2 |
|                                       |                     | ON             |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>         | enumeration    |
|                                       | <b>Default</b>      | OFF            |
|                                       | <b>Valid Values</b> | OFF            |
|                                       |                     | OFF_PERMISSIVE |
|                                       |                     | ON_PERMISSIVE  |
|                                       |                     | ON             |

This option specifies whether global transaction identifiers (GTIDs) are used to identify transactions. Setting this option to `--gtid-mode=ON` requires that `enforce-gtid-consistency` be set to `ON`. Prior to MySQL 5.7.6 the `gtid_mode` variable which this option controls could only be set at server startup. In MySQL 5.7.6 and later the `gtid_mode` variable is dynamic and enables GTID based replication to be configured online. Before using this feature, see [Section 18.1.5, "Changing Replication Modes on Online Servers"](#).

Prior to MySQL 5.7.5, starting the server with `--gtid-mode=ON` required that the server also be started with the `--log-bin`, `--log-slave-updates`, options. In versions of MySQL 5.7.5 and later this is not a requirement. See [mysql.gtid\\_executed Table](#).

- `--gtid-executed-compression-period`

|                            |   |            |
|----------------------------|---|------------|
| <b>Introduced</b>          | 5.7.6   |            |
| <b>Command-Line Format</b> | <code>--gtid-executed-compression-period=#</code> |            |
| <b>Permitted Values</b>    | <b>Type</b>                                       | integer    |
|                            | <b>Default</b>                                    | 1000       |
|                            | <b>Min Value</b>                                  | 0          |
|                            | <b>Max Value</b>                                  | 4294967295 |

Compress the `mysql.gtid_executed` table each time this many transactions have taken place. A setting of 0 means that this table is not compressed. No compression of the table occurs when binary logging is enabled, therefore the option has no effect unless `log_bin` is `OFF`.

See [mysql.gtid\\_executed Table Compression](#), for more information.

In MySQL version 5.7.5, this variable was added as `executed_gtid_compression_period` and in MySQL version 5.7.6 it was renamed to `gtid_executed_compression_period`.

## System Variables Used with GTID Replication

The following system variables are used with GTID-based replication:

- `binlog_gtid_simple_recovery`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.6                                      |  |
| <b>Command-Line Format</b> | <code>--binlog-gtid-simple-recovery</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>binlog_gtid_simple_recovery</code> |
|                            | <b>Variable Scope</b>                      | Global                                   |

|                                       |                         |                    |
|---------------------------------------|-------------------------|--------------------|
|                                       | <b>Dynamic Variable</b> | No                 |
| <b>Permitted Values</b>               | <b>Type</b>             | boolean            |
|                                       | <b>Default</b>          | <code>FALSE</code> |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>             | boolean            |
|                                       | <b>Default</b>          | <code>TRUE</code>  |

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts. In MySQL version 5.7.5, this variable was added as `simplified_binlog_gtid_recovery` and in MySQL version 5.7.6 it was renamed to `binlog_gtid_simple_recovery`.

When `binlog_gtid_simple_recovery=FALSE`, the method of iterating the binary log files is:

- To initialize `gtid_executed`, binary log files are iterated from the newest file, stopping at the first binary log that has any `Previous_gtid_log_event`. All GTIDs from `Previous_gtid_log_event` and `Gtid_log_events` are read from this binary log file. This GTID set is stored internally and called `gtids_in_binlog`. The value of `gtid_executed` is computed as the union of this set and the GTIDs stored in the `mysql.gtid_executed` table.

This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

- To initialize `gtid_purged`, binary log files are iterated from the oldest to the newest, stopping at the first binary log that contains either a `Previous_gtid_log_event` that is non-empty (that has at least one GTID) or that has at least one `Gtid_log_event`. From this binary log it reads `Previous_gtid_log_event`. This GTID set is subtracted from `gtids_in_binlog` and the result stored in the internal variable `gtids_in_binlog_not_purged`. The value of `gtid_purged` is initialized to the value of `gtid_executed`, minus `gtids_in_binlog_not_purged`.

When `binlog_gtid_simple_recovery=TRUE`, which is the default in MySQL 5.7.7 and later, the server iterates only the oldest and the newest binary log files and the values of `gtid_purged` and `gtid_executed` are computed based only on `Previous_gtid_log_event` or `Gtid_log_event` found in these files. This ensures only two binary log files are iterated during server restart or when binary logs are being purged.

#### Note

If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:

- The newest binary log was generated by MySQL 5.7.5 or older, and `gtid_mode` was `ON` for some binary logs but `OFF` for the newest binary log.
- A `SET GTID_PURGED` statement was issued on a MySQL version prior to 5.7.7, and the binary log that was active at the time of the `SET GTID_PURGED` has not yet been purged.

If an incorrect GTID set is computed in either situation, it will remain incorrect even if the server is later restarted, regardless of the value of this option.

- `enforce_gtid_consistency`

|                                      |   |                                       |
|--------------------------------------|---|---------------------------------------|
| <b>Command-Line Format</b>           | <code>--enforce-gtid-consistency[=value]</code> |                                       |
| <b>System Variable (&lt;= 5.7.5)</b> | <b>Name</b>                                     | <code>enforce_gtid_consistency</code> |

|                                    |                         |  |
|------------------------------------|-------------------------|--|
|                                    | <b>Variable Scope</b>   | Global                                   |
|                                    | <b>Dynamic Variable</b> | No                                       |
| <b>System Variable</b> (>= 5.7.6)  | <b>Name</b>             | <a href="#">enforce_gtid_consistency</a> |
|                                    | <b>Variable Scope</b>   | Global                                   |
|                                    | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>             | boolean                                  |
|                                    | <b>Default</b>          | <a href="#">false</a>                    |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>             | enumeration                              |
|                                    | <b>Default</b>          | <a href="#">OFF</a>                      |
|                                    | <b>Valid Values</b>     | <a href="#">OFF</a>                      |
|                                    |                         | <a href="#">ON</a>                       |
|                                    |                         | <a href="#">WARN</a>                     |

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this variable to [ON](#) before enabling GTID based replication.

The values that [enforce\\_gtid\\_consistency](#) can be configured to are:

- [OFF](#): all transactions are allowed to violate GTID consistency.
- [ON](#): no transaction is allowed to violate GTID consistency.
- [WARN](#): all transactions are allowed to violate GTID consistency, but a warning is generated in this case. Added in MySQL 5.7.6.

For more information on statements that can be logged using GTID based replication, see [--enforce-gtid-consistency](#).

Prior to MySQL 5.7.6, the boolean [enforce-gtid-consistency](#) defaulted to [OFF](#). To maintain compatibility with previous versions, in MySQL 5.7.6 the enumeration defaults to [OFF](#), and setting [--enforce-gtid-consistency](#) without a value is interpreted as setting the value to [ON](#). The variable also has multiple textual aliases for the values: [0=OFF=FALSE](#), [1=ON=TRUE](#), [2=WARN](#). This differs from other enumeration types but maintains compatibility with the boolean type used in previous versions. These changes impact on what is returned by the variable. Using [SELECT @@ENFORCE\\_GTID\\_CONSISTENCY](#), [SHOW VARIABLES LIKE 'ENFORCE\\_GTID\\_CONSISTENCY'](#), and [SELECT \\* FROM INFORMATION\\_SCHEMA.VARIABLES WHERE 'VARIABLE\\_NAME' = 'ENFORCE\\_GTID\\_CONSISTENCY'](#), all return the textual form, not the numeric form. This is an incompatible change, since [@@ENFORCE\\_GTID\\_CONSISTENCY](#) returns the numeric form for booleans but returns the textual form for [SHOW](#) and the Information Schema.

- [executed\\_gtids\\_compression\\_period](#)

|                                   |                       |   |
|-----------------------------------|-----------------------|---|
| <b>Introduced</b>                 | 5.7.5                 |   |
| <b>Deprecated</b>                 | 5.7.6                 |   |
| <b>System Variable</b> (>= 5.7.5) | <b>Name</b>           | <a href="#">executed_gtids_compression_period</a> |
|                                   | <b>Variable Scope</b> | Global  |

|                         |                         |            |
|-------------------------|-------------------------|------------|
|                         | <b>Dynamic Variable</b> | Yes        |
| <b>Permitted Values</b> | <b>Type</b>             | integer    |
|                         | <b>Default</b>          | 1000       |
|                         | <b>Min Value</b>        | 0          |
|                         | <b>Max Value</b>        | 4294967295 |

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `gtid_executed`

|                                      |                         |                            |
|--------------------------------------|-------------------------|----------------------------|
| <b>System Variable</b>               | <b>Name</b>             | <code>gtid_executed</code> |
|                                      | <b>Variable Scope</b>   | Global, Session            |
|                                      | <b>Dynamic Variable</b> | No                         |
| <b>System Variable (&gt;= 5.7.7)</b> | <b>Name</b>             | <code>gtid_executed</code> |
|                                      | <b>Variable Scope</b>   | Global                     |
|                                      | <b>Dynamic Variable</b> | No                         |
| <b>Permitted Values</b>              | <b>Type</b>             | string                     |

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a `SET gtid_purged` statement. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, `@@global.gtid_executed` is initialized. See [binlog\\_gtid\\_simple\\_recovery](#) for more information on how binary logs are iterated to populate `gtid_executed`. GTIDs are then added to the set as transactions are executed, or if any `SET gtid_purged` statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@global.gtid_executed, @@global.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`.

Prior to MySQL 5.7.7, this variable could also be used with session scope, where it contained a representation of the set of transactions that are written to the cache in the current session. The session scope was deprecated in MySQL 5.7.7.

- `gtid_executed_compression_period`

|                                      |             |   |
|--------------------------------------|-------------|---|
| <b>Introduced</b>                    | 5.7.6       |   |
| <b>System Variable (&gt;= 5.7.6)</b> | <b>Name</b> | <code>gtid_executed_compression_period</code> |

|                         |                         |            |
|-------------------------|-------------------------|------------|
| <b>Permitted Values</b> | <b>Variable Scope</b>   | Global     |
|                         | <b>Dynamic Variable</b> | Yes        |
|                         | <b>Type</b>             | integer    |
|                         | <b>Default</b>          | 1000       |
|                         | <b>Min Value</b>        | 0          |
|                         | <b>Max Value</b>        | 4294967295 |

Compress the `mysql.gtid_executed` table each time this many transactions have been processed. A setting of 0 means that this table is not compressed. Since no compression of the table occurs when using the binary log, setting the value of the variable has no effect unless binary logging is disabled.

See [mysql.gtid\\_executed Table Compression](#), for more information.

In MySQL version 5.7.5, this variable was added as `executed_gtid_compression_period` and in MySQL version 5.7.6 it was renamed to `gtid_executed_compression_period`.

- `gtid_mode`

|                                    |                         |                        |
|------------------------------------|-------------------------|------------------------|
| <b>System Variable</b> (<= 5.7.5)  | <b>Name</b>             | <code>gtid_mode</code> |
|                                    | <b>Variable Scope</b>   | Global                 |
|                                    | <b>Dynamic Variable</b> | No                     |
| <b>System Variable</b> (>= 5.7.6)  | <b>Name</b>             | <code>gtid_mode</code> |
|                                    | <b>Variable Scope</b>   | Global                 |
|                                    | <b>Dynamic Variable</b> | Yes                    |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>             | enumeration            |
|                                    | <b>Default</b>          | OFF                    |
|                                    | <b>Valid Values</b>     | OFF                    |
|                                    |                         | UPGRADE_STEP_1         |
|                                    |                         | UPGRADE_STEP_2         |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Valid Values</b>     | ON                     |
|                                    |                         | OFF                    |
|                                    |                         | OFF_PERMISSIVE         |
|                                    | <b>Valid Values</b>     | ON_PERMISSIVE          |
|                                    |                         | ON                     |
|                                    |                         | ON                     |

Controls whether GTID based logging is enabled and what type of transactions the logs can contain. Prior to MySQL 5.7.6 this variable was read-only and was set using the `--gtid-mode` option only. MySQL 5.7.6 enables this variable to be set dynamically. You must have the `SUPER` privilege to set

this variable. `enforce_gtid_consistency` must be true before you can set `gtid_mode=ON`. Before modifying this variable, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

Transactions logged in MySQL 5.7.6 and later can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID transactions have a unique identifier that is used to refer to transactions. The `OFF_PERMISSIVE` and `ON_PERMISSIVE` modes added in MySQL 5.7.6 permit a mix of these transaction types in the topology. The different modes are now:

- `OFF`: Both new and replicated transactions must be anonymous.
- `OFF_PERMISSIVE`: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.
- `ON_PERMISSIVE`: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.
- `ON`: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`.

In MySQL 5.7.6 and later, the values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values. In MySQL 5.7.5 and earlier, the values of `gtid_purged` and `gtid_executed` are not persistent while `gtid_mode=OFF`. Therefore, after changing `gtid_mode` to `OFF`, once all binary logs containing GTIDs are purged, the values of these variables are lost.

- `gtid_next`

|                         |                         |                          |
|-------------------------|-------------------------|--------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>gtid_next</code>   |
|                         | <b>Variable Scope</b>   | Session                  |
|                         | <b>Dynamic Variable</b> | Yes                      |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration              |
|                         | <b>Default</b>          | <code>AUTOMATIC</code>   |
|                         | <b>Valid Values</b>     | <code>AUTOMATIC</code>   |
|                         |                         | <code>ANONYMOUS</code>   |
|                         |                         | <code>UUID:NUMBER</code> |

This variable is used to specify whether and how the next GTID is obtained. `gtid_next` can take any of the following values:

- `AUTOMATIC`: Use the next automatically-generated global transaction ID.
- `ANONYMOUS`: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in `UUID:NUMBER` format.

Exactly which of the above options are valid depends on the setting of `gtid_mode`, see [Section 18.1.5.1, “Replication Mode Concepts”](#) for more information. Setting this variable has no effect if `gtid_mode` is `OFF`.

After this variable has been set to `UUID:NUMBER`, and a transaction has been committed or rolled back, an explicit `SET GTID_NEXT` statement must again be issued before any other statement.

In MySQL 5.7.5 and later, `DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines. Prior to MySQL 5.7.5, when GTIDs were enabled but `gtid_next` was not `AUTOMATIC`, `DROP TABLE` did not work correctly when used with either of these combinations of tables. (Bug #17620053)

In MySQL 5.7.1, you cannot execute any of the statements `CHANGE MASTER TO`, `START SLAVE`, `STOP SLAVE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE SERVER`, `ALTER SERVER`, `DROP SERVER`, `CACHE INDEX`, `LOAD INDEX INTO CACHE`, `FLUSH`, or `RESET` when `gtid_next` is set to any value other than `AUTOMATIC`; in such cases, the statement fails with an error. Such statements are *not* disallowed in MySQL 5.7.2 and later. (Bug #16062608, Bug #16715809, Bug #69045) (Bug #16062608)

- `gtid_owned`

|                         |                         |                         |
|-------------------------|-------------------------|-------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>gtid_owned</code> |
|                         | <b>Variable Scope</b>   | Global, Session         |
|                         | <b>Dynamic Variable</b> | No                      |
| <b>Permitted Values</b> | <b>Type</b>             | string                  |

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

- `gtid_purged`

|                         |                         |                          |
|-------------------------|-------------------------|--------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>gtid_purged</code> |
|                         | <b>Variable Scope</b>   | Global                   |
|                         | <b>Dynamic Variable</b> | Yes                      |
| <b>Permitted Values</b> | <b>Type</b>             | string                   |

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in `gtid_executed`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, the global value of `gtid_purged` is initialized to a set of GTIDs. See `binlog_gtid_simple_recovery` for more information on how binary logs are iterated to populate `gtid_purged`. Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

It is possible to update the value of this variable, but only when `gtid_executed` is the empty string, and therefore `gtid_purged` is the empty string. This can occur either when replication has not been started previously, or when replication was not previously using GTIDs. Prior to MySQL 5.7.6, this variable was settable only when `gtid_mode=ON`. In MySQL 5.7.6 and later, this variable is settable regardless of the value of `gtid_mode`.

If all existing binary logs were generated using MySQL 5.7.6 or later, after issuing a `SET gtid_purged` statement, `binlog_gtid_simple_recovery=TRUE` (the default setting in MySQL

5.7.7 and later) can safely be used. If binary logs from MySQL 5.7.7 or earlier exist, there is a chance that `gtid_purged` may be computed incorrectly. See `binlog_gtid_simple_recovery` for more information. If you are using MySQL 5.7.7 or earlier, after issuing a `SET gtid_purged` statement note down the current binary log file name, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=FALSE` to avoid `gtid_purged` or `gtid_executed` being computed incorrectly.

- `simplified_binlog_gtid_recovery`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.5  |  |
| <b>Deprecated</b>          | 5.7.6  |  |
| <b>Command-Line Format</b> | <code>--simplified-binlog-gtid-recovery</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>simplified_binlog_gtid_recovery</code> |
|                            | <b>Variable Scope</b>                          | Global                                       |
|                            | <b>Dynamic Variable</b>                        | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean                                      |
|                            | <b>Default</b>                                 | <code>FALSE</code>                           |

This option is deprecated and will be removed in a future MySQL release. Use the renamed `binlog_gtid_simple_recovery` to control how MySQL iterates through binary log files after a crash.

## 18.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication and how to pause a slave.

### 18.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: master1
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 60
      Master_Log_File: mysql-bin.000004
      Read_Master_Log_Pos: 931
      Relay_Log_File: slavel-relay-bin.000056
      Relay_Log_Pos: 950
      Relay_Master_Log_File: mysql-bin.000004
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
      Last_Errno: 0
      Last_Error:
```

```

        Skip_Counter: 0
    Exec_Master_Log_Pos: 931
        Relay_Log_Space: 1365
        Until_Condition: None
        Until_Log_File:
        Until_Log_Pos: 0
    Master_SSL_Allowed: No
    Master_SSL_CA_File:
    Master_SSL_CA_Path:
    Master_SSL_Cert:
    Master_SSL_Cipher:
    Master_SSL_Key:
    Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
        Last_IO_Errno: 0
        Last_IO_Error:
        Last_SQL_Errno: 0
        Last_SQL_Error:
    Replicate_Ignore_Server_Ids: 0

```

The key fields from the status report to examine are:

- [Slave\\_IO\\_State](#): The current status of the slave. See [Section 9.14.5, “Replication Slave I/O Thread States”](#), and [Section 9.14.6, “Replication Slave SQL Thread States”](#), for more information.
- [Slave\\_IO\\_Running](#): Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be [Yes](#) unless you have not yet started replication or have explicitly stopped it with [STOP SLAVE](#).
- [Slave\\_SQL\\_Running](#): Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be [Yes](#).
- [Last\\_IO\\_Error](#), [Last\\_SQL\\_Error](#): The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- [Seconds\\_Behind\\_Master](#): The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for [Seconds\\_Behind\\_Master](#) can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, [slave\\_net\\_timeout](#) has not yet elapsed.

It is also possible that transient values for [Seconds\\_Behind\\_Master](#) may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, [Seconds\\_Behind\\_Master](#) displays 0; but when the slave I/O thread is still queuing up a new event, [Seconds\\_Behind\\_Master](#) may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute [SHOW SLAVE STATUS](#) several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- ([Master\\_Log\\_file](#), [Read\\_Master\\_Log\\_Pos](#)): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- ([Relay\\_Master\\_Log\\_File](#), [Exec\\_Master\\_Log\\_Pos](#)): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- ([Relay\\_Log\\_File](#), [Relay\\_Log\\_Pos](#)): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
      Id: 10
     User: root
    Host: slave1:58371
       db: NULL
  Command: Binlog Dump
      Time: 777
     State: Has sent all binlog to slave; waiting for binlog to be updated
      Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
|          10 | slave1 | 3306 |                  0 |          1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

### 18.1.7.2 Pausing Replication on the Slave

You can stop and start replication on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch

up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

## 18.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 18.2.2, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 9.14, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 18.2.4, “Replication Relay and Status Logs”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

### 18.2.1 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the master writes SQL statements to the binary log. Replication of the master to the slave works by executing the SQL statements on the slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard MySQL statement-based binary logging format. Replication capabilities in MySQL version 5.1.4 and earlier used this format exclusively.
- When using row-based logging, the master writes *events* to the binary log that indicate how individual table rows are changed. Replication of the master to the slave works by copying the events representing the changes to the table rows to the slave. This is called *row-based replication* (often abbreviated as *RBR*).

- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called *mixed-format logging*. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 6.4.4.3, “Mixed Binary Logging Format”](#).

Prior to MySQL 5.7.7, statement-based format was the default. In MySQL 5.7.7 and later, row-based format is the default.

**MySQL Cluster.** The default binary logging format in MySQL Cluster NDB 7.5 is `MIXED`. You should note that MySQL Cluster Replication always uses row-based replication, and that the `NDB` storage engine is incompatible with statement-based replication. See [Section 20.6.2, “General Requirements for NDB Cluster Replication”](#), for more information.

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 6.4.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#).

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See [Section 6.4.4.2, “Setting The Binary Log Format”](#).

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 22.7, “Binary Logging of Stored Programs”](#).

### 18.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

#### Advantages of statement-based replication

- Proven technology.

- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

### Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**

Not all statements which modify data (such as `INSERT`, `DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:

- A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 18.4.1.12, “Replication of Invoked Features”](#), for more information.
- `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See [Section 18.4.1.17, “Replication and LIMIT”](#).
- Deterministic UDFs must be applied on the slaves.
- Statements using any of the following functions cannot be replicated properly using statement-based replication:
  - `LOAD_FILE()`
  - `UUID()`, `UUID_SHORT()`
  - `USER()`
  - `FOUND_ROWS()`
  - `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)
  - `GET_LOCK()`
  - `IS_FREE_LOCK()`
  - `IS_USED_LOCK()`
  - `MASTER_POS_WAIT()`
  - `RAND()`
  - `RELEASE_LOCK()`
  - `SLEEP()`
  - `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see [Section 18.4.1.16, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

[Warning] Statement is not safe to log in statement format.

A similar warning is also issued to the client in such cases. The client can display it using [SHOW WARNINGS](#).

- [INSERT ... SELECT](#) requires a greater number of row-level locks than with row-based replication.
- [UPDATE](#) statements that require a table scan (because no index is used in the [WHERE](#) clause) must lock a greater number of rows than with row-based replication.
- For [InnoDB](#): An [INSERT](#) statement that uses [AUTO\\_INCREMENT](#) blocks other nonconflicting [INSERT](#) statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 18.4.1.28, “Slave Errors During Replication”](#).
- Stored functions execute with the same [NOW\( \)](#) value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

### Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

#### Note

Statements that update the information in the [mysql](#) database—such as [GRANT](#), [REVOKE](#) and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as [CREATE TABLE ... SELECT](#), a [CREATE](#) statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - [INSERT ... SELECT](#)
  - [INSERT](#) statements with [AUTO\\_INCREMENT](#)
  - [UPDATE](#) or [DELETE](#) statements with [WHERE](#) clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any [INSERT](#), [UPDATE](#), or [DELETE](#) statement.

### Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an [UPDATE](#) or [DELETE](#) statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement

changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.

- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot see on the slave what statements were received from the master and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

### 18.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.

For additional information, see [Section 18.2.1, “Replication Formats”](#), and [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#).

- **Row-based logging of temporary tables.** As noted in [Section 18.4.1.24, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format. When using mixed format logging, “safe” statements involving temporary tables are logged using statement-based format. For more information, see [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

In MySQL 5.7, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists for a given client session when that session ends. While this means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF EXISTS` option.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to

the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. Depending on the engine used for the slave's copy of the table, this may or may not be effective.

- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 14.7.6.1, “BINLOG Syntax”](#)). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see [Section 5.6.7.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and `slave_exec_mode`.** Using `slave_exec_mode=IDEMPOTENT` is generally only useful with MySQL NDB Cluster replication, for which `IDEMPOTENT` is the default value. (See [Section 20.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”](#)). When `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 6.1.5, “Server System Variables”](#).

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than NDB.

- **Lack of binary log checksums.** RBL does not use checksums, so network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption use SSL for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#), for general information about setting up MySQL with SSL.
- **Filtering based on server ID not supported.** In MySQL 5.7, you can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats. Another method to filter out changes on some slaves is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.
- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).
- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as InnoDB for all tables replicated using the row-based format. Use of `STOP SLAVE` or `STOP SLAVE SQL_THREAD` prior to shutting down the slave MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

### 18.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL Replication, refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see [Section 18.4.1.13, “Replication and Floating-Point Values”](#)).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.
- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. Formerly, if a large number of such statements were executed on the master, this could lead to excessively large error log files. To prevent this, MySQL 5.7 provides a warning suppression mechanism, which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note *The last warning was repeated N times in last S seconds* is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see [Section 18.2.1, “Replication Formats”](#).

#### Statements considered unsafe.

Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.** These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `PASSWORD()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

**Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

For more information, see [Section 18.4.1.16, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See [Section 18.4.1.38, “Replication and Variables”](#). For exceptions, see [Section 6.4.4.3, “Mixed Binary Logging Format”](#).
- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

- **Fulltext plugin.** This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe in MySQL 5.7.1 and later. (Bug #11756280, Bug #48183)
- **Trigger or stored program updates a table having an `AUTO_INCREMENT` column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

For more information, see [Section 18.4.1.1, “Replication and `AUTO\_INCREMENT`”](#).

- **`INSERT ... ON DUPLICATE KEY UPDATE` statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

- **Updates using `LIMIT`.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See [Section 18.4.1.17, “Replication and `LIMIT`”](#).
- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 18.4.1.33, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **`LOAD DATA INFILE` statements.** `LOAD DATA INFILE` is treated as unsafe and when `binlog_format=mixed` the statement is logged in row-based format. When `binlog_format=statement` `LOAD DATA INFILE` does not generate a warning, unlike other unsafe statements.

For additional information, see [Section 18.4.1, “Replication Features and Issues”](#).

## 18.2.2 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's [Binlog Dump](#) thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as [Slave\\_IO\\_running](#) in the output of `SHOW SLAVE STATUS` or as [Slave\\_running](#) in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 9.14.4, “Replication Master Thread States”](#). For slave states, see [Section 9.14.5, “Replication Slave I/O Thread States”](#), and [Section 9.14.6, “Replication Slave SQL Thread States”](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a [Binlog Dump](#) replication thread that services a connected slave. The [State](#) information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no [Binlog Dump](#) threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
  User: system user
  Host:
  db: NULL
Command: Connect
  Time: 11
  State: Waiting for master to send event
  Info: NULL
***** 2. row *****
  Id: 11
  User: system user
```

```

Host:
  db: NULL
Command: Connect
  Time: 11
  State: Has read all relay log; waiting for the slave I/O
        thread to update it
  Info: NULL

```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section A.13, “MySQL 5.7 FAQ: Replication”](#). If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 6.1.5, “Server System Variables”](#).

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See [Section 18.1.7.1, “Checking Replication Status”](#).

## 18.2.3 Replication Channels

MySQL 5.7.6 introduces the concept of a replication channel, which represents the path of transactions flowing from a master to a slave. This section describes how channels can be used in a replication topology, and the impact they have on single-source replication.

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string ("" ). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older slaves function as expected (see [Section 18.2.3.2, “Compatibility with Previous Replication Statements”](#)). Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

A replication channel encompasses the path of transactions transmitted from a master to a slave. In multi-source replication a slave opens multiple channels, one per master, and each channel has its own relay log and applier (SQL) threads. Once transactions are received by a replication channel's receiver (I/O) thread, they are added to the channel's relay log file and passed through to an applier thread. This enables channels to function independently.

A replication channel is also associated with a host name and port. You can assign multiple channels to the same combination of host name and port; in MySQL 5.7, the maximum number of channels that can be added to one slave in a multi-source replication topology is 256. Each replication channel must have a unique (nonempty) name (see [Section 18.2.3.4, “Replication Channel Naming Conventions”](#)). Channels can be configured independently.

### 18.2.3.1 Commands for Operations on a Single Channel

To enable existing MySQL replication statements to act on individual replication channels, MySQL 5.7.6 introduces the `FOR CHANNEL channel_name` option for use with the following replication statements in managing a replication channel independently of other channels:

- `CHANGE MASTER TO`
- `START SLAVE`
- `STOP SLAVE`
- `SHOW RELAYLOG EVENTS`
- `FLUSH RELAY LOGS`

- `SHOW SLAVE STATUS`
- `RESET SLAVE`

Similarly, an additional `channel_name` parameter is introduced for the following functions:

- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`

Beginning with MySQL 5.7.9, the following statements are disallowed for the `group_replication_recovery` channel.

- `START SLAVE`
- `STOP SLAVE`

### 18.2.3.2 Compatibility with Previous Replication Statements

When a replication slave has multiple channels and a `FOR CHANNEL channel_name` option is not specified, a valid statement generally acts on all available channels.

For example, the following statements behave as expected:

- `START SLAVE` starts replication threads for all channels. (In MySQL 5.7.9 and later, this does not include the `group_replication_recovery` channel.)
- `STOP SLAVE` stops replication threads for all the channels. (In MySQL 5.7.9 and later, this does not include the `group_replication_recovery` channel.)
- `SHOW SLAVE STATUS` reports the status for all channels.
- `FLUSH RELAY LOGS` flushes the relay logs for all channels.
- `RESET SLAVE` resets all channels.

#### Warning

Use `RESET SLAVE` with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 `Multiple channels exist on the slave. Please provide channel name as an argument.` is generated. The following statements and functions generate this error when used in a multi-source replication topology and a `FOR CHANNEL channel_name` option is not used to specify which channel to act on:

- `SHOW RELAYLOG EVENTS`
- `CHANGE MASTER TO`
- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`
- `WAIT_FOR_EXECUTED_GTID_SET()`

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

### 18.2.3.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup options *must* be configured correctly to use multi-source replication.

- `--relay-log-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

- `--master-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

The following startup options now affect *all* channels in a replication topology.

- `--log-slave-updates`

All transactions received by the slave (even from multiple sources) are written in the binary log.

- `--relay-log-purge`

When set, each channel purges its own relay log automatically.

- `--slave_transaction_retries`

Applier threads of all channels retry transactions.

- `--skip-slave-start`

No replication threads start on any channels.

- `--slave-skip-errors`

Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are `mysqld` startup options, they are applied on every channel.

- `--max-relay-log-size=size`

Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- `--relay-log-space-limit=size`

Upper limit for the total size of all relay logs combined, for each individual channel. For *N* channels, the combined size of these logs is limited to `relay_log_space_limit * N`.

- `--slave-parallel-workers=value`

Number of slave parallel workers per channel.

- `--slave-checkpoint-group`

Waiting time by an I/O thread for each source.

- `--relay-log-index=filename`

Base name for each channel's relay log index file. See [Section 18.2.3.4, "Replication Channel Naming Conventions"](#).

- `--relay-log=filename`

Denotes the base name of each channel's relay log file. See [Section 18.2.3.4, "Replication Channel Naming Conventions"](#).

- `--slave_net_timeout=N`

This value is set per channel, so that each channel waits for *N* seconds to check for a broken connection.

- `--slave-skip-counter=N`

This value is set per channel, so that each channel skips *N* events from its master.

### 18.2.3.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case insensitive. Because channel names are used in slave tables, the character set used for these is always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- `group_replication_applier`
- `group_replication_recovery`

The name you choose for a replication channel also influences the file names used by a multi-source replication slave. The relay log files and index files for each channel are named `base_name-relay-bin-channel_name.0000x`, where `base_name` is generally a host name (if not specified using `--log-bin`) and `channel_name` is the name of the channel logged to this file.

## 18.2.4 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

This log can be written to the `mysql.slave_master_info` table instead of a file, by starting the slave with `--master-info-repository=TABLE`.

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *relay log info log* holds status information about the execution point within the slave's relay log.

This log can be written to the `mysql.slave_relay_log_info` table instead of a file by starting the slave with `--relay-log-info-repository=TABLE`.

In MySQL 5.7, setting `relay_log_info_repository` and `master_info_repository` to `TABLE` can improve resilience to unexpected halts (crash-safe replication). See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#). When using this configuration, a warning is given if `mysqld` is unable to initialize the replication logging tables, but the slave is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support slave logging tables to one in which they are supported.

#### Important

Do not attempt to update or insert rows in the `slave_master_info` or `slave_relay_log_info` table manually. Doing so can cause undefined behavior, and is not supported.

Execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing, while statements that perform only reads are permitted at any time.

### 18.2.4.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 5.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 18.2.4.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. In MySQL 5.7, either or both of these logs can also be written to tables in the `mysql` database by starting the server with the appropriate option: use `--master-info-repository` to have the

master info log written to the `mysql.slave_master_info` table, and use `--relay-log-info-repository` to have the relay log info log written to the `mysql.slave_relay_log_info` table. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 14.4.2, “SQL Statements for Controlling Slave Servers”](#). Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log file or table should be protected because it contains the password for connecting to the master. See [Section 7.1.2.3, “Passwords and Logging”](#).

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file, the columns in the `mysql.slave_master_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

| Line in <code>master.info</code> File | <code>slave_master_info</code> Table Column | <code>SHOW SLAVE STATUS</code> Column                   | Description   |
|---------------------------------------|---|---|---|
| 1                                     | <code>Number_of_lines</code>                | [None]  | Number of lines in the file, or columns in the table                                      |
| 2                                     | <code>Master_log_name</code>                | <code>Master_Log_File</code>                            | The name of the master binary log currently being read from the master                    |
| 3                                     | <code>Master_log_pos</code>                 | <code>Read_Master_Log_Pos</code>                        | The current position within the master binary log that have been read from the master     |
| 4                                     | <code>Host</code>                           | <code>Master_Host</code>                                | The host name of the master   |
| 5                                     | <code>User_name</code>                      | <code>Master_User</code>                                | The user name used to connect to the master   |
| 6                                     | <code>User_password</code>                  | Password (not shown by <code>SHOW SLAVE STATUS</code> ) | The password used to connect to the master  |
| 7                                     | <code>Port</code>                           | <code>Master_Port</code>                                | The network port used to connect to the master  |
| 8                                     | <code>Connect_retry</code>                  | <code>Connect_Retry</code>                              | The period (in seconds) that the slave will wait before trying to reconnect to the master |
| 9                                     | <code>Enabled_ssl</code>                    | <code>Master_SSL_Allowed</code>                         | Indicates whether   |

| Line in<br>master.info<br>File | slave_master_info<br>Table Column | SHOW SLAVE STATUS Column      | Description  |
|--------------------------------|-----------------------------------|-------------------------------|--|
|                                |                                   |                               | the server supports SSL connections  |
| 10                             | Ssl_ca                            | Master_SSL_CA_File            | The file used for the Certificate Authority (CA) certificate   |
| 11                             | Ssl_capath                        | Master_SSL_CA_Path            | The path to the Certificate Authority (CA) certificates  |
| 12                             | Ssl_cert                          | Master_SSL_Cert               | The name of the SSL certificate file   |
| 13                             | Ssl_cipher                        | Master_SSL_Cipher             | The list of possible ciphers used in the handshake for the SSL connection  |
| 14                             | Ssl_key                           | Master_SSL_Key                | The name of the SSL key file   |
| 15                             | Ssl_verify_server_cert            | Master_SSL_Verify_Server_Cert | Whether to verify the server certificate   |
| 16                             | Heartbeat                         | [None]                        | Interval between replication heartbeats, in seconds  |
| 17                             | Bind                              | Master_Bind                   | Which of the slave's network interfaces should be used for connecting to the master  |
| 18                             | Ignored_server_ids                | Replicate_Ignore_Server_Ids   | The list of server IDs to be ignored. Note that for Ignored_server_ids the list of server IDs is preceded by the total number of server IDs to ignore. |
| 19                             | Uuid                              | Master_UUID                   | The master's unique ID   |
| 20                             | Retry_count                       | Master_Retry_Count            | Maximum number of  |

| Line in<br><code>master.info</code><br>File | <code>slave_master_info</code><br>Table Column | <code>SHOW SLAVE STATUS</code> Column | Description  |
|---|--|---------------------------------------|--|
|   |  |                                       | reconnection attempts permitted                                      |
| 21  | <code>Ssl_crl</code>                           | [None]                                | Path to an ssl certificate revocation list file                      |
| 22  | <code>Ssl_crl_path</code>                      | [None]                                | Path to a directory containing ssl certificate revocation list files |
| 23  | <code>Enabled_auto_position</code>             | <code>Auto_position</code>            | If autopositioning is in use or not                                  |
| 24  | <code>Channel_name</code>                      | <code>Channel_name</code>             | The name of the replication channel                                  |

The slave SQL thread updates the relay log info log. In MySQL 5.7, the `relay-log.info` file includes a line count and a replication delay value. The following table shows the correspondence between the lines in the `relay-log.info` file, the columns in the `mysql.slave_relay_log_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

| Line in<br><code>relay-log.info</code> | <code>slave_relay_log_info</code><br>Table Column | <code>SHOW SLAVE STATUS</code> Column | Description   |
|--|---|---------------------------------------|---|
| 1                                      | <code>Number_of_lines</code>                      | [None]                                | Number of lines in the file or columns in the table   |
| 2                                      | <code>Relay_log_name</code>                       | <code>Relay_Log_File</code>           | The name of the current relay log file  |
| 3                                      | <code>Relay_log_pos</code>                        | <code>Relay_Log_Pos</code>            | The current position within the relay log file; events up to this position have been executed on the slave database |
| 4                                      | <code>Master_log_name</code>                      | <code>Relay_Master_Log_File</code>    | The name of the master binary log file from which the events in the relay log file were read                        |
| 5                                      | <code>Master_log_pos</code>                       | <code>Exec_Master_Log_Pos</code>      | The equivalent position within the master's binary log file of events   |

| Line in relay-log.info | slave_relay_log_info Table Column | SHOW SLAVE STATUS Column | Description  |
|------------------------|-----------------------------------|--------------------------|--|
|                        |                                   |                          | that have already been executed  |
| 6                      | Sql_delay                         | SQL_Delay                | The number of seconds that the slave must lag the master                                       |
| 7                      | Number_of_workers                 | [None]                   | The number of slave worker threads for executing replication events (transactions) in parallel |
| 8                      | Id                                | [None]                   | ID used for internal purposes; currently this is always 1                                      |
| 9                      | Channel_name                      | Channel_name             | The name of the replication channel  |

In older versions of MySQL (prior to MySQL 5.6), the `relay-log.info` file does not include a line count or a delay value (and the `slave_relay_log_info` table is not available).

| Line | Status Column         | Description   |
|------|-----------------------|---|
| 1    | Relay_Log_File        | The name of the current relay log file  |
| 2    | Relay_Log_Pos         | The current position within the relay log file; events up to this position have been executed on the slave database |
| 3    | Relay_Master_Log_File | The name of the master binary log file from which the events in the relay log file were read                        |
| 4    | Exec_Master_Log_Pos   | The equivalent position within the master's binary log file of events that have already been executed               |

#### Note

If you downgrade a slave server to a version older than MySQL 5.6, the older server does not read the `relay-log.info` file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, you can use `SHOW SLAVE STATUS`, or query the `slave_master_info` and `slave_relay_log_info` tables if you are writing the status logs to tables.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

## 18.2.5 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).) In MySQL 5.7.3 and later, the filters governed by these options can also be set dynamically using the `CHANGE REPLICATION FILTER` statement. The rules governing such filters are the same whether they are created on startup using `--replicate-*` options or while the slave server is running by `CHANGE REPLICATION FILTER`.

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 18.2.5.2, “Evaluation of Table-Level Replication Options”](#), for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement `CREATE DATABASE dbx` was not replicated if the slave had been started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. (Bug #46110)

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

### Note

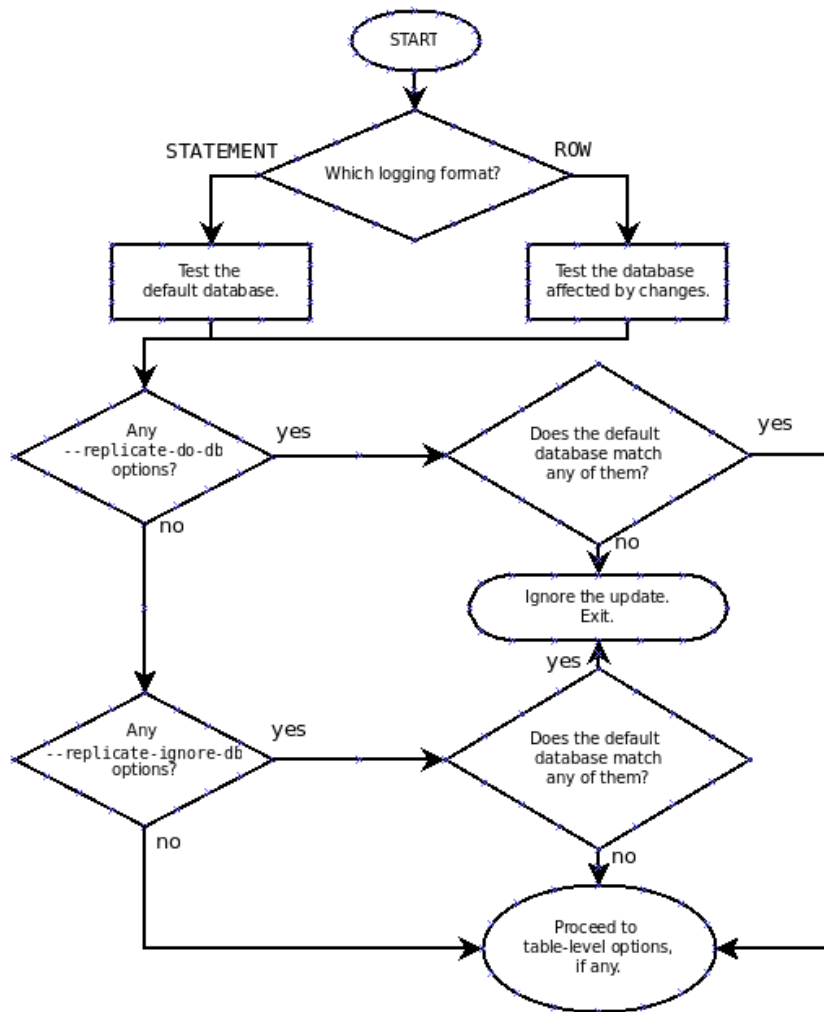

In MySQL 5.7, all replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.

This is a change from previous versions of MySQL. (Bug #51639)

### 18.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Execute the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 2.
2. Are there any `--replicate-ignore-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Ignore the statement and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.

3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 18.2.5.2, “Evaluation of Table-Level Replication Options”](#).

#### Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

#### Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

### 18.2.5.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits.

If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

**Note**

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.

The following steps describe this evaluation in more detail:

1. Are there any table options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?

- **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
- **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
- **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 5.
  - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` options?
- **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 6.
  - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
- **Yes.** Ignore the event and exit.
  - **No.** Execute the event and exit.

### 18.2.5.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

| Condition (Types of Options)                                       | Outcome  |
|--|--|
| No <code>--replicate-*</code> options at all:                      | The slave executes all events that it receives from the master.  |
| <code>--replicate-*-db</code> options, but no table options:       | The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.               |
| <code>--replicate-*-table</code> options, but no database options: | All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options. |

| Condition (Types of Options)                 | Outcome  |
|--|--|
| A combination of database and table options: | The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example. |

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

## 18.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 18.3.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 18.3.3, “Using Replication with Different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 18.3.4, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 18.3.5, “Replicating Different Databases to Different Slaves”](#).

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see [Section 18.3.6, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 18.3.7, “Switching Masters During Failover”](#).

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see [Section 18.3.8, “Setting Up Replication to Use Secure Connections”](#).

### 18.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 18.3.1.1, “Backing Up a Slave Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 18.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 18.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

#### 18.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 5.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 18.1.7.1, “Checking Replication Status”](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 18.3.5, “Replicating Different Databases to Different Slaves”](#).

### 18.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as [InnoDB](#). With [InnoDB](#), these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including [cp](#), [tar](#) or [WinZip](#). For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, the master info and relay log info repositories, and the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the [relay-log.info](#) file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use [CHANGE MASTER TO](#) with the [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating [LOAD DATA INFILE](#) statements, you should also back up any [SQL\\_LOAD\\_\\*](#) files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted [LOAD DATA INFILE](#) operations. The location of this directory is the value of the [--slave-load-tmpdir](#) option. If the server was not started with that option, the directory location is the value of the [tmpdir](#) system variable.

### 18.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the [read\\_only](#) system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.

3. Change the server back to its normal read/write state.

**Note**

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 5.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

**Scenario 1: Backup with a Read-Only Master**

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

**Scenario 2: Backup with a Read-Only Slave**

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

## 18.3.2 Handling an Unexpected Halt of a Replication Slave

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the slave to recover its state before halting. This section describes the impact of an unexpected halt of a slave during replication and how to configure a slave for the best chance of recovery to continue replication.

After an unexpected halt of a slave, upon restart the I/O thread must recover the information about which transactions have been received, and the SQL thread must recover which transactions have been executed already. For information on the slave logs required for recovery, see [Section 18.2.4, “Replication Relay and Status Logs”](#). The information required for recovery was traditionally stored in files, which had the risk of losing synchrony with the master depending at which stage of processing a transaction the slave halted at, or even corruption of the files themselves. In MySQL 5.7 you can instead use tables to store this information. These tables are created using `InnoDB`, and by using this transactional storage engine the information is always recoverable upon restart. To configure MySQL 5.7 to store the replication information in tables, set `relay_log_info_repository` and `master_info_repository` to `TABLE`. The server then stores information required for the recovery of the I/O thread in the `mysql.slave_master_info` table and information required for the recovery of the SQL thread in the `mysql.slave_relay_log_info` table.

Exactly how a replication slave recovers from an unexpected halt is influenced by the chosen method of replication, whether the slave is single-threaded or multi-threaded, the setting of variables such as `relay_log_recovery`, and whether features such as `MASTER_AUTO_POSITION` are being used.

The following table shows the impact of these different factors on how a single-threaded slave recovers from an unexpected halt.

**Table 18.5 Factors Influencing Single-threaded Replication Slave Recovery**

| <code>GTID</code> | <code>MASTER_AUTO_POSITION</code> | <code>relay_log_recovery</code> | <code>relay_log_info_repository</code> | Crash type | Recovery guaranteed | Relay log impact |
|-------------------|-----------------------------------|---------------------------------|--|------------|---------------------|------------------|
| OFF               | Any                               | 1                               | TABLE                                  | Any        | Yes                 | Lost             |
| OFF               | Any                               | 1                               | TABLE                                  | Server     | Yes                 | Lost             |
| OFF               | Any                               | 1                               | Any                                    | OS         | No                  | Lost             |
| OFF               | Any                               | 0                               | TABLE                                  | Server     | Yes                 | Remains          |
| OFF               | Any                               | 0                               | TABLE                                  | OS         | No                  | Remains          |
| ON                | ON                                | Any                             | Any                                    | Any        | Yes                 | Lost             |

| GTID | MASTER_AUTO_POSITION | relay_log_recovery | relay_log_info_repository | Crash type | Recovery guaranteed | Relay log impact |
|------|----------------------|--------------------|---------------------------|------------|---------------------|------------------|
| ON   | OFF                  | 0                  | TABLE                     | Server     | Yes                 | Remains          |
| ON   | OFF                  | 0                  | Any                       | OS         | No                  | Remains          |

As the table shows, when using a single-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=0`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery.
- When using file position based replication, set `relay_log_recovery=1` and `relay_log_info_repository=TABLE`.

#### Note

During recovery the relay log is lost.

The following table shows the impact of these different factors on how a multi-threaded slave recovers from an unexpected halt.

**Table 18.6 Factors Influencing Multi-threaded Replication Slave Recovery**

| GTID | sync_relay_log | MASTER_AUTO_POSITION | relay_log_recovery | relay_log_info_repository | Crash type | Recovery guaranteed | Relay log impact |
|------|----------------|----------------------|--------------------|---------------------------|------------|---------------------|------------------|
| OFF  | 1              | Any                  | 1                  | TABLE                     | Any        | Yes                 | Lost             |
| OFF  | >1             | Any                  | 1                  | TABLE                     | Server     | Yes                 | Lost             |
| OFF  | >1             | Any                  | 1                  | Any                       | OS         | No                  | Lost             |
| OFF  | 1              | Any                  | 0                  | TABLE                     | Server     | Yes                 | Remains          |
| OFF  | 1              | Any                  | 0                  | TABLE                     | OS         | No                  | Remains          |
| ON   | Any            | ON                   | Any                | Any                       | Any        | Yes                 | Lost             |
| ON   | 1              | OFF                  | 0                  | TABLE                     | Server     | Yes                 | Remains          |
| ON   | 1              | OFF                  | 0                  | Any                       | OS         | No                  | Remains          |

As the table shows, when using a multi-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=0`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery.
- When using file position based replication, set `relay_log_recovery=1`, `sync_relay_log=1`, and `relay_log_info_repository=TABLE`.

#### Note

During recovery the relay log is lost.

It is important to note the impact of `sync_relay_log=1`, which requires a write of to the relay log per transaction. Although this setting is the most resilient to an unexpected halt, with at most one unwritten transaction being lost, it also has the potential to greatly increase the load on storage. Without `sync_relay_log=1`, the effect of an unexpected halt depends on how the relay log is handled by the operating system. Also note that when `relay_log_recovery=0`, the next time the slave is started after an unexpected halt the relay log is processed as part of recovery. After this process completes, the relay log is deleted.

An unexpected halt of a multi-threaded replication slave using the recommended file position based replication configuration above may result in a relay log with transaction inconsistencies (gaps in the sequence of transactions) caused by the unexpected halt. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#). In MySQL 5.7.13 and later, if the relay log recovery process encounters such transaction inconsistencies they are filled and the recovery process continues automatically. In MySQL versions prior to MySQL 5.7.13, this process is not automatic and requires starting the server with `relay_log_recovery=0`, starting the slave with `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to fix any transaction inconsistencies and then restarting the slave with `relay_log_recovery=1`.

When you are using multi-source replication and `relay_log_recovery=1`, after restarting due to an unexpected halt all replication channels go through the relay log recovery process. Any inconsistencies found in the relay log due to an unexpected halt of a multi-threaded slave are filled.

### 18.3.3 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 18.3.4, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-federated` option on your slave to disable the `FEDERATED` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `default_storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

### 18.3.4 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 18.1, "Using Replication to Improve Performance During Scale-Out"](#).

**Figure 18.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 18.3.5 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 18.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#).

**Figure 18.2 Using Replication to Replicate Databases to Separate Replication Slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

#### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 18.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

#### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

## 18.3.6 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 18.3, “Using an Additional Replication Host to Improve Performance”](#).

**Figure 18.3 Using an Additional Replication Host to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

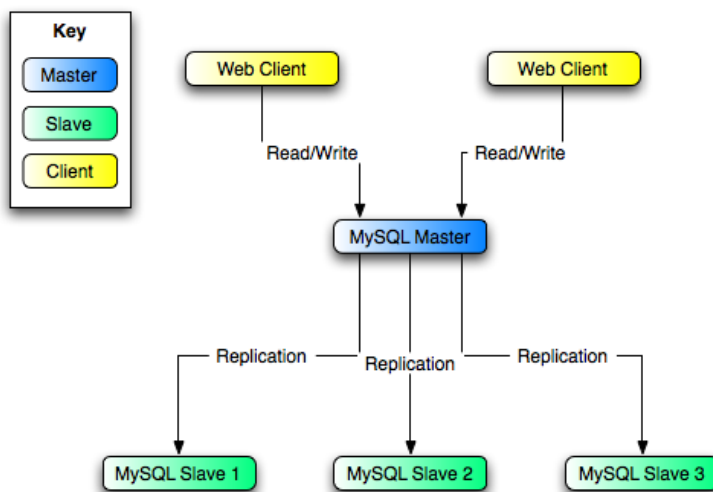

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 18.3.5, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 18.3.3, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

### 18.3.7 Switching Masters During Failover

When using replication with GTIDs (see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#)), you can provide failover between master and slaves in the event of a failure using `mysqlfailover`, which is provided by the MySQL Utilities; see [mysqlfailover — Automatic replication health monitoring and failover](#), for more information. If you are not using GTIDs and therefore cannot use `mysqlfailover`, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change to another master in case of failure. This section discusses some of the issues encountered when setting up failover in this way.

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the `--log-bin` option, and if not using GTIDs then they should also be run without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in [Figure 18.4, “Redundancy Using Replication, Initial Structure”](#).

**Figure 18.4 Redundancy Using Replication, Initial Structure**

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 18.3.4, “Using Replication for Scale-Out”](#).

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

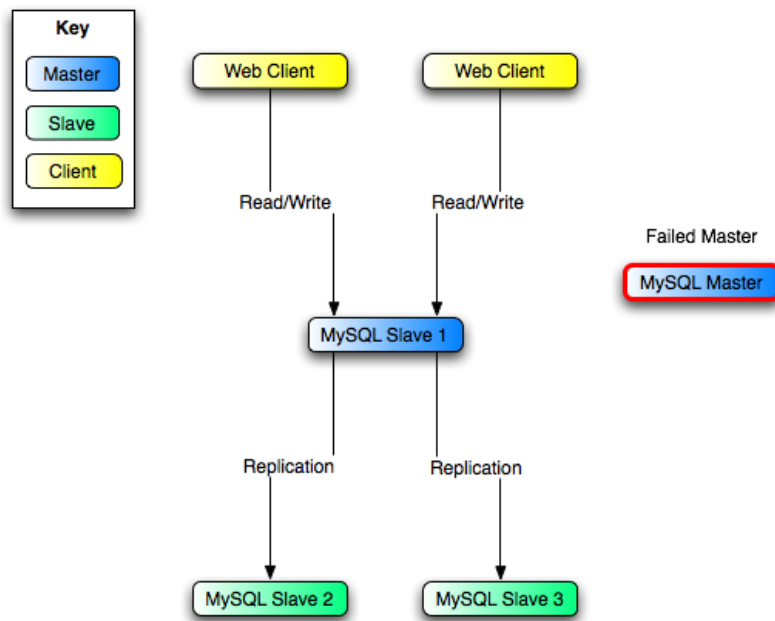

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 18.5, “Redundancy Using Replication, After Master Failure”](#).

**Figure 18.5 Redundancy Using Replication, After Master Failure**

When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

### 18.3.8 Setting Up Replication to Use Secure Connections

To use a secure connection for encrypting the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support secure connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up secure connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for secure connections, see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

To enable secure connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, there are two ways to specify the information required for connecting securely to the master. You can either name the slave certificate and key files in the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement:

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to connect securely:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1;
```

- To specify the certificate and key names using the `CHANGE MASTER TO` statement, append the appropriate `MASTER_SSL_XXX` options:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1,
-> MASTER_SSL_CA = 'ca_file_name',
-> MASTER_SSL_CAPATH = 'ca_directory_name',
-> MASTER_SSL_CERT = 'cert_file_name',
-> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that a secure connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce the use of secure connections during replication, create a user and use the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass'
-> REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%mydomain.com';
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%mydomain.com' REQUIRE SSL;
```

### 18.3.9 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.7 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

As of MySQL 5.7.3, the number of slave acknowledgments the master must receive per transaction before proceeding is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable. The default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement

commits implicitly. With semisynchronous replication, the master blocks for each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.
- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous master receives acknowledgment from the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count`, the transaction is on hold and not committed.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

### 18.3.9.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:

- `rpl_semi_sync_master_enabled`

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- `rpl_semi_sync_master_timeout`

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_xxx` system variables are described at [Section 6.1.5, “Server System Variables”](#).

- Status variables enable semisynchronous replication monitoring. Some examples:

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_xxx` status variables are described at [Section 6.1.7, “Server Status Variables”](#).

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

### 18.3.9.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.
- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see [Section 18.1, “Configuring Replication”](#).
- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See [Section 18.2.3, “Replication Channels”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from <http://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE '%semi%';
+-----+-----+
| PLUGIN_NAME          | PLUGIN_STATUS |
+-----+-----+
| rpl_semi_sync_master  | ACTIVE        |
+-----+-----+
```

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

### 18.3.9.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

## 18.3.10 Delayed Replication

MySQL 5.7 supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time. The default delay is 0 seconds. Use the `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay to *N* seconds:

```
CHANGE MASTER TO MASTER_DELAY = N;
```

An event received from the master is not executed until at least *N* seconds later than its execution on the master. The exceptions are that there is no delay for format description events or log file rotation events, which affect only the internal state of the SQL thread.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the master. A DBA can roll back a delayed slave to the time just before the disaster.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.

- To inspect what the database looked like long ago, without having to reload a backup. For example, if the delay is one week and the DBA needs to see what the database looked like before the last few days' worth of development, the delayed slave can be inspected.

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

`SHOW SLAVE STATUS` has three fields that provide information about the delay:

- `SQL_Delay`: A nonnegative integer indicating the number of seconds that the slave must lag the master.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the slave SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

## 18.4 Replication Notes and Tips

### 18.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.7 (or later), you cannot replicate to a slave that uses MySQL 5.6 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP( )` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.7 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 22.7, “Binary Logging of Stored Programs”](#). For more information about row-based logging and row-based replication, see [Section 6.4.4.1, “Binary Logging Formats”](#), and [Section 18.2.1, “Replication Formats”](#).

For additional information specific to replication and `InnoDB`, see [Section 15.19, “InnoDB and MySQL Replication”](#). For information relating to replication with MySQL Cluster, see [Section 20.6, “NDB Cluster Replication”](#).

#### 18.4.1.1 Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.7.1, `AUTO_INCREMENT` columns in tables on the slave must match the same columns on the master; that is, `AUTO_INCREMENT` columns must be replicated to `AUTO_INCREMENT` columns.
- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. In MySQL 5.7, such statements are marked as unsafe. (Bug #45677)
- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. In MySQL 5.7 and later, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the `InnoDB` storage engine, since an `InnoDB` table with an `AUTO_INCREMENT` column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

### 18.4.1.2 Replication and BLACKHOLE Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. In MySQL 5.7.2 and later, a warning is logged whenever this occurs (Bug #13004581)

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

### 18.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 18.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

### 18.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 18.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.7, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

### 18.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

MySQL 5.7 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. Some older versions of MySQL permitted these statements to do so; this means that, when using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. To prevent this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 5.7. (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement fails following the upgrade unless it is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 14.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL 5.7 ignores the statement completely; nothing is inserted or logged. The handling of such statements in this regard has changed considerably in previous MySQL releases; if you are replicating from a MySQL 5.5.6 or older master to a newer slave, see [Replication of CREATE ... IF NOT EXISTS Statements](#), for more information.

#### 18.4.1.7 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.7, the statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

#### 18.4.1.8 Replication of CURRENT\_USER()

The following statements support use of the `CURRENT_USER( )` function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER( )` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When `CURRENT_USER( )` or `CURRENT_USER` is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. `CURRENT_USER( )` or `CURRENT_USER` is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`.

#### 18.4.1.9 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

#### 18.4.1.10 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

##### Note

Replication between tables which are partitioned differently from one another is not supported. See [Section 18.4.1.19, “Replication and Partitioning”](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

#### Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

(This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  c1 INT,
  c2 INT,
  c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 12.7, "Data Type Default Values"](#).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

### Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, "If the statement run on the master would also execute successfully on the slave, it should also replicate successfully". In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.7.1, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the master and the slave; otherwise, updates could be applied to the wrong table on the slave. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.** Row-based replication in MySQL 5.7 supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a "fit" in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

**Type conversion modes (slave\_type\_conversions variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

| Mode                   | Effect   |
|------------------------|--|
| <code>ALL_LOSSY</code> | <p>In this mode, type conversions that would mean loss of information are permitted.</p> <p>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.</p> |

| Mode                                 | Effect   |
|--------------------------------------|--|
| <code>ALL_NON_LOSSY</code>           | <p>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.</p> <p>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code>, then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code>, or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the slave to stop with an error.</p> |
| <code>ALL_LOSSY,ALL_NON_LOSSY</code> | When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.  |
| <code>ALL_SIGNED</code>              | Treat promoted integer types as signed values (the default behavior).  |
| <code>ALL_UNSIGNED</code>            | Treat promoted integer types as unsigned values.   |
| <code>ALL_SIGNED,ALL_UNSIGNED</code> | Treat promoted integer types as signed if possible, otherwise as unsigned.   |
| [empty]                              | <p>When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.</p> <p>This mode is the default.</p>   |

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. Beginning with MySQL 5.7.2, you can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. (Bug#15831300) `ALL_SIGNED` tells the slave to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $D' \geq D$  and  $(M'-D') \geq (M-D)$  is non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 13.21.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* characters of the string on the slave, where *N* is the width of the target column.

#### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* bytes of the string on the slave, where *N* is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where  $M' > M$ , the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the *M* bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where  $M' < M$ , the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

#### 18.4.1.11 Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 6.1.8, “Server SQL Modes”](#).

#### 18.4.1.12 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CREATE FUNCTION`

- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

#### Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 23.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), and [Section 14.7.5.18, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where *event\_name* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *master\_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
```

```
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

#### 18.4.1.13 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 13.2, “Type Conversion in Expression Evaluation”](#), and [Section B.5.4.8, “Problems with Floating-Point Values”](#).

#### 18.4.1.14 Replication and Fractional Seconds Support

MySQL 5.7 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 12.3.6, “Fractional Seconds in Time Values”](#).

There may be problems replicating from a master server that understands fractional seconds to an older slave (MySQL 5.6.3 and earlier) that does not:

- For `CREATE TABLE` statements containing columns that have an `fsp` (fractional seconds precision) value greater than 0, replication will fail due to parser errors.
- Statements that use temporal data types with an `fsp` value of 0 will work for with statement-based logging but not row-based logging. In the latter case, the data types have binary formats and type codes on the master that differ from those on the slave.
- Some expression results will differ on master and slave. Examples: On the master, the `timestamp` system variable returns a value that includes a microseconds fractional part; on the slave, it returns an integer. On the master, functions that return a result that includes the current time (such as `CURTIME()`, `SYSDATE()`, or `UTC_TIMESTAMP()`) interpret an argument as an `fsp` value and the return value includes a fractional seconds part of that many digits. On the slave, these functions permit an argument but ignore it.

#### 18.4.1.15 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 14.7.6.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue

a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 18.4.1.16 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 18.2.1](#), “Replication Formats”.)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 18.4.1.8](#), “Replication of `CURRENT_USER()`”.) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also [Section 18.4.1.32](#), “Replication and Time Zones”

To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning

is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 18.4.1.32, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;  
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.7.3, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the slave. (Bug #17234370, BUG# 69861)

#### 18.4.1.17 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

#### 18.4.1.18 Replication and LOAD DATA INFILE

In MySQL 5.7, `LOAD DATA INFILE` is considered unsafe (see [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)).

#### 18.4.1.19 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#)).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

#### 18.4.1.20 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 18.4.1.21 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 18.4.1.24, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

### 18.4.1.22 Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

### 18.4.1.23 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.

- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in MySQL Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 18.4.1.38, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See [Section 16.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

#### 18.4.1.24 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever `binlog_format` is `STATEMENT` or `MIXED`, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or

`--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

#### 18.4.1.25 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

#### 18.4.1.26 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 18.4.1.17](#), “Replication and LIMIT”, for a detailed discussion of these.

#### 18.4.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `virtual` on a 5.6 master that is replicating to a 5.7 or higher slave because `VIRTUAL` is a reserved word beginning in MySQL 5.7. Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 10.2](#), “Schema Object Names”.

#### 18.4.1.28 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the

slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

### 18.4.1.29 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see [Section 14.8.3, “HELP Syntax”](#)). These tables can be loaded manually as described at [Section 6.1.10, “Server-Side Help”](#).

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.6 help content into a MySQL 5.6 master server, but not necessarily replicate that content to a MySQL 5.7 slave server for which 5.7 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that the help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from <http://dev.mysql.com/doc/index-other.html>.

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.
2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.

#### Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version (enter the command on one line):

```
mysql --init-command="SET sql_log_bin=0"
mysql < fill_help_tables.sql
```

Use the `--init-command` option on each server, including the slaves, in case a slave also acts as a master to other slaves in your replication topology. The `SET` statement suppresses binary logging. After the command has been run on each server to be upgraded, you are done.

#### Note

As of MySQL 5.7.5, the `fill_help_tables.sql` file includes the `SET` statement to cause the file contents not to replicate. Thus, for 5.7.5 and higher, the command is simpler:

```
mysql mysql < fill_help_tables.sql
```

## Loading Help Table Content With Replication to Slaves

#### Note

As mentioned previously, `fill_help_tables.sql` in MySQL 5.7.5 and up includes a `SET` statement to suppress binary logging of the file contents. If you want to replicate help table contents for MySQL 5.7.5 or later, you must edit `fill_help_tables.sql` to remove the `SET` statement. This should rarely be desirable because help table contents are specific to the version of the server into which they are loaded, which may differ for master and slave.

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

| TABLE_NAME    | COLUMN_NAME | COLUMN_TYPE |
|---------------|-------------|-------------|
| help_category | url         | char(128)   |
| help_topic    | url         | char(128)   |

For tables with the new structure, the statement produces this result:

| TABLE_NAME    | COLUMN_NAME | COLUMN_TYPE |
|---------------|-------------|-------------|
| help_category | url         | text        |
| help_topic    | url         | text        |

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.
- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

```
SET sql_log_bin=0;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
```

Then run this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

#### 18.4.1.30 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 6.1.8, “Server SQL Modes”](#). In particular, see [SQL Mode Changes in MySQL 5.7](#), which describes changes in MySQL 5.7 so that you can assess whether your applications will be affected.

#### 18.4.1.31 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDB TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 6.1.7, “Server Status Variables”](#).

#### 18.4.1.32 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. Set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also [Section 18.4.1.16, “Replication and System Functions”](#).

#### 18.4.1.33 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.**

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. In MySQL 5.7, a statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a “mixed” statement. (In previous MySQL release series, a statement that changed both nontransactional and transactional tables was considered mixed.) Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a transactional table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_trans_update` is `OFF`

For more information, see [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

**Note**

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave

is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

In MySQL 5.7, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases, an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** The `binlog_format` system variable is read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. In MySQL 5.7, this true is even for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

#### 18.4.1.34 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions.* A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps.* A gap is a transaction that has not been (fully) applied, even though some later transaction has been applied. Gaps can only appear when using a multi-threaded slave. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that `log-bin` and `log-slave-updates` are also enabled.
- *Gap-free low-watermark position.* Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have not been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. This can only happen on multi-threaded slaves. Enabling `slave_preserve_commit_order` does *not* prevent gap-free low-watermark positions.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and gap-free low-watermark position inconsistencies:

1. While slave threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded slave, the coordinator thread when using a multi-threaded slave). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multi-threaded slave, workers which have not received an error complete their queues, so it may take time to stop all threads.

5. `STOP SLAVE` when using a multi-threaded slave. After issuing `STOP SLAVE`, the slave waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or gap-free low-watermark positions, unless any of the cases above applies (in other words, before `STOP SLAVE` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP SLAVE` returns successfully.)
6. If the last transaction in the relay log is only half-received and the multi-threaded slave coordinator has started to schedule the transaction to a worker, then `STOP SLAVE` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP SLAVE` when using a single-threaded slave. If the ongoing transaction only updates transactional tables, it is rolled back and `STOP SLAVE` stops immediately. If the ongoing transaction is mixed, `STOP SLAVE` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP SLAVE` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The slave database is in a state that may never have existed on the master.
2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a "low-watermark". In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE MASTER TO` statements for that channel fail with an error, unless the applier threads are running and the `CHANGE MASTER TO` statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-slave`, it does not record the existence of gaps; thus it prints `CHANGE MASTER TO` with `RELAY_LOG_POS` set to the low-watermark position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-slave`).

If a replication channel has a gap-free low-watermark position, cases 2 to 5 above apply, but case 1 does not.

The gap-free low-watermark position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START SLAVE [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before `START SLAVE`, and even if `START SLAVE` is used with `UNTIL` clauses. `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` only applies as many transactions as needed in order to fill in the gaps. If `START SLAVE` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

### Warning

`RESET SLAVE` removes the relay logs and resets the replication position. Thus issuing `RESET SLAVE` on a slave with gaps means the slave loses any information about the gaps, without correcting the gaps.

`slave-preserve-commit-order` ensures that there are no gaps. However, it is still possible that `Exec_master_log_pos` is just a gap-free low-watermark position in scenarios 1 to 4 above. That

is, there may be transactions after `Exec_master_log_pos` which have been applied. Therefore the cases numbered 2 to 5 above (but not case 1) apply, even when `slave-preserve-commit-order` is enabled.

### 18.4.1.35 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 5.7 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), but before MySQL 5.7.2 cannot have multiple triggers that have the same trigger event and action time. MySQL 5.7.2 lifts this limitation and multiple triggers are permitted. This change has replication implications for upgrades and downgrades.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

**Upgrades.** Suppose that you upgrade an old server that does not support multiple triggers to MySQL 5.7.2 or higher. If the new server is a replication master and has old slaves that do not support multiple triggers, an error occurs on those slaves if a trigger is created on the master for a table that already has a trigger with the same trigger event and action time. To avoid this problem, upgrade the slaves first, then upgrade the master.

**Downgrades.** If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions remain in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see [Table Trigger Storage](#).
- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.

3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

#### 18.4.1.36 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 14.1.34, “TRUNCATE TABLE Syntax”](#) governing such tables. (Bug #36763)

#### 18.4.1.37 Replication and User Name Length

The maximum length of MySQL user names was increased from 16 characters to 32 characters in MySQL 5.7.8. Replication of user names longer than 16 characters to a slave that supports only shorter user names will fail. However, this should occur only when replicating from a newer master to an older slave, which is not a recommended configuration.

#### 18.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`

- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 6.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see [Section 18.4.1.23, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 18.2.1, “Replication Formats”](#).

In MySQL 5.7, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

**Important**

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems.

### 18.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.7.1 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

## 18.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.5 to a slave running MySQL 5.6, from a master running MySQL 5.6 to a slave running MySQL 5.7, and so on.

However, you may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, in MySQL 5.5, `CREATE TABLE ... SELECT` statements are permitted to change tables other than the one being created, but are no longer allowed to do so in MySQL 5.6 (see [Section 18.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#)).

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.7.1, MySQL 5.7.2, and MySQL 5.7.4 concurrently, although you could use any two of these releases together.

**Important**

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

This also has significant implications for upgrading replication servers; see [Section 18.4.3, “Upgrading a Replication Setup”](#), for more information.

- For more information about row-based replication, see [Section 18.2.1, “Replication Formats”](#).
- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 18.4.1, “Replication Features and Issues”](#).

### 18.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#)

When you upgrade a master to 5.7 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.7.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.7.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 5.7 format.

Changes affecting operations in strict SQL mode may result in replication failure on an updated slave. For example, as of MySQL 5.7.2, the server restricts insertion of a `DEFAULT` value of 0 for temporal data types in strict mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`). A resulting incompatibility for replication if you use statement-based logging (`binlog_format=STATEMENT`) is that if a slave is upgraded, a nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (`binlog_format=ROW`) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.7.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 5.7 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.7 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.7 format. These too are recognized by the 5.7 slaves.

In other words, when upgrading to MySQL 5.7, the slaves must be MySQL 5.7 before you can upgrade the master to 5.7. Note that downgrading from 5.7 to older versions does not work so simply: You must ensure that any 5.7 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binary log. See [Section 18.2.1, “Replication Formats”](#).

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.7”](#). It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all the requirements for GTID-based replication. For example `server_uuid`, which was added in MySQL 5.6, must exist for GTIDs to function correctly. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#), which contains information about converting existing replication setups to use GTID-based replication.

## 18.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 18.2.2, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.
  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
  - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.

- Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 18.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 18.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;  
mysql> START SLAVE;
```

The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 14.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 18.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the master
  - All binary log files from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

This chapter explains MySQL Group Replication and how to install, configure and monitor groups. MySQL Group Replication is a MySQL Server plugin that enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

The chapter is structured as follows:

- [Section 19.1, “Group Replication Background”](#) provides an introduction to groups and how Group Replication works.

- [Section 19.2, “Getting Started”](#) explains how to configure multiple MySQL Server instances to create a group.
- [Section 19.3, “Monitoring Group Replication”](#) explains how to monitor a group.
- [Section 19.5, “Group Replication Security”](#) explains how to secure a group.
- [Section 19.9, “Group Replication Technical Details”](#) provides in-depth information about how Group Replication works.

## 19.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided group communication protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication systems engine.

### 19.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what

is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

### 19.1.1.1 Primary-Secondary Replication

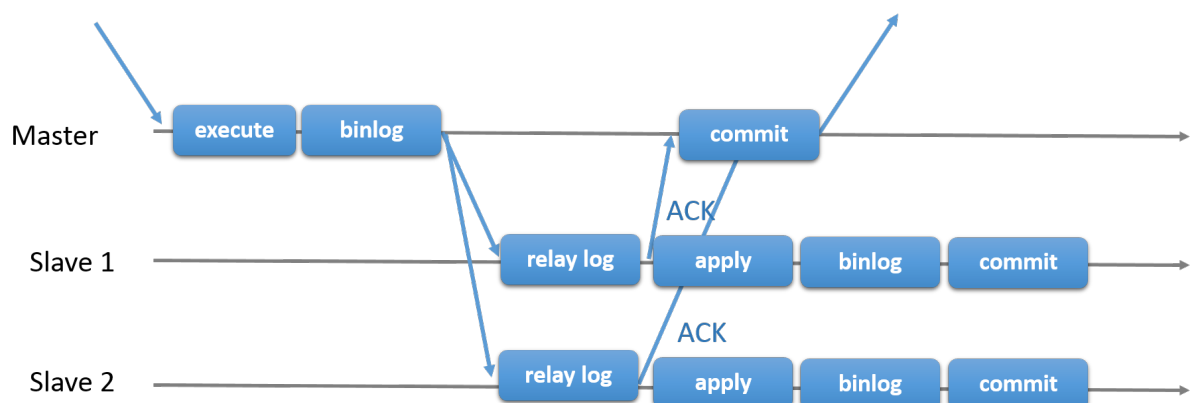

Traditional MySQL Replication provides a simple Primary-Secondary approach to replication. There is a primary (master) and there is one or more secondaries (slaves). The primary executes transactions, commits them and then they are later (thus asynchronously) sent to the secondaries to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

**Figure 19.1 MySQL Asynchronous Replication**

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the Primary waits, at commit time, for the secondary to acknowledge that it has *received* the transaction. Only then does the Primary resume the commit operation.

**Figure 19.2 MySQL Semisynchronous Replication**

In the two pictures above, you can see a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). Blue arrows represent messages exchanged between servers or messages exchanged between servers and the client application.

### 19.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. The replication group is a set of servers that interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-master update everywhere replication protocol. In essence, a replication group is formed by multiple servers and each server in the group may execute transactions independently. But all read-write (RW) transactions commit only after they have been approved by the group. Read-only (RO) transactions need no coordination within the group and thus commit immediately. In other words, for any RW transaction the group needs to decide whether it commits or not, thus the commit operation is not a unilateral decision from the originating server. To be precise, when a transaction is ready to commit at the originating server, the server atomically broadcasts the write values (rows changed) and the correspondent write set (unique identifiers of the rows that were updated). Then a global total order is established for that transaction. Ultimately, this means that all servers receive the same set of transactions in the same order. As a consequence, all servers apply the same set of changes in the same order, therefore they remain consistent within the group.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting the write sets of two different and concurrent transactions, in a process called *certification*. If two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The resolution procedure states that the transaction that was ordered first commits on all servers, whereas the transaction ordered second aborts, and thus is rolled back on the originating server and dropped by the other servers in the group. This is in fact a distributed first commit wins rule.

**Figure 19.3 MySQL Group Replication Protocol**

Finally, Group Replication is a shared-nothing replication scheme where each server has its own entire copy of the data.

The Figure above depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Note that some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

### 19.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state throughout a set of servers. Consequently, even if some of the servers fail, as long it is not all or a majority, the system is still available, and all it could have degraded performance or scalability, it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server fail-over, and the multi-master update everywhere nature ensures that not

even updates are blocked in the event of a single server failure. Therefore MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of a server crash, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue.

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

### 19.1.2.1 Examples of Use Case Scenarios

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to Master-Slave replication* - In certain situations, using a single master server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

## 19.1.3 Group Replication Details

This section presents details about some of the services that Group Replication builds on.

### 19.1.3.1 Failure Detection

There is a failure detection mechanism provided that is able to find and report which servers are silent and as such assumed to be dead. At a high level, the failure detector is a distributed service that provides information about which servers may be dead (suspicions). Later if the group agrees that the suspicions are probably true, then the group decides that a given server has indeed failed. This means that the remaining members in the group take a coordinated decision to exclude a given member.

Suspicions are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised.

If a server gets isolated from the rest of the group, then it suspects that all others have failed. Being unable to secure agreement with the group (as it cannot secure a quorum), its suspicion does not have consequences. When a server is isolated from the group in this way, it is unable to execute any local transactions.

### 19.1.3.2 Group Membership

MySQL Group Replication relies on a group membership service. This is built into the plugin. It defines which servers are online and participating in the group. The list of online servers is often referred to as a *view*. Therefore, every server in the group has a consistent view of which are the members participating actively in the group at a given moment in time.

Servers have to agree not only on transaction commits, but also which is the current view. Therefore, if servers agree that a new server becomes part of the group, then the group itself is reconfigured to

integrate that server in it, triggering a view change. The opposite also happens, if a server leaves the group, voluntarily or not, then the group dynamically rearranges its configuration and a view change is triggered.

Note though that when a member leaves voluntarily, it first initiates a dynamic group reconfiguration. This triggers a procedure, where all members have to agree on the new view without the leaving server. However, if a member leaves involuntarily (for example it has stopped unexpectedly or the network connection is down) then the failure detection mechanism realizes this fact and a reconfiguration of the group is proposed, this one without the failed member. As mentioned this requires agreement from the majority of servers in the group. If the group is not able to reach agreement (for example it partitioned in such a way that there is no majority of servers online), then the system is not be able to dynamically change the configuration and as such, blocks to prevent a split-brain situation. Ultimately, this means that the administrator needs to step in and fix this.

### 19.1.3.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers ( $n$ ) needed to tolerate  $f$  failures is then  $n = 2 \times f + 1$ .

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

| Group Size | Majority | Instant Failures Tolerated |
|------------|----------|----------------------------|
| 1          | 1        | 0                          |
| 2          | 2        | 0                          |
| 3          | 2        | 1                          |
| 4          | 3        | 1                          |
| 5          | 3        | 2                          |
| 6          | 4        | 2                          |
| 7          | 4        | 3                          |

The next Chapter covers technical aspects of Group Replication.

## 19.2 Getting Started

MySQL Group Replication is provided as a plugin to MySQL server, and each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three servers.

### 19.2.1 Deploying Group Replication in Single-Primary Mode

Each of the server instances in a group can run on an independent physical machine, or on the same machine. This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently.

Figure 19.4 Group Architecture

This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

### 19.2.1.1 Deploying Instances for Group Replication

The first step is to deploy three instances of MySQL Server. Group Replication is a built-in MySQL plugin provided with MySQL Server 5.7.17 and later. For more background information on MySQL plugins, see [Section 6.5, “MySQL Server Plugins”](#). Once you have download the MySQL Server package, unpack it and install the binaries. This procedure assumes that MySQL Server was downloaded and unpacked into the current directory, under the directory named `mysql-5.7`. As this tutorial uses one physical machine, each MySQL instance requires a specific data directory, which stores the data for the instance. Create the data directories in a directory named `data` and initialize each one.

```
mkdir data
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s1
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s2
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#).

#### Warning

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see [Section 19.5, “Group Replication Security”](#).

### 19.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see [Section 19.7.2, “Limitations”](#).

#### Group Replication Server Settings

To install and use the Group Replication plugin you must configure the MySQL Server instance correctly. It is recommended to store the configuration in your `my.cnf` file. See [Section 5.2.6, “Using Option Files”](#) for more information. Unless stated otherwise, what follows is the configuration for the first instance in the group, referred to as *s1* in this procedure. The following section shows an example server configuration.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-5.7/

port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

#### Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

#### Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW
```

These settings configure the server to use the unique identifier number 1, to enable global transaction identifiers and to store replication metadata in system tables instead of files. Additionally, it instructs the server to turn on binary logging, use row-based format and disable binary log event checksums. For more details see [Section 19.7.2, “Limitations”](#).

#### Group Replication Settings

At this point the `my.cnf` file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24901"
```

```
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"  
loose-group_replication_bootstrap_group= off
```

**Note**

The `loose-` prefix used for the `group_replication` variables above instructs the server to continue to start if the Group Replication plugin has not been loaded at the time the server is started.

- *Line 1* instructs the server that for each transaction it has to collect the write set and encode it as a hash using the XXHASH64 hashing algorithm.
- *Line 2* tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa".
- *Line 3* instructs the plugin to not start operations automatically when the server starts.
- *Line 4* tells the plugin to use the IP address 127.0.0.1, or localhost, and port 24901 for incoming connections from other members in the group.

**Important**

The server listens on this port for member-to-member connections. This port must not be used for user applications at all, it must be reserved for inter-communication between different members of the group while running Group Replication.

The local address configured by `group_replication_local_address` must be accessible to all group members. For example, if each server instance is on a different machine use the IP and port of the machine, such as 10.0.0.1:33061. The recommended port for `group_replication_local_address` is 33061, but in this tutorial we use three server instances running on one machine, thus ports 24901 to 24903 are used.

- *Line 5* tells the plugin that the following members on those hosts and ports should be contacted in case it needs to join the group. These are seed members, which are used when this member wants to connect to the group. Upon joining the server contacts one of them first (seed) and then it asks the group to reconfigure to allow the joiner to be accepted in the group. Note that this option does *not* need to list all members in the group, but rather a list of servers that should be contacted in case this server wishes to join the group.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. The second server joining asks the one and only member in the group to join and then the group expands. The third server joining can ask any of these two to join, and then the group expands again. Subsequent servers repeat this procedure when joining.

**Warning**

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they may not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It may work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

- *Line 6* instructs the plugin whether to bootstrap the group or not.

### Important

This option must only be used on one server instance at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Disable this option after the first server instance comes online.

Configuration for all servers in the group is quite similar. You need to change the specifics about each server (for example `server_id`, `datadir`, `group_replication_local_address`). This is illustrated later in this tutorial.

### 19.2.1.3 User Credentials

Group Replication relies on the asynchronous replication protocol to be able to run distributed recovery. Therefore you need to set up a replication user to be able to establish direct member-to-member recovery channels.

Start the server:

```
mysql-5.7/bin/mysql --defaults-file=data/s1/s1.cnf
```

Disable binary logging, create a user with the correct permissions and save the credentials for the Group Replication recovery channel.

```
SET SQL_LOG_BIN=0;
CREATE USER repl_user@'%';
GRANT REPLICATION SLAVE ON *.* TO repl_user@%' IDENTIFIED BY 'rpl_pass';
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
```

The final line seen above configures this server to use the given credentials next time it needs to recover its state from another member. Distributed recovery is the first step taken by a server that joins the group. If these credentials are not set properly, the server can not run the recovery protocol, and ultimately can not join the group.

### 19.2.1.4 Launching Group Replication

Assuming that server `s1` has already been configured and started as instructed above, the next step is to install the Group Replication plugin. Connect to the server and issue the following command:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name          | Status | Type          | Library          | License          |
+-----+-----+-----+-----+-----+
| binlog        | ACTIVE | STORAGE ENGINE | NULL             | PROPRIETARY     |
+-----+-----+-----+-----+-----+
| (...)         |       |               |                  |                  |
+-----+-----+-----+-----+-----+
| group_replication | ACTIVE | GROUP REPLICATION | group_replication.so | PROPRIETARY     |
+-----+-----+-----+-----+-----+
```

To start the group, instruct server `s1` to bootstrap the group and then start Group Replication. This bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the bootstrap configuration option was not saved in the configuration file. If it is saved in the configuration file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`.

```
SET GLOBAL group_replication_bootstrap_group=ON;
START GROUP_REPLICATION;
SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_ROLE |
|---------------------------|--------------------------------------|-------------|-------------|-------------|
| group_replication_applier | ce9be252-2b71-11e6-b8f4-00212844f856 | myhost      | 24801       | ONLINE      |

1 row in set (0,00 sec)

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `myhost` listening for client connections on port `24801`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
Query OK, 1 row affected (0,00 sec)

mysql> use test
Database changed
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
Query OK, 0 rows affected (0,00 sec)

mysql> INSERT INTO t1 VALUES (1, 'Luis');
Query OK, 1 row affected (0,01 sec)
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
```

| c1 | c2   |
|----|------|
| 1  | Luis |

1 row in set (0,00 sec)

```
mysql> SHOW BINLOG EVENTS;
```

| Log_name      | Pos | Event_type    | Server_id | End_log_pos | Info                                 |
|---------------|-----|---------------|-----------|-------------|--------------------------------------|
| binlog.000001 | 4   | Format_desc   | 1         | 123         | Server ver: 5.7.17-gr080-log, Binlog |
| binlog.000001 | 123 | Previous_gtid | 1         | 150         |                                      |
| binlog.000001 | 150 | Gtid          | 1         | 211         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-a |
| binlog.000001 | 211 | Query         | 1         | 270         | BEGIN                                |
| binlog.000001 | 270 | View_change   | 1         | 369         | view_id=14724817264259180:1          |
| binlog.000001 | 369 | Query         | 1         | 434         | COMMIT                               |
| binlog.000001 | 434 | Gtid          | 1         | 495         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-a |
| binlog.000001 | 495 | Query         | 1         | 585         | CREATE DATABASE test                 |
| binlog.000001 | 585 | Gtid          | 1         | 646         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-a |
| binlog.000001 | 646 | Query         | 1         | 770         | use `test`; CREATE TABLE t1 (c1 INT  |

```
mysql> SET SQL_LOG_BIN=0;
Query OK, 0 rows affected (0,00 sec)

mysql> CREATE USER rpl_user@'%';
Query OK, 0 rows affected (0,00 sec)

mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%' IDENTIFIED BY 'rpl_pass';
Query OK, 0 rows affected, 1 warning (0,00 sec)

mysql> FLUSH PRIVILEGES;
Query OK, 0 rows affected (0,00 sec)

mysql> SET SQL_LOG_BIN=1;
Query OK, 0 rows affected (0,00 sec)

mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
Query OK, 0 rows affected, 2 warnings (0,01 sec)
```

Install the Group Replication plugin and start the process of joining the server to the group. The following example installs the plugin in the same way as used while deploying server s1.

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
Query OK, 0 rows affected (0,01 sec)
```

Add server s2 to the group.

```
mysql> START GROUP_REPLICATION;
Query OK, 0 rows affected (44,88 sec)
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do *not* issue `SET GLOBAL group_replication_bootstrap_group=ON;` before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two *ONLINE* servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
+-----+-----+-----+-----+-----+
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | myhost | 24801 | ONLINE |
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | myhost | 24802 | ONLINE |
+-----+-----+-----+-----+-----+
2 rows in set (0,00 sec)
```

As server s2 is also marked as *ONLINE*, it must have already caught up with server s1 automatically. Verify that it has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
+-----+
| Database (test) |
+-----+
| test |
+-----+
1 row in set (0,00 sec)

mysql> SELECT * FROM test.t1;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 1 | Luis |
+-----+-----+
1 row in set (0,00 sec)
```

```
mysql> SHOW BINLOG EVENTS;
```

| Log_name      | Pos  | Event_type    | Server_id | End_log_pos | Info                                     |
|---------------|------|---------------|-----------|-------------|--|
| binlog.000001 | 4    | Format_desc   | 2         | 123         | Server ver: 5.7.17-log, Binlog ver: 4    |
| binlog.000001 | 123  | Previous_gtid | 2         | 150         |  |
| binlog.000001 | 150  | Gtid          | 1         | 211         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa' |
| binlog.000001 | 211  | Query         | 1         | 270         | BEGIN                                    |
| binlog.000001 | 270  | View_change   | 1         | 369         | view_id=14724832985483517:1              |
| binlog.000001 | 369  | Query         | 1         | 434         | COMMIT                                   |
| binlog.000001 | 434  | Gtid          | 1         | 495         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa' |
| binlog.000001 | 495  | Query         | 1         | 585         | CREATE DATABASE test                     |
| binlog.000001 | 585  | Gtid          | 1         | 646         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa' |

19 rows in set (0,00 sec)

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. According to the distributed recovery procedure, this means that just after joining the group and immediately before being declared online, server s2 has connected to server s1 automatically and fetched the missing data from it. In other words, it copied transactions from the binary log of s1 that it was missing, up to the point in time that it joined the group.

## Adding a Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

### 1. Create the configuration file

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s3
basedir=<full_path_to_bin>/mysql-5.7/

port=24802
socket=<full_path_to_sock_dir>/s3.sock

#
# Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

#
# Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
```

```
loose-group_replication_local_address= "127.0.0.1:24903"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off
```

## 2. Start the server

```
mysql-5.7/bin/mysqld --defaults-file=data/s3/s3.cnf
```

## 3. Configure the recovery credentials for the group\_replication\_recovery channel.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@%' IDENTIFIED BY 'rpl_pass';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
```

## 4. Install the Group Replication plugin and start it.

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
START GROUP_REPLICATION;
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the [performance\\_schema.replication\\_group\\_members](#) table again confirms this is the case.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_ROLE |
|---------------------------|--------------------------------------|-------------|-------------|-------------|
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | myhost      | 24801       | ONLINE      |
| group_replication_applier | 7eb217ff-6df3-11e6-966c-00212844f856 | myhost      | 24803       | ONLINE      |
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | myhost      | 24802       | ONLINE      |

3 rows in set (0,00 sec)

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has also caught up:

```
mysql> SHOW DATABASES LIKE 'test';
```

| Database (test) |
|-----------------|
| test            |

1 row in set (0,00 sec)

```
mysql> SELECT * FROM test.t1;
```

| c1 | c2   |
|----|------|
| 1  | Luis |

1 row in set (0,00 sec)

```
mysql> SHOW BINLOG EVENTS;
```

| Log_name      | Pos | Event_type    | Server_id | End_log_pos | Info                                 |
|---------------|-----|---------------|-----------|-------------|--------------------------------------|
| binlog.000001 | 4   | Format_desc   | 3         | 123         | Server ver: 5.7.17-log, Binlog ver:  |
| binlog.000001 | 123 | Previous_gtid | 3         | 150         |                                      |
| binlog.000001 | 150 | Gtid          | 1         | 211         | SET @@SESSION.GTID_NEXT= 'aaaaaaaaa- |
| binlog.000001 | 211 | Query         | 1         | 270         | BEGIN                                |
| binlog.000001 | 270 | View_change   | 1         | 369         | view_id=14724832985483517:1          |

|               |      |             |   |      |   |

## 19.3 Monitoring Group Replication

Use the Performance Schema tables to monitor Group Replication, assuming that MySQL has been compiled with the Performance Schema enabled. Group Replication adds the following two new P\_S tables:

- [performance\\_schema.replication\\_group\\_member\\_stats](#)
- [performance\\_schema.replication\\_group\\_members](#)

These existing P\_S replication tables also show information regarding Group Replication.

- [performance\\_schema.replication\\_connection\\_status](#)
- [performance\\_schema.replication\\_applier\\_status](#)

The replication channels created by the Group Replication plugin are named:

- [group\\_replication\\_recovery](#) - This channel is used for the replication changes that are related to the distributed recovery phase.
- [group\\_replication\\_applier](#) - This channel is used for the incoming changes from the group. This is the channel used to apply transactions coming directly from the group.

The following sections describe the information available in each of these tables.

### 19.3.1 Replication\_group\_member\_stats

Each member in a replication group certifies and applies transactions committed by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on. The table [performance\\_schema.replication\\_group\\_member\\_stats](#) provides the following information related to the certification process.

**Table 19.1** [replication\\_group\\_member\\_stats](#)

| Field        | Description   |
|--------------|---|
| Channel_name | The name of the Group Replication channel.  |
| Member_id    | This gives the member server UUID to which we are currently connected to. This has a different value for each |

| Field                              | Description   |
|------------------------------------|---|
|                                    | member in the group. This also serves a key since it is unique to each member.  |
| Count_Transactions_in_queue        | Number of transactions in queue pending conflict detection checks. Once checked for conflicts, and if they pass the check, they are queued to be applied as well. |
| Count_transactions_checked         | Indicates the number of transactions that were checked for conflicts.   |
| Count_conflicts_detected           | Indicates the number of transactions that did not pass the conflict detection check.  |
| Count_transactions_validating      | Indicates the current size of the conflict detection database (against which each transaction is certified).  |
| Transactions_committed_all_members | Indicates those transactions that have been successfully committed on all members of the current view. This is updated at a fixed time interval.                  |
| Last_conflict_free_transaction     | Shows the transaction identifier of the last conflict free transaction checked.   |

These fields are important for monitoring the performance of the members connected in the group. For example, suppose that one of the group's members is delayed and is not able to keep up to date with the other members of the group. In this case you might see a large number of transactions in the queue. Based on this information, you could decide to either remove the member from the group or delay the processing of transactions on the other members of the group thus reducing the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin.

### 19.3.2 Replication\_group\_members

This table is used for monitoring the status of the different servers that are tracked in the current view, or in other words are part of the group and as such are tracked by the membership service.

**Table 19.2 replication\_group\_members**

| Field        | Description   |
|--------------|---|
| Channel_name | The name of the Group Replication channel.  |
| Member_id    | This shows the member server UUID.  |
| Member_host  | The network address of the member.  |
| Member_port  | The MySQL connection port on which member is listening.   |
| Member_state | This gives the status of the members of the group (whether they are ONLINE, RECOVERING, OFFLINE or UNREACHABLE) |

### 19.3.3 Replication\_connection\_status

When connected to a group, some fields in this table show information regarding Group Replication. For instance, the transactions that have been received from the group and queued in the applier queue (the relay log).

**Table 19.3 replication\_connection\_status**

| Field        | Description                                |
|--------------|--|
| Channel_name | The name of the Group Replication channel. |

| Field                    | Description  |
|--------------------------|--|
| Group_name               | Shows the value of the name of the group. It is always a valid UUID.   |
| Source_UUID              | Shows the identifier for the group. It is similar to the group name and it is used as the UUID for all the transactions that are generated during group replication. |
| Service_state            | Shows whether the member is a part of the group or not. The possible values of service state can be {ON, OFF and CONNECTING};  |
| Received_transaction_set | Transactions in this GTID set have been received by this member of the group.  |

### 19.3.4 Replication\_applier\_status

The state of the Group Replication related channels and threads can be observed using the regular replication\_applier\_status table as well. If there are many different worker threads applying transactions, then the worker tables can also be used to monitor what each worker thread is doing.

**Table 19.4 replication\_applier\_status**

| Field                      | Description   |
|----------------------------|---|
| Channel_name               | The name of the Group Replication channel.                                    |
| Service_state              | Shows whether the applier service is ON or OFF.                               |
| Remaining_delay            | Shows whether there is some applier delay configured.                         |
| Count_transactions_retries | The number of retries performed while applying a transaction.                 |
| Received_transaction_set   | Transactions in this GTID set have been received by this member of the group. |

### 19.3.5 Group Replication Server States

The table [replication\\_group\\_members](#) is updated whenever there is a view change, for example when the configuration of the group is dynamically changed. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together.

There are various states that a server instance can be in. If servers are communicating properly, all report the same states for all servers. However, if there is a network partition, or a server leaves the group, then different information may be reported, depending on which server is queried. Note that if the server has left the group then obviously it cannot report updated information about other servers' state. If there is a partition, such that quorum is lost, servers are not able to coordinate between themselves. As a consequence, they cannot guess what the status of different servers is. Therefore, instead of guessing their state they report that some servers are unreachable.

**Table 19.5 Server State**

| Field      | Description  | Group Synchronized |
|------------|--|--------------------|
| ONLINE     | The member is ready to serve as a fully functional group member, meaning that the client can connect and start executing transactions. | Yes                |
| RECOVERING | The member is in the process of becoming an active member of the group and is currently going  | No                 |

| Field       | Description   | Group Synchronized |
|-------------|---|--------------------|
|             | through the recovery process, receiving state information from a donor.   |                    |
| OFFLINE     | The plugin is loaded but the member does not belong to any group.   | No                 |
| ERROR       | The state of the local node. Whenever there is an error on the recovery phase or while applying changes, the server enters this state.  | No                 |
| UNREACHABLE | Whenever the local failure detector suspects that a given server is not reachable, because maybe it has crashed or was disconnected involuntarily, it shows that server's state as 'unreachable'. | No                 |

Note that Group Replication is *not* synchronous, but eventually synchronous. More precisely, transactions are delivered to all group members in the same order, but their execution is not synchronized, meaning that after a transaction is accepted to be committed, each member commits at its own pace.

## 19.4 Group Replication Operations

This section describes the different modes of deploying Group Replication, explains common operations for managing groups and provides information about how to tune your groups .

### 19.4.1 Deploying in Multi-Primary or Single-Primary Mode

Group Replication operates in the following different modes:

- single-primary mode
- multi-primary mode

The default mode is single-primary. It is not possible to have members of the group deployed in different modes, for example one configured in multi-primary mode while another one is in single-primary mode. To switch between modes, the group and not the server, needs to be restarted with a different operating configuration. Regardless of the deployed mode, Group Replication does not handle client-side fail-over, that must be handled by the application itself, a connector or a middleware framework such as a proxy or router.

When deployed in multi-primary mode, statements are checked to ensure they are compatible with the mode. The following checks are made when Group Replication is deployed in multi-master mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

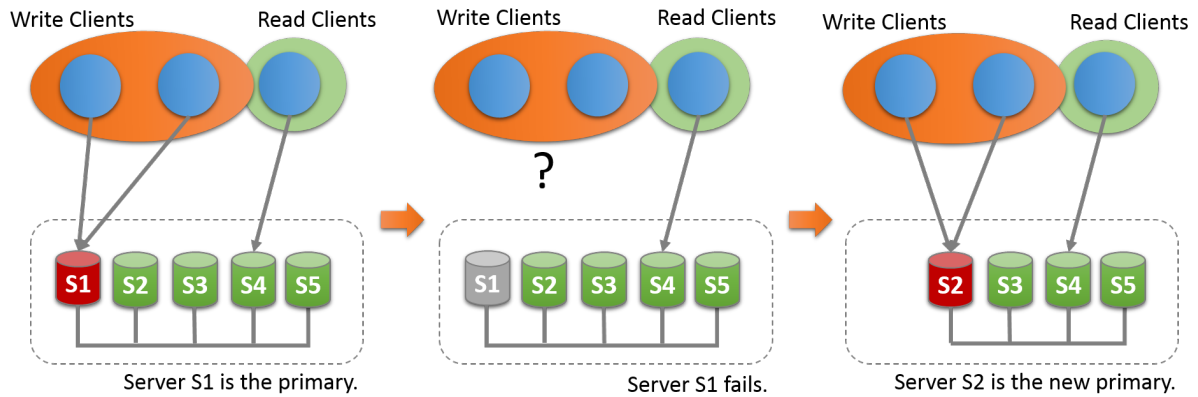

These checks can be deactivated by setting the option `group_replication_enforce_update_everywhere_checks` to `FALSE`. When deploying in single-primary mode, this option *must* be set to `FALSE`.

#### 19.4.1.1 Single-Primary Mode

In this mode the group has a single-primary server that is set to read-write mode. All the other members in the group are set to read-only mode (i.e., super-read-only ). This happens automatically.

The primary is typically the first server to bootstrap the group, all other servers that join automatically learn about the primary server and are set to read only.

**Figure 19.5 New Primary Election**

When in single-primary mode, some of the checks deployed in multi-primary mode are disabled, because the system enforces that only a single writer server is in the group at a time. For example, changes to tables that have cascading foreign keys are allowed, whereas in multi-primary mode are not. Upon primary member failure, an automatic leader election mechanism chooses the next primary member. The next primary is selected by ordering the remaining servers lexicographically (using their UUID) and picking the first member in the list.

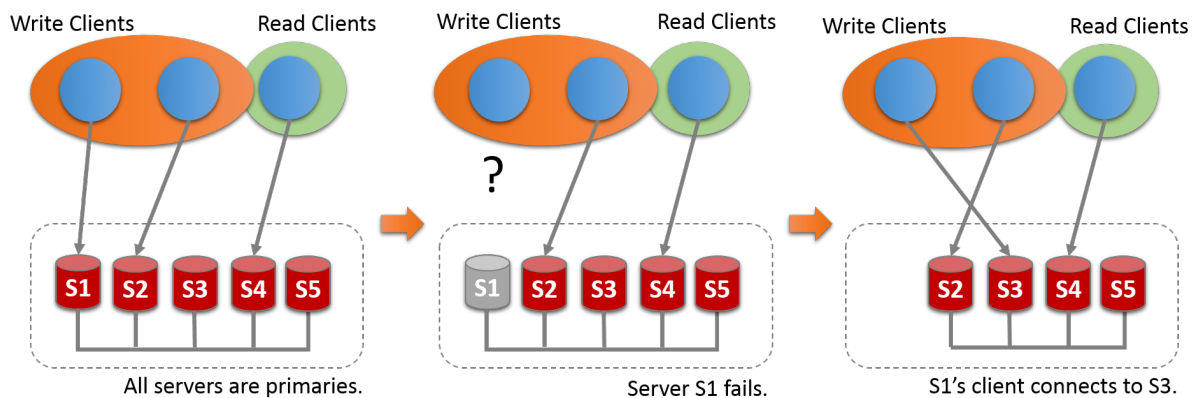

In the event the primary member is removed from the group, then an election is performed and a new primary is chosen from the remaining servers in the group. This election is performed by looking at the new view, ordering the server UUIDs in lexicographical order and by picking the first one. Once a new primary is elected, it is automatically set to read-only and the other secondaries remain as secondaries, and as such, read-only.

It is a good practice to wait for the new primary to apply its replication related relay-log before re-routing the client applications to it.

### 19.4.1.2 Multi-Primary Mode

In multi-primary mode, there is no notion of a single primary. There is no need to engage an election procedure since there is no server playing any special role.

**Figure 19.6 Client Failover**

All servers are set to read-write mode when joining the group.

### 19.4.1.3 Finding the Primary

The following example shows how to find out which server is currently the primary when deployed in single-primary mode.

```
mysql> SELECT VARIABLE_VALUE FROM performance_schema.global_status WHERE VARIABLE_NAME= 'group_replicat
+-----+
| VARIABLE_VALUE |
+-----+
| 69e1a3b8-8397-11e6-8e67-bf68cbc061a4 |
+-----+
1 row in set (0,00 sec)
```

## 19.4.2 Tuning Recovery

Whenever a new member joins a replication group, it connects to a suitable donor and fetches the data that it has missed up until the point it is declared online. This critical component in Group Replication is fault tolerant and configurable. The following section explains how recovery works and how to tune the settings

### Donor Selection

A random donor is selected from the existing online members in the group. This way there is a good chance that the same server is not selected more than once when multiple members enter the group.

If the connection to the selected donor fails, a new connection is automatically attempted to a new candidate donor. Once the connection retry limit is reached the recovery procedure terminates with an error.

#### Note

A donor is picked randomly from the list of online members in the current view.

### Enhanced Automatic Donor Switchover

The other main point of concern in recovery as a whole is to make sure that it copes with failures. Hence, Group Replication provides robust error detection mechanisms. In earlier versions of Group Replication, when reaching out to a donor, recovery could only detect connection errors due to authentication issues or some other problem. The reaction to such problematic scenarios was to switch over to a new donor thus a new connection attempt was made to a different member.

This behavior was extended to also cover other failure scenarios:

- *Purged data scenarios* - If the selected donor contains some purged data that is needed for the recovery process then an error occurs. Recovery detects this error and a new donor is selected.
- *Duplicated data* - If a joiner already contains some data that conflicts with the data coming from the selected donor during recovery then an error occurs. This could be caused by some errant transactions present in the joiner.

One could argue that recovery should fail instead of switching over to another donor, but in heterogeneous groups there is chance that other members share the conflicting transactions and others do not. For that reason, upon error, recovery selects another donor from the group.

- *Other errors* - If any of the recovery threads fail (receiver or applier threads fail) then an error occurs and recovery switches over to a new donor.

#### Note

In case of some persistent failures or even transient failures recovery automatically retries connecting to the same or a new donor.

## Donor Connection Retries

The recovery data transfer relies on the binary log and existing MySQL replication framework, therefore it is possible that some transient errors could cause errors in the receiver or applier threads. In such cases, the donor switch over process has retry functionality, similar to that found in regular replication.

## Number of Attempts

The number of attempts a joiner makes when trying to connect to a donor from the pool of donors is 10. This is configured through the `group_replication_recovery_retry_count` plugin variable. The following command sets the maximum number of attempts to connect to a donor to 10.

```
SET GLOBAL group_replication_recovery_retry_count= 10;
```

Note that this accounts for the global number of attempts that the joiner makes connecting to each one of the suitable donors.

## Sleep Routines

The `group_replication_recovery_reconnect_interval` plugin variable defines how much time the recovery process should sleep between donor connection attempts. This variable has its default set to 60 seconds and you can change this value dynamically. The following command sets the recovery donor connection retry interval to 120 seconds.

```
SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

Note, however, that recovery does not sleep after every donor connection attempt. As the joiner is connecting to different servers and not to the same one over and over again, it can assume that the problem that affects server A maybe not affect server B. As such, recovery suspends only when it has gone through all the possible donors. Once the joiner has tried to connect to all the suitable donors in the group and none remains, the recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` variable.

## 19.4.3 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

### Note

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

### 19.4.3.1 Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 19.7 Losing Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, let's assume that there is a group with these 5 servers in it:

- Server s1 with member identifier `199b2df7-4aaf-11e6-bb16-28b2bd168d07`

- Server s2 with member identifier `199bb88e-4aaf-11e6-babe-28b2bd168d07`
- Server s3 with member identifier `1999b9fb-4aaf-11e6-bb54-28b2bd168d07`
- Server s4 with member identifier `19ab72fc-4aaf-11e6-bb51-28b2bd168d07`
- Server s5 with member identifier `19b33846-4aaf-11e6-ba81-28b2bd168d07`

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
|---------------------------|--------------------------------------|-------------|-------------|---------------|
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   | 13002       | ONLINE        |
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   | 13001       | ONLINE        |
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1   | 13000       | ONLINE        |
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1   | 13003       | ONLINE        |
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1   | 13004       | ONLINE        |

5 rows in set (0,00 sec)

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
|---------------------------|--------------------------------------|-------------|-------------|---------------|
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   | 13002       | UNREACHABLE   |
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   | 13001       | ONLINE        |
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1   | 13000       | ONLINE        |
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1   | 13003       | UNREACHABLE   |
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1   | 13004       | UNREACHABLE   |

5 rows in set (0,00 sec)

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

### 19.4.3.2 Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could choose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

Figure 19.8 Forcing a New Membership

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

#### Warning

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STATE |
|---------------------------|--------------------------------------|-------------|-------------|--------------|
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   | 13002       | UNREACHABLE  |
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   | 13001       | ONLINE       |
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1   | 13000       | ONLINE       |

```
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1 | 13003 | UNREACHABLE |
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1 | 13004 | UNREACHABLE |
+-----+-----+-----+-----+-----+
5 rows in set (0,00 sec)
```

The first thing to do is to check what is the peer address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
+-----+
| @@group_replication_local_address |
+-----+
| 127.0.0.1:10000 |
+-----+
1 row in set (0,00 sec)
```

Then log in to s2 and do the same thing:

```
mysql> SELECT @@group_replication_local_address;
+-----+
| @@group_replication_local_address |
+-----+
| 127.0.0.1:10001 |
+-----+
1 row in set (0,00 sec)
```

Once you know the group communication addresses of s1 (127.0.0.1:10000) and s2 (127.0.0.1:10001), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
Query OK, 0 rows affected (7,13 sec)
```

This unblocks the group by forcing a different configuration. Check [replication\\_group\\_members](#) on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> select * from performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
+-----+-----+-----+-----+-----+
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1 | 13000 | ONLINE |
| group_replication_applier | b60907e7-4ab6-11e6-afb7-28b2bd168d07 | 127.0.0.1 | 13001 | ONLINE |
+-----+-----+-----+-----+-----+
2 rows in set (0,00 sec)
```

And then on s2.

```
mysql> select * from performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
+-----+-----+-----+-----+-----+
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1 | 13000 | ONLINE |
| group_replication_applier | b60907e7-4ab6-11e6-afb7-28b2bd168d07 | 127.0.0.1 | 13001 | ONLINE |
+-----+-----+-----+-----+-----+
2 rows in set (0,00 sec)
```

When forcing a new membership configuration, make sure that whatever servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shutdown and if they are not, shut them down before proceeding.

## 19.5 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using address whitelisting.

### 19.5.1 IP Address Whitelisting

The Group Replication plugin has a configuration option to determine from which hosts an incoming Group Communication connection can be accepted. This option is called `group_replication_ip_whitelist`. If you set this option on a server s1, then when server s2 is establishing a connection to s1 for the purpose of engaging group communication, then s1 first checks the whitelist before accepting the connection from s2. If s2 is in the whitelist, then s1 accepts the connection, otherwise s1 rejects the connection attempt by s2.

#### Note

By default, if not specified explicitly, the whitelist is automatically set to the private network addresses that the server has network interfaces on.

If you do not configure any whitelist, the server automatically sets the whitelist to the private networks that the server has an interface on. This means that a server, even if it has interfaces on public IPs, does not by default allow connections from external hosts.

Whenever the IP whitelist is set to AUTOMATIC, an entry in the error log can be emitted in such case, similar to:

```
2016-07-07T06:40:49.320686Z 4 [Note] Plugin group_replication reported: 'Added automatically \\
IP ranges 10.120.40.237/18,10.178.59.44/22,127.0.0.1/8 to the whitelist'
```

You can improve the security of the group further by manually setting the list of IP addresses permitted for group communication connections to come from. The list can be specified in CIDR notation or as simple IP addresses. A comma must separate each entry. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_whitelist="10.120.40.237/18,10.178.59.44/22,127.0.0.1/8";
mysql> START GROUP_REPLICATION;
```

#### Note

The localhost IP address (127.0.0.1) is always added to the whitelist. If not explicitly, it is implicitly and automatically added.

### 19.5.2 Secure Socket Layer Support (SSL)

MySQL Group Replication supports both OpenSSL and YaSSL builds of MySQL Server.

Group communication connections as well as recovery connections, are secured using SSL. The following sections explain how to configure connections.

#### Configuring SSL for Recovery

Recovery is performed through a regular asynchronous replication connection. Once the donor is selected, the joiner establishes an asynchronous replication connection. This is all automatic.

However, a user that requires an SSL connection must have been created before the joiner connects to the donor. Typically, this is set up at the time one is provisioning a server to join the group.

```
donor> SET SQL_LOG_BIN=0;
donor> CREATE USER 'rec_ssl_user'@'%' REQUIRE SSL;
donor> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%%';
donor> SET SQL_LOG_BIN=1;
```

Assuming that all servers already in the group have a replication user set up to use SSL, you configure the joiner to use those credentials when connecting to the donor. That is done according to the values of the SSL options provided for the Group Replication plugin.

```
new_member> SET GLOBAL group_replication_recovery_use_ssl=1;
new_member> SET GLOBAL group_replication_recovery_ssl_ca= '.../cacert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_cert= '.../client-cert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_key= '.../client-key.pem';
```

And by configuring the recovery channel to use the credentials of the user that requires an SSL connection.

```
new_member> CHANGE MASTER TO MASTER_USER="rec_ssl_user" FOR CHANNEL "group_replication_recovery";
new_member> START GROUP_REPLICATION;
```

## Configuring SSL for Group Communication

Secure sockets can be used to establish communication between members in a group. The configuration for this depends on the server's SSL configuration. As such, if the server has SSL configured, the Group Replication plugin also has SSL configured. For more information on the options for configuring the server SSL, see [Section 7.4.5, “Command Options for Secure Connections”](#). The options which configure Group Replication are shown in the following table.

**Table 19.6 SSL Options**

| Server Configuration | Plugin Configuration Description  |
|----------------------|---|
| ssl_key              | Path of key file. To be used as client and server certificate.          |
| ssl_cert             | Path of certificate file. To be used as client and server certificate.  |
| ssl_ca               | Path of file with SSL CAs that are trusted.                             |
| ssl_capath           | Path of directory containing certificates for SSL CAs that are trusted. |
| ssl_crl              | Path of file containing the certificate revocation lists.               |
| ssl_crlpath          | Path of directory containing revoked certificate lists files.           |
| ssl_cipher           | Permitted ciphers to use while encrypting data over the connection.     |
| tls_version          | Secure communication will use this version and its protocols.           |

These options are MySQL Server configuration options which Group Replication relies on for its configuration. In addition there is the following Group Replication specific option to configure SSL on the plugin itself.

- `group_replication_ssl_mode` - specifies the security state of the connection between Group Replication members.

**Table 19.7 group\_replication\_ssl\_mode configuration values**

| Value                  | Description   |
|------------------------|---|
| <code>DISABLED</code>  | Establish an unencrypted connection ( <i>default</i> ).   |
| <code>REQUIRED</code>  | Establish a secure connection if the server supports secure connections.  |
| <code>VERIFY_CA</code> | Like <code>REQUIRED</code> , but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates. |

| Value           | Description  |
|-----------------|--|
| VERIFY_IDENTITY | Like VERIFY_CA, but additionally verify that the server certificate matches the host to which the connection is attempted. |

The following example shows an example my.cnf file section used to configure SSL on a server and how activate it for Group Replication.

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "/../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "/../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

The only plugin specific configuration option that is listed is `group_replication_ssl_mode`. This option activates the SSL communication between members of the group, by configuring the SSL framework with the `ssl_*` parameters that are provided to the server.

### 19.5.3 Virtual Private Networks (VPN)

There is nothing preventing Group Replication from operating over a virtual private network. At its core, it just relies on an IPv4 socket to establish connections between servers for the purpose of propagating messages between them.

## 19.6 Group Replication System Variables

These are the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with "group\_replication".

#### Important

Although most variables are described as dynamic and can be changed while the server is running, most changes only take effect upon restarting the Group Replication plugin. Variables which can be changed without requiring a restart of the plugin are specifically noted as such in this section.

- `group_replication_group_name`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-group-name=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                       | <code>group_replication_group_name</code> |
|                            | <b>Variable Scope</b>                             | Global                                    |
|                            | <b>Dynamic Variable</b>                           | Yes                                       |
| <b>Permitted Values</b>    | <b>Type</b>                                       | string                                    |

The name of the group.

- `group_replication_start_on_boot`

|                            |  |
|----------------------------|--|
| <b>Introduced</b>          | 5.7.17   |
| <b>Command-Line Format</b> | <code>--group-replication-start-on-boot=value</code> |

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>group_replication_start_on_boot</code> |
|                         | <b>Variable Scope</b>   | Global                                       |
|                         | <b>Dynamic Variable</b> | Yes  |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                      |
|                         | <b>Default</b>          | <code>OFF</code>                             |

Whether the server should start Group Replication or not during server start.

- `group_replication_local_address`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-local-address=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_local_address</code> |
|                            | <b>Variable Scope</b>                                | Global                                       |
|                            | <b>Dynamic Variable</b>                              | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | string                                       |

The local address in host:port formatted string.

- `group_replication_group_seeds`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-group-seeds=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_group_seeds</code> |
|                            | <b>Variable Scope</b>                              | Global                                     |
|                            | <b>Dynamic Variable</b>                            | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | string                                     |

A list of peer addresses, comma separated list such as host1:port1,host2:port2.

- `group_replication_force_members`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-force-members=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_force_members</code> |
|                            | <b>Variable Scope</b>                                | Global                                       |
|                            | <b>Dynamic Variable</b>                              | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | string                                       |

A list of peer addresses, comma separated list such as host1:port1,host2:port2. This option is used to force a new group membership, in which the excluded members do not receive a new view and are blocked. You need to manually kill the excluded servers.

- `group_replication_bootstrap_group`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-bootstrap-group=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_bootstrap_group</code> |
|                            | <b>Variable Scope</b>                                  | Global   |
|                            | <b>Dynamic Variable</b>                                | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean  |
|                            | <b>Default</b>   | OFF  |

Configure this server to bootstrap the group. This option must only be set on one server and only when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to OFF. It should be set to OFF both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- `group_replication_poll_spin_loops`

|  |  |  |
|--|--|--|
| <b>Introduced</b>                          | 5.7.17   |  |
| <b>Command-Line Format</b>                 | <code>--group-replication-poll-spin-loops=value</code> |  |
| <b>System Variable</b>                     | <b>Name</b>  | <code>group_replication_poll_spin_loops</code> |
|  | <b>Variable Scope</b>                                  | Global   |
|  | <b>Dynamic Variable</b>                                | Yes  |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>  | integer  |
|  | <b>Default</b>   | 33060  |
|  | <b>Min Value</b>                                       | 0  |
|  | <b>Max Value</b>                                       | 4294967295                                     |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>  | integer  |
|  | <b>Default</b>   | 33060  |
|  | <b>Min Value</b>                                       | 0  |
|  | <b>Max Value</b>                                       | 18446744073709547520                           |

The number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- `group_replication_recovery_retry_count`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-retry-count=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_recovery_retry_count</code> |
|                            | <b>Variable Scope</b>                                       | Global  |

|                         |                         |          |
|-------------------------|-------------------------|----------|
|                         | <b>Dynamic Variable</b> | Yes      |
| <b>Permitted Values</b> | <b>Type</b>             | integer  |
|                         | <b>Default</b>          | 33060    |
|                         | <b>Min Value</b>        | 0        |
|                         | <b>Max Value</b>        | 31536000 |

The number of times that the member that is joining tries to connect to the available donors before giving up.

- `group_replication_recovery_reconnect_interval`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-reconnect-interval=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_recovery_reconnect_interval</code> |
|                            | <b>Variable Scope</b>  | Global   |
|                            | <b>Dynamic Variable</b>  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | 60   |
|                            | <b>Min Value</b>   | 0  |
|                            | <b>Max Value</b>   | 0  |

The sleep time, in seconds, between reconnection attempts when no donor was found in the group.

- `group_replication_recovery_use_ssl`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-use-ssl=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_recovery_use_ssl</code> |
|                            | <b>Variable Scope</b>                                   | Global  |
|                            | <b>Dynamic Variable</b>                                 | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | boolean   |
|                            | <b>Default</b>  | OFF   |

Whether Group Replication recovery connection should use SSL or not.

- `group_replication_recovery_ssl_ca`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-ca=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_recovery_ssl_ca</code> |

|                         |                         |        |
|-------------------------|-------------------------|--------|
|                         | <b>Variable Scope</b>   | Global |
|                         | <b>Dynamic Variable</b> | Yes    |
| <b>Permitted Values</b> | <b>Type</b>             | string |

The path to a file that contains a list of trusted SSL certificate authorities.

- `group_replication_recovery_ssl_capath`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-capath=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_recovery_ssl_capath</code> |
|                            | <b>Variable Scope</b>                                      | Global   |
|                            | <b>Dynamic Variable</b>                                    | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | string   |

The path to a directory that contains trusted SSL certificate authority certificates.

- `group_replication_recovery_ssl_cert`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-cert=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_recovery_ssl_cert</code> |
|                            | <b>Variable Scope</b>                                    | Global   |
|                            | <b>Dynamic Variable</b>                                  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | string   |

The name of the SSL certificate file to use for establishing a secure connection.

- `group_replication_recovery_ssl_key`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-key=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_recovery_ssl_key</code> |
|                            | <b>Variable Scope</b>                                   | Global  |
|                            | <b>Dynamic Variable</b>                                 | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | string  |

The name of the SSL key file to use for establishing a secure connection.

- `group_replication_recovery_ssl_cipher`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-cipher=value</code> |  |

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">group_replication_recovery_ssl_cipher</a> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | string  |

A list of permissible ciphers to use for SSL encryption.

- [group\\_replication\\_recovery\\_ssl\\_crl](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.17  |  |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-crl=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">group_replication_recovery_ssl_crl</a> |
|                            | <b>Variable Scope</b>                                   | Global   |
|                            | <b>Dynamic Variable</b>                                 | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>   | string   |

The path to a directory that contains files containing certificate revocation lists.

- [group\\_replication\\_recovery\\_ssl\\_crlpath](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.17  |  |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-crlpath=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">group_replication_recovery_ssl_crlpath</a> |
|                            | <b>Variable Scope</b>                                       | Global   |
|                            | <b>Dynamic Variable</b>                                     | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>   | string   |

The path to a directory that contains files containing certificate revocation lists.

- [group\\_replication\\_recovery\\_ssl\\_verify\\_server\\_cert](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.17   |   |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-ssl-verify-server-cert=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>  | <a href="#">group_replication_recovery_ssl_verify_server_cert</a> |
|                            | <b>Variable Scope</b>  | Global  |
|                            | <b>Dynamic Variable</b>  | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean   |
|                            | <b>Default</b>   | <code>OFF</code>  |

Make the recovery process check the server's Common Name value in the donor sent certificate.

- [group\\_replication\\_recovery\\_complete\\_at](#)

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-recovery-complete-at=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_recovery_complete_at</code> |
|                            | <b>Variable Scope</b>                                       | Global  |
|                            | <b>Dynamic Variable</b>                                     | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | enumeration   |
|                            | <b>Default</b>  | OFF   |
|                            | <b>Valid Values</b>   | TRANSACTIONS_CERTIFIED<br>TRANSACTIONS_APPLIED      |

Recovery policies when handling cached transactions after state transfer. This option specifies whether a member is marked online after it has received all transactions that it missed before it joined the group (TRANSACTIONS\_CERTIFIED) or after it has received and applied them (TRANSACTIONS\_APPLIED).

- `group_replication_components_stop_timeout`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-components-stop-timeout=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_components_stop_timeout</code> |
|                            | <b>Variable Scope</b>  | Global   |
|                            | <b>Dynamic Variable</b>  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |

Timeout, in seconds, that the plugin waits for each of the components when shutting down.

- `group_replication_allow_local_lower_version_join`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-allow-local-lower-version-join=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_allow_local_lower_version_join</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>   | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | boolean   |
|                            | <b>Default</b>  | OFF   |

Allow the current server to join the group even if it has a lower plugin version than the group.

- `group_replication_allow_local_disjoint_gtids_join`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-allow-local-disjoint-gtids-join=value</code> |  |

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>group_replication_allow_local_disjoint_gtids_join</code> |
|                         | <b>Variable Scope</b>   | Global   |
|                         | <b>Dynamic Variable</b> | Yes  |
| <b>Permitted Values</b> | <b>Type</b>             | boolean  |
|                         | <b>Default</b>          | <code>OFF</code>   |

Allow the current server to join the group even if it has transactions not present in the group.

#### Warning

Use caution when enabling this option as incorrect usage could lead to inconsistencies in the group.

- `group_replication_auto_increment_increment`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-auto-increment-increment=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_auto_increment_increment</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>   | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 7   |
|                            | <b>Min Value</b>  | 1   |
|                            | <b>Max Value</b>  | 65535   |

Determines the interval between successive column values for transactions that execute on this server instance.

- `group_replication_compression_threshold`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-compression-threshold=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_compression_threshold</code> |
|                            | <b>Variable Scope</b>  | Global   |
|                            | <b>Dynamic Variable</b>                                      | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | 1000000  |
|                            | <b>Min Value</b>   | 0  |
|                            | <b>Max Value</b>   | 4294967296   |

The value in bytes above which (lz4) compression is enforced. When set to zero, deactivates compression.

- `group_replication_gtid_assignment_block_size`

|  |   |   |
|--|---|---|
| <b>Introduced</b>                          | 5.7.17  |   |
| <b>Command-Line Format</b>                 | <code>--group-replication-gtid-assignment-block-size=value</code> |   |
| <b>System Variable</b>                     | <b>Name</b>   | <code>group_replication_gtid_assignment_block_size</code> |
|  | <b>Variable Scope</b>   | Global  |
|  | <b>Dynamic Variable</b>   | Yes   |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>   | integer   |
|  | <b>Default</b>  | 1000000   |
|  | <b>Min Value</b>  | 1   |
|  | <b>Max Value</b>  | 4294967295  |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>   | integer   |
|  | <b>Default</b>  | 1000000   |
|  | <b>Min Value</b>  | 1   |
|  | <b>Max Value</b>  | 18446744073709547520                                      |

The number of consecutive GTIDs that are reserved for each member. Each member consumes its blocks and reserve more when needed.

- `group_replication_ssl_mode`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-ssl-mode=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>group_replication_ssl_mode</code> |
|                            | <b>Variable Scope</b>                           | Global                                  |
|                            | <b>Dynamic Variable</b>                         | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                     | enumeration                             |
|                            | <b>Default</b>                                  | DISABLED                                |
|                            | <b>Valid Values</b>                             | DISABLED                                |
|                            |   | REQUIRED                                |
|                            |   | VERIFY_CA                               |
|                            |   | VERIFY_IDENTITY                         |

Specifies the security state of the connection between Group Replication members.

- `group_replication_single_primary_mode`

|                   |        |
|-------------------|--------|
| <b>Introduced</b> | 5.7.17 |
|-------------------|--------|

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--group-replication-single-primary-mode=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_single_primary_mode</code> |
|                            | <b>Variable Scope</b>                                      | Global   |
|                            | <b>Dynamic Variable</b>                                    | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean  |
|                            | <b>Default</b>   | ON   |

Instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

- `group_replication_enforce_update_everywhere_checks`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-enforce-update-everywhere-checks=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_enforce_update_everywhere_checks</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>   | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | boolean   |
|                            | <b>Default</b>  | OFF   |

Enable/Disable strict consistency checks for multi-master update everywhere.

- `group_replication_flow_control_mode`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--group-replication-flow-control-mode=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>group_replication_flow_control_mode</code> |
|                            | <b>Variable Scope</b>                                    | Global   |
|                            | <b>Dynamic Variable</b>                                  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | enumeration                                      |
|                            | <b>Default</b>   | QUOTA  |
|                            | <b>Valid Values</b>                                      | DISABLED   |
|                            |  | QUOTA  |

Specifies the mode used for flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_certifier_threshold`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-flow-control-certifier-threshold=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_flow_control_certifier_threshold</code> |

|                         |                         |            |
|-------------------------|-------------------------|------------|
| <b>Permitted Values</b> | <b>Variable Scope</b>   | Global     |
|                         | <b>Dynamic Variable</b> | Yes        |
|                         | <b>Type</b>             | integer    |
|                         | <b>Default</b>          | 25000      |
|                         | <b>Min Value</b>        | 0          |
|                         | <b>Max Value</b>        | 2147483648 |

Specifies the number of waiting transactions in the certifier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_applier_threshold`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.17  |   |
| <b>Command-Line Format</b> | <code>--group-replication-flow-control-applier-threshold=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_flow_control_applier_threshold</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>   | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 25000   |
|                            | <b>Min Value</b>  | 0   |
|                            | <b>Max Value</b>  | 2147483648  |

Specifies the number of waiting transactions in the applier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_ip_whitelist`

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.17  |  |
| <b>Command-Line Format</b> | <code>--group-replication-ip-whitelist=value</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <code>group_replication_recovery_ip_whitelist</code> |
|                            | <b>Variable Scope</b>                               | Global   |
|                            | <b>Dynamic Variable</b>                             | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>   | string   |
|                            | <b>Default</b>                                      | <code>AUTOMATIC</code>                               |

Specifies which hosts are permitted to connect to the group. By default set to `AUTOMATIC`, which permits connections from private subnetworks active on the host. Active interfaces on the host are scanned and those with addresses on private subnetworks are automatically added to the permitted list. Alternatively you can specify the permitted hosts using a comma separated list of IPv4 addresses or subnet CIDR notation. For example `192.168.1.0/24,10.0.0.1`.

**Note**

Address 127.0.0.1 is always permitted to connect, even when not specified using `group_replication_ip_whitelist`.

## 19.7 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

### 19.7.1 Group Replication Requirements

Server instances that you want to use for Group Replication must satisfy the following requirements.

#### Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the `InnoDB` transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, `InnoDB` provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication.
- **Primary Keys.** Every table that is to be replicated by the group must have an explicit primary key defined. Primary keys play an extremely important role in determining which transactions conflict by identifying exactly which rows each transaction has modified.
- **IPv4 Network.** The group communication engine used by MySQL Group Replication only supports IPv4. Therefore, Group Replication requires an IPv4 network infrastructure.
- **Network Performance.** Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other, and is impacted by both network latency as well as network bandwidth.

#### Server Instance Configuration

The following options must be configured on server instances that are members of a group.

- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be turned on for it to operate. See [Section 6.4.4, “The Binary Log”](#).
- **Slave Updates Logged.** Set `--log-slave-updates`. Servers need to log binary logs that are applied through the replication applier. Servers in the group need to log all transactions that they receive and apply from the group. This is required because recovery is conducted by relying on binary logs from participants in the group. Therefore, copies of each transaction need to exist on every server, even for those transactions that were not initiated on the server itself.
- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. See [Section 18.2.1, “Replication Formats”](#).
- **Global Transaction Identifiers On.** Set `--gtid-mode=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

- **Replication Information Repositories.** Set `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE`. The replication applier needs to have the master information and relay log metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin has consistent recoverability and transactional management of the replication metadata. See [Section 18.2.4.2, “Slave Status Logs”](#).
- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts.

## 19.7.2 Limitations

The following known limitations exist for Group Replication.

- **Replication Event Checksums.** Due to a design limitation of replication event checksums, Group Replication cannot currently make use of them. Therefore set `--binlog-checksum=NONE`.
- **Gap Locks.** The certification process does not take into account [gap locks](#), as information about gap locks is not available outside of [InnoDB](#). See [Gap Locks](#) for more information.

### Note

Unless you rely on [REPEATABLE READ](#) semantics in your applications, we recommend using the [READ COMMITTED](#) isolation level with Group Replication. InnoDB does not use gap locks in [READ COMMITTED](#), which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see [Section 14.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#)) or named locks (see [GET\\_LOCK\(\)](#)).
- **Savepoints Not Supported.** Transaction savepoints are not supported.
- **SERIALIZABLE Isolation Level.** [SERIALIZABLE](#) isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to [SERIALIZABLE](#) configures Group Replication to refuse to commit the transaction.
- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.
- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined [CASCADING foreign key constraints](#). This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

## 19.8 Frequently Asked Questions

This section provides answers to frequently asked questions.

### What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused.

### How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group.

### What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

### How do I set credentials for the recovery procedure?

You pre-configure the Group Replication recovery channel credentials using the [CHANGE MASTER TO](#) statement.

### Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

### Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

## **Can I deploy Group Replication across wide-area networks?**

This is not supported.

Fast networks with good bandwidth are a requirement for optimal performance. To improve tolerance to the effects of narrow bandwidth, you can turn ON compression for example. However, if the network drops packets, leading to retransmissions and higher end-to-end latency, then throughput and latency are negatively affected.

## **Do nodes automatically rejoin a group in case of temporary connectivity problems?**

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Once a server is removed from the group, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

## **When is a member excluded from a group?**

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

## **What happens when one node is significantly lagging behind?**

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

## **Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?**

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

## **19.9 Group Replication Technical Details**

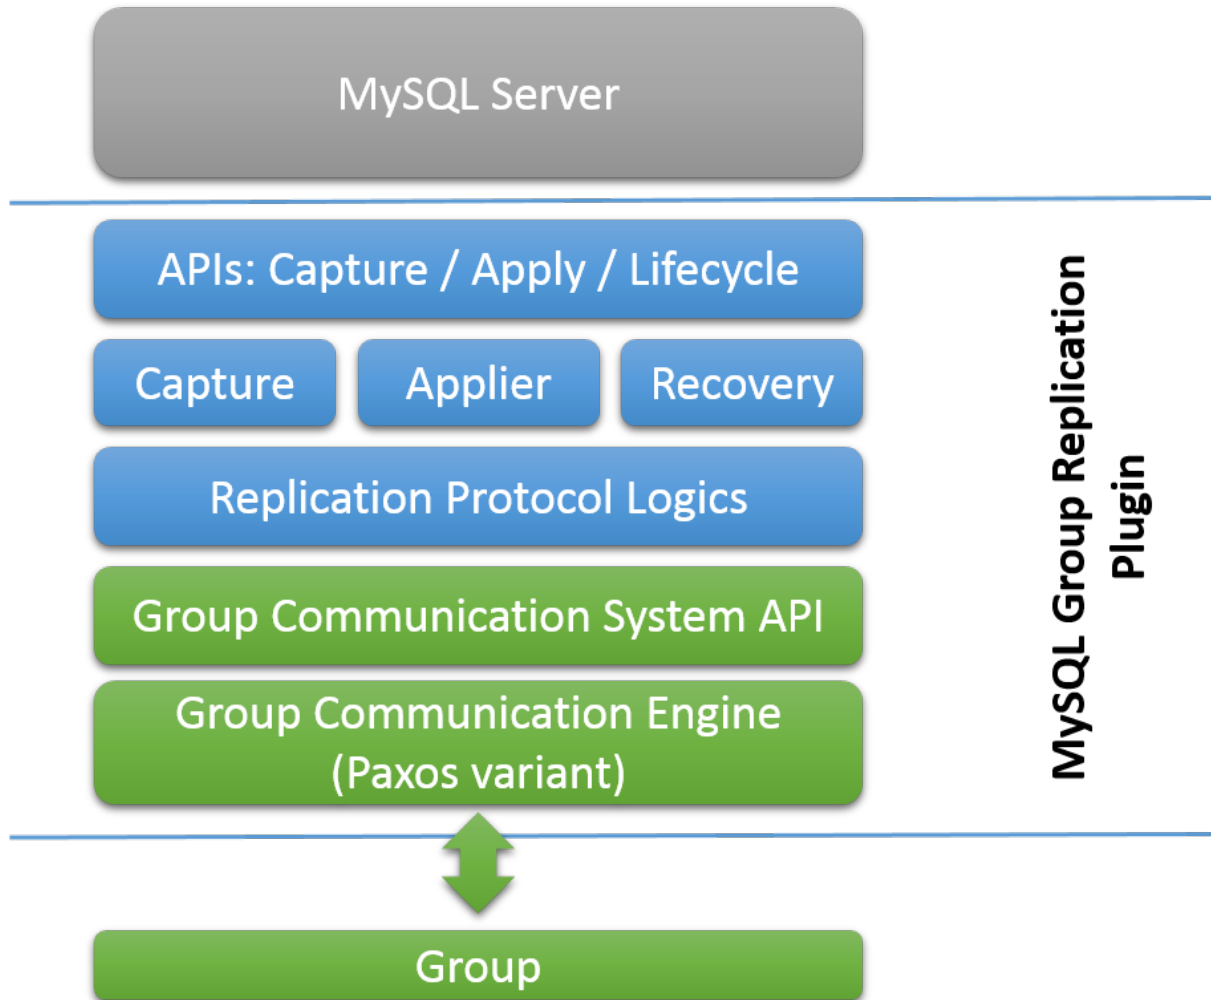

This section provides more technical details about MySQL Group Replication.

### **19.9.1 Group Replication Plugin Architecture**

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global

transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

**Figure 19.9 Group Replication Plugin Block Diagram**

Starting from the top of the figure, there is a set of APIs that control how the Group Replication plugin interacts with MySQL Server (the gray box). There are interfaces to make information flow from the server to the plugin and vice versa. Such interfaces isolate the server core from the plugin and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications such as the server is starting, the server is recovering, the server is ready to accept connections, the server is about to commit a transaction, and so on. In the other direction, the plugin instructs the server to commit or abort ongoing transactions, queue transactions in the relay-log, and so on.

Below the API block is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery and is responsible for getting a server that is joining the group up to date by selecting the donor, orchestrating the catch up procedure and reacting on donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, receives and propagates transactions to the group.

The first green box is the Group Communication API. It is a high level API abstracting the properties required to build a replicated state machine (details in the Background chapter ). Therefore it decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The MySQL Group Replication plugin contains an implementation of a Paxos based group communication engine.

## 19.9.2 The Group

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. This state is transferred by means of Asynchronous MySQL replication. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically. The group membership service described at [Section 19.1.3.2, “Group Membership”](#) powers all of this.

## 19.9.3 Data Manipulation Statements

As there are no primary servers (masters) for any particular data set, every server in the group is allowed to execute transactions at any time, even transactions that change state (RW transactions).

Any server may execute a transaction without any *a priori* coordination. But, at commit time, it coordinates with the rest of the servers in the group to reach a decision on the fate of that transaction. This coordination serves two purposes: (i) check whether the transaction should commit or not; (ii) and propagate the changes so that other servers can apply the transaction as well.

As a transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. Conflict detection is carried out by inspecting and comparing write sets of transactions. Thus, they are detected at the row level. Conflict resolution follows the first committer wins rule. If t1 and t2 execute concurrently at different sites, because t2 is ordered before t1, and both changed the same row, then t2 wins the conflict and t1 aborts. In other words, t1 was trying to change data that had been rendered stale by t2.

### Note

If two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server. They then have a chance to synchronize on the local lock manager instead of aborting later in the replication protocol.

## 19.9.4 Data Definition Statements

Care needs to be taken when executing data definition statements also commonly known as data definition language (DDL). Given that MySQL does not support atomic or transactional DDL, one cannot optimistically execute DDL statements and later roll back if needs be. Consequently, the lack of atomicity does not fit directly into the optimistic replication paradigm that Group Replication is based on.

Therefore, more care needs to be taken when replicating data definition statements. Schema changes and changes to the data that the object contains need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so, may result in data inconsistency.

### Note

If the group is deployed in single-primary mode, then this is not a problem, because all changes are performed through the same server, the primary.

**Warning**

MySQL DDL execution is not atomic or transactional. The server executes and commits without securing group agreement first. As such, you must route DDL and DML for the same object through the same server, while the DDL is executing and has not replicated everywhere yet.

## 19.9.5 Distributed Recovery

This section describes the process through which a joining member catches up with the remaining servers, called the distributed recovery phase.

### 19.9.5.1 Group Replication Basics

The Group Replication distributed recovery procedure can be summarized as the process through which a new server gets missing data from a online server in the group, while listening for events happening in the group. During recovery a server listens to membership events and also to the transactions that are happening while recovery is happening. This is a high level summary. The following sections provide additional detail, by describing the two phases of the procedure.

#### Phase 1

In the first phase, the joiner (joining server), will select one of the online servers on the group to be the *donor* of the state that it is missing. The donor is responsible for handing the joiner all the data it is missing up to the moment it has joined the group. This is achieved by relying on a standard asynchronous replication channel, established between donor and joiner. Through that channel, binary logs flow up until the point that the view change happened when the joiner became part of the group. While the joiner receives binary logs from the donor, it is also applying them.

Furthermore, while the binary logs transfer is ongoing, the joiner is also caching every transaction that is exchanged within the group. I.e., it is listening for transactions that are happening after it joined the group and while it is applying the missing state from the donor. When the first phase ends and the replication channel to the donor is closed, the joiner then starts phase two: the catch up.

#### Phase 2

In this phase, the joiner proceeds to the execution of the cached transactions and when the number of transactions queued for execution finally reaches zero, then the member is declared online.

#### Resilience

The recovery procedure withstands donor failures while the joiner is fetching binary logs from it. In such cases, whenever a donor fails during phase 1, the joiner fails over to a new donor and resumes from that one. When that happens the joiner closes the connection to the failed joiner explicitly and opens a connection to a new donor. This happens automatically.

### 19.9.5.2 Recovering From a Point-in-time

To synchronize the joiner with the donor up to a specific point in time, the joiner and donor make use of the MySQL global transaction identifiers (GTIDs) mechanism. However, that is not enough, since that only provides a mean to realize which transactions the joiner is missing. It does not help marking a specific point in time to which the joiner must catch up, nor does it help conveying certification information. This is where the binary log view markers come into play. They mark view changes in the binary log stream, and also contain additional metadata information, provisioning the joiner with missing certification related data.

#### View and View Changes

To explain the concept of view change markers, it is important to understand what a view and a view change are.

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are correct and online in the system.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens

At the group communication layer, view changes with their associated view ids are then boundaries between the data exchanged before and after a member joins. This concept is implemented through a new binary log event: the "view change log event". The view id thus becomes a marker as well for transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: (i) one that is randomly generated and (ii) a monotonically increasing integer. The first part is generated when the group is created, and remains unchanged while there is at least one member in the group. The second part is incremented every time a view change happens.

The reason for this heterogeneous pair that makes up the view id is the need to unambiguously mark group changes whenever a member joins or leaves but also whenever all members leave the group and no information remains of what view the group was in. In fact, the sole use of monotonic increasing identifiers could lead to the reuse of the same id after full group shutdowns, destroying the uniqueness of the binary log data markers that recovery depends on. To summarize, the first part identifies whenever the group was started from the beginning and the incremental part when the group changed from that point on.

### 19.9.5.3 View Changes

This section explains the process which controls how the view change identifier is incorporated into a binary log event and written to the log, The following steps are taken:

#### **Begin: Stable Group**

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

**Figure 19.10 Stable Group****View Change: a Member Joins**

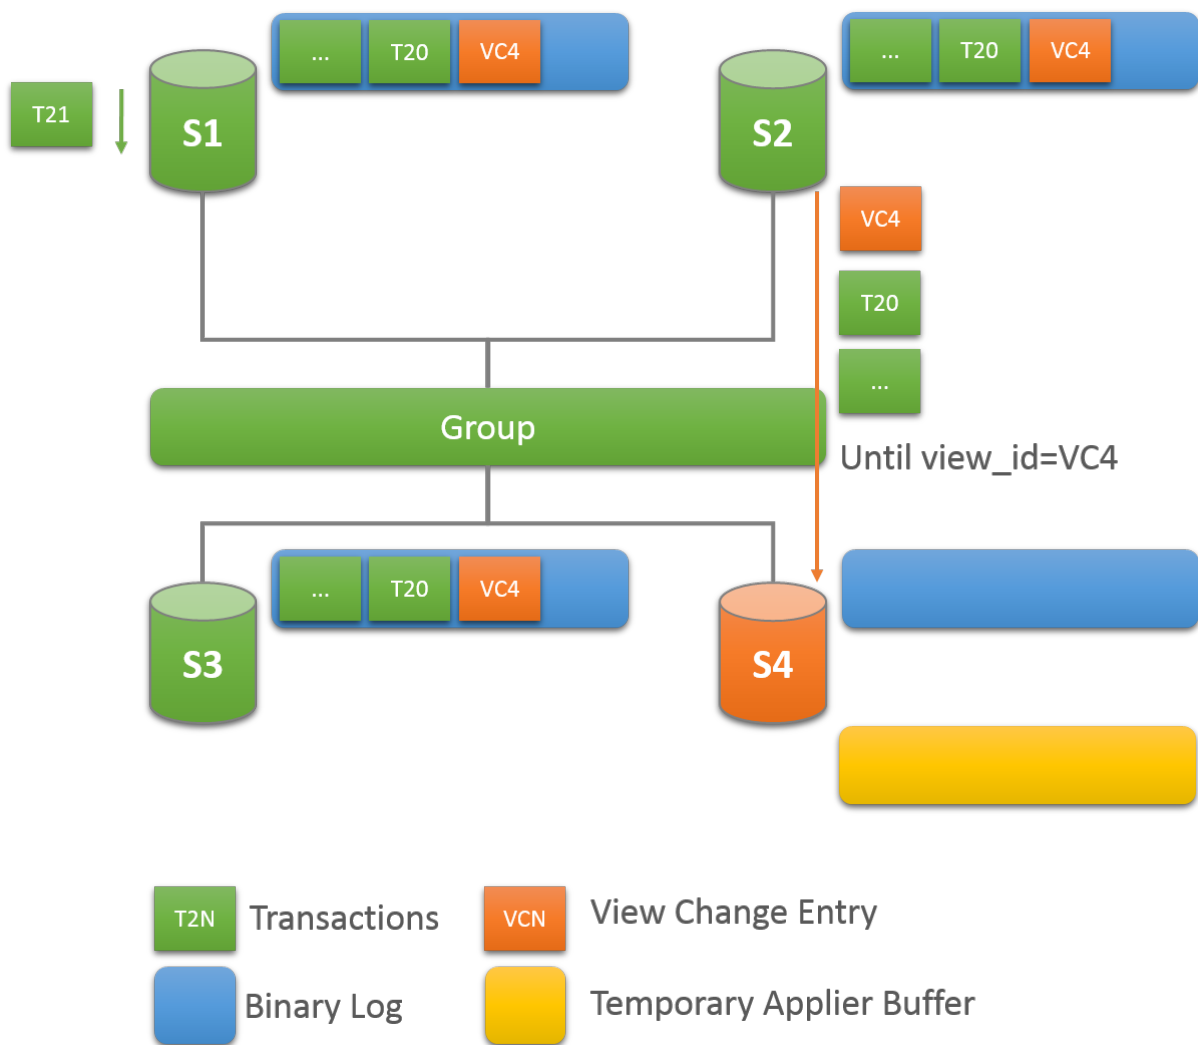

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the joiner selects the donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a View change event to the binary log.

**Figure 19.11 A Member Joins****State Transfer: Catching Up**

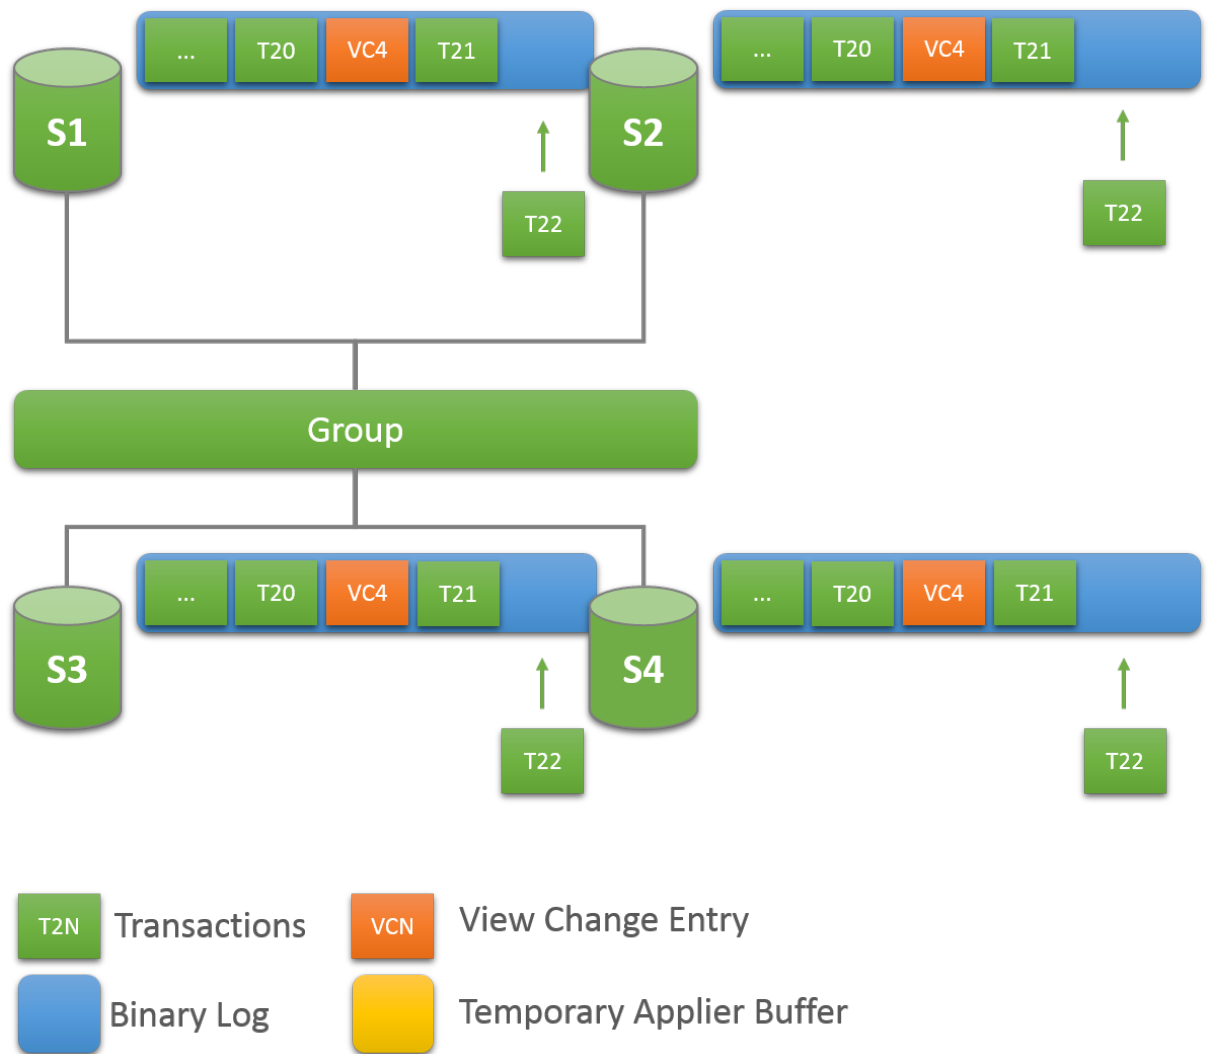

Once the joiner has chosen which server in the group is to be the donor, a new asynchronous replication connection is established between the two and the state transfer begins (phase 1). This interaction with the donor continues until the joiner's applier thread processes the view change log event that corresponds to the view change triggered when the joiner came into the group. In other words, the joiner replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

Figure 19.12 State Transfer: Catching Up

As view identifiers are transmitted to all members in the group at the same logical time, the joiner knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view id clearly marks which data belongs to each group view.

While the joiner is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

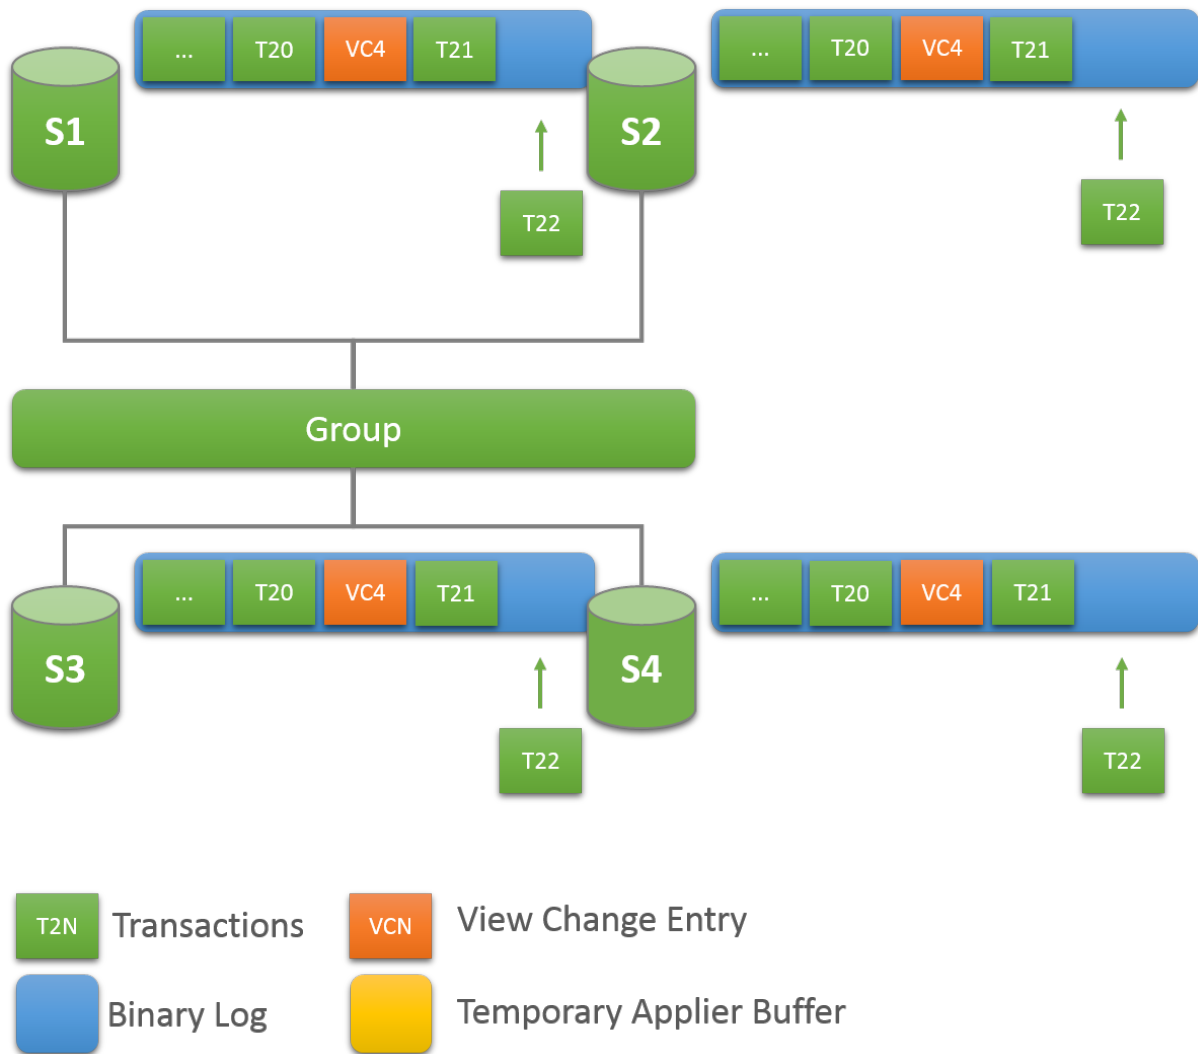

**Figure 19.13 Queued Transactions****Finish: Caught Up**

When the joiner recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. An important point to understand is the final recovery procedure. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the joiner entered the group, in other words the last view change. Without it, the joiner would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up (phase 2) is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the joiner does not block any other server in the group while it is catching up. Therefore the number of transactions the joiner is behind when it moves to phase 2 can, for this reason, vary and thus increase or decrease according to the workload.

When the joiner's queued transactions reach zero and its stored data is equal to the other members, its public state changes to online.

Figure 19.14 Instance Online

#### 19.9.5.4 Usage Advice and Limitations of Distributed Recovery

Distributed recovery does have some limitations. It is based on classic asynchronous replication and as such it may be slow if the joiner is not provisioned at all or is provisioned with a very old backup image. This means that if the data to transfer is too big at phase 1, the server may take a very long time to recover. As such, the recommendation is that before adding a server to the group, one should provision it with a fairly recent snapshot of a server already in the group. This minimizes the length of phase 1 and reduces the impact on the donor server, since it has to save and transfer less binary logs.

##### Warning

It is recommended that a server is provisioned before it is added to a group. That way, one minimizes the time spent on the recovery step.

#### 19.9.6 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through performance\_schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For

example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see [Section 19.3, “Monitoring Group Replication”](#).

## 19.9.7 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your group.

### 19.9.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

### 19.9.7.2 Message Compression

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load.

**Table 19.8 LZ4 Compression Ratios for Different Binary Log Formats.**

| Workload  | Ratio |      |
|-----------|-------|------|
|           | ROW   | STMT |
| mysqslapd | 4,5   | 4,1  |
| sysbench  | 3,4   | 2,9  |

The TCP peer-to-peer nature of the interconnections between  $N$  participants on the group makes the sender send the same amount of data  $N$  times. Furthermore, binary logs are likely to exhibit a high compression ratio (see table above). This makes compression a compelling feature for workloads that contain large transaction.

**Figure 19.15 Compression Support**

Compression happens at the group communication engine level, before the data is handed over to the group communication thread, so it happens within the context of the mysql user session thread. Transaction payloads may be compressed before being sent out to the group and decompressed when received. Compression is conditional and depends on a configured threshold. By default compression is enabled.

In addition, there is no requirement that all servers in the group have compression enabled to be able to work together. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer.

The compression algorithm used is LZ4. Compression is enabled by default with threshold of 1000000 bytes. The compression threshold, in bytes, may be set to something larger than default. In that case, only transactions that have a payload larger than the threshold are compressed. Below is an example of how to set a compression threshold.

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold= 2097152;
START GROUP_REPLICATION;
```

This sets the compression threshold to 2MB. If a transaction generates a replication message with a payload larger than 2MB, for example a binary log transaction entry larger than 2MB, then it is compressed. To disable compression set threshold to 0.

### 19.9.7.3 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently.

This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: (i) the *certification* queue; (ii) and on the binary log *applier* queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: (i) whether to do flow control at the certifier or at the applier level, or both; and (ii) what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

### Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

### Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota will be enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

---

## Chapter 20 MySQL NDB Cluster 7.5

### Table of Contents

|   |      |
|---|------|
| 20.1 NDB Cluster Overview .....   | 2874 |
| 20.1.1 NDB Cluster Core Concepts .....  | 2876 |
| 20.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions .....                                     | 2878 |
| 20.1.3 NDB Cluster Hardware, Software, and Networking Requirements .....                                  | 2881 |
| 20.1.4 What is New in MySQL NDB Cluster 7.5 .....   | 2882 |
| 20.1.5 MySQL Server Using InnoDB Compared with NDB Cluster .....  | 2887 |
| 20.1.6 Known Limitations of NDB Cluster .....   | 2890 |
| 20.2 NDB Cluster Installation .....   | 2900 |
| 20.2.1 The NDB Cluster Auto-Installer .....   | 2902 |
| 20.2.2 Installation of NDB Cluster on Linux .....   | 2918 |
| 20.2.3 Installing NDB Cluster on Windows .....  | 2927 |
| 20.2.4 Initial Configuration of NDB Cluster .....   | 2936 |
| 20.2.5 Initial Startup of NDB Cluster .....   | 2938 |
| 20.2.6 NDB Cluster Example with Tables and Data .....   | 2939 |
| 20.2.7 Safe Shutdown and Restart of NDB Cluster .....   | 2942 |
| 20.2.8 Upgrading and Downgrading NDB Cluster .....  | 2943 |
| 20.3 Configuration of NDB Cluster .....   | 2944 |
| 20.3.1 Quick Test Setup of NDB Cluster .....  | 2945 |
| 20.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables .....                     | 2947 |
| 20.3.3 NDB Cluster Configuration Files .....  | 2988 |
| 20.3.4 Using High-Speed Interconnects with NDB Cluster .....  | 3119 |
| 20.4 NDB Cluster Programs .....   | 3120 |
| 20.4.1 <code>ndbd</code> — The NDB Cluster Data Node Daemon .....   | 3120 |
| 20.4.2 <code>ndbinfo_select_all</code> — Select From <code>ndbinfo</code> Tables .....                    | 3127 |
| 20.4.3 <code>ndbmtd</code> — The NDB Cluster Data Node Daemon (Multi-Threaded) .....                      | 3129 |
| 20.4.4 <code>ndb_mgmd</code> — The NDB Cluster Management Server Daemon .....                             | 3130 |
| 20.4.5 <code>ndb_mgm</code> — The NDB Cluster Management Client .....                                     | 3137 |
| 20.4.6 <code>ndb_blob_tool</code> — Check and Repair BLOB and TEXT columns of NDB Cluster<br>Tables ..... | 3139 |
| 20.4.7 <code>ndb_config</code> — Extract NDB Cluster Configuration Information .....                      | 3141 |
| 20.4.8 <code>ndb_cpcd</code> — Automate Testing for NDB Development .....                                 | 3149 |
| 20.4.9 <code>ndb_delete_all</code> — Delete All Rows from an NDB Table .....                              | 3150 |
| 20.4.10 <code>ndb_desc</code> — Describe NDB Tables .....   | 3150 |
| 20.4.11 <code>ndb_drop_index</code> — Drop Index from an NDB Table .....                                  | 3156 |
| 20.4.12 <code>ndb_drop_table</code> — Drop an NDB Table .....   | 3157 |
| 20.4.13 <code>ndb_error_reporter</code> — NDB Error-Reporting Utility .....                               | 3157 |
| 20.4.14 <code>ndb_index_stat</code> — NDB Index Statistics Utility .....                                  | 3159 |
| 20.4.15 <code>ndb_print_backup_file</code> — Print NDB Backup File Contents .....                         | 3164 |
| 20.4.16 <code>ndb_print_file</code> — Print NDB Disk Data File Contents .....                             | 3165 |
| 20.4.17 <code>ndb_print_schema_file</code> — Print NDB Schema File Contents .....                         | 3165 |
| 20.4.18 <code>ndb_print_sys_file</code> — Print NDB System File Contents .....                            | 3165 |
| 20.4.19 <code>ndbd_redo_log_reader</code> — Check and Print Content of Cluster Redo Log .....             | 3166 |
| 20.4.20 <code>ndb_restore</code> — Restore an NDB Cluster Backup .....                                    | 3167 |
| 20.4.21 <code>ndb_select_all</code> — Print Rows from an NDB Table .....                                  | 3182 |
| 20.4.22 <code>ndb_select_count</code> — Print Row Counts for NDB Tables .....                             | 3185 |
| 20.4.23 <code>ndb_setup.py</code> — Start browser-based Auto-Installer for NDB Cluster .....              | 3186 |
| 20.4.24 <code>ndb_show_tables</code> — Display List of NDB Tables .....                                   | 3189 |
| 20.4.25 <code>ndb_size.pl</code> — NDBCLUSTER Size Requirement Estimator .....                            | 3190 |
| 20.4.26 <code>ndb_waiter</code> — Wait for NDB Cluster to Reach a Given Status .....                      | 3193 |
| 20.4.27 Options Common to NDB Cluster Programs — Options Common to NDB Cluster<br>Programs .....          | 3195 |
| 20.5 Management of NDB Cluster .....  | 3199 |

|  |      |
|--|------|
| 20.5.1 Summary of NDB Cluster Start Phases .....                             | 3200 |

| 20.7 NDB Cluster Release Notes .....   | 3364 |

This chapter contains information about MySQL *NDB Cluster*, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Recent NDB Cluster release series use version 7 of the [NDB](#) storage engine (also known as [NDBCLUSTER](#)) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 7.5, now available as a General Availability (GA) release beginning with version 7.5.4, incorporates version 7.5 of the [NDB](#) storage engine. Previous GA releases still available for production, NDB 7.3 and NDB Cluster 7.4, incorporate [NDB](#) versions 7.3 and 7.4, respectively.

Support for the [NDB](#) storage engine is not included in standard MySQL Server 5.7 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster users who build from source should use the sources provided for NDB Cluster . (Locations where the sources can be obtained are listed later in this section.)

This chapter contains information about NDB Cluster 7.5 releases through 5.7.16-ndb-7.5.5. NDB Cluster 7.5 is available as a General Availability release, and recommended for new deployments. The NDB Cluster 7.4 and NDB Cluster 7.3 release series are previous GA releases still supported in production. NDB Cluster 7.2 is a previous GA release series which is still supported. We currently recommend that new deployments for production use NDB Cluster 7.5. For more information about NDB Cluster 7.4 and NDB Cluster 7.3, see [MySQL NDB Cluster 7.3 and NDB Cluster 7.4](#). For information about NDB Cluster 7.2, see [MySQL NDB Cluster 7.2](#).

**Supported Platforms.** NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <http://www.mysql.com/support/supportedplatforms/cluster.html>.

**Availability.** NDB Cluster binary and source packages are available for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

---

**NDB Cluster release numbers.** NDB Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.7 series of releases. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the [NDBCLUSTER](#) storage engine used in the release, and not of the MySQL server version on which the NDB Cluster release is based.

**Version strings used in NDB Cluster software.** The version string displayed by NDB Cluster programs uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

[mysql\\_server\\_version](#) represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 7.5 releases, this is “5.7”. [ndb\\_engine\\_version](#) is the version of the [NDB](#) storage engine used by this release of the NDB Cluster software. You can see this format used in the [mysql](#) client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.7.16-ndb-7.5.5 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 5.7.16-ndb-7.5.5
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the [SHOW](#) command in the [ndb\\_mgm](#) client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=2 @10.0.10.8 (5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3 @10.0.10.2 (5.7.16-ndb-7.5.5)

[mysqld(API)] 2 node(s)
id=4 @10.0.10.10 (5.7.16-ndb-7.5.5)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the NDB Cluster release was branched and the version of the [NDB](#) storage engine used. For example, the full version string for NDB 7.5.4 (the first NDB 7.5 GA release) was [mysql-5.7.16-ndb-7.5.4](#). From this we can determine the following:

- Since the portion of the version string preceding [-ndb-](#) is the base MySQL Server version, this means that NDB 7.5.4 derived from MySQL 5.7.16, and contained all feature enhancements and bug fixes from MySQL 5.7 up to and including MySQL 5.7.16.
- Since the portion of the version string following [-ndb-](#) represents the version number of the [NDB](#) (or [NDBCLUSTER](#)) storage engine, NDB 7.5.4 used version 7.5.4 of the [NDBCLUSTER](#) storage engine.

New NDB Cluster releases are numbered according to updates in the [NDB](#) storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, NDB 7.5.4 (as previously noted) was based on MySQL 5.7.16, while NDB 7.5.3 was based on MySQL 5.7.13 (version string: [mysql-5.7.13-ndb-7.5.3](#)).

**Compatibility with standard MySQL 5.7 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database

schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see [Section 20.1.6, “Known Limitations of NDB Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, [MyISAM](#) or [InnoDB](#)—to use the [NDB](#) storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and NDB Cluster codebases diverge considerably, so that the standard `mysqld` cannot function as a drop-in replacement for the version of `mysqld` supplied with NDB Cluster.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from <https://github.com/mysql/mysql-server>.

The NDB Cluster development sources maintained at <https://github.com/mysql/mysql-server> are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

**Note**

As with MySQL Server 5.7, NDB Cluster 7.5 releases are built using [CMake](#).

NDB Cluster 7.5 is available as a General Availability (GA) release, and recommended for new deployments beginning with version 7.5.4. NDB Cluster 7.4 and NDB Cluster 7.3 are previous GA releases which are still supported in production. NDB 7.2 is a previous GA release series which is still supported, although it is no longer recommended for new deployments. We currently recommend that new deployments for production use NDB 7.5. For an overview of major features added in NDB 7.4, see [What is New in NDB Cluster 7.4](#). For similar information about NDB Cluster 7.3, see [What is New in NDB Cluster 7.3](#). For an overview of major features added in previous NDB Cluster releases, see [What is New in NDB Cluster in NDB Cluster 7.2](#). NDB 7.1 and earlier versions of NDB Cluster are no longer being developed or maintained.

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL Web site at <http://www.mysql.com/products/cluster/>.

**Additional Resources.** More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see [Section A.10, “MySQL 5.7 FAQ: MySQL Cluster”](#).
- The NDB Cluster mailing list: <http://lists.mysql.com/cluster>.
- The NDB Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through [PlanetMySQL](#).

## 20.1 NDB Cluster Overview

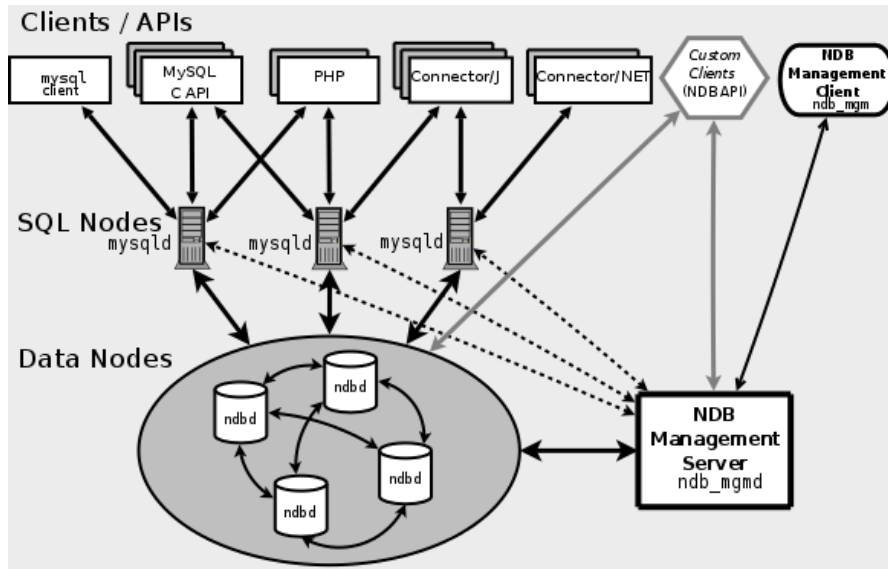

*NDB Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called [NDB](#) (which stands for “Network DataBase”). In our documentation, the term [NDB](#) refers to the part of the setup that is specific to the storage engine, whereas “NDB Cluster” refers to the combination of one or more MySQL servers with the [NDB](#) storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 20.1 NDB Cluster Components**

All these programs work together to form an NDB Cluster (see [Section 20.4, “NDB Cluster Programs”](#)). When data is stored by the [NDB](#) storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.7 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the [NDB](#) storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)). Rolling restarts are also used as part of the process of adding new data nodes online (see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Backing up and restoring NDB Cluster databases can be done using the [NDB](#)-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see [Section 20.5.3, “Online Backup of NDB Cluster”](#), and [Section 20.4.20, “ndb\\_restore — Restore an NDB Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 5.5.4, “mysqldump — A Database Backup Program”](#), for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

## 20.1.1 NDB Cluster Core Concepts

**NDBCLUSTER** (also known as **NDB**) is an in-memory storage engine offering high-availability and data-persistence features.

The **NDBCLUSTER** storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's **NDB** storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node:** The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- **Data node:** This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#)). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 20.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#)) or `ndbmtdd` (see [Section 20.4.3, “ndbmtdd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#)).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#), for more information.

- **SQL node:** This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the **NDBCLUSTER** storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

### Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in NDB Cluster, see [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, [NDB-specific API programs](#), and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see [Using Connector/J with NDB Cluster](#).

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the [NDBCLUSTER](#) storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see [The NDB API](#).

[NDB-specific Java applications](#) can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to [NDBCLUSTER](#), and so does not require access to a MySQL Server. Support is also provided in NDB Cluster for *ClusterJPA*, an OpenJPA implementation for NDB Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See [Java and NDB Cluster](#), and [The ClusterJ API and Data Object Model](#), for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the [NDB](#) storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see [MySQL NoSQL Connector for JavaScript](#).

The Memcache API for NDB Cluster, implemented as the loadable *ndbmemcache* storage engine for memcached version 1.6 and later, can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard [memcached](#) caching engine is included in the NDB Cluster 7.5 distribution. Each [memcached](#) server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see [ndbmemcache—Memcache API for NDB Cluster](#).

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions

only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with NDB Cluster (see [Section 20.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#)). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see [The MGM API](#).

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such as restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See [MySQL™ Cluster Manager 1.4.1 User Manual](#), for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 20.5.6, “Event Reports Generated in NDB Cluster”](#). Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

#### Note

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the [NDB](#) storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see [NDB Cluster Data Node File System Directory Files](#).

## 20.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**(Data) Node.** An `ndbd` or `ndbmt` process, which stores one or more *replicas*—that is, copies of the *partitions* (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmt` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NoOfReplicas
```

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NoOfReplicas`, see [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#).

#### Note

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster ; see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#), for more information.

**Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

**NDB and user-defined partitioning.** NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.
2. The maximum number of partitions that may be defined explicitly for any `NDB` table is  $8 * \text{MaxNoOfExecutionThreads} * [\text{number of node groups}]$ , the number of node groups in an NDB Cluster being determined as discussed previously in this section. When using `ndbd` for data node processes, setting `MaxNoOfExecutionThreads` has no effect; in such a case, it can be treated as though it were equal to 1 for purposes of performing this calculation.

See [Section 20.4.3, “ndbmt — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

For more information relating to NDB Cluster and user-defined partitioning, see [Section 20.1.6, “Known Limitations of NDB Cluster”](#), and [Section 21.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates an NDB Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

#### Note

Only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

**Figure 20.2 NDB Cluster with Two Node Groups**

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

**Figure 20.3 Nodes Required for a 2x2 Cluster**

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an X); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

In NDB 7.5.4 and later, the maximum number of node groups supported for a single NDB Cluster instance is 48 (Bug#80845, Bug #22996305).

### 20.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at <http://dev.mysql.com/downloads/cluster/>.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

---

See [Section 20.5.12.1, “NDB Cluster Security and Networking Issues”](#), for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100  $\mu$ s), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

**SCI support.** It is also possible to use the high-speed Scalable Coherent Interface (SCI) with NDB Cluster, but this is not a requirement. See [Section 20.3.4, “Using High-Speed Interconnects with NDB Cluster”](#), for more about this protocol and its use with NDB Cluster.

## 20.1.4 What is New in MySQL NDB Cluster 7.5

In this section, we describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 7.5 as compared to NDB 7.4 and earlier release series. NDB Cluster 7.5 is available as a General

Availability release beginning with NDB 7.5.4, and is recommended for new deployments. NDB Cluster 7.4 a recent General Availability release still supported for new deployments. NDB Cluster 7.3, is a previous GA release, still supported in production for existing deployments. NDB Cluster 7.2 is also a previous GA release series which is still supported in production. NDB 7.1 and earlier releases series are no longer maintained or supported in production. We recommend that new deployments use NDB Cluster 7.4 or NDB Cluster 7.5, which is the latest GA release. For information about features added in NDB 7.4, see [What is New in NDB Cluster 7.4](#); [What is New in NDB Cluster 7.4](#) contains information about features added in NDB 7.3. For information about NDB Cluster 7.2 and previous NDB Cluster releases, see [What is New in NDB Cluster in NDB Cluster 7.2](#).

Major changes and new features in NDB Cluster 7.5 which are likely to be of interest are shown in the following list:

- **ndbinfo Enhancements.** A number of changes are made in the `ndbinfo` database, chief of which is that it now provides detailed information about NDB Cluster node configuration parameters.

The `config_params` table has been made read-only, and has been enhanced with additional columns providing information about each configuration parameter, including the parameter's type, default value, maximum and minimum values (where applicable), a brief description of the parameter, and whether the parameter is required. This table also provides each parameter with a unique `param_number`.

A row in the `config_values` table shows the current value of a given parameter on the node having a specified ID. The parameter is identified by the value of the `config_param` column, which maps to the `config_params` table's `param_number`.

Using this relationship you can write a join on these two tables to obtain the default, maximum, minimum, and current values for one or more NDB Cluster configuration parameters by name. An example SQL statement using such a join is shown here:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name IN ('NodeId', 'HostName', 'DataMemory', 'IndexMemory');
```

For more information about these changes, see [Section 20.5.10.7, “The ndbinfo config\\_params Table”](#). See [Section 20.5.10.8, “The ndbinfo config\\_values Table”](#), for further information and examples.

In addition, the `ndbinfo` database no longer depends on the `MyISAM` storage engine. All `ndbinfo` tables and views now use `NDB` (shown as `NDBINFO`).

Several new `ndbinfo` tables were introduced in NDB 7.5.4. These tables are listed here, with brief descriptions:

- `dict_obj_info` provides the names and types of database objects in `NDB`, as well as information about parent objects where applicable
- `table_distribution_status` provides `NDB` table distribution status information
- `table_fragments` provides information about the distribution of `NDB` table fragments
- `table_info` provides information about logging, checkpointing, storage, and other options in force for each `NDB` table

- `table_replicas` provides information about fragment replicas

See the descriptions of the individual tables for more information.

- **Default row and column format changes.** Starting with NDB 7.5.1, the default value for both the `ROW_FORMAT` option and the `COLUMN_FORMAT` option for `CREATE TABLE` can be set to `DYNAMIC` rather than `FIXED`, using a new MySQL server variable `ndb_default_column_format` is added as part of this change; set this to `FIXED` or `DYNAMIC` (or start `mysqld` with the equivalent option `--ndb-default-column-format=FIXED`) to force this value to be used for `COLUMN_FORMAT` and `ROW_FORMAT`. Prior to NDB 7.5.4, the default for this variable was `DYNAMIC`; in this and later versions, the default is `FIXED`, which provides backwards compatibility with prior releases (Bug #24487363).

The row format and column format used by existing table columns are unaffected by this change. New columns added to such tables use the new defaults for these (possibly overridden by `ndb_default_column_format`), and existing columns are changed to use these as well, provided that the `ALTER TABLE` statement performing this operation specifies `ALGORITHM=COPY`.

#### Note

A copying `ALTER TABLE` cannot be done implicitly if `mysqld` is run with `--ndb-allow-copying-alter-table=FALSE`.

- **ndb\_binlog\_index No Longer Dependent On MyISAM.** As of NDB 7.5.2, the `ndb_binlog_index` table employed in NDB Cluster Replication now uses the `InnoDB` storage engine instead of `MyISAM`. When upgrading, you can run `mysql_upgrade` with `--force --upgrade-system-tables` to cause it to execute `ALTER TABLE ... ENGINE=INNODB` on this table. Use of `MyISAM` for this table remains supported for backward compatibility.
- **ALTER TABLE Changes.** NDB Cluster formerly supported an alternative syntax for online `ALTER TABLE`. This is no longer supported in NDB Cluster 7.5, which makes exclusive use of `ALGORITHM = DEFAULT | COPY | INPLACE` for table DDL, as in the standard MySQL Server.

Another change affecting the use of this statement is that `ALTER TABLE ... ALGORITHM=INPLACE RENAME` may now contain DDL operations in addition to the renaming.

- **ExecuteOnComputer Parameter Deprecated.** The `ExecuteOnComputer` configuration parameter for `management nodes`, `data nodes`, and `API nodes` has been deprecated and is now subject to removal in a future release of NDB Cluster. You should use the equivalent `HostName` parameter for all three types of nodes.
- **records-per-key Optimization.** The NDB handler now uses the records-per-key interface for index statistics implemented for the optimizer in MySQL 5.7.5. Some of the benefits from this change include those listed here:
  - The optimizer now chooses better execution plans in many cases where a less optimal join index or table join order would previously have been chosen
  - Row estimates shown by `EXPLAIN` are more accurate
  - Cardinality estimates shown by `SHOW INDEX` are improved
- **Connection Pool Node IDs.** NDB 7.5.0 adds the `mysqld --ndb-cluster-connection-pool-nodeids` option, which allows a set of node IDs to be set for the connection pool. This setting overrides `--ndb-nodeid`, which means that it also overrides both the `--ndb-connectstring` option and the `NDB_CONNECTSTRING` environment variable.

**Note**

You can set the size for the connection pool using the `--ndb-cluster-connection-pool` option for `mysqld`.

- **create\_old\_temporals Removed.** The `create_old_temporals` system variable was deprecated in NDB Cluster 7.4, and has now been removed.
- **ndb\_mgm Client PROMPT Command.** NDB Cluster 7.5 adds a new command for setting the client's command-line prompt. The following example illustrates the use of the `PROMPT` command:

```
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
-----
[ndbd(NDB)]      4 node(s)
id=5      @10.100.1.1  (mysql-5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=6      @10.100.1.3  (mysql-5.7.16-ndb-7.5.5, Nodegroup: 0)
id=7      @10.100.1.9  (mysql-5.7.16-ndb-7.5.5, Nodegroup: 1)
id=8      @10.100.1.11 (mysql-5.7.16-ndb-7.5.5, Nodegroup: 1)

[ndb_mgmd(MGM)]  1 node(s)
id=50     @10.100.1.8  (mysql-5.7.16-ndb-7.5.5)

[mysqld(API)]   2 node(s)
id=100     @10.100.1.8  (5.7.16-ndb-7.5.5)
id=101     @10.100.1.10 (5.7.16-ndb-7.5.5)

mgm#1: PROMPT
ndb_mgm> EXIT
jon@valhaj:/usr/local/mysql/bin>
```

For additional information and examples, see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#).

- **Increased FIXED column storage per fragment.** NDB Cluster 7.5 and later supports a maximum of 128 TB per fragment of data in `FIXED` columns. In NDB Cluster 7.4 and earlier, this was 16 GB per fragment.
- **Deprecated Parameters Removed.** The following NDB Cluster data node configuration parameters were deprecated in previous releases of NDB Cluster, and were removed in NDB 7.5.0:
  - `Id`: deprecated in NDB 7.1.9; replaced by `NodeId`.
  - `NoOfDiskPagesToDiskDuringRestartTUP`, `NoOfDiskPagesToDiskDuringRestartACC`: both deprecated, had no effect; replaced in MySQL 5.1.6 by `DiskCheckpointSpeedInRestart`, which itself was later deprecated (in NDB 7.4.1) and is now also removed.
  - `NoOfDiskPagesToDiskAfterRestartACC`, `NoOfDiskPagesToDiskAfterRestartTUP`: both deprecated, had no effect; replaced in MySQL 5.1.6 by `DiskCheckpointSpeed`, which itself was later deprecated (in NDB 7.4.1) and is now also removed.
  - `ReservedSendBufferMemory`: deprecated in NDB 7.2.5; no longer had any effect.
  - `MaxNoOfIndexes`: archaic (pre-MySQL 4.1), had no effect; long since replaced by `MaxNoOfOrderedIndexes` or `MaxNoOfUniqueHashIndexes`.
  - `Discless`: archaic (pre-MySQL 4.1) synonym for and long since replaced by `Diskless`.

The archaic and unused (and for this reason also previously undocumented) `ByteOrder` computer configuration parameter was also removed in NDB 7.5.0.

The parameters just described are not supported in NDB 7.5. Attempting to use any of these parameters in an NDB Cluster configuration file now results in an error.

- **DBTC Scan Enhancements.** Scans have been improved by reducing the number of signals used for communication between the [DBTC](#) and [DEDIH](#) kernel blocks in [NDB](#), enabling higher scalability of data nodes when used for scan operations by decreasing the use of CPU resources for scan operations, in some cases by an estimated five percent.

Also as result of these changes response times should be greatly improved, which could help prevent issues with overload of the main threads. In addition, scans made in the [BACKUP](#) kernel block have also been improved and made more efficient than in previous releases.

- **JSON column support.** NDB 7.5.2 and later supports the [JSON](#) column type for [NDB](#) tables and the JSON functions found in the MySQL Server, subject to the limitation that an [NDB](#) table can have at most 3 [JSON](#) columns.
- **Read from any replica; specify number of hashmap partition fragments.** Previously, all reads were directed towards the primary replica except for simple reads. (A simple read is a reads that lock the row while reading it.) Beginning with NDB 7.5.2, it is possible to enabling reads from any replica. This is disabled by default but can be enabled for a given SQL node using the [ndb\\_read\\_backup](#) system variable added in this release.

Previously, it was possible to define tables with only one type of partition mapping, with one primary partition on each LDM in each node, but in NDB 7.5.2 it becomes possible to be more flexible about the assignment of partitions by setting a partition balance (fragment count type). Possible balance schemes are one per node, one per node group, one per LDM per node, and one per LDM per node group.

This setting can be controlled for individual tables by means of a [PARTITION\\_BALANCE](#) option (renamed from [FRAGMENT\\_COUNT\\_TYPE](#) in NDB 7.5.4) embedded in [NDB\\_TABLE](#) comments in [CREATE TABLE](#) or [ALTER TABLE](#) statements. Settings for table-level [READ\\_BACKUP](#) are also supported using this syntax. For more information and examples, see [Section 14.1.18.9, “Setting NDB\\_TABLE Options in Table Comments”](#).

In NDB API applications, a table's partition balance can also be get and set using methods supplied for this purpose; see [Table::getPartitionBalance\(\)](#), and [Table::setPartitionBalance\(\)](#), as well as [Object::PartitionBalance](#), for more information about these.

As part of this work, NDB 7.5.2 also introduces the [ndb\\_data\\_node\\_neighbour](#) system variable. This is intended for use, in transaction hinting, to provide a “nearby” data node to this SQL node.

NDB 7.5.3 adds a further enhancement to [READ\\_BACKUP](#): In this and later versions, it is possible to set [READ\\_BACKUP](#) for a given table online as part of [ALTER TABLE ... ALGORITHM=INPLACE ...](#)

- **ThreadConfig improvements.** A number of enhancements and feature additions are implemented in NDB 7.5.2 for the [ThreadConfig](#) multithreaded data node ([ndbmt](#)) configuration parameter, including support for an increased number of platforms. These changes are described in the next few paragraphs.

Non-exclusive CPU locking is now supported on FreeBSD and Windows, using [cpubind](#) and [cpuset](#). Exclusive CPU locking is now supported on Solaris (only) using the [cpubind\\_exclusive](#) and [cpuset\\_exclusive](#) parameters which are introduced in this release.

Thread prioritization is now available, controlled by the new [thread\\_prio](#) parameter. [thread\\_prio](#) is supported on Linux, FreeBSD, Windows, and Solaris, and varies somewhat by platform. For more information, see the description of [ThreadConfig](#).

The [realtime](#) parameter is now supported on Windows platforms.

- **Partitions larger than 16 GB.** Due to an improvement in the hash index implementation used by NDB Cluster data nodes, partitions of [NDB](#) tables may now contain more than 16 GB of data for fixed columns, and the maximum partition size for fixed columns is now raised to 128 TB. The previous limitation was due to the fact that the [DBACC](#) block in the [NDB](#) kernel used only 32-bit references to the fixed-size part of a row in the [DBTUP](#) block, although 45-bit references to this data are used in [DBTUP](#) itself and elsewhere in the kernel outside [DBACC](#); all such references in to the data handled in the [DBACC](#) block now use 45 bits instead.
- **Print SQL statements from `ndb_restore`.** NDB 7.5.4 adds the `--print-sql-log` option for the `ndb_restore` utility provided with the NDB Cluster distribution. This option enables SQL logging to `stdout`. **Important:** Every table to be restored using this option must have an explicitly defined primary key.

See [Section 20.4.20, “`ndb\_restore` — Restore an NDB Cluster Backup](#)”, for more information.

- **Organization of RPM packages.** Beginning with NDB 7.5.4, the naming and organization of RPM packages provided for NDB Cluster align more closely with those released for the MySQL server. The names of all NDB Cluster RPMs are now prefixed with `mysql-cluster`. Data nodes are now installed using the `data-node` package; management nodes are now installed from the `management-server` package; and SQL nodes require the `server` and `common` packages. MySQL and [NDB](#) client programs, including the `mysql` client and the `ndb_mgm` management client, are now included in the `client` RPM.

For a detailed listing of NDB Cluster RPMs and other information, see [Section 20.2.2.2, “Installing NDB Cluster from RPM”](#).

NDB Cluster 7.5 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See [MySQL™ Cluster Manager 1.4.1 User Manual](#), for more information.

## 20.1.5 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both [NDB](#) and [InnoDB](#) can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster . They see [NDB](#) as a possible alternative or upgrade to the default [InnoDB](#) storage engine in MySQL 5.7. While [NDB](#) and [InnoDB](#) share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster , but not all of them.

In this section, we discuss and compare some characteristics of the [NDB](#) storage engine used by NDB 7.5 with [InnoDB](#) used in MySQL 5.7. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for [NDB](#) as opposed to [InnoDB](#) backends.

NDB Cluster 7.5 uses a `mysqld` based on MySQL 5.7, including support for [InnoDB](#) 1.1. While it is possible to use [InnoDB](#) tables with NDB Cluster , such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 7.5 distribution with MySQL Server 5.7, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the [InnoDB](#) storage engine), there are some important architectural and implementation differences. [Section 20.1.5.1, “Differences Between the NDB and InnoDB Storage Engines”](#), provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see [Section 20.1.5.2, “NDB and InnoDB Workloads”](#). This in turn has an impact on the types of applications that better suited for use with [NDB](#) or [InnoDB](#). See [Section 20.1.5.3, “NDB and InnoDB Feature Usage Summary”](#), for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the [NDB](#) and [MEMORY](#) storage engines, see [When to Use MEMORY or MySQL Cluster](#).

See [Chapter 16, Alternative Storage Engines](#), for additional information about MySQL storage engines.

### 20.1.5.1 Differences Between the NDB and InnoDB Storage Engines

The NDB Cluster [NDB](#) storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from [InnoDB](#) in a number of ways. For those unaccustomed to working with [NDB](#), unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

| Feature                                   | InnoDB 1.1  | NDB Cluster <a href="#">NDB 7.5</a>   |
|---|---|---|
| <i>MySQL Server Version</i>               | 5.7   | 5.7   |
| <i>InnoDB Version</i>                     | <a href="#">InnoDB 5.7.18</a>   | <a href="#">InnoDB 5.7.18</a>   |
| <i>NDB Cluster Version</i>                | N/A   | <a href="#">NDB 7.5.5</a>   |
| <i>Storage Limits</i>                     | 64TB  | 3TB<br><br>(Practical upper limit based on 48 data nodes with 64GB RAM each; can be increased with disk-based data and BLOBs)   |
| <i>Foreign Keys</i>                       | Yes   | Yes.  |
| <i>Transactions</i>                       | All standard types  | <a href="#">READ COMMITTED</a>  |
| <i>MVCC</i>                               | Yes   | No  |
| <i>Data Compression</i>                   | Yes   | No<br><br>(NDB Cluster checkpoint and backup files can be compressed)   |
| <i>Large Row Support (&gt; 14K)</i>       | Supported for <a href="#">VARBINARY</a> , <a href="#">VARCHAR</a> , <a href="#">BLOB</a> , and <a href="#">TEXT</a> columns | Supported for <a href="#">BLOB</a> and <a href="#">TEXT</a> columns only<br><br>(Using these types to store very large amounts of data can lower NDB Cluster performance) |
| <i>Replication Support</i>                | Asynchronous and semisynchronous replication using MySQL Replication  | Automatic synchronous replication within an NDB Cluster .<br><br>Asynchronous replication between NDB Cluster s, using MySQL Replication                                  |
| <i>Scaleout for Read Operations</i>       | Yes (MySQL Replication)   | Yes (Automatic partitioning in NDB Cluster ; NDB Cluster Replication)   |
| <i>Scaleout for Write Operations</i>      | Requires application-level partitioning (sharding)  | Yes (Automatic partitioning in NDB Cluster is transparent to applications)  |
| <i>High Availability (HA)</i>             | Requires additional software  | Yes (Designed for 99.999% uptime)   |
| <i>Node Failure Recovery and Failover</i> | Requires additional software  | Automatic   |

| Feature   | InnoDB 1.1                                 | NDB Cluster <a href="#">NDB 7.5</a>   |
|---|--|---|
|   |  | (Key element in NDB Cluster architecture)   |
| <i>Time for Node Failure Recovery</i>                                   | 30 seconds or longer                       | Typically < 1 second  |
| <i>Real-Time Performance</i>  | No   | Yes   |
| <i>In-Memory Tables</i>   | No   | Yes<br><br>(Some data can optionally be stored on disk; both in-memory and disk data storage are durable) |
| <i>NoSQL Access to Storage Engine</i>                                   | Yes  | Yes<br><br>Multiple APIs, including Memcached, Node.js/JavaScript, Java, JPA, C++, and HTTP/REST          |
| <i>Concurrent and Parallel Writes</i>                                   | Not supported                              | Up to 48 writers, optimized for concurrent writes   |
| <i>Conflict Detection and Resolution (Multiple Replication Masters)</i> | No   | Yes   |
| <i>Hash Indexes</i>   | No   | Yes   |
| <i>Online Addition of Nodes</i>   | Read-only replicas using MySQL Replication | Yes (all node types)  |
| <i>Online Upgrades</i>  | No   | Yes   |
| <i>Online Schema Modifications</i>                                      | Yes, as part of MySQL 5.6.                 | Yes.  |

### 20.1.5.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the [NDB](#) and [InnoDB](#) storage engines with regard to some common types of database-driven application workloads are shown in the following table::

| Workload  | InnoDB | NDB Cluster ( <a href="#">NDB</a> )  |
|---|--------|--|
| <i>High-Volume OLTP Applications</i>                    | Yes    | Yes  |
| <i>DSS Applications (data marts, analytics)</i>         | Yes    | Limited (Join operations across OLTP datasets not exceeding 3TB in size)                     |
| <i>Custom Applications</i>                              | Yes    | Yes  |
| <i>Packaged Applications</i>                            | Yes    | Limited (should be mostly primary key access).<br><br>NDB Cluster 7.5 supports foreign keys. |
| <i>In-Network Telecoms Applications (HLR, HSS, SDP)</i> | No     | Yes  |
| <i>Session Management and Caching</i>                   | Yes    | Yes  |

| Workload                                     | InnoDB | NDB Cluster (NDB) |
|--|--------|-------------------|
| <i>E-Commerce Applications</i>               | Yes    | Yes               |
| <i>User Profile Management, AAA Protocol</i> | Yes    | Yes               |

### 20.1.5.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

| Preferred application requirements for InnoDB   | Preferred application requirements for NDB  |
|---|---|
| <ul style="list-style-type: none"> <li>Foreign keys</li> </ul> <div style="display: flex; align-items: center;">  <div style="margin-left: 10px;"> <p><b>Note</b></p> <p>NDB Cluster 7.5 supports foreign keys.</p> </div> </div> <ul style="list-style-type: none"> <li>Full table scans</li> <li>Very large databases, rows, or transactions</li> <li>Transactions other than <code>READ COMMITTED</code></li> </ul> | <ul style="list-style-type: none"> <li>Write scaling</li> <li>99.999% uptime</li> <li>Online addition of nodes and online schema operations</li> <li>Multiple SQL and NoSQL APIs (see <a href="#">NDB Cluster APIs: Overview and Concepts</a>)</li> <li>Real-time performance</li> <li>Limited use of <code>BLOB</code> columns</li> <li>Foreign keys are supported, although their use may have an impact on performance at high throughput</li> </ul> |

### 20.1.6 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of NDB Cluster :

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in NDB Cluster 7.5, we will add it to the list.

See [Previous NDB Cluster Issues Resolved in NDB Cluster 7.3](#) for a list of issues in earlier releases that have been resolved in NDB Cluster 7.5.

**Note**

Limitations and other issues specific to NDB Cluster Replication are described in [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#).

### 20.1.6.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with [NDB](#) tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the [NDB](#) storage engine or to alter an existing temporary table to use [NDB](#) fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'.`
- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an [NDB](#) table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on [NDB](#) table columns that use any of the [TEXT](#) or [BLOB](#) data types.
  - **FULLTEXT indexes.** The [NDB](#) storage engine does not support [FULLTEXT](#) indexes, which are possible for [MyISAM](#) and [InnoDB](#) tables only.

However, you can create indexes on [VARCHAR](#) columns of [NDB](#) tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.
- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an [NDB](#) column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see [Section 20.1.6.6, “Unsupported or Missing Features in NDB Cluster”](#), for additional information.)
- **BIT columns.** A [BIT](#) column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO\_INCREMENT columns.** Like other MySQL storage engines, the [NDB](#) storage engine can handle a maximum of one [AUTO\\_INCREMENT](#) column per table. However, in the case of a Cluster table with no explicit primary key, an [AUTO\\_INCREMENT](#) column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit [AUTO\\_INCREMENT](#) column unless that column is also declared using the `PRIMARY KEY` option. Attempting to create a table with an [AUTO\\_INCREMENT](#) column that is not the table's primary key, and using the [NDB](#) storage engine, fails with an error.
- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 7.5 is comparable to that provided by [InnoDB](#), subject to the following restrictions:
  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.
  - `ON UPDATE CASCADE` is not supported when the reference is to the parent table's primary key.

This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to

the [NDB](#) kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

- `SET DEFAULT` is not supported. (Also not supported by [InnoDB](#).)
- The `NO ACTION` keywords are accepted but treated as `RESCRICT`. (Also the same as with [InnoDB](#).)
- In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

For more information, see [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#), and [Section 1.8.3.2, “FOREIGN KEY Constraints”](#).

- **NDB Cluster and geometry data types.**

Geometry data types ([WKT](#) and [WKB](#)) are supported for [NDB](#) tables. However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to `[LINEAR] KEY` partitioning. Using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see [User-defined partitioning and the NDB storage engine \(MySQL Cluster\)](#).

**Default partitioning scheme.** All NDB Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the [NDB](#) storage engine is used instead. For additional discussion of these and related issues, see [Section 21.2.5, “KEY Partitioning”](#).

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

**Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can be defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group. (See [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information about NDB Cluster node groups.)

**DROP PARTITION not supported.** It is not possible to drop partitions from [NDB](#) tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD`

`PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for Cluster tables, but use copying and so are not optimized. See [Section 21.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 14.1.8, “ALTER TABLE Syntax”](#).

- **Row-based replication.**

When using row-based replication with NDB Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of `sql_log_bin`.

- **JSON data type.** The MySQL `JSON` data type is supported for NDB tables in the `mysqld` supplied with NDB 7.5.2 and later.

An NDB table can have a maximum of 3 `JSON` columns.

The NDB API has no special provision for working with `JSON` data, which it views simply as `BLOB` data. Handling data as `JSON` must be performed by the application.

- **CPU and thread info ndbinfo tables.** NDB 7.5.2 adds several new tables to the `ndbinfo` information database providing information about CPU and thread activity by node, thread ID, and thread type. The tables are listed here:

- `cpustat`: Provides per-second, per-thread CPU statistics
- `cpustat_50ms`: Raw per-thread CPU statistics data, gathered every 50ms
- `cpustat_1sec`: Raw per-thread CPU statistics data, gathered each second
- `cpustat_20sec`: Raw per-thread CPU statistics data, gathered every 20 seconds
- `threads`: Names and descriptions of thread types

For more information about these tables, see [Section 20.5.10, “The ndbinfo NDB Cluster Information Database”](#).

- **Lock info ndbinfo tables.** NDB 7.5.3 adds new tables to the `ndbinfo` information database providing information about locks and lock attempts in a running NDB Cluster. These tables are listed here:

- `cluster_locks`: Current lock requests which are waiting for or holding locks; this information can be useful when investigating stalls and deadlocks. Analogous to `cluster_operations`.
- `locks_per_fragment`: Counts of lock claim requests, and their outcomes per fragment, as well as total time spent waiting for locks successfully and unsuccessfully. Analogous to `operations_per_fragment` and `memory_per_fragment`.
- `server_locks`: Subset of cluster transactions—those running on the local `mysqld`, showing a connection id per transaction. Analogous to `server_operations`.

## 20.1.6.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

A rolling restart of the cluster also frees any memory used by deleted rows. See [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#).

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

**Note**

Recall that `TRUNCATE TABLE` drops and re-creates the table. See [Section 14.1.34, “TRUNCATE TABLE Syntax”](#).

- **Limits imposed by the cluster's configuration.**

A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 20.3.3, “NDB Cluster Configuration Files”](#). Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#), for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

**Note**

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

- The maximum number of data nodes is 48.

A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

- The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
- The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

See [Previous NDB Cluster Issues Resolved in NDB Cluster 7.3](#), for more information.

### 20.1.6.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that NDB implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

- Increased frequency of lock wait timeout errors, and reduced concurrency
- Increased transaction processing overhead due to reads requiring a commit phase
- Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

NDB uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; `BLOB` reads also employ extra locking for consistency.

See [Section 20.5.3.4, “NDB Cluster Backup Troubleshooting”](#), for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- **Transactions and BLOB or TEXT columns.** `NDBCLUSTER` stores only part of a column value that uses any of MySQL's `BLOB` or `TEXT` data types in the table visible to MySQL; the remainder of the `BLOB` or `TEXT` is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing `SELECT` statements on tables that contain columns of these types:
  1. For any `SELECT` from an NDB Cluster table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
  2. For any `SELECT` which uses a unique key lookup to retrieve any columns that use any of the `BLOB` or `TEXT` data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having `BLOB` or `TEXT` columns.

For example, consider the table `t` defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b INT NOT NULL,
  c INT NOT NULL,
  d TEXT,
  INDEX i(b),
  UNIQUE KEY u(c)
) ENGINE = NDB,
```

Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```
SELECT * FROM t WHERE a = 1;

SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;

SELECT * FROM t WHERE d = '1';

SELECT * FROM t;

SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any [BLOB](#) or [TEXT](#) columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve [BLOB](#) or [TEXT](#) columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as [InnoDB](#) that may roll back individual statements.

- **Transactions and memory usage.**

As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:

- [TRUNCATE TABLE](#) is not transactional when used on [NDB](#) tables. If a [TRUNCATE TABLE](#) fails to empty the table, then it must be re-run until it is successful.
- [DELETE FROM](#) (even with no [WHERE](#) clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several [DELETE FROM ... LIMIT ...](#) statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use [TRUNCATE TABLE](#) instead.
- **LOAD DATA statements.** [LOAD DATA INFILE](#) is not transactional when used on [NDB](#) tables.

#### Important

When executing a [LOAD DATA INFILE](#) statement, the [NDB](#) engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.** When copying an [NDB](#) table as part of an [ALTER TABLE](#), the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the [COUNT\(\)](#) function on the slave. In other words, when performing on the master a series of statements ([INSERT](#), [DELETE](#), or both) that changes the number of rows in a table within a single transaction, executing [SELECT COUNT\(\\*\) FROM table](#) queries on the slave may yield intermediate results. This is due to the fact that [SELECT COUNT\(...\)](#) may perform dirty reads, and is not a bug in the [NDB](#) storage engine.

### 20.1.6.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 20.1.6.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”](#).

### 20.1.6.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Database and table names.** When using the `NDB` storage engine, the maximum allowed length both for database names and for table names is 63 characters. A statement using a database name or table name longer than this limit fails with an appropriate error.
- **Number of database objects.** The maximum number of *all* `NDB` database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 14000 bytes. Each `BLOB` or `TEXT` column contributes  $256 + 8 = 264$  bytes to this total.
- **BIT column storage per table.** The maximum combined width for all `BIT` columns used in a given `NDB` table is 4096.
- **FIXED column storage.** NDB Cluster 7.5 and later supports a maximum of 128 TB per fragment of data in `FIXED` columns. (Previously, this was 16 GB.)

### 20.1.6.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by `NDB`, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for `NDB` tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is not created by `NDB`.

A statement containing an index prefix, and creating or modifying an `NDB` table, must still be syntactically valid. For example, the following statement always fails with Error 1089 `Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys`, regardless of storage engine:

```
CREATE TABLE t1 (
  c1 INT NOT NULL,
  c2 VARCHAR(100),
```

```
INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in [MyISAM](#).
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication and binary logging.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 20.6, “NDB Cluster Replication”](#), for more information.

Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 7.5. Do not enable GTIDs when using the [NDB](#) storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

- **Generated columns.** The [NDB](#) storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that [NDB](#) uses [DataMemory](#) for storage of the generated column as well as [IndexMemory](#) for the index. See [JSON columns and indirect indexing in MySQL Cluster](#), for an example.

NDB Cluster writes changes in stored generated columns to the binary log, but does log not those made to virtual columns. This should not effect NDB Cluster Replication or replication between [NDB](#) and other MySQL storage engines.

#### Note

See [Section 20.1.6.3, “Limits Relating to Transaction Handling in NDB Cluster”](#), for more information relating to limitations on transaction handling in [NDB](#).

### 20.1.6.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster :

- **Range scans.** There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- **Reliability of Records in range.** The [Records in range](#) statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) to alter the execution plan. See [Section 9.9.4, “Index Hints”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.

### 20.1.6.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the [NDB](#) storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running [mysql](#) or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.**

NDB Cluster has the following limitations or restrictions with regard to binary logging:

- `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
- NDB Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
- Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
  - `CREATE TABLE`
  - `ALTER TABLE`
  - `DROP TABLE`
  - `CREATE DATABASE / CREATE SCHEMA`
  - `DROP DATABASE / DROP SCHEMA`
  - `CREATE TABLESPACE`
  - `ALTER TABLESPACE`
  - `DROP TABLESPACE`
  - `CREATE LOGFILE GROUP`
  - `ALTER LOGFILE GROUP`
  - `DROP LOGFILE GROUP`
- Schema operations (DDL statements) are rejected while any data node restarts.

See also [Section 20.1.6.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 20.1.6.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces:  $2^{32}$  (4294967296)
- Maximum number of data files per tablespace:  $2^{16}$  (65536)
- Maximum data file size: The theoretical limit is 64G; however, the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

Since an NDB Cluster Disk Data table can use at most 1 tablespace, this means that the theoretical upper limit to the amount of data (in bytes) that can be stored on disk by a single `NDB` table is  $32\text{G} * 65536 = 2251799813685248$ , or approximately 2 petabytes.

- The theoretical maximum number of extents per tablespace data file is  $2^{16}$  (65536); however, for practical purposes, the recommended maximum number of extents per data file is  $2^{15}$  (32768).

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 14.1.19, “CREATE TABLESPACE Syntax”](#), for more information.

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.

### 20.1.6.10 Limitations Relating to Multiple NDB Cluster Nodes

**Multiple SQL nodes.**

The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the [NDBCLUSTER](#) storage engine:

- **No distributed table locks.** A [LOCK TABLES](#) works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** [ALTER TABLE](#) is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

#### Multiple management nodes.

When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.
- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

#### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#), for more information.

## 20.2 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in [Section 20.3, “Configuration of NDB Cluster”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see [Section 20.2.8, “Upgrading and Downgrading NDB Cluster”](#).

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

NDB Cluster 7.5 also provides an NDB Cluster Auto-Installer, a web-based graphical installer, as part of the NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB Cluster on one (for testing) or more host computers. See [Section 20.2.1, “The NDB Cluster Auto-Installer”](#), for more information.

**Assumptions.** The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

**Cluster nodes and host computers.** The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

| Node                                  | IP Address   |
|---------------------------------------|--------------|
| Management node ( <code>mgmd</code> ) | 192.168.0.10 |
| SQL node ( <code>mysqld</code> )      | 192.168.0.20 |
| Data node "A" ( <code>ndbd</code> )   | 192.168.0.30 |
| Data node "B" ( <code>ndbd</code> )   | 192.168.0.40 |

This may be made clearer by the following diagram:

**Figure 20.4 NDB Cluster Multi-Computer Setup**

**Network addressing.** In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1    ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1    ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1      localhost
127.0.0.2      ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1      localhost
127.0.0.2      ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

### Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

### Important

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL Web site (see <http://dev.mysql.com/doc/index-other.html>). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see [Chapter 2, \*Installing and Upgrading MySQL\*](#). For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see [Section 20.2.2, “Installation of NDB Cluster on Linux”](#). For information about installation of NDB Cluster on Windows operating systems, see [Section 20.2.3, “Installing NDB Cluster on Windows”](#).

For general information about NDB Cluster hardware, software, and networking requirements, see [Section 20.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”](#).

## 20.2.1 The NDB Cluster Auto-Installer

- [Section 20.2.1.1, “NDB Cluster Auto-Installer Requirements”](#)
- [Section 20.2.1.2, “NDB Cluster Auto-Installer Overview”](#)
- [Section 20.2.1.3, “Using the NDB Cluster Auto-Installer”](#)

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

### 20.2.1.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

**Supported platforms.** The NDB Cluster Auto-Installer is available with most NDB 7.5.2 and later NDB Cluster distributions for recent versions of Linux, Windows, Solaris, and MacOS X. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see <http://www.mysql.com/support/supportedplatforms/cluster.html>.

The NDB Cluster Auto-Installer is not supported with NDB 7.5.0 or 7.5.1 (Bug #79853, Bug #22502247).

**Supported Web browsers.** The Web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compability with these browsers.

**Required software—setup host.** The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, they can be downloaded from <http://python.org/download/>.
- **Paramiko 1.7.7.1 or higher.** This is required to communicate with remote hosts using SSH. You can download it from <http://www.lag.net/paramiko/>. Paramiko may also be available from your system's package manager.
- **Pycrypto version 2.6 or higher.** This cryptography module is required by Paramiko. If it is not available using your system's package manager, you can download it from <https://www.dlitz.net/software/pycrypto/>.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

The Paramiko and Pycrypto libraries are required only if you intend to deploy NDB Cluster nodes on remote hosts, and are not needed if all nodes are on the same host where the installer is run.

**Required software—remote hosts.** The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_servers](http://en.wikipedia.org/wiki/Comparison_of_SSH_servers).

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

**Authentication and security.** Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

#### Important

You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see [Section 7.1.5, “How to Run MySQL as a Normal User”](#).

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user's SSH password is transmitted in clear text that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https` and `--cert-file` options.
- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file` option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also [Section 20.5.12, “NDB Cluster Security Issues”](#), which discusses security considerations to take into account when deploying NDB Cluster, as well as [Chapter 7, Security](#), for more general MySQL security information.

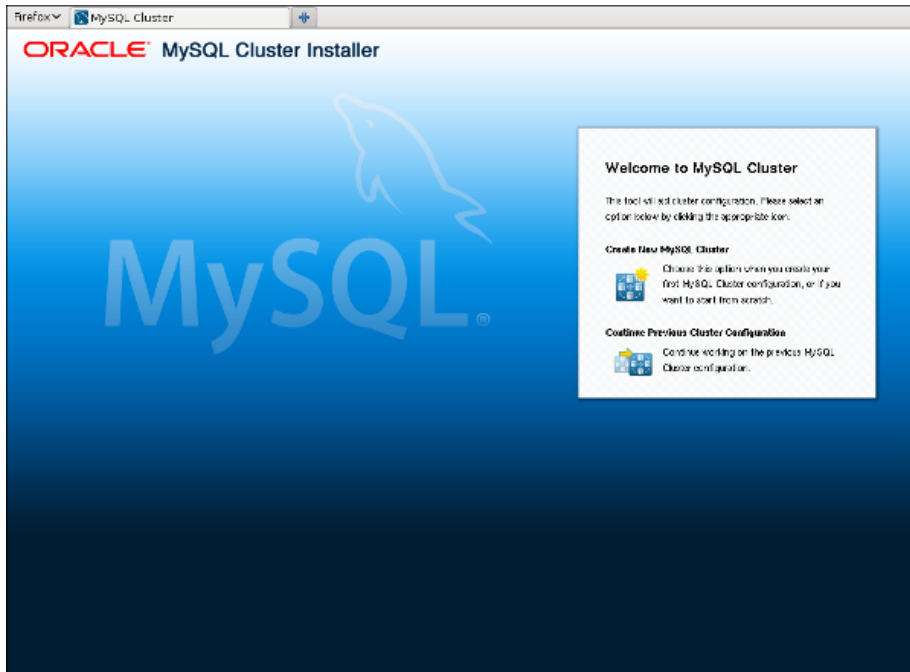

### 20.2.1.2 NDB Cluster Auto-Installer Overview

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer (see [Section 20.2.1.1, “NDB Cluster Auto-Installer Requirements”](#)). The back end is a server process (`ndb_setup.py`) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access, using the Paramiko library for executing commands remotely (see [Section 20.2.1.1, “NDB Cluster Auto-Installer Requirements”](#)).

The remainder of this section is concerned primarily with the Web client. For more information about using the command-line tool, see [Section 20.4.23, “ndb\\_setup.py — Start browser-based Auto-Installer for NDB Cluster”](#).

**NDB Cluster Auto-Installer Interface.** This section describes the layout and navigation of the NDB Cluster Auto-Installer, whose Welcome screen looks similar to what is shown here when it is first opened in the Web browser:

**Figure 20.5 Welcome Screen For NDB Cluster Auto-Installer**

You can access the installer UI by selecting either of the options **Create New NDB Cluster** or **Continue Previous Cluster Configuration**. A typical screen in the Auto-Installer includes the following elements:

1. **Display panel.** The central area where data regarding configuration settings and controls for changing them are displayed.
2. **Breadcrumb navigation.** Located in the top left and top center of the GUI, the breadcrumb navigation bar consists of a series of titles linking to screens that correspond to steps in the configuration of an NDB Cluster. The breadcrumb allows you to jump between these stages in arbitrary order.
3. **Sequential navigation.** This consists of a set of buttons labelled **Previous**, **Next**, and **Finished**, and can be found in the lower right-hand corner of the GUI. The sequential navigation is used to move between steps in the suggested order.
4. **Settings and Help menus.** These menus can be found in the top right corner of the GUI (to the right of the breadcrumb navigation bar). **Settings** provides a way check and possibly alter configuration settings for the Auto-Installer; **Help** can be used to access the installer's built-in help files.

The locations of the elements just described are shown here in a typical page in the Auto-Installer; the numbers superimposed thereupon correspond to those used in the preceding list.

**Figure 20.6 Layout of the NDB Cluster Auto-Installer GUI**

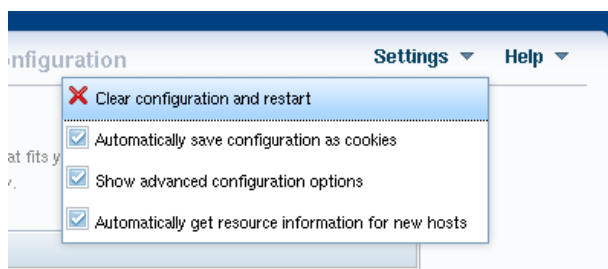

All of these elements except for the display panel are described in greater detail in the remainder of this section. [Section 20.2.1.3, “Using the NDB Cluster Auto-Installer”](#), describes the panels shown in the display area as well as the functionality of each panel and the controls it contains.

**Arbitrary and sequential navigation.** The Auto-Installer can display any of a number of pages covering different stages in the setup and configuration of an NDB Cluster deployment. You can navigate between pages in either of two ways. The first of these is the breadcrumb trail navigation toolbar displaying the titles of the various pages (in which the title of the current page is highlighted and disabled). From these, any desired page, in any desired order, can be reached by selecting the title of the corresponding page. This toolbar is shown here:

**Figure 20.7 Detail of NDB Cluster Auto-Installer breadcrumb navigation, showing page titles/links**

The second navigation mechanism provided by the Auto-Installer consists of the **Next**, **Previous**, and **Finish** sequential navigation buttons at the bottom right of the page. These can be used to move to the next or previous page in predetermined order, or to go to the very last page. The buttons are enabled and disabled as needed, so that you cannot, for example, advance beyond the last page.

**Settings and Help menus.** These menus are positioned adjacent to one another in the top right corner of the GUI, as shown earlier in this section. The **Settings** menu is shown here in more detail:

**Figure 20.8 NDB Cluster Auto-Installer Settings menu detail**

The entries in the **Settings** menu are described here, in the following list:

- **Clear configuration and restart:** Remove all hosts and processes; reset all parameter values to their defaults; start the installer over at the first page.
- **Automatically save configuration as cookies:** Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session).

Since the SSH password is never saved, you must supply this once again at the beginning of a new session, if one is used.

- **Show advanced configuration options:** Show advanced configuration parameters in the Auto-Installer and make these settable by the user.

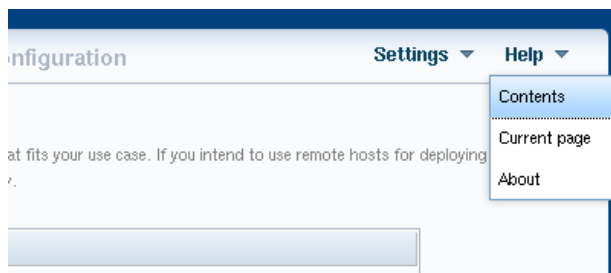

Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.

- **Automatically get resource information for new hosts:** Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

As with the installer's navigation elements, one or more of the entries in the **Settings** menu may be disabled due to choices you have made previously.

The **Help** menu is shown here, as it appears when expanded:

**Figure 20.9 The NDB Cluster Auto-Installer Help menu, expanded**

The **Help** menu provides several options, described in the following list:

- **Content:** Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.
- **Current page:** Open the built-in user guide to the section describing the page currently displayed in the installer.
- **About:** This will show a small dialog displaying the installer name and the version number of the NDB Cluster distribution it was supplied with, similar to what is shown here:

**Figure 20.10 The NDB Cluster Auto-Installer About dialog**

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets. One of these tooltips is displayed when the mouse hovers over a widget or the small question mark which can sometimes appear next to a widget label.

In addition, the names of NDB Cluster configuration parameters are linked to their descriptions in the online NDB Cluster documentation, so that if you click on the name of a given parameter, the documentation for that parameter is shown in a separate window.

### 20.2.1.3 Using the NDB Cluster Auto-Installer

- [Starting the NDB Cluster Auto-Installer](#)
- [NDB Cluster Auto-Installer Welcome Screen](#)
- [NDB Cluster Auto-Installer Define Cluster Screen](#)
- [NDB Cluster Auto-Installer Define Hosts Screen](#)
- [NDB Cluster Auto-Installer Define Processes Screen](#)
- [NDB Cluster Auto-Installer Define Attributes Screen](#)
- [NDB Cluster Auto-Installer Deploy Cluster Screen](#)

The NDB Cluster Auto-Installer consists of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster , and listed here:

- **Welcome:** Begin using the Auto-Installer by choosing either to configure a new NDB Cluster , or to continue configuring an existing one.
- **Define Cluster:** Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
- **Define Hosts:** Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes:** Assign one or more processes of a given type or types to each cluster host.
- **Define Attributes:** Set configuration attributes for processes or types of processes.
- **Deploy Cluster:** Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

The following sections describe in greater detail the purpose and function of each of these pages, in the order just listed.

#### Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. (See [Section 20.2, “NDB Cluster Installation”](#).) The present section explains how to start the installer. You can do by invoking the

`ndb_setup.py` executable. `ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 5.6\bin` on a Windows system, but this can vary according to where the NDB Cluster software is installed on your system.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, it accepts the same options as does `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

```
shell> ndb_setup
```

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the **`ndb_setup.py`** file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the **`setup.bat`** file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's **Welcome screen** should open in the system's default Web browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying a different port for the Auto-Installer's included Web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) For information about advanced startup options for the NDB Cluster Auto-Installer, see [Section 20.4.23, “`ndb\_setup.py` — Start browser-based Auto-Installer for NDB Cluster](#)”.

## NDB Cluster Auto-Installer Welcome Screen

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked, as shown here:

**Figure 20.11 The NDB Cluster Auto-Installer Welcome screen (Closeup)**

This screen provides the following two choices for entering the installer, one of which must be selected to continue:

1. **Create New NDB Cluster** : Start the Auto-Installer with a completely new cluster to be set up and deployed.
2. **Continue Previous Cluster Configuration**: Start the Auto-Installer at the same point where the previous session ended, with all previous settings preserved.

The second option requires that the browser be able to access its cookies from the previous session, as these provide the mechanism by which configuration and other information generated during a session is stored. In other words, to continue the previous session with the Auto-Installer, you must use the same web browser running on the same host as you did for the previous session.

## **NDB Cluster Auto-Installer Define Cluster Screen**

The **Define Cluster** screen is the first screen to appear following the choice made in the [Welcome screen](#), and is used for setting general properties of the cluster. The layout of the **Define Cluster** screen is shown here:

**Figure 20.12 The NDB Cluster Auto-Installer Define Cluster screen**

Define cluster > Define hosts > Define processes > Define parameters > Deploy configuration

**Cluster type and SSH Credentials**  
MySQL Cluster is able to operate in various configurations. Please specify the settings below to define the right cluster type that fits your use case. If you intend to use remote hosts for deploying MySQL Cluster, SSH must be enabled. Unless key-based SSH is possible, you must submit your user name and password below.

| Cluster property | Value          |
|------------------|----------------|
| Cluster name     | MyCluster      |
| Host list        | 127.0.0.1      |
| Application area | Simple testing |
| Write load       | medium         |

| SSH property  | Value                               |
|---------------|-------------------------------------|
| Key-based SSH | <input checked="" type="checkbox"/> |
| User name     |                                     |
| Password      |                                     |

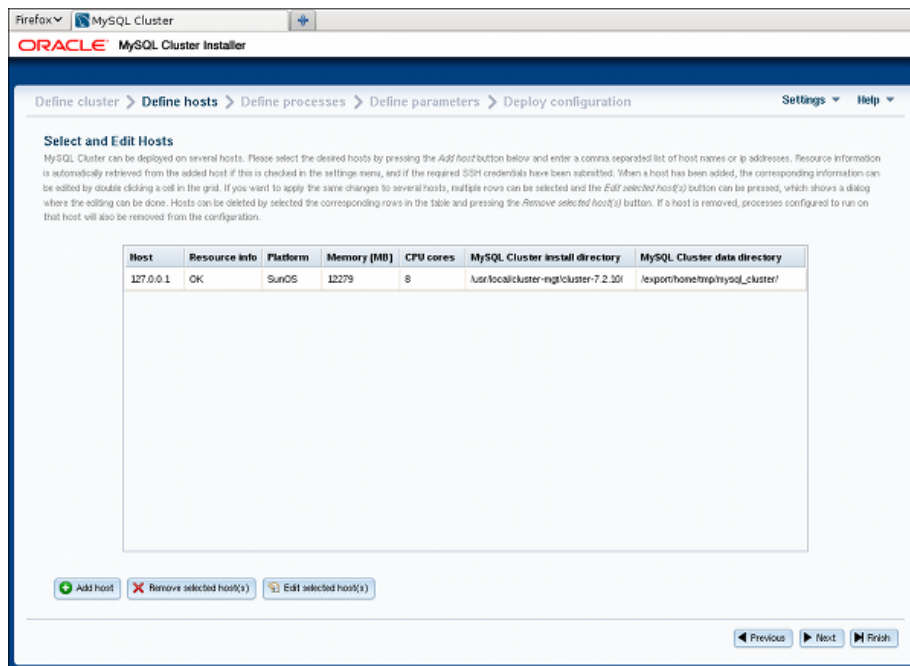

Previous Next Finish

The **Define Cluster** screen allows you to set a number of general properties for the cluster, as described in this list:

- **Cluster name:** A name that identifies the cluster. The default is `MyCluster`.
- **Host list:** A comma-delimited list of one or more hosts where cluster processes should run. By default, this is `127.0.0.1`. If you add remote hosts to the list, you must be able to connect to them using the **SSH Credentials** supplied.
- **Application type:** Choose one of the following:
  1. **Simple testing:** Minimal resource usage for small-scale testing. This the default. *Not intended for production environments.*
  2. **Web:** Maximize performance for the given hardware.
  3. **Real-time:** Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.
- **Write load:** Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
  1. **Low:** The expected load includes fewer than 100 write transactions for second.
  2. **Medium:** The expected load includes 100 to 1000 write transactions per second.
  3. **High:** The expected load includes more than 1000 write transactions per second.
- **SSH Credentials:** Choose **Key-Based SSH** or enter **User** and **Password** credentials. The SSH key or a user name with password is required for connecting to any remote hosts specified in the **Host list**. By default, **Key-Based SSH** is selected, and the **User** and **Password** fields are blank.

## NDB Cluster Auto-Installer Define Hosts Screen

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

**Figure 20.13 NDB Cluster Define Hosts screen**

The hosts currently entered are displayed in the grid with various pieces of information. You can add hosts by clicking the **Add hosts** button and entering a list of one or more comma-separated host names, IP addresses, or both (as when editing the host list on the [Define Cluster screen](#)).

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. When you remove a host in this fashion, any process which was configured for that host is also removed.

If **Automatically get resource information for new hosts** is checked in the [Settings menu](#), the Auto-Installer attempts to retrieve the platform name, amount of memory, and number of CPU cores and to fill these in automatically. The status of this is displayed in the *Resource info* column. Fetching the information from remote hosts is not instantaneous and may take some time, particularly from remote hosts running Windows.

If the SSH user credentials on the [Define Cluster screen](#) are changed, the tool tries to refresh the hardware information from any hosts for which information is missing. However, if a given field has already been edited, the user-supplied information is *not* overwritten by any value fetched from that host.

The hardware resource information, platform name, installation directory, and data directory can be edited by the user by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

**Figure 20.14 NDB Cluster Auto-Installer Edit Hosts dialog**

When more than one host is selected, any edited values are applied to all selected hosts.

## NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

**Figure 20.15 NDB Cluster Auto-Installer Define Processes dialog**

The left-hand portion of this screen contains a process tree showing cluster hosts and processes set up to run on each one. On the right is a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the **Define Hosts** screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the following types:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.
- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtdd`.
- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.
- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See [MySQL NDB Cluster API Developer Guide](#), for more information.

For more information about process (node) types, see [Section 20.1.1, “NDB Cluster Core Concepts”](#).

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node *may* be assigned to a single host, but this is not

required. Instead, you can assign it to the special **Any host** entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this **Any host** entry.*

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

**Figure 20.16 NDB Cluster Auto-Installer Add Process Dialog**

Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

**Removing processes.** To delete a process, right-click on a process in the tree and select **delete process** from the pop up menu that appears, or select a process, then use the **delete process** button below the process tree.

When a process is selected in the process tree, information about that process is displayed in the panel to the right of the tree, where you can change the process name and possibly its type. *Important:* Currently, you can change a single-threaded data node (`ndbd`) to a multi-threaded data node (`ndbmt_d`), or the reverse, only; no other process type changes are allowed. If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.

## NDB Cluster Auto-Installer Define Attributes Screen

This screen has a layout similar to that of the [Define Processes screen](#), with a process tree at the left. Unlike that screen's tree, the **Define Attributes** process tree is organized by process or node type, with single-threaded and multi-threaded data nodes considered to be of the same type for this purpose, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. A panel to the right of this tree displays information regarding the item currently selected. The **Define Attributes** screen is shown here:

Figure 20.17 NDB Cluster Auto-Installer Define Attributes screen

A checkbox labelled **Show advanced configuration** is located below the process tree. Checking this box makes advanced options visible in the information pane. These options are set and used whether or not they are visible.

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:

Figure 20.18 Define Attributes Detail With SQL Process Attributes

For some of the attributes shown in the information panel, a button bearing a plus sign is displayed to the right, which means that the value of this attribute can be overridden. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X, as shown here:

**Figure 20.19 Define Attributes Detail, Overriding Attribute Default Value**

Clicking the **X** button next to an attribute undoes any changes made to it; it immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

## NDB Cluster Auto-Installer Deploy Cluster Screen

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Cluster** screen is shown here:

**Figure 20.20 NDB Cluster Auto-Installer Deploy Cluster screen**

Like the [Define Attributes screen](#), this screen features a process tree, organized by process type, on the left hand side. Next to each process is a status icon whose color indicates the current status of the process: green if it is running; yellow if it is starting or stopping; red if the process is stopped.

To the right of the process tree are two information panels, the upper panel showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The lower panel shows the contents of the configuration file, if any, for the given process; currently, the management node process is only type of process having a configuration file. Other process types are configured using command-line parameters when starting the process, or by obtaining configuration information from the management nodes as needed in real time.

Three buttons are located immediately below the process tree. These are labelled as and perform the functions described in the following list:

- **Deploy cluster:** Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded.
- **Start cluster:** The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

**Figure 20.21 Progress Bar With Status of Node Startup Process**

The process status icons adjoining the process tree mentioned previously also update with the status of each process.

- **Stop cluster:** After the cluster has been started, you can stop it using the this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree.

The Auto-Installer generates a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster.

## 20.2.2 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see [Section 20.2.3, “Installing NDB Cluster on Windows”](#).

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmtd`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a `.tar.gz` archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See [Section 20.2.4, “Initial Configuration of NDB Cluster”](#).

### 20.2.2.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest NDB Cluster 7.5 binary archive (`mysql-cluster-gpl-7.5.5-linux-i686-glibc23.tar.gz`) from the [NDB Cluster downloads area](#). We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).)

#### Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see [Section 20.2.4, “Initial Configuration of NDB Cluster”](#)).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql -s /bin/false mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

#### Note

The actual file and directory names vary according to the NDB Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzf mysql-cluster-gpl-7.5.5-linux2.6.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-7.5.5-linux2.6-i686 /usr/local/mysql
```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

```
shell> cd mysql
shell> mysqld --initialize
```

This generates a random password for the MySQL `root` account. If you do *not* want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#), for additional information before performing this step. See also [Section 5.4.4, “mysql\\_secure\\_installation — Improve MySQL Installation Security”](#).

Alternatively, you can change location to the `mysql` directory and run `mysql_install_db` to create the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

However, this method is not recommended, due to the fact that `mysql_install_db` is deprecated, and thus subject to removal in a future release.

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtbd` (multi-threaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtbd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.7.16-ndb-7.5.5-linux-i686-glibc23.tar.gz
shell> cd mysql-5.7.16-ndb-7.5.5-linux-i686-glibc23
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtbd /usr/local/bin/ndbmtbd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtbd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

#### Note

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 20.2.4, "Initial Configuration of NDB Cluster"](#).)

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.7.16-ndb-7.5.5-linux2.6-i686.tar.gz
shell> cd mysql-5.7.16-ndb-7.5.5-linux2.6-i686
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster .

### 20.2.2.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster node using RPM packages supplied by Oracle beginning with NDB 7.5.4. For information about RPMs for previous versions of NDB Cluster , see [Installation using old-style RPMs \(NDB 7.5.3 and earlier\)](#).

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-license-component-ver-rev.distro.arch.rpm

license:= {commercial | community}

component: {management-server | data-node | server | client | other-see text}

ver: major.minor.release

rev: major.minor

distro: {el5 | el6 | el7 | sles12}

arch: {i686 | x86_64}
```

*license* indicates whether the RPM is part of a Commercial or Community release of NDB Cluster . In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for *component*, with descriptions, can be found in the following table:

| Component              | Description  |
|------------------------|--|
| <i>auto-installer</i>  | NDB Cluster Auto Installer program; see <a href="#">Section 20.2.1, “The NDB Cluster Auto-Installer”</a> , for usage |
| <i>client</i>          | MySQL and NDB client programs; includes <i>mysql</i> client, <i>ndb_mgm</i> client, and other client tools           |
| <i>common</i>          | Character set and error message information needed by the MySQL server   |
| <i>data-node</i>       | <i>ndbd</i> and <i>ndbmt</i> data node binaries  |
| <i>devel</i>           | Headers and library files needed for MySQL client development  |
| <i>embedded</i>        | Embedded MySQL server  |
| <i>embedded-compat</i> | Backwards-compatible embedded MySQL server   |
| <i>embedded-devel</i>  | Header and library files for developing applications for embedded MySQL  |

| Component                      | Description   |
|--------------------------------|---|
| <code>java</code>              | JAR files needed for support of ClusterJ applications   |
| <code>libs</code>              | MySQL client libraries  |
| <code>libs-compat</code>       | Backwards-compatible MySQL client libraries   |
| <code>management-server</code> | The NDB Cluster management server ( <code>ndb_mgmd</code> )   |
| <code>memcached</code>         | Files needed to support <code>ndbmemcache</code>  |
| <code>ndbclient</code>         | NDB client library for running NDB API and MGM API applications ( <code>libndbclient</code> )                           |
| <code>ndbclient-devel</code>   | Header and other files needed for developing NDB API and MGM API applications   |
| <code>nodejs</code>            | Files needed to set up Node.JS support for NDB Cluster  |
| <code>server</code>            | The MySQL server ( <code>mysqld</code> ) with NDB storage engine support included, and associated MySQL server programs |
| <code>test</code>              | <code>mysqltest</code> , other MySQL test programs, and support files   |

A single bundle (`.tar` file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- *Management node*: `management-server`
- *Data node*: `data-node`
- *SQL node*: `server` and `common`

In addition, the `client` RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part NDB storage engine version number in 7.5.x format, shown as 7.5.5 in the examples. `rev` provides the RPM revision number in *major.minor* format. In the examples shown in this section, we use 1.1 for this value.

The `distro` (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `el6` (Oracle Linux 6, Red Hat Enterprise Linux 6), `el7` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (`el7`).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as `7.5.5`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

**Data nodes.** On a computer that is to host an NDB Cluster data node it is necessary to install only the `data-node` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv mysql-cluster-community-data-node-7.5.5-1.1.el7.x86_64.rpm
```

This installs the `ndbd` and `ndbmtd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

**SQL nodes.** Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv mysql-cluster-community-server-7.5.5-1.1.el7.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with NDB storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

#### Important

You must use the versions of these RPMs released for NDB Cluster ; those released for the standard MySQL server do not provide support for the NDB storage engine.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv mysql-cluster-community-client-7.5.5-1.1.el7.x86_64.rpm
```

This installs the `mysql` client and other MySQL client programs, such as `mysqladmin` and `mysqldump`, to `/usr/bin`.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `management-server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `management-server` RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv mysql-cluster-commercial-management-server-7.5.5-1.1.el7.x86_64.rpm
```

This RPM installs the management server binary `ndb_mgmd` in the `/usr/sbin` directory. While this is the only program actually required for running a management node, it is also a good idea to have the `ndb_mgm` NDB Cluster management client available as well. You can obtain this program, as well as other NDB client programs such as `ndb_desc` and `ndb_config`, by installing the `client` RPM as described previously.

**Note**

Previously, `ndb_mgm` was installed by the same RPM used to install the management server. In NDB 7.5.4 and later, all NDB client programs are obtained from the same `client` RPM that installs `mysql` and other MySQL clients.

See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), for the relevant information.

**Installation using old-style RPMs (NDB 7.5.3 and earlier).** *The information in the remainder of this section applies only to NDB 7.5.3 and earlier, and provides the steps necessary to install the correct executables for each type of NDB Cluster node using “old-style” RPM packages as supplied by Oracle prior to NDB 7.5.4. The filenames for these “old-style” RPMs use the following pattern:*

```
MySQL-Cluster-component-producttype-ndbversion-revision.distribution.architecture.rpm

component:= {server | client [| other]}

producttype:= {gpl | advanced}

ndbversion:= major.minor.release

distribution:= {sles11 | rhel5 | el6}

architecture:= {i386 | x86_64}
```

The `component` can be `server` or `client`. (Other values are possible, but since only the `server` and `client` components are required for a working NDB Cluster installation, we do not discuss them here.) The `producttype` for Community RPMs downloaded from <http://dev.mysql.com/downloads/cluster/> is always `gpl`; `advanced` is used to indicate commercial releases. `ndbversion` represents the three-part NDB storage engine version number in 7.5.x format; we use 7.5.3 throughout the rest of this section. The RPM `revision` is shown as 1 in the examples following. The `distribution` can be one of `sles11` (SUSE Enterprise Linux 11), `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), or `el6` (Oracle Linux 6, Red Hat Enterprise Linux 6). The `architecture` is `i386` for 32-bit RPMs and `x86_64` for 64-bit versions.

For an NDB Cluster, one and possibly two RPMs are required:

- The `server` RPM (for example, `MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm`), which supplies the core files needed to run a MySQL Server with NDBCLUSTER storage engine support (that is, as an NDB Cluster SQL node) as well as all NDB Cluster executables, including the management node, data node, and `ndb_mgm` client binaries. This RPM is always required for installing NDB Cluster.
- If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the `client` RPM (for example, `MySQL-Cluster-client-gpl-7.5.3-1.sles11.i386.rpm`), which supplies the `mysql` client

*It is very important that all of the Cluster RPMs to be installed have the same version number. The `architecture` designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.*

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the `server` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program `ndbd` or `ndbmtdd` (both in `/usr/sbin`) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm
```

This installs the MySQL server binary (`mysqld`) with NDB storage engine support in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-client-gpl-7.5.3-1.sles11.i386.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `server` RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.5.3-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The `server` RPM also installs `ndb_mgm`, the NDB management client.

See [Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”](#), for general information about installing MySQL using RPMs supplied by Oracle. See [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), for information about required post-installation configuration.

### 20.2.2.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such as Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle provides `.deb` installer files for NDB Cluster 7.5 for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, `ndbver` is the 3-part NDB engine version number, `debianver` is the major version of Debian (6.0 or 7), and `arch` is one of `i386` or `x86_64`. In the examples that follow, we assume you wish to install NDB 7.5.5 on a 64-bit Debian 7 system; in this case, the installer file is named `mysql-cluster-gpl-7.5.5-debian7-x86_64.deb`.

Once you have downloaded the appropriate `.deb` file, you can install it from the command line using `dpkg`, like this:

```
shell> dpkg -i mysql-cluster-gpl-7.5.5-debian7-i386.deb
```

You can also remove it using `dpkg` as shown here:

```
shell> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as `GDebi` for the Gnome desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where `version` is the 2-part release series version for the included MySQL server. For NDB 7.5, this is always `5.7`. The directory layout is the same as that for the generic Linux binary distribution (see [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

## 20.2.2.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see [Section 2.9, “Installing MySQL from Source”](#). For information about compiling NDB Cluster on Windows platforms, see [Section 20.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at <http://dev.mysql.com/downloads/cluster/>. The archived source file should have a name similar to `mysql-cluster-gpl-7.5.5.tar.gz`. You can also obtain MySQL development sources from [launchpad.net](http://launchpad.net). *Building NDB Cluster from standard MySQL Server 5.7 sources is not supported.*

The `WITH_NDBCLUSTER_STORAGE_ENGINE` option for `CMake` causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option (or its alias `WITH_NDBCLUSTER`) is required when building NDB Cluster .

### Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster , see [Options for Compiling NDB Cluster](#) .

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.** When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.** The only executable required on a data node host is the data node binary `ndbd` or `ndbmt.d`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmt.d` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multi-threaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmtbd` to be built automatically; `make install` places the `ndbmtbd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.9, “Installing MySQL from Source”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.9, “Installing MySQL from Source”](#) on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), we create configuration files for all of the nodes in our example NDB Cluster.

## 20.2.3 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 7.5 binaries for Windows can be obtained from <http://dev.mysql.com/downloads/cluster/>. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see [Section 20.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see [Section 20.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

### 20.2.3.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary `no-install` NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see [Section 20.2, “NDB Cluster Installation”](#)), as shown in the following table:

| Node                    | IP Address   |
|-------------------------|--------------|
| Management (MGMD) node  | 192.168.0.10 |
| MySQL server (SQL) node | 192.168.0.20 |
| Data (NDBD) node "A"    | 192.168.0.30 |
| Data (NDBD) node "B"    | 192.168.0.40 |

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtbd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtbd.exe`, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

#### Note

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows binary archive from <http://dev.mysql.com/downloads/cluster/>. This archive has a filename of the form `mysql-cluster-gpl-noinstall-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as 7.5.5), and `arch` is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the NDB Cluster 7.5.5 `no-install` archive for 32-bit Windows systems is named `mysql-cluster-gpl-noinstall-7.5.5-win32.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the `no-install` archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address 192.168.0.20, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-noinstall-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.7`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.7\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see [Section 2.3.5, "Installing MySQL on Microsoft Windows Using a noinstall Zip Archive"](#).

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see [Section 2.3.5.2, "Creating an Option File"](#)), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

**Data nodes.** An NDB Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmtl.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmtl.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=192.168.0.10 # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
# Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

- The IP address or hostname of any SQL nodes
- The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
- The number of replicas, using the `NoOfReplicas` configuration parameter (see [Section 20.1.2, "NDB Cluster Nodes, Node Groups, Replicas, and Partitions"](#))
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2 # Number of replicas
```

```

DataDir=C:/mysql/cluster-data      # Directory for each data node's data files
                                   # Forward slashes used in directory path,
                                   # rather than backslashes. This is correct;
                                   # see Important note in text
DataMemory=80M                    # Memory allocated to data storage
IndexMemory=18M                   # Memory allocated to index storage
                                   # For DataMemory and IndexMemory, we have used the
                                   # default values. Since the "world" database takes up
                                   # only about 500KB, this should be more than enough for
                                   # this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=192.168.0.10              # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs  # Directory for management node log files

[ndbd]
# Options for data node "A":
                                   # (one [ndbd] section per data node)
HostName=192.168.0.30              # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=192.168.0.40              # Hostname or IP address

[mysqld]
# SQL node options:
HostName=192.168.0.20              # Hostname or IP address

```

Save this file as the text file `C:\mysql\bin\config.ini`.

### Important

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the `[ndb_mgmd]` section of an NDB Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs    # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

## 20.2.3.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build NDB Cluster, you must use the NDB Cluster sources, which you can obtain from <http://dev.mysql.com/downloads/cluster/>.

Attempting to build NDB Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` or `WITH_NDBCLUSTER` option in addition to any other build options you wish to use with CMake. (`WITH_NDBCLUSTER` is supported as an alias for `WITH_NDBCLUSTER_STORAGE_ENGINE`, and works in exactly the same way.)

#### Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see [Options for Compiling NDB Cluster](#).

Once the build process is complete, you can create a Zip archive containing the compiled binaries; [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#) provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see [Section 20.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”](#).

### 20.2.3.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.7.16-ndb-7.5.5
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See [Section 20.2.3.4, “Installing NDB Cluster Processes as Windows Services”](#), where we show how to install and run NDB Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

#### Important

An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by

starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

For additional information about options which can be used with `ndb_mgmd`, see [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), as well as [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see [Section 20.2.3.4, “Installing NDB Cluster Processes as Windows Services”](#).)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.7.16-ndb-7.5.5)
Node 3: starting (Last completed phase 3) (mysql-5.7.16-ndb-7.5.5)

Node 2: starting (Last completed phase 4) (mysql-5.7.16-ndb-7.5.5)
Node 3: starting (Last completed phase 4) (mysql-5.7.16-ndb-7.5.5)

Node 2: Started (version 7.5.5)
Node 3: Started (version 7.5.5)

ndb_mgm>
```

#### Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#).

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=3 @192.168.0.40 (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.7.16-ndb-7.5.5)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.7.16-ndb-7.5.5)
```

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster's `NDBCLUSTER` storage engine. See [Section 20.2.6, "NDB Cluster Example with Tables and Data"](#), for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtdd.exe` as Windows services. For information on how to do this, see [Section 20.2.3.4, "Installing NDB Cluster Processes as Windows Services"](#).

### 20.2.3.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical `Services` utility.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
as 'C:\mysql\bin\ndbd.exe' "--service=ndb_mgmd"
Service successfully installed.
```

### Important

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> NET START ndb_mgmd
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP ndb_mgmd
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmdl
Installing service 'NDB Cluster Management Server'
as 'C:\mysql\bin\ndb_mgmd.exe' "--service=mgmdl"
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> NET START mgmdl
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP mgmdl
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster  Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the `--remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmdl
Removing service 'mgmdl'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtl.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster  Data Node Daemon' as 'C:\mysql\bin\ndbd.exe' "--service=ndbd"
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd
The NDB Cluster  Data Node Daemon service is starting.
The NDB Cluster  Data Node Daemon service was started successfully.

C:\> NET STOP ndbd
The NDB Cluster  Data Node Daemon service is stopping..
The NDB Cluster  Data Node Daemon service was stopped successfully.

C:\> NET START 'NDB Cluster  Data Node Daemon'
The NDB Cluster  Data Node Daemon service is starting.
The NDB Cluster  Data Node Daemon service was started successfully.

C:\> NET STOP 'NDB Cluster  Data Node Daemon'
The NDB Cluster  Data Node Daemon service is stopping..
The NDB Cluster  Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster  Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as 'C:\mysql\bin\ndbd.exe' "--service=dnode1"
Service successfully installed.

C:\> NET START dnode1
The NDB Cluster  Data Node Daemon service is starting.
The NDB Cluster  Data Node Daemon service was started successfully.

C:\> NET STOP dnode1
The NDB Cluster  Data Node Daemon service is stopping..
The NDB Cluster  Data Node Daemon service was stopped successfully.
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnodel
Removing service 'dnodel'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove`. For additional information, see [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

## 20.2.4 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see [Section 20.2.1, “The NDB Cluster Auto-Installer”](#).

For our four-node, four-host NDB Cluster (see [Cluster nodes and host computers](#)), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connection strings, see [Section 20.3.3.3, “NDB Cluster Connection Strings”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

**Configuring the data nodes and SQL nodes.** The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

### Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                               # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

### Important

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any

**CREATE TABLE** or **ALTER TABLE** statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2      # Number of replicas
DataMemory=80M      # How much memory to allocate for data storage
IndexMemory=18M     # How much memory to allocate for index storage
                    # For DataMemory and IndexMemory, we have used the
                    # default values. Since the "world" database takes up
                    # only about 500KB, this should be more than enough for
                    # this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202     # This the default; however, you can use any
                    # port that is free for all the hosts in the cluster
                    # Note: It is recommended that you do not specify the port
                    # number at all and simply allow the default value to be used
                    # instead

[ndb_mgmd]
# Management process options:
hostname=192.168.0.10      # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node log files

[ndbd]
# Options for data node "A":
                    # (one [ndbd] section per data node)
hostname=192.168.0.30      # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

[ndbd]
# Options for data node "B":
hostname=192.168.0.40      # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20      # Hostname or IP address
                    # (additional mysqld connections can be
                    # specified for this node for various
                    # purposes such as running ndb_restore)
```

#### Note

The `world` database can be downloaded from <http://dev.mysql.com/doc/index-other.html>.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 20.2.5, "Initial Startup of NDB Cluster"](#).

For more detailed information about the available NDB Cluster configuration parameters and their uses, see [Section 20.3.3, "NDB Cluster Configuration Files"](#), and [Section 20.3, "Configuration of NDB Cluster"](#). For configuration of NDB Cluster as relates to making backups, see [Section 20.5.3.3, "Configuration for NDB Cluster Backups"](#).

**Note**

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

## 20.2.5 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), for details.)

For additional options which can be used with `ndb_mgmd`, see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=3 @192.168.0.40 (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.7.16-ndb-7.5.5)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.7.16-ndb-7.5.5)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

**Note**

The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster . See [Section 20.2.6, “NDB Cluster Example with Tables and Data”](#), for a brief discussion.

## 20.2.6 NDB Cluster Example with Tables and Data

### Note

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster , and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
```

```

`CountryCode` char(3) NOT NULL default '',
`District` char(20) NOT NULL default '',
`Population` int(11) NOT NULL default '0',
PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)

```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```

shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.7.16-ndb-7.5.5

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>

```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 20.5.12.2, “NDB Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```

mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;

```

```
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a [SELECT](#) query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access [NDB](#) tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the [SELECT](#) statement just shown by using the PHP 5.X [mysqli](#) extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
    ?>
    <table border="1" width="40%" cellpadding="4" cellspacing="1">
      <tbody>
        <tr>
          <th width="10%">City</th>
          <th>Population</th>
        </tr>
      <?
      # then display the results...
      while($row = $result->fetch_object())
        printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
              $row->Name, $row->Population);
    ?>
      </tbody>
    </table>
```

```

<?
# ...and verify the number of rows that were retrieved
printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
}
else
# otherwise, tell us what went wrong
echo mysqli_error();

# free the result set and the mysqli connection object
$result->close();
$link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

## 20.2.7 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#), for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmt` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MYSQL`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (192.168.0.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.
- On the SQL host (192.168.0.20):

```
shell> mysqld_safe &
```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see [Section 20.2.3.4, “Installing NDB Cluster Processes as Windows Services”](#)), you can restart the cluster as follows:

- On the management host (192.168.0.10 in our example setup), execute the following command:

```
C:\> NET START ndb_mgmd
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40), execute the following command:

```
C:\> NET START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see [Section 20.2.3.3, “Initial Startup of NDB Cluster on Windows”](#)).
- On the SQL node host (`192.168.0.20`), execute the following command:

```
C:\> NET START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#).

## 20.2.8 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 7.5 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring an NDB Cluster prior to attempting an upgrade or downgrade. See [Section 20.3, “Configuration of NDB Cluster”](#).

### Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software.* See [Section 2.11.1, “Upgrading MySQL”](#).

The table shown here provides information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB 7.5. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 7.5 release series can be found following the table.

## Upgrades and Downgrades, NDB Cluster 7.5

Figure 20.22 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 7.5

**Version support.** The following versions of NDB Cluster are supported for upgrades to GA releases of NDB Cluster 7.5 (7.5.4 and later):

- NDB Cluster 7.4 GA releases (7.4.4 and later)
- NDB Cluster 7.3 GA releases (7.3.2 and later)
- NDB Cluster 7.2 GA releases (7.2.4 and later)

**Known Issues.** The following issues are known to occur when upgrading to or between the stated releases:

- When upgrading from NDB 7.5.2 or 7.5.3 to a later version, the use of `mysqld` with the `--initialize` and `--ndbcluster` options together caused problems later running `mysql_upgrade`.

When run with `--initialize`, the server does not require NDB support; having NDB enabled at this time can cause problems with `ndbinfo` tables. To keep this from happening, the `--initialize` option now causes `mysqld` to ignore the `--ndbcluster` option if the latter is also specified.

A workaround for an upgrade that has failed for these reasons can be accomplished as follows:

1. Perform a rolling restart of the entire cluster
2. Delete all `.frm` files in the `data/ndbinfo` directory
3. Run `mysql_upgrade`.

(Bug #81689, Bug #82724, Bug #24521927, Bug #23518923)

- During an online upgrade from an NDB Cluster 7.3 release to an NDB 7.4 (or later) release, the failures of several data nodes running the lower version during local checkpoints (LCPs), and just prior to upgrading these nodes, led to additional node failures following the upgrade. This was due to lingering elements of the `EMPTY_LCP` protocol initiated by the older nodes as part of an LCP-plus-restart sequence, and which is no longer used in NDB 7.4 and later due to LCP optimizations implemented in those versions. This issue was fixed in NDB 7.5.4. (Bug #23129433)
- Beginning with NDB 7.5.2, the `ndb_binlog_index` table uses the `InnoDB` storage engine. (Use of the `MyISAM` storage engine for this table continues to be supported for backward compatibility.)

When upgrading a previous release to NDB 7.5.2 or later, you can use the `--force --upgrade-system-tables` options with `mysql_upgrade` so that it performs `ALTER TABLE ... ENGINE=INNODB` on the `ndb_binlog_index` table.

For more information, see [Section 20.6.4, “NDB Cluster Replication Schema and Tables”](#).

- Online upgrades from previous versions of NDB Cluster to NDB 7.5.1 were not possible due to missing entries in the matrix used to test upgrade compatibility between versions. (Bug #22024947)

Also in NDB 7.5.1, `mysql_upgrade` failed to upgrade the `sys` schema if a `sys` database directory existed but was empty. (Bug #81352, Bug #23249846, Bug #22875519)

## 20.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDB` storage engine. This engine is also referred to sometimes as `NDBCLUSTER`, although `NDB` is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see [MySQL Server Options for NDB Cluster](#).

You can use also the NDB Cluster Auto-Installer to set up and deploy an NDB Cluster on one or more hosts using a browser-based GUI. For more information, see [Section 20.2.1, “The NDB Cluster Auto-Installer”](#).

For general information about installing NDB Cluster, see [Section 20.2, “NDB Cluster Installation”](#).

### 20.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

By default, `ndbd` looks for the management server at `localhost` on port 1186.

#### Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.7.18

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
Table: ctest
```

```
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      1 node(s)
id=2      @127.0.0.1 (Version: 5.7.16-ndb-7.5.5, Nodegroup: 0, *)

[ndb_mgmd(MGM)]  1 node(s)
id=1      @127.0.0.1 (Version: 5.7.16-ndb-7.5.5)

[mysqld(API)]    3 node(s)
id=3      @127.0.0.1 (Version: 5.7.16-ndb-7.5.5)
id=4      (not connected, accepting connect from any host)
id=5      (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster . You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

## 20.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, `shm`, or `sci`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

**Considerations when restarting nodes.** For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

### Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of

the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

**Note**

4294967039 often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFFFF`, or  $2^{32} - 2^8 - 1$ .

20.3.2.1 NDB Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#).

These parameters also apply to `ndbmtd`, the multi-threaded version of `ndbd`. For more information, see [Section 20.4.3, “ndbmtd — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

NDB Cluster also supports the addition of new data node groups online, to a running cluster. For more information, see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#).

Table 20.1 Data Node Configuration Parameters

| Parameter Name     | Type or Units                       | Restart Type | In Version ... (and later) |
|--------------------|-------------------------------------|--------------|----------------------------|
|                    | Default Value                       |              |                            |
|                    | Minimum/Maximum or Permitted Values |              |                            |
|                    |                                     |              |                            |
| Arbitration        | enumeration                         | N            | NDB 7.5.0                  |
|                    | Default                             |              |                            |
|                    | Default, Disabled, WaitExternal     |              |                            |
| ArbitrationTimeout | milliseconds                        | N            | NDB 7.5.0                  |
|                    | 7500                                |              |                            |

| Parameter Name          | Type or Units                       | Restart Type | In Version ... (and later) |
|-------------------------|-------------------------------------|--------------|----------------------------|
|                         | Default Value                       |              |                            |
|                         | Minimum/Maximum or Permitted Values |              |                            |
|                         | 10 / 4294967039 (0xFFFFFFFF)        |              |                            |
| BackupDataBufferSize    | bytes                               | N            | NDB 7.5.1                  |
|                         | 16M                                 |              |                            |
|                         | 512K / 4294967039 (0xFFFFFFFF)      |              |                            |
| BackupDataDir           | path                                | IN           | NDB 7.5.0                  |
|                         | FileSystemPath                      |              |                            |
|                         | ...                                 |              |                            |
| BackupDiskWriteSpeedPct | percent                             | N            | NDB 7.5.0                  |
|                         | 50                                  |              |                            |
|                         | 0 / 90                              |              |                            |
| BackupLogBufferSize     | bytes                               | N            | NDB 7.5.0                  |
|                         | 16M                                 |              |                            |
|                         | 2M / 4294967039 (0xFFFFFFFF)        |              |                            |

### 20.3.2.2 NDB Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#).

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

**Table 20.3 Management Node Configuration Parameters**

| Parameter Name                         | Type or Units                       | Restart Type | In Version ... (and later) |
|--|-------------------------------------|--------------|----------------------------|
|  | Default Value                       |              |                            |
|  | Minimum/Maximum or Permitted Values |              |                            |
| <code>ArbitrationDelay</code>          | milliseconds                        | N            | NDB 7.5.0                  |
|  | 0                                   |              |                            |
|  | 0 / 4294967039 (0xFFFFFFFF)         |              |                            |
| <code>ArbitrationRank</code>           | 0-2                                 | N            | NDB 7.5.0                  |
|  | 1                                   |              |                            |
|  | 0 / 2                               |              |                            |
| <code>DataDir</code>                   | path                                | N            | NDB 7.5.0                  |
|  | .                                   |              |                            |
|  | ...                                 |              |                            |
| <code>ExecuteOnComputer</code>         | name                                | S            | NDB 7.5.0                  |
|  | [none]                              |              |                            |
|  | ...                                 |              |                            |
| <code>HeartbeatIntervalMgmdMgmd</code> | milliseconds                        | N            | NDB 7.5.0                  |
|  | 1500                                |              |                            |
|  | 100 / 4294967039 (0xFFFFFFFF)       |              |                            |
| <code>HeartbeatThreadPriority</code>   | string                              | S            | NDB 7.5.0                  |

| <code>PortNumber</code>            | unsigned                            | S            | NDB 7.5.0                  |
|                                    | 1186                                |              |                            |
|                                    | 0 / 64K                             |              |                            |
| <code>PortNumberStats</code>       | unsigned                            | N            | NDB 7.5.0                  |
|                                    | [none]                              |              |                            |
|                                    | 0 / 64K                             |              |                            |
| <code>TotalSendBufferMemory</code> | bytes                               | N            | NDB 7.5.0                  |
|                                    | 0                                   |              |                            |
|                                    | 256K / 4294967039 (0xFFFFFFFF)      |              |                            |
| <code>wan</code>                   | boolean                             | N            | NDB 7.5.0                  |
|                                    | false                               |              |                            |
|                                    | true, false                         |              |                            |

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#), for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 20.1.6.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 20.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

**Note**

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#); for information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

**Table 20.4 SQL Node / API Node Configuration Parameters**

| Parameter Name                        | Type or Units  | Restart Type | In Version ... (and later) |
|---------------------------------------|--|--------------|----------------------------|
|                                       | Default Value<br>Minimum/<br>Maximum<br>or Permitted<br>Values |              |                            |
| <a href="#">ApiVerbose</a>            | bytes  | N            | NDB 7.5.2                  |
|                                       | undefined  |              |                            |
|                                       | 0 / 100  |              |                            |
| <a href="#">ArbitrationDelay</a>      | milliseconds   | N            | NDB 7.5.0                  |
|                                       | 0  |              |                            |
|                                       | 0 / 4294967039 (0xFFFFFFFF)                                    |              |                            |
| <a href="#">ArbitrationRank</a>       | 0-2  | N            | NDB 7.5.0                  |
|                                       | 0  |              |                            |
|                                       | 0 / 2  |              |                            |
| <a href="#">AutoReconnect</a>         | boolean  | N            | NDB 7.5.0                  |

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 20.3.2.4 Other NDB Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#), [Section 20.3.3.11, “NDB Cluster Shared-Memory Connections”](#), or [Section 20.3.3.12, “SCI Transport Connections in NDB Cluster”](#), as appropriate.

**Restart types.** Changes in NDB Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 20.3.2, “Overview of NDB Cluster Configuration Parameters, Options, and Variables”](#).

**Table 20.5 Computer Configuration Parameters**

| Parameter Name           | Type or Units                       | Restart Type | In Version ... (and later) |
|--------------------------|-------------------------------------|--------------|----------------------------|
|                          | Default Value                       |              |                            |
|                          | Minimum/Maximum or Permitted Values |              |                            |
| <a href="#">HostName</a> | name or IP address                  | N            | NDB 7.5.0                  |
|                          | [none]                              |              |                            |
|                          | ...                                 |              |                            |
| <a href="#">Id</a>       | string                              | IS           | NDB 7.5.0                  |
|                          | [none]                              |              |                            |
|                          | ...                                 |              |                            |

**Table 20.6 TCP Configuration Parameters**

| Parameter Name                | Type or Units                       | Restart Type | In Version ... (and later) |
|-------------------------------|-------------------------------------|--------------|----------------------------|
|                               | Default Value                       |              |                            |
|                               | Minimum/Maximum or Permitted Values |              |                            |

### 20.3.2.5 NDB Cluster `mysqld` Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 6.1.3, “Server Option and Variable Reference”](#).

**Table 20.9 MySQL Server Options and Variables for MySQL Cluster: MySQL Cluster NDB 7.5**

| Option or Variable Name                          |                 |                 |
|--|-----------------|-----------------|
| Command Line                                     | System Variable | Status Variable |
| Option File                                      | Scope           | Dynamic         |
| <b>Notes</b>                                     |                 |                 |
| <code>Com_show_ndb_status</code>                 |                 |                 |
| No   | No              | Yes             |
| No   | Both            | No              |
| DESCRIPTION: Count of SHOW NDB STATUS statements |                 |                 |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| <a href="#">Handler_discover</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: Number of times that tables have been discovered   |                 |                 |
| <a href="#">ndb-batch-size</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Size (in bytes) to use for NDB transaction batches   |                 |                 |
| <a href="#">ndb-blob-read-batch-bytes</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.  |                 |                 |
| <a href="#">ndb-blob-write-batch-bytes</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.   |                 |                 |
| <a href="#">ndb-cluster-connection-pool</a>   |                 |                 |
| Yes   | Yes             | Yes             |
| Yes   | Global          | No              |
| DESCRIPTION: Number of connections to the cluster used by MySQL   |                 |                 |
| <a href="#">ndb-cluster-connection-pool-nodeids</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for --ndb-cluster-connection-pool |                 |                 |
| <a href="#">ndb-connectstring</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Point to the management server that distributes the cluster configuration  |                 |                 |
| <a href="#">ndb-default-column-format</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table.  |                 |                 |
| <a href="#">ndb-deferred-constraints</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.       |                 |                 |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb-distribution</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)  |                 |                 |
| <a href="#">ndb-log-apply-status</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option. |                 |                 |
| <a href="#">ndb-log-empty-epochs</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.   |                 |                 |
| <a href="#">ndb-log-empty-update</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.  |                 |                 |
| <a href="#">ndb-log-exclusive-reads</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.  |                 |                 |
| <a href="#">ndb-log-orig</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table.  |                 |                 |
| <a href="#">ndb-log-transaction-id</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.  |                 |                 |
| <a href="#">ndb-mgmd-host</a>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Set the host (and port, if desired) for connecting to management server   |                 |                 |
| <a href="#">ndb-nodeid</a>   |                 |                 |
| Yes  | No              | Yes             |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| Yes   | Global          | No              |
| DESCRIPTION: MySQL Cluster node ID for this MySQL server<br><a href="#">ndb-recv-thread-activation-threshold</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)<br><a href="#">ndb-recv-thread-cpu-mask</a>                          |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.<br><a href="#">ndb-transid-mysql-connection-map</a>                                     |                 |                 |
| Yes   | No              | No              |
| No  |                 | No              |
| DESCRIPTION: Enable or disable the <code>ndb_transid_mysql_connection_map</code> plugin; that is, enable or disable the <code>INFORMATION_SCHEMA</code> table having that name.<br><a href="#">ndb-wait-connected</a> |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.<br><a href="#">ndb-wait-setup</a>                          |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.<br><a href="#">ndb-allow-copying-alter-table</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |

| DESCRIPTION: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave.                   |                 |                 |
| <a href="#">Ndb_api_wait_scan_result_count</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node).         |                 |                 |
| <a href="#">Ndb_api_wait_scan_result_count_session</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Session         | No              |
| DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal in this client session.                  |                 |                 |
| <a href="#">Ndb_api_wait_scan_result_count_slave</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of times thread has been blocked while waiting for a scan-based signal by this slave.                           |                 |                 |
| <a href="#">ndb_autoincrement_prefetch_sz</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| DESCRIPTION: NDB auto-increment prefetch size   |                 |                 |
| <a href="#">ndb_cache_check_time</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache   |                 |                 |
| <a href="#">ndb_clear_apply_status</a>  |                 |                 |
| Yes   | Yes             | No              |
| No  | Global          | Yes             |
| DESCRIPTION: Causes RESET SLAVE to clear all rows from the ndb_apply_status table. ON by default.   |                 |                 |
| <a href="#">Ndb_cluster_node_id</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster  |                 |                 |
| <a href="#">Ndb_config_from_host</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: The host name or IP address of the Cluster management server. Formerly Ndb_connected_host  |                 |                 |
| <a href="#">Ndb_config_from_port</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Both            | No              |
| DESCRIPTION: The port for connecting to Cluster management server. Formerly Ndb_connected_port  |                 |                 |
| <a href="#">Ndb_conflict_fn_epoch_trans</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of rows that have been found in conflict by the NDB\$EPOCH_TRANS() conflict detection function  |                 |                 |
| <a href="#">Ndb_conflict_fn_max</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied |                 |                 |
| <a href="#">Ndb_conflict_fn_old</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| DESCRIPTION: If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied                   |                 |                 |
| <a href="#">Ndb_conflict_trans_detect_iter_count</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.   |                 |                 |
| <a href="#">Ndb_conflict_trans_row_reject_count</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions. |                 |                 |
| <a href="#">ndb_data_node_neighbour</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables  |                 |                 |
| <a href="#">ndb_default_column_format</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables.  |                 |                 |
| <a href="#">ndb_deferred_constraints</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.   |                 |                 |
| <a href="#">ndb_distribution</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)   |                 |                 |
| <a href="#">ndb_eventbuffer_free_percent</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc.  |                 |                 |
| <a href="#">ndb_eventbuffer_max_alloc</a>   |                 |                 |
| Yes   | Yes             | No              |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| Yes   | Global          | Yes             |
| DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).  |                 |                 |
| <a href="#">ndb_extra_logging</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Controls logging of MySQL Cluster schema, connection, and data distribution events in the MySQL error log  |                 |                 |
| <a href="#">ndb_force_send</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Forces sending of buffers to NDB immediately, without waiting for other threads  |                 |                 |
| <a href="#">ndb_fully_replicated</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Whether new NDB tables are fully replicated  |                 |                 |
| <a href="#">ndb_index_stat_enable</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Use NDB index statistics in query optimization   |                 |                 |
| <a href="#">ndb_index_stat_option</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| DESCRIPTION: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces  |                 |                 |
| <a href="#">ndb_join_pushdown</a>   |                 |                 |
| No  | Yes             | No              |
| No  | Both            | Yes             |
| DESCRIPTION: Enables pushing down of joins to data nodes  |                 |                 |
| <a href="#">ndb_log_apply_status</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. |                 |                 |
| <a href="#">ndb_log_bin</a>   |                 |                 |
| Yes   | Yes             | No              |
| No  | Both            | Yes             |
| DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.   |                 |                 |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_log_binlog_index</a>   |                 |                 |
| Yes  | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Insert mapping between epochs and binary log positions into the <code>ndb_binlog_index</code> table. Defaults to ON. Effective only if binary logging is enabled on the server.                     |                 |                 |
| <a href="#">ndb_log_empty_epochs</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: When enabled, epochs in which there were no changes are written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>log_slave_updates</code> is enabled. |                 |                 |
| <a href="#">ndb_log_empty_update</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: When enabled, updates which produce no changes are written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>log_slave_updates</code> is enabled.      |                 |                 |
| <a href="#">ndb_log_exclusive_reads</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.  |                 |                 |
| <a href="#">ndb_log_orig</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Whether the id and epoch of the originating server are recorded in the <code>mysql.ndb_binlog_index</code> table. Set using the <code>--ndb-log-orig</code> option when starting mysqld.            |                 |                 |
| <a href="#">ndb_log_transaction_id</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | No              |
| DESCRIPTION: Whether NDB transaction IDs are written into the binary log. (Read-only.)   |                 |                 |
| <a href="#">ndb_log_updated_only</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Log complete rows (ON) or updates only (OFF)  |                 |                 |
| <a href="#">Ndb_number_of_data_nodes</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster   |                 |                 |
| <a href="#">ndb_optimization_delay</a>   |                 |                 |
| No   | Yes             | No              |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| No   | Global          | Yes             |
| DESCRIPTION: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.  |                 |                 |
| <a href="#">ndb_optimized_node_selection</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator  |                 |                 |
| <a href="#">Ndb_pushed_queries_defined</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of joins that API nodes have attempted to push down to the data nodes  |                 |                 |
| <a href="#">Ndb_pushed_queries_executed</a>  |                 |                 |

| No   | Global          | Yes             |
| DESCRIPTION: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views.           |                 |                 |
| <a href="#">ndbinfo_show_hidden</a>  |                 |                 |
| Yes  | Yes             | No              |
| No   | Both            | Yes             |
| DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.                     |                 |                 |
| <a href="#">ndbinfo_table_prefix</a>   |                 |                 |
| Yes  | Yes             | No              |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| No  | Both            | Yes             |
| DESCRIPTION: The prefix to use for naming ndbinfo internal base tables  |                 |                 |
| <a href="#">ndbinfo_version</a>   |                 |                 |
| No  | Yes             | No              |
| No  | Global          | No              |
| DESCRIPTION: The version of the ndbinfo engine; read only.  |                 |                 |
| <a href="#">server-id-bits</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value. |                 |                 |
| <a href="#">server_id_bits</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value.   |                 |                 |
| <a href="#">slave_allow_batching</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Turns update batching on and off for a replication slave   |                 |                 |
| <a href="#">transaction_allow_batching</a>  |                 |                 |
| No  | Yes             | No              |
| No  | Session         | Yes             |
| DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.   |                 |                 |

### 20.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- [my.cnf](#): Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- [config.ini](#): This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. [config.ini](#) contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

**Caching of configuration data.** [NDB](#) uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the

configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the `--initial` option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the `--reload` option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using `--config-cache=FALSE`.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

#### Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#).

### 20.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

#### Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 5.7)
```

```
# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see [Section 20.3.3.3, “NDB Cluster Connection Strings”](#).)

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the `my.cnf` file, see [NDB Cluster System Variables](#).

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (`:`) as well as the equal sign (`=`); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]`

section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

#### Note

In some older releases of NDB Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

#### Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See [Section 20.3.3.2, “Recommended Starting Configuration for NDB Cluster”](#), which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

#### Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

## Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but it may be used as a convenience when setting up a large cluster. See [Section 20.3.3.4, “Defining Computers in an NDB Cluster”](#), for more information.

- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 20.3.3.10, “NDB Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.7, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 20.3.3.11, “NDB Cluster Shared-Memory Connections”](#).
- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 7.2 or later.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

### 20.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

**Starting `config.ini` file.** The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 7.5:

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.
```

```
# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb\_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
```

```
# are not needed when using ndbmtd; in particular, you should not set
# RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

**Recommended my.cnf options for SQL nodes.** MySQL Servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--engine-condition-pushdown=1`

### 20.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]
host-definition:
    host_name[:port_number]
```

*node\_id* is an integer greater than or equal to 1 which identifies a node in `config.ini`. *host\_name* is a string representing a valid Internet host name or IP address. *port\_number* is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):   "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If *port\_num* is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
    [bind-address=host-definition, ]
    host-definition[: bind-address=host-definition]
    host-definition[: bind-address=host-definition]
    [, ...]

host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `192.168.178.242` regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `192.168.178.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `192.168.178.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

### 20.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | string     | [none]  | ...          | IS           |

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

#### Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

This is the computer's hostname or IP address.

### 20.3.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

#### Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 1 - 255      | IS           |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster .

- `NodeId`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 1 - 255      | IS           |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

#### Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- `ExecuteOnComputer`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | name       | [none]  | ...          | S            |

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

#### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `PortNumber`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | 1186    | 0 - 64K      | S            |

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LogDestination`

| Effective Version | Type/Units            | Default    | Range/Values | Restart Type |
|-------------------|-----------------------|------------|--------------|--------------|
| NDB 7.5.0         | {CONSOLE SYSLOG FILE} | [see text] | ...          | N            |

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

#### Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:
  - **filename**: The name of the log file.

The default log file name used in such cases is `ndb_nodeid_cluster.log`.

- **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
- **maxfiles**: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the **FILE** parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | 0-2        | 1       | 0 - 2        | N            |

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. **ArbitrationRank** can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its **ArbitrationRank** to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting **ArbitrationRank** to 0 on all management and SQL nodes, or by setting the **Arbitration** parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting **Arbitration** causes any settings for **ArbitrationRank** to be disregarded.

- **ArbitrationDelay**

| Effective Version | Type/Units   | Default | Range/Values                   | Restart Type |
|-------------------|--------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- [DataDir](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | path       | .       | ...          | N            |

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the [FILE](#) parameter for [LogDestination](#) as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- [PortNumberStats](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 0 - 64K      | N            |

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- [Wan](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

Use WAN TCP setting as default.

- [HeartbeatThreadPriority](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | string     | [none]  | ...          | S            |

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]  
  
policy:  
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first out) or [RR](#) (round robin). The policy value is followed optionally by the priority (an integer).

- [TotalSendBufferMemory](#)

| Effective Version | Type/Units | Default | Range/Values                         | Restart Type |
|-------------------|------------|---------|--------------------------------------|--------------|
| NDB 7.5.0         | bytes      | 0       | 256K -<br>4294967039<br>(0xFFFFFFFF) | N            |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [HeartbeatIntervalMgmdMgmd](#)

| Effective Version | Type/Units   | Default | Range/Values                     | Restart Type |
|-------------------|--------------|---------|----------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 1500    | 100 - 4294967039<br>(0xFFFFFFFF) | N            |

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

#### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 20.1.6.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#).

### 20.3.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmt` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see [Disk Data Configuration Parameters](#)).

All of these parameters also apply to `ndbmt` (the multi-threaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmt` only; these have no effect when used with `ndbd`. For more information, see [Multi-Threading Configuration Parameters \(ndbmt\)](#). See also [Section 20.4.3, “ndbmt — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- [NodeId](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 1 - 48       | IS           |

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the only supported parameter name to use when identifying data nodes. (`Id` was removed in NDB 7.5.0.)

- `ExecuteOnComputer`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | name       | [none]  | ...          | S            |

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `HostName`

| Effective Version | Type/Units         | Default   | Range/Values | Restart Type |
|-------------------|--------------------|-----------|--------------|--------------|
| NDB 7.5.0         | name or IP address | localhost | ...          | N            |

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `ServerPort`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 1 - 64K      | S            |

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

### Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- `NodeGroup`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         |            | [none]  | 0 - 65536    | IS           |

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 20.5.14.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

- `NoOfReplicas`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 2       | 1 - 4        | IS           |

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2, which is the recommended setting in most common usage scenarios.

The maximum possible value is 4; *currently, only the values 1 and 2 are actually supported.*

#### Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since  $2/3$  and  $2/4$  both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- [DataDir](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | path       | .       | ...          | IN           |

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- [FileSystemPath](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | path       | DataDir | ...          | IN           |

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by [DataDir](#).

#### Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- [BackupDataDir](#)

| Effective Version | Type/Units | Default    | Range/Values | Restart Type |
|-------------------|------------|------------|--------------|--------------|
| NDB 7.5.0         | path       | [see text] | ...          | IN           |

This parameter specifies the directory in which backups are placed.

#### Important

The string `'/BACKUP'` is always appended to this value. For example, if you set the value of [BackupDataDir](#) to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the [FileSystemPath](#) parameter.

## Data Memory, Index Memory, and String Memory

[DataMemory](#) and [IndexMemory](#) are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how [DataMemory](#) and [IndexMemory](#) are used, as they usually need to be updated to reflect actual usage by the cluster:

- [DataMemory](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 80M     | 1M - 1024G   | N            |

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by [DataMemory](#) is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it

is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from [DataMemory](#). Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

The memory space defined by [DataMemory](#) is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by [IndexMemory](#), but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by [DataMemory](#). However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free [DataMemory](#). This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force [NDB](#) to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient. You can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts. (Bug #13436216)

The memory space allocated by [DataMemory](#) consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in [NoOfReplicas](#).

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that [DataMemory](#) pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The [DataMemory](#) memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the [DataMemory](#). There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for [DataMemory](#) is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- [IndexMemory](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 18M     | 1M - 1T      | N            |

This parameter controls the amount of storage used for hash indexes in NDB Cluster . Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

You can estimate the size of a hash index using this formula:

```
size = ( (fragments * 32K) + (rows * 18) )
      * replicas
```

*fragments* is the number of fragments, *replicas* is the number of replicas (normally 2), and *rows* is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)

sample_rows = IndexStatSaveSize
              * ((0.01 * IndexStatSaveScale * log2(rows * sample_size)) + 1)
              / sample_size
```

In the preceding formula, *key\_size* is the size of the ordered index key in bytes, *key\_attributes* is the number of attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8 + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
              * ((0.01 * 100 * log2(1000000*20)) + 1)
              / 20
              = 32768 * ( (1 * ~16.811) +1) / 20
              = 32768 * ~17.811 / 20
              = ~29182 rows
```

The expected index memory usage is thus  $2 * 18 * 29182 = \sim 1050550$  bytes.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

- [StringMemory](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | % or bytes | 25      | 0 - 4294967039<br>(0xFFFFFFFF) | S            |

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that

such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

**MinFreePct.** A proportion (5% by default) of data node resources including [DataMemory](#) and [IndexMemory](#) is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the [MinFreePct](#) data node configuration parameter (default 5).

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | 5       | 0 - 100      | N            |

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few [\[ndbd\]](#) parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. [MaxNoOfConcurrentTransactions](#) sets the number of parallel transactions possible in a node. [MaxNoOfConcurrentOperations](#) sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially [MaxNoOfConcurrentOperations](#)) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

[MaxDMLOperationsPerTransaction](#) sets the maximum number of DML operations that can be performed in a given transaction.

- [MaxNoOfConcurrentTransactions](#)

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | integer    | 4096    | 32 - 4294967039<br>(0xFFFFFFFF) | N            |

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

```
MinTotalNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then  $10 * 11 = 110$  transaction records are required for this transaction, per MySQL server, or  $110 * 10 = 1100$  transaction records total. Each data node can be expected to handle  $\text{MinTotalNoOfConcurrentTransactions} / \text{number of data nodes}$ . For an NDB Cluster having 4 data nodes, this would mean setting [MaxNoOfConcurrentTransactions](#) on each data node to  $1100 / 4 = 275$ . In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's [MaxNoOfConcurrentTransactions](#) is sufficient to cover a number of transactions equal to  $\text{MinTotalNoOfConcurrentTransactions} / \text{number of node groups}$ . If this cluster has a single node group, then [MaxNoOfConcurrentTransactions](#) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for `MaxNoOfConcurrentTransactions` should always be no more than the value of `MaxNoOfConcurrentOperations`.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | integer    | 32K     | 32 - 4294967039<br>(0xFFFFFFFF) | N            |

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ . To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction.

However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. [MaxNoOfConcurrentOperations](#) will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- [MaxNoOfLocalOperations](#)

| Effective Version | Type/Units | Default   | Range/Values                    | Restart Type |
|-------------------|------------|-----------|---------------------------------|--------------|
| NDB 7.5.0         | integer    | UNDEFINED | 32 - 4294967039<br>(0xFFFFFFFF) | N            |

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- [MaxDMLOperationsPerTransaction](#)

| Effective Version | Type/Units       | Default    | Range/Values    | Restart Type |
|-------------------|------------------|------------|-----------------|--------------|
| NDB 7.5.0         | operations (DML) | 4294967295 | 32 - 4294967295 | N            |

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set [MaxDMLOperationsPerTransaction](#) to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of [\[ndbd\]](#) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 8K      | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- [MaxNoOfFiredTriggers](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 4000    | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `TransactionBufferMemory`

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | bytes      | 1M      | 1K - 4294967039<br>(0xFFFFFFFF) | N            |

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains  $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.** There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to  $10000 \times 128$  bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to  $10000 \times 16$  bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `MaxNoOfConcurrentScans`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 256     | 2 - 500      | N            |

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is

an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- `MaxNoOfLocalScans`

| Effective Version | Type/Units | Default    | Range/Values                    | Restart Type |
|-------------------|------------|------------|---------------------------------|--------------|
| NDB 7.5.0         | integer    | [see text] | 32 - 4294967039<br>(0xFFFFFFFF) | N            |

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

```
4 * MaxNoOfConcurrentScans * [# data nodes] + 2
```

The minimum value is 32.

- `BatchSizePerLocalScan`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 256     | 1 - 992      | N            |

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

`BatchSizePerLocalScan` has a strong connection to the `BatchSize` defined in the SQL nodes.

- `LongMessageBuffer`

| Effective Version | Type/Units | Default | Range/Values                         | Restart Type |
|-------------------|------------|---------|--------------------------------------|--------------|
| NDB 7.5.0         | bytes      | 64M     | 512K -<br>4294967039<br>(0xFFFFFFFF) | N            |

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- `MaxParallelCopyInstances`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 64       | S            |

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, `MaxParallelCopyInstances` provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- `MaxParallelScansPerFragment`

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | bytes      | 256     | 1 - 4294967039<br>(0xFFFFFFFF) | N            |

It is possible to configure the maximum number of parallel scans ([TUP](#) scans and [TUX](#) scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

The default value for this parameter is 256.

## Memory Allocation

### [MaxAllocate](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | 32M     | 1M - 1G      | N            |

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where [NDB](#) gives *Out of memory* errors, but it is evident by examining the cluster logs or the output of [DUMP 1000](#) that all available memory has not yet been used, you can increase the value of this parameter (or [MaxNoOfTables](#), or both) to cause [NDB](#) to make sufficient memory available.

## Hash Map Size

### [DefaultHashMapSize](#)

| Effective Version | Type/Units  | Default | Range/Values | Restart Type |
|-------------------|-------------|---------|--------------|--------------|
| NDB 7.5.0         | LDM threads | 3840    | 0 - 3840     | N            |

The size of the table hash maps used by [NDB](#) is configurable using this parameter. [DefaultHashMapSize](#) can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

| Value | Description / Effect   |
|-------|--|
| 0     | Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value. |
| 240   | Original hash map size (used by default in all NDB Cluster releases prior to NDB 7.2.7)  |
| 3840  | Larger hash map size (used by default beginning with NDB 7.2.7)  |

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.4 to NDB Cluster 7.5.

**Logging and checkpointing.** The following [\[ndbd\]](#) parameters control log and checkpoint behavior.

- [NoOfFragmentLogFiles](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 16      | 3 - 4294967039<br>(0xFFFFFFFF) | IN           |

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A [REDO](#) log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the [FragmentLogFileSize](#) parameter. In scenarios requiring a great many updates, the value for [NoOfFragmentLogFiles](#) may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 ([Out of log file space temporarily](#)). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

#### Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- [FragmentLogFileSize](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 16M     | 4M - 1G      | IN           |

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for [NoOfFragmentLogFiles](#).

- [InitFragmentLogFiles](#)

| Effective Version | Type/Units   | Default | Range/Values | Restart Type |
|-------------------|--------------|---------|--------------|--------------|
| NDB 7.5.0         | [see values] | SPARSE  | SPARSE, FULL | IN           |

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. [InitFragmentLogFiles](#) takes either of two values:

- [SPARSE](#). Fragment log files are created sparsely. This is the default value.
- [FULL](#). Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting [InitFragmentLogFiles=FULL](#) may help eliminate I/O errors on writes to the REDO log.

- [MaxNoOfOpenFiles](#)

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 20 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- [InitialNoOfOpenFiles](#)

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | files      | 27      | 20 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [MaxNoOfSavedMessages](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 25      | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- [MaxLCPStartDelay](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | seconds    | 0       | 0 - 600      | N            |

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- [LcpScanProgressTimeout](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | second     | 60      | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the [LcpScanProgressTimeout](#) data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

#### Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | integer    | 1000    | 32 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (*greatest\_number\_of\_attributes*) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be  $6 * \text{greatest\_number\_of\_attributes} = 600$ .

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 128     | 8 - 20320    | N            |

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a [BLOB](#) data type an extra table is used to store most of the [BLOB](#) data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

#### Note

The sum of [MaxNoOfTables](#) and [MaxNoOfOrderedIndexes](#) must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfOrderedIndexes](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 128     | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. [MaxNoOfOrderedIndexes](#) sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

#### Note

The sum of [MaxNoOfTables](#) and [MaxNoOfOrderedIndexes](#) must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfTriggers](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 768     | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- [MaxNoOfSubscriptions](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

Each [NDB](#) table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for [MaxNoOfSubscriptions](#) is 0, which is treated as equal to [MaxNoOfTables](#). Each subscription consumes 108 bytes.

- [MaxNoOfSubscribers](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as  $2 * \text{MaxNoOfTables}$ ; that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Cluster s, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to  $3 * \text{MaxNoOfTables}$ .

For more information, see [Section 20.6, “NDB Cluster Replication”](#).

- [MaxNoOfConcurrentSubOperations](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 256     | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- [LateAlloc](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 1       | 0 - 1        | N            |

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- [LockPagesInMainMemory](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 0       | 0 - 2        | N            |

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values `0`, `1`, or `2`, which act as shown in the following list:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.

- `2`: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (`LockPagesInMainMemory` uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and <http://linux.die.net/man/2/mlock>).

#### Note

In older NDB Cluster releases, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated. NDB Cluster 7.5 treats `true` or `false` for the value of this parameter as an error.

#### Important

Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also [http://sourceware.org/bugzilla/show\\_bug.cgi?id=13137](http://sourceware.org/bugzilla/show_bug.cgi?id=13137) for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- `StopOnError`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | 1       | 0, 1         | N            |

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

#### Important

If the data node process exits in an uncontrolled fashion (due, for example, to performing `kill -9` on the data node process while performing a query, or to a segmentation fault), and `StopOnError` is set to 0, the angel process attempts to restart it in exactly the same way as it was started previously—that is, using the same startup options that were employed the last time the node was started. Thus, if the data node process was originally started using the `--initial` option, it is also restarted with `--initial`. This means that, in such cases, if the failure occurs on a sufficient number of data nodes in a very short interval, the effect is the same as if you had performed an initial restart of the entire cluster, leading to loss of all data. (Bug #24945638)

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- `CrashOnCorruptedTuple`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | true    | true, false  | S            |

When this parameter is enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. In NDB 7.5, it is enabled by default.

- `Diskless`

| Effective Version | Type/Units       | Default | Range/Values | Restart Type |
|-------------------|------------------|---------|--------------|--------------|
| NDB 7.5.0         | true false (1 0) | false   | true, false  | IS           |

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

#### Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `ODirect`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `RestartOnErrorInsert`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | error code | 2       | 0 - 4        | N            |

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `CompressedBackup`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

Setting this parameter to `1` causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

#### Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- `CompressedLCP`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

#### Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

## Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

| Effective Version | Type/Units   | Default | Range/Values                    | Restart Type |
|-------------------|--------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 6000    | 70 - 4294967039<br>(0xFFFFFFFF) | N            |

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial`

| Effective Version | Type/Units   | Default | Range/Values                    | Restart Type |
|-------------------|--------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 6000    | 70 - 4294967039<br>(0xFFFFFFFF) | N            |

This is similar to the [TimeBetweenWatchDogCheck](#) parameter, except that [TimeBetweenWatchDogCheckInitial](#) controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- [StartPartialTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values                   | Restart Type |
|-------------------|--------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 30000   | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- [StartPartitionedTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values                   | Restart Type |
|-------------------|--------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 60000   | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

If the cluster is ready to start after waiting for [StartPartialTimeout](#) milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If [StartPartitionedTimeout](#) is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- [StartFailureTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values                   | Restart Type |
|-------------------|--------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- [StartNoNodeGroupTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values                   | Restart Type |
|-------------------|--------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 15000   | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#), for more information.

- `HeartbeatIntervalDbDb`

| Effective Version | Type/Units   | Default | Range/Values                    | Restart Type |
|-------------------|--------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 5000    | 10 - 4294967039<br>(0xFFFFFFFF) | N            |

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also [Network communication and latency](#), as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.

- `HeartbeatIntervalDbApi`

| Effective Version | Type/Units   | Default | Range/Values                     | Restart Type |
|-------------------|--------------|---------|----------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 1500    | 100 - 4294967039<br>(0xFFFFFFFF) | N            |

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see [Network communication and latency](#).

- `HeartbeatOrder`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 0       | 0 - 65535    | S            |

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous

data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

| Node Group    | Nodes Running on <code>host1</code> | Nodes Running on <code>host2</code> |
|---------------|-------------------------------------|-------------------------------------|
| Node Group 0: | Node A                              | Node B                              |
| Node Group 1: | Node C                              | Node D                              |

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

| Node | HeartbeatOrder |
|------|----------------|
| A    | 10             |
| B    | 20             |
| C    | 30             |
| D    | 25             |

To use this parameter to change the heartbeat transmission order in a running NDB Cluster , you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- [ConnectCheckIntervalDelay](#)

| Effective Version | Type/Units   | Default | Range/Values                   | Restart Type |
|-------------------|--------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to [HeartbeatIntervalDbDb](#) milliseconds.

Such a data node that further fails to respond within an interval of [ConnectCheckIntervalDelay](#) milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- [TimeBetweenLocalCheckpoints](#)

| Effective Version | Type/Units                                    | Default | Range/Values | Restart Type |
|-------------------|---|---------|--------------|--------------|
| NDB 7.5.0         | number of 4-byte words, as a base-2 logarithm | 20      | 0 - 31       | N            |

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting [TimeBetweenLocalCheckpoints](#) to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

| Effective Version | Type/Units   | Default | Range/Values | Restart Type |
|-------------------|--------------|---------|--------------|--------------|
| NDB 7.5.0         | milliseconds | 2000    | 20 - 32000   | N            |

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenGlobalCheckpointsTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values                    | Restart Type |
|-------------------|--------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 120000  | 10 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- [TimeBetweenEpochs](#)

| Effective Version | Type/Units   | Default | Range/Values | Restart Type |
|-------------------|--------------|---------|--------------|--------------|
| NDB 7.5.0         | milliseconds | 100     | 0 - 32000    | N            |

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- [TimeBetweenEpochsTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values | Restart Type |
|-------------------|--------------|---------|--------------|--------------|
| NDB 7.5.0         | milliseconds | 0       | 0 - 256000   | N            |

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP save takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- [MaxBufferedEpochs](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | epochs     | 100     | 0 - 100000   | N            |

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the [NDB client](#).) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- [MaxBufferedEpochBytes](#)

| Effective Version | Type/Units | Default  | Range/Values   | Restart Type |
|-------------------|------------|----------|--|--------------|
| NDB 7.5.0         | bytes      | 26214400 | 26214400<br>(0x01900000)<br>- 4294967039<br>(0xFFFFFEFF) | N            |

The total number of bytes allocated for buffering epochs by this node.

- [TimeBetweenInactiveTransactionAbortCheck](#)

| Effective Version | Type/Units   | Default | Range/Values                         | Restart Type |
|-------------------|--------------|---------|--------------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 1000    | 1000 -<br>4294967039<br>(0xFFFFFEFF) | N            |

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

| Effective Version | Type/Units   | Default    | Range/Values                   | Restart Type |
|-------------------|--------------|------------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | [see text] | 0 - 4294967039<br>(0xFFFFFEFF) | N            |

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values                    | Restart Type |
|-------------------|--------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 1200    | 50 - 4294967039<br>(0xFFFFFEFF) | N            |

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- [DiskSyncSize](#)

| Effective Version | Type/Units | Default | Range/Values                     | Restart Type |
|-------------------|------------|---------|----------------------------------|--------------|
| NDB 7.5.0         | bytes      | 4M      | 32K - 4294967039<br>(0xFFFFFFFF) | N            |

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLocalCheckpoints](#).

#### Note

When [ODirect](#) is enabled, it is not necessary to set [DiskSyncSize](#); in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- [MaxDiskWriteSpeed](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 20M     | 1M - 1024G   | S            |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster .

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOtherNodeRestart](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 50M     | 1M - 1024G   | S            |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use [MaxDiskWriteSpeedOwnRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MaxDiskWriteSpeedOwnRestart](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 200M    | 1M - 1024G   | S            |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use [MaxDiskWriteSpeedOtherNodeRestart](#). For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use [MaxDiskWriteSpeed](#). The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting [MinDiskWriteSpeed](#).

- [MinDiskWriteSpeed](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 10M     | 1M - 1024G   | S            |

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters [MaxDiskWriteSpeed](#), [MaxDiskWriteSpeedOwnRestart](#), and [MaxDiskWriteSpeedOtherNodeRestart](#). See the descriptions of these parameters for more information.

- [ArbitrationTimeout](#)

| Effective Version | Type/Units   | Default | Range/Values                    | Restart Type |
|-------------------|--------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 7500    | 10 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- [Arbitration](#)

| Effective Version | Type/Units  | Default | Range/Values                    | Restart Type |
|-------------------|-------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | enumeration | Default | Default, Disabled, WaitExternal | N            |

The [Arbitration](#) parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the [ArbitrationRank](#) settings for the management and API nodes. This is the default value.
- **Disabled.** Setting [Arbitration](#) = [Disabled](#) in the `[ndbd default]` section of the `config.ini` file to accomplish the same task as setting [ArbitrationRank](#) to 0 on all management and API nodes. When [Arbitration](#) is set in this way, any [ArbitrationRank](#) settings are ignored.
- **WaitExternal.** The [Arbitration](#) parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by [ArbitrationTimeout](#) has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting [Arbitration](#) = [WaitExternal](#) in the `[ndbd default]` section of the `config.ini` file. For best results with the [WaitExternal](#) setting, it is recommended that [ArbitrationTimeout](#) be 2 times as long as the interval required by the external cluster manager to perform arbitration.

#### Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when [Arbitration](#) is set to different values for individual data nodes.

- [RestartSubscriberConnectTimeout](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | ms         | 12000   | 0 - 4294967039<br>(0xFFFFFFFF) | S            |

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

**Buffering and logging.** Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine's file system abstraction layer.

- `UndoIndexBuffer`

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 2M      | 1M - 4294967039<br>(0xFFFFFFFF) | N            |

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

#### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- `UndoDataBuffer`

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 16M     | 1M - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`Data UNDO buffers overloaded`).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [RedoBuffer](#)

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | bytes      | 32M     | 1M - 4294967039<br>(0xFFFFFFFF) | N            |

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO log buffers overloaded`). For this reason, you should exercise care if you attempt to decrease the value of [RedoBuffer](#) as part of an online change in the cluster's configuration.

`ndbmt` allocates a separate buffer for each LDM thread (see [ThreadConfig](#)). For example, with 4 LDM threads, an `ndbmt` data node actually has 4 buffers and allocates [RedoBuffer](#) bytes to each one, for a total of  $4 * \text{RedoBuffer}$  bytes.

- [EventLogBufferSize](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 8192    | 0 - 64K      | S            |

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- [LogLevelStartup](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 1       | 0 - 15       | N            |

The reporting level for events generated during startup of the process.

The default level is 1.

- [LogLevelShutdown](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 15       | N            |

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- [LogLevelStatistic](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 15       | N            |

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- [LogLevelCheckpoint](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | log level  | 0       | 0 - 15       | N            |

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 15       | N            |

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 15       | N            |

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 15       | N            |

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | levelr     | 0       | 0 - 15       | N            |

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 15       | N            |

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the [DataMemory](#) and [IndexMemory](#), respectively, set in the [config.ini](#) file. For example, if [DataMemory](#) is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

[MemReportFrequency](#) is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of [config.ini](#), and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 20.5.6.2, “NDB Cluster Log Events”](#).

- [StartupStatusReportFrequency](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | seconds    | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see [Section 20.5.1, “Summary of NDB Cluster Start Phases”](#)). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Data Node Debugging Parameters.** It is also possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 (default - no logging) and 1 (logging enabled) are the only supported values prior to NDB 7.5.2. In NDB 7.5.2 and later, setting this parameter to 2 enables logging of additional `DBDICT` debugging output (Bug #20368450).

**Backup parameters.** The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

| Effective Version | Type/Units | Default | Range/Values                         | Restart Type |
|-------------------|------------|---------|--------------------------------------|--------------|
| NDB 7.5.0         | bytes      | 16M     | 512K -<br>4294967039<br>(0xFFFFFFFF) | N            |
| NDB 7.5.0         | bytes      | 16M     | 2M - 4294967039<br>(0xFFFFFFFF)      | N            |
| NDB 7.5.1         | bytes      | 16M     | 512K -<br>4294967039<br>(0xFFFFFFFF) | N            |

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum was changed from 2M to 512K in NDB 7.5.1. (Bug #22749509)

- `BackupDiskWriteSpeedPct`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | percent    | 50      | 0 - 90       | N            |

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by [MinDiskWriteSpeed](#) and [MaxDiskWriteSpeed](#). Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the [BackupDiskWriteSpeedPct](#) configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints. (This makes the disk write rate budget behave similarly to how it was handled in NDB Cluster 7.3 and earlier.)

The default value for this parameter is 50 (interpreted as 50%).

- [BackupLogBufferSize](#)

| Effective Version | Type/Units | Default | Range/Values                    | Restart Type |
|-------------------|------------|---------|---------------------------------|--------------|
| NDB 7.5.0         | bytes      | 16M     | 2M - 4294967039<br>(0xFFFFFFFF) | N            |

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 20.5.3.3, "Configuration for NDB Cluster Backups"](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- [BackupMemory](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | bytes      | 32M     | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter is deprecated, and subject to removal in a future version of NDB Cluster . Any setting made for it is ignored.

- [BackupReportFrequency](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | seconds    | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

- [BackupWriteSize](#)

| Effective Version | Type/Units | Default | Range/Values                     | Restart Type |
|-------------------|------------|---------|----------------------------------|--------------|
| NDB 7.5.0         | bytes      | 256K    | 32K - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- [BackupMaxWriteSize](#)

| Effective Version | Type/Units | Default | Range/Values                         | Restart Type |
|-------------------|------------|---------|--------------------------------------|--------------|
| NDB 7.5.0         | bytes      | 1M      | 256K -<br>4294967039<br>(0xFFFFFFFF) | N            |

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

#### Note

The location of the backup files is determined by the [BackupDataDir](#) data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- [BackupDataBufferSize](#)  $\geq$  [BackupWriteSize](#) + 188KB
- [BackupLogBufferSize](#)  $\geq$  [BackupWriteSize](#) + 16KB
- [BackupMaxWriteSize](#)  $\geq$  [BackupWriteSize](#)

## NDB Cluster Realtime Performance Parameters

The [\[ndbd\]](#) parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

#### Note

To make use of these parameters, the data node process must be run as system root.

- [LockExecuteThreadToCPU](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | CPU ID     | 64K     | 0 - 64K      | N            |

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmt`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | CPU ID     | [none]  | 0 - 64K      | N            |

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). *There is no default value.*

- `RealtimeScheduler`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- `SchedulerExecutionTimer`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | µs         | 50      | 0 - 11000    | N            |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- `SchedulerResponsiveness`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 5       | 0 - 10       | S            |

Set the balance in the `NDB` scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- `SchedulerSpinTimer`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | µs         | 0       | 0 - 500      | N            |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- [BuildIndexThreads](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | 0       | 0 - 128      | S            |

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multi-threaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmttd`.

You can enable multi-threaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- [TwoPassInitialNodeRestartCopy](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

Multi-threaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

- [Numa](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | 1       | ...          | N            |

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating or by the data node process, whether the data node uses `ndbd` or `ndbmttd`. By default, `NDB` attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmttd`; this is because `ndbmttd` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.)

Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

**Multi-Threading Configuration Parameters (ndbmttd).** `ndbmttd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method, makes it possible to set up more complex rules for `ndbmttd` multi-threading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multi-threaded data nodes.

- `MaxNoOfExecutionThreads`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | integer    | 2       | 2 - 72       | IS           |

This parameter directly controls the number of execution threads used by `ndbmttd`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmttd` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

| <code>MaxNoOfExecutionThreads</code> Value | LDM Threads | TC Threads | Send Threads | Receive Threads |
|--|-------------|------------|--------------|-----------------|
| 0 .. 3                                     | 1           | 0          | 0            | 1               |
| 4 .. 6                                     | 2           | 0          | 0            | 1               |
| 7 .. 8                                     | 4           | 0          | 0            | 1               |
| 9  | 4           | 2          | 0            | 1               |
| 10   | 4           | 2          | 1            | 1               |

| 70                                   | 32                 | 19                | 8                   | 9                      |
| 71                                   | 32                 | 20                | 8                   | 9                      |
| 72                                   | 32                 | 20                | 8                   | 10                     |

There is always one SUMA (replication) thread.

The number of LDM threads must not exceed `NoOfFragmentLogParts`. If this parameter's value is the default (4), this means that you must increase it as well, when setting `MaxNoOfExecutionThreads` to 16 or greater; that is, you should set `NoOfFragmentLogParts` to the corresponding number of LDM threads value shown for that value of `MaxNoOfExecutionThreads` in the preceding table.

The thread types are described later in this section (see `ThreadConfig`).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use `ThreadConfig` instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multi-threaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads always requires a system restart, whether it is changed using this parameter or `ThreadConfig`. If the cluster's `IndexMemory` usage is greater than 50%, changing this requires an initial restart of the cluster. (A maximum of 30-35% `IndexMemory` usage is recommended in such cases.) Otherwise, resource usage and LDM thread allocation cannot be balanced between nodes, which can result in underutilized and overutilized LDM threads, and ultimately data node failures.

- `NoOfFragmentLogParts`

| <b>Effective Version</b> | <b>Type/Units</b> | <b>Default</b> | <b>Range/Values</b>  | <b>Restart Type</b> |
|--------------------------|-------------------|----------------|----------------------|---------------------|
| NDB 7.5.0                | numeric           | 4              | 4, 8, 12, 16, 24, 32 | IN                  |

Set the number of log file groups for redo logs belonging to this `ndbmtid`. The maximum value is 32; the value set must be an even multiple of 4.

The number of LQH threads used by `ndbmtid` must not exceed `NoOfFragmentLogParts`, and this number may increase when increasing `MaxNoOfExecutionThreads`; see the description of this parameter for more information.

- `ThreadConfig`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | string     | "       | ...          | IS           |

This parameter is used with `ndbmtid` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
entry := type={param[,param[,...]]}
type := ldm | main | recv | send | rep | io | tc | watchdog
param := count=number
        | cpubind=cpu_list
        | cpuset=cpu_list
        | spintime=number
        | realtime={0|1}
        | thread_prio={0..10}
        | cpubind_exclusive=cpu_list
        | cpuset_exclusive=cpu_list
```

The curly braces (`{...}`) surrounding the list of parameters are required, even if there is only one parameter in the list.

A `param` (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`. `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. `cpubind_exclusive` causes each thread to be bound exclusively to a CPU in the set; `cpuset_exclusive` means that each thread is bound exclusively to the set of CPUs specified.

Only one of `cpubind`, `cpuset`, `cpubind_exclusive`, or `cpuset_exclusive` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

`spintime` does not apply to I/O threads or watchdog threads and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

- `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

**thread\_prio settings and effects by platform.** The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

- *Linux and FreeBSD:* We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.

| <code>thread_prio</code> value | <code>nice</code> value |
|--------------------------------|-------------------------|
| 0                              | 19                      |
| 1                              | 16                      |
| 2                              | 12                      |
| 3                              | 8                       |
| 4                              | 4                       |
| 5                              | 0                       |
| 6                              | -4                      |
| 7                              | -8                      |
| 8                              | -12                     |
| 9                              | -16                     |
| 10                             | -20                     |

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

- *Solaris:* Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

| <code>thread_prio</code> value | Solaris FX priority |
|--------------------------------|---------------------|
| 0                              | 15                  |
| 1                              | 20                  |
| 2                              | 25                  |
| 3                              | 30                  |
| 4                              | 35                  |
| 5                              | 40                  |
| 6                              | 45                  |
| 7                              | 50                  |
| 8                              | 55                  |
| 9                              | 59                  |
| 10                             | 60                  |

A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- **Windows:** We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

| <code>thread_prio</code> value | Windows thread priority                   |
|--------------------------------|---|
| 0 - 1                          | <code>THREAD_PRIORITY_LOWEST</code>       |
| 2 - 3                          | <code>THREAD_PRIORITY_BELOW_NORMAL</code> |
| 4 - 5                          | <code>THREAD_PRIORITY_NORMAL</code>       |
| 6 - 7                          | <code>THREAD_PRIORITY_ABOVE_NORMAL</code> |
| 8 - 10                         | <code>THREAD_PRIORITY_HIGHEST</code>      |

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

- **ldm:** Local query handler (`DBLQH` kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32.

#### Important

Changing the number of LDM threads requires a system restart to be effective and safe for cluster operations. (This is also true when this is done using `MaxNoOfExecutionThreads`.) If `IndexMemory` usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% `IndexMemory` usage is recommended in such cases. Otherwise, `IndexMemory` and `DataMemory` usage as well as the allocation of LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

- **tc:** Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 32.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: 0 - 32

- **main:** Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks), providing schema management. This is always handled by a single dedicated thread.

Range: 1 only.

- **recv:** Receive thread (`CMVMI` kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

Range: 1 - 16

- `send`: Send thread (`CMVMI` kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when `MaxNoOfExecutionThreads` is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

Range: 0 - 16

- `rep`: Replication thread (`SUMA` kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

Range: 1 only.

- `io`: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

Range: 1 only.

- `watchdog`: Settings to this parameter are actually applied to several threads of this type having specific uses. These threads include the `SocketServer` thread which receives connection setups from other nodes, the `SocketClient` thread which attempts to set up connections to other nodes, and the thread watchdog thread that checks that threads are progressing.

Range: 1 only.

Simple examples:

```
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \
ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, \
tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, \
main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \
tc={count=4,cpuset=6-7,18-19,thread_prio=8},send={count=1,cpuset=8}, \
recv={count=1,cpuset=20},main={count=1,cpuset=9,21},rep={count=1,cpuset=9,21}, \
io={count=1,cpuset=9,21,thread_prio=8},watchdog={count=1,cpuset=9,21,thread_prio=9}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | 32K pages  | 10      | 1 - 1000     | N            |

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in `DiskPageBufferMemory`. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- `DiskPageBufferMemory`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 64M     | 4M - 1T      | N            |

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that NDB Cluster Disk Data storage always uses  $N * 32$  KB memory where  $N$  is some nonnegative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See [Section 20.5.10.19, “The ndbinfo diskpagebuffer Table”](#), for more information.

- `SharedGlobalMemory`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 128M    | 0 - 64T      | N            |

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, [UNDO](#) files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the [UNDO\\_BUFFER\\_SIZE](#) option used with [CREATE LOGFILE GROUP](#) and [ALTER LOGFILE GROUP](#) statements, including any default value implied for this options by the setting of the [InitialLogFileGroup](#) data node configuration parameter. [SharedGlobalMemory](#) can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `128M`.

- [DiskIOThreadPool](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | threads    | 2       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter determines the number of unbound threads used for Disk Data file access. Before [DiskIOThreadPool](#) was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With [DiskIOThreadPool](#), you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set [DiskIOThreadPool](#) higher to enable separate threads to handle the files on each disk.
- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for [DiskIOThreadPool](#).

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.
- [FileSystemPathDD](#)

| Effective Version | Type/Units | Default    | Range/Values | Restart Type |
|-------------------|------------|------------|--------------|--------------|
| NDB 7.5.0         | filename   | [see text] | ...          | IN           |

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for [FileSystemPathDataFiles](#), [FileSystemPathUndoFiles](#), or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the [ADD DATAFILE](#) clause of a [CREATE TABLESPACE](#) or [ALTER TABLESPACE](#) statement, and for undo log files by specifying a path in the [ADD UNDOFILE](#) clause of a [CREATE LOGFILE GROUP](#) or [ALTER LOGFILE GROUP](#) statement. If [FileSystemPathDD](#) is not specified, then [FileSystemPath](#) is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

| Effective Version | Type/Units | Default    | Range/Values | Restart Type |
|-------------------|------------|------------|--------------|--------------|
| NDB 7.5.0         | filename   | [see text] | ...          | IN           |

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

| Effective Version | Type/Units | Default    | Range/Values | Restart Type |
|-------------------|------------|------------|--------------|--------------|
| NDB 7.5.0         | filename   | [see text] | ...          | IN           |

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 20.5.13.1, “NDB Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.
- `InitialLogFileGroup`

| Effective Version | Type/Units | Default    | Range/Values | Restart Type |
|-------------------|------------|------------|--------------|--------------|
| NDB 7.5.0         | string     | [see text] | ...          | S            |

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:
    file-specification[; file-specification[; ...]]

file-specification:
    filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each *file-specification* corresponds to an undo log file, and at least one must be specified in the *file-specification-list*. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

| Effective Version | Type/Units | Default    | Range/Values | Restart Type |
|-------------------|------------|------------|--------------|--------------|
| NDB 7.5.0         | string     | [see text] | ...          | S            |

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The *file-specification-list* uses the same syntax as shown with the `InitialLogFileGroup` parameter, the only difference being that each *file-specification* used with `InitialTablespace` corresponds to a data file. At least one must be specified in the *file-specification-list*. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogFileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as `Node nodeid killed this node because GCP stop was detected` (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

- `ExtraSendBufferMemory`

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `TotalSendBufferMemory`

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

See also [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#).

**Redo log over-commit handling.** It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- `RedoOverCommitCounter`

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | numeric    | 3       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

`RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit.

- `RedoOverCommitLimit`

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | seconds    | 20      | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts.

**Controlling restart attempts.** It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

`MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are listed here:

- `StartFailRetryDelay`

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Both this parameter and `MaxStartFailRetries` are ignored unless `StopOnError` is equal to 0.

- [MaxStartFailRetries](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 3       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and [StartFailRetryDelay](#) are ignored unless [StopOnError](#) is equal to 0.

**NDB index statistics parameters.** The parameters in the following list relate to NDB index statistics generation.

- [IndexStatAutoCreate](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | false, true  | S            |

Enable or disable automatic statistics collection when indexes are created. Disabled by default.

- [IndexStatAutoUpdate](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | false, true  | S            |

Enable or disable monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the [IndexStatTriggerPct](#) and [IndexStatTriggerScale](#) options.

- [IndexStatSaveSize](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | bytes      | 32768   | 0 - 4294967039<br>(0xFFFFFFFF) | IN           |

Maximum space in bytes allowed for the saved statistics of any given index in the [NDB](#) system tables and in the [mysqld](#) memory cache. This consumes [IndexMemory](#).

At least one sample is always produced, regardless of any size limit. This size is scaled by [IndexStatSaveScale](#).

The size specified by [IndexStatSaveSize](#) is scaled by the value of [IndexStatTriggerPct](#) for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting [IndexStatTriggerPct](#) equal to 0 disables the scaling effect.

- [IndexStatSaveScale](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | percentage | 100     | 0 - 4294967039<br>(0xFFFFFFFF) | IN           |

The size specified by [IndexStatSaveSize](#) is scaled by the value of [IndexStatTriggerPct](#) for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting [IndexStatTriggerPct](#) equal to 0 disables the scaling effect.

- [IndexStatTriggerPct](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | percentage | 100     | 0 - 4294967039<br>(0xFFFFFFFF) | IN           |

Percentage change in updates that triggers an index statistics update. The value is scaled by [IndexStatTriggerScale](#). You can disable this trigger altogether by setting [IndexStatTriggerPct](#) to 0.

- [IndexStatTriggerScale](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | percentage | 100     | 0 - 4294967039<br>(0xFFFFFFFF) | IN           |

Scale [IndexStatTriggerPct](#) by this amount times 0.01 for a large index. A value of 0 disables scaling.

- [IndexStatUpdateDelay](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | seconds    | 60      | 0 - 4294967039<br>(0xFFFFFFFF) | IN           |

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

### 20.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The [\[mysqld\]](#) and [\[api\]](#) sections in the [config.ini](#) file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a [\[mysqld\]](#) section is used to indicate a MySQL server providing an SQL interface to the cluster, and an [\[api\]](#) section is used for applications other than [mysqld](#) processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an [\[api\]](#) section.

#### Note

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#); for information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

- [Id](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 1 - 255      | IS           |

The [Id](#) is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

#### Note

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

[NodeId](#) is the preferred parameter name to use when identifying API nodes. ([Id](#) continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- [ConnectionMap](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | string     | [none]  | ...          | N            |

Specifies which data nodes to connect.

- [NodeId](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 1 - 255      | IS           |

The [NodeId](#) is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

#### Note

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

[NodeId](#) is the preferred parameter name to use when identifying management nodes. An alias, [Id](#), was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- [ExecuteOnComputer](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | name       | [none]  | ...          | S            |

This refers to the [Id](#) set for one of the computers (hosts) defined in a [\[computer\]](#) section of the configuration file.

#### Important

This parameter is deprecated as of NDB 7.5.0, and is subject to removal in a future release. Use the [HostName](#) parameter instead.

- [HostName](#)

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or [ExecuteOnComputer](#) is required.

If no [HostName](#) or [ExecuteOnComputer](#) is specified in a given [\[mysql\]](#) or [\[api\]](#) section of the [config.ini](#) file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This*

differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.

- [ArbitrationRank](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | 0-2        | 0       | 0 - 2        | N            |

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its [ArbitrationRank](#) to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting [ArbitrationRank](#) to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the [Arbitration](#) parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- [ArbitrationDelay](#)

| Effective Version | Type/Units   | Default | Range/Values                   | Restart Type |
|-------------------|--------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | milliseconds | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 16K     | 1024 - 1M    | N            |

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- [BatchSize](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | records    | 256     | 1 - 992      | N            |

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- [ExtraSendBufferMemory](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | bytes      | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using [TotalSendBufferMemory](#), [SendBufferMemory](#), or both.

- [HeartbeatThreadPriority](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | string     | [none]  | ...          | S            |

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
{FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first in) or [RR](#) (round robin). This followed optionally by the priority (an integer).

- [MaxScanBatchSize](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | bytes      | 256K    | 32K - 16M    | N            |

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- [TotalSendBufferMemory](#)

| Effective Version | Type/Units | Default | Range/Values                         | Restart Type |
|-------------------|------------|---------|--------------------------------------|--------------|
| NDB 7.5.0         | bytes      | 0       | 256K -<br>4294967039<br>(0xFFFFFFFF) | N            |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

- [AutoReconnect](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

This parameter is [false](#) by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see [Ndb\\_cluster\\_connection::set\\_auto\\_reconnect\(\)](#), and [Ndb\\_cluster\\_connection::get\\_auto\\_reconnect\(\)](#).

- [DefaultOperationRedoProblemAction](#)

| Effective Version | Type/Units  | Default | Range/Values | Restart Type |
|-------------------|-------------|---------|--------------|--------------|
| NDB 7.5.0         | enumeration | QUEUE   | ABORT, QUEUE | S            |

This parameter (along with [RedoOverCommitLimit](#) and [RedoOverCommitCounter](#)) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than [RedoOverCommitLimit](#) seconds, more than [RedoOverCommitCounter](#) times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of [DefaultOperationRedoProblemAction](#), listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried. This the default. Pending operations are still aborted when the redo log runs out of space—that is, when **P\_TAIL\_PROBLEM** errors occur.
- [DefaultHashMapSize](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | buckets    | 3840    | 0 - 3840     | N            |

The size of the table hash maps used by [NDB](#) is configurable using this parameter. [DefaultHashMapSize](#) can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

| Value | Description / Effect   |
|-------|--|
| 0     | Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value. |
| 240   | Original hash map size (used by default prior to NDB 7.2.7).   |
| 3840  | Larger hash map size as (used by default in NDB 7.2.7 and later)   |

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading or downgrading from NDB Cluster 7.5.

- [Wan](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

Use WAN TCP setting as default.

- [ConnectBackoffMaxTime](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [ConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

- [StartConnectBackoffMaxTime](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | integer    | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the [StartConnectBackoffMaxTime](#) parameter is applied; otherwise, [ConnectBackoffMaxTime](#) is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches [StartConnectBackoffMaxTime](#) milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up [HeartbeatIntervalDbApi](#) for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** Beginning with NDB 7.5.2, you can use the [ApiVerbose](#) configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds [DBDICT](#) debugging output as well. (Bug #20638450) See also [DUMP 1229](#).

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using [SHOW STATUS](#) in the [mysql](#) client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

```

| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 192.168.0.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)

```

For information about the status variables appearing in the output from this statement, see [NDB Cluster Status Variables](#).

#### Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 20.3.3.8 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see [Section 6.1, “The MySQL Server”](#).

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 20.3, “Configuration of NDB Cluster”](#).

#### MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see [Section 6.1.4, “Server Command Options”](#).

For information about command-line options used with other NDB Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#). For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see [Section 20.4, “NDB Cluster Programs”](#).

- `--ndb-allow-copying-alter-table=[ON|OFF]`

**Table 20.10 Type and value information for `ndb-allow-copying-alter-table`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|

| <b>Notes</b>  |                 |                 |
| <code>ndb-cluster-connection-pool</code>                        |                 |                 |
| Yes   | Yes             | Yes             |
| Yes   | Global          | No              |
| NDB 7.5   | integer         | 1 / 1 - 63      |
| DESCRIPTION: Number of connections to the cluster used by MySQL |                 |                 |

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

#### Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`

**Table 20.13** Type and value information for `ndb-cluster-connection-pool-nodeids`

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <code>ndb-cluster-connection-pool-nodeids</code>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| NDB 7.5  | set             | /               |
| DESCRIPTION: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for <code>--ndb-cluster-connection-pool</code> |                 |                 |

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

`--ndb-cluster-connection-pool-nodeids` was added in NDB 7.5.0.

- `--ndb-blob-read-batch-bytes=bytes`

**Table 20.14** Type and value information for `ndb-blob-read-batch-bytes`

| Command Line   | System Variable | Status Variable        |
|--|-----------------|------------------------|
| Option File  | Scope           | Dynamic                |
| From Version   | Type            | Default, Range         |
| <b>Notes</b>   |                 |                        |
| <code>ndb-blob-read-batch-bytes</code>   |                 |                        |
| Yes  | Yes             | No                     |
| Yes  | Both            | Yes                    |
| NDB 7.5  | integer         | 65536 / 0 - 4294967295 |
| DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit. |                 |                        |

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` read batching.

#### Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-blob-write-batch-bytes=bytes`

**Table 20.15 Type and value information for `ndb-blob-write-batch-bytes`**

| Command Line  | System Variable | Status Variable        |

| <b>Notes</b>   |                 |                          |
| <code>ndb-default-column-format</code>   |                 |                          |
| Yes  | Yes             | No                       |
| Yes  | Global          | Yes                      |
| 5.7.11-ndb-7.5.1   | enumeration     | DYNAMIC / FIXED, DYNAMIC |
| 5.7.16-ndb-7.5.4   | enumeration     | FIXED / FIXED, DYNAMIC   |
| DESCRIPTION: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table. |                 |                          |

In NDB 7.5.1 and later, sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see [Section 14.1.18, “CREATE TABLE Syntax”](#)).

In NDB 7.5.1, the default for this option was `DYNAMIC`; in NDB 7.5.4, the default was changed to `FIXED` to maintain backwards compatibility with older release series (Bug #24487363).

- `--ndb-deferred-constraints=[0|1]`

**Table 20.18 Type and value information for `ndb-deferred-constraints`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>ndb-deferred-constraints</code>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| NDB 7.5   | integer         | 0 / 0 - 1       |
| DESCRIPTION: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only. |                 |                 |

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `--ndb-distribution=[KEYHASH|LINHASH]`

**Table 20.19 Type and value information for `ndb-distribution`**

| Command Line                  | System Variable | Status Variable |

| Option File   | Scope           | Dynamic                    |
| From Version  | Type            | Default, Range             |
| <b>Notes</b>  |                 |                            |
| Yes   | Yes             | No                         |
| Yes   | Global          | Yes                        |
| NDB 7.5   | enumeration     | KEYHASH / LINHASH, KEYHASH |
| DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH) |                 |                            |

Controls the default distribution method for NDB tables. Can be set to either of [KEYHASH](#) (key hashing) or [LINHASH](#) (linear hashing). [KEYHASH](#) is the default.

- `--ndb-mgmd-host=host[:port]`

**Table 20.20 Type and value information for ndb-mgmd-host**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb-mgmd-host</a>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| NDB 7.5  | string          | localhost:1186  |
| DESCRIPTION: Set the host (and port, if desired) for connecting to management server |                 |                 |

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndbcluster`

**Table 20.21 Type and value information for ndbcluster**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndbcluster</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| NDB 7.5  | boolean         | FALSE           |
| DESCRIPTION: Enable NDB Cluster (if this version of MySQL supports it) |                 |                 |
| Disabled by <code>--skip-ndbcluster</code>                             |                 |                 |

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster . If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

It is not necessary or desirable to use this option together with `--initialize`. Beginning with NDB 7.5.4, `--ndbcluster` is ignored (and the `NDB` storage engine is *not* enabled) if `--initialize` is also used. (Bug #81689, Bug #23518923)

- `--ndb-log-apply-status`

**Table 20.22 Type and value information for `ndb-log-apply-status`**

| Command Line   | System Variable | Status Variable |

| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <code>ndb-log-apply-status</code>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| NDB 7.5  | boolean         | OFF             |
| DESCRIPTION: Cause a MySQL server acting as a slave to log <code>mysql.ndb_apply_status</code> updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the <code>--ndbcluster</code> option. |                 |                 |

Causes a slave `mysqld` to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current `mysqld`.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster . This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

**Table 20.23 Type and value information for `ndb-log-empty-epochs`**

| Command Line                      | System Variable | Status Variable |
|-----------------------------------|-----------------|-----------------|
| Option File                       | Scope           | Dynamic         |
| From Version                      | Type            | Default, Range  |
| <b>Notes</b>                      |                 |                 |
| <code>ndb-log-empty-epochs</code> |                 |                 |
| Yes                               | Yes             | No              |
| Yes                               | Global          | Yes             |
| NDB 7.5                           | boolean         | OFF             |

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>--log-slave-updates</code> is enabled. |                 |                 |

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

**Table 20.24 Type and value information for `ndb-log-empty-update`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <code>ndb-log-empty-update</code>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| NDB 7.5  | boolean         | OFF             |
| DESCRIPTION: When enabled, causes updates that produced no changes to be written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>--log-slave-updates</code> is enabled. |                 |                 |

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled (`OFF`). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`

**Table 20.25 Type and value information for `ndb-log-exclusive-reads`**

| Command Line                         | System Variable | Status Variable |
|--------------------------------------|-----------------|-----------------|
| Option File                          | Scope           | Dynamic         |

| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts. |                 |                 |

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see [Read conflict detection and resolution](#).

- `--ndb-log-orig`

**Table 20.26** Type and value information for `ndb-log-orig`

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>ndb-log-orig</code>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| NDB 7.5   | boolean         | OFF             |
| DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table. |                 |                 |

Log the originating server ID and epoch in the `ndb_binlog_index` table.

**Note**

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see [Section 20.6.4, “NDB Cluster Replication Schema and Tables”](#).

- `--ndb-log-transaction-id`

**Table 20.27** Type and value information for `ndb-log-transaction-id`

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>ndb-log-transaction-id</code>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| NDB 7.5   | boolean         | OFF             |
| DESCRIPTION: Write NDB transaction IDs in the binary log. Requires <code>--log-bin-v1-events=OFF</code> . |                 |                 |

Causes a slave `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, `--log-bin-use-v1-row-events` must be set to `FALSE` in order to use this option.

This option is not supported in mainline MySQL Server 5.7. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see `NDB$EPOCH_TRANS()`).

The default value is `FALSE`.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `--ndb-nodeid=#`

**Table 20.28 Type and value information for `ndb-nodeid`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <code>ndb-nodeid</code>                                  |                 |                 |
| Yes  | No              | Yes             |
| Yes  | Global          | No              |
| 5.0.45   | integer         | / 1 - 63        |
| 5.1.5  | integer         | / 1 - 255       |
| DESCRIPTION: MySQL Cluster node ID for this MySQL server |                 |                 |

Set this MySQL server's node ID in an NDB Cluster .

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `--ndb_optimization_delay=milliseconds`

**Table 20.29 Type and value information for `ndb_optimization_delay`**

| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| NDB 7.5   | integer         | 10 / 0 - 100000 |
| DESCRIPTION: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables. |                 |                 |

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on NDB tables. The default is 10.

- `--ndb-recv-thread-activation-threshold=threshold`

**Table 20.30 Type and value information for `ndb-recv-thread-activation-threshold`**

| Command Line   | System Variable | Status Variable   |
|--|-----------------|---|
| Option File  | Scope           | Dynamic   |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |   |
| <code>ndb-recv-thread-activation-threshold</code>  |                 |   |
| Yes  | No              | No  |
| Yes  |                 | No  |
| 5.6.10-ndb-7.3.1   | integer         | 8 / 0<br>(MIN_ACTIVATION_THRESHOLD)<br>- 16<br>(MAX_ACTIVATION_THRESHOLD) |
| DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads) |                 |   |

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

- `--ndb-recv-thread-cpu-mask=bitmask`

**Table 20.31 Type and value information for `ndb-recv-thread-cpu-mask`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>ndb-recv-thread-cpu-mask</code>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| NDB 7.5   | bitmap          | [empty]         |
| DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details. |                 |                 |

Set a CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask; for example, `0x33` means that one CPU is used per receiver thread. An empty string (no locking of receiver threads) is the default.

- `ndb-transid-mysql-connection-map=state`

**Table 20.32 Type and value information for `ndb-transid-mysql-connection-map`**

| Command Line  | System Variable | Status Variable     |
|---|-----------------|---------------------|
| Option File   | Scope           | Dynamic             |
| From Version  | Type            | Default, Range      |
| <b>Notes</b>  |                 |                     |
| <code>ndb-transid-mysql-connection-map</code>   |                 |                     |
| Yes   | No              | No                  |
| No  |                 | No                  |
| NDB 7.5   | enumeration     | ON / ON, OFF, FORCE |
| DESCRIPTION: Enable or disable the <code>ndb_transid_mysql_connection_map</code> plugin; that is, enable or disable the <code>INFORMATION_SCHEMA</code> table having that name. |                 |                     |

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=seconds`

**Table 20.33 Type and value information for `ndb-wait-connected`**

| 5.1.56-ndb-7.1.16   | integer         | 30 / 0 - 31536000 |
| DESCRIPTION: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete. |                 |                   |

This variable shows the period of time that the MySQL server waits for the [NDB](#) storage engine to complete setup before timing out and treating [NDB](#) as unavailable. The time is specified in seconds. The default value is `30`.

- `--server-id-bits=#`

**Table 20.35 Type and value information for `server-id-bits`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>server-id-bits</code>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| NDB 7.5   | integer         | 32 / 7 - 32     |
| DESCRIPTION: Sets the number of least significant bits in the <code>server_id</code> actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. <code>server_id</code> must be less than 2 to the power of this value. |                 |                 |

This option indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of `server_id` in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of `server_id` must be less than  $2^{\text{server\_id\_bits}}$ ; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster . It is not supported in the standard MySQL 5.7 Server.

- `--skip-ndbcluster`

**Table 20.36** Type and value information for `skip-ndbcluster`

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>skip-ndbcluster</code>                        |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Disable the NDB Cluster storage engine |                 |                 |

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See [Section 20.3.1, “Quick Test Setup of NDB Cluster”](#), for an example.

## NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the `NDB` storage engine. For system variables not specific to NDB Cluster , see [Section 6.1.5, “Server System Variables”](#). For general information on using system variables, see [Section 6.1.6, “Using System Variables”](#).

- `ndb_autoincrement_prefetch_sz`

**Table 20.37** Type and value information for `ndb_autoincrement_prefetch_sz`

| Command Line                               | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File                                | Scope           | Dynamic         |
| From Version                               | Type            | Default, Range  |
| <b>Notes</b>                               |                 |                 |
| <code>ndb_autoincrement_prefetch_sz</code> |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| NDB 7.5                                    | integer         | 32 / 1 - 256    |
| 5.0.56                                     | integer         | 1 / 1 - 256     |
| 5.1.1                                      | integer         | 32 / 1 - 256    |
| 5.1.23                                     | integer         | 1 / 1 - 256     |
| 5.1.16-ndb-6.2.0                           | integer         | 32 / 1 - 256    |
| 5.1.23-ndb-6.2.10                          | integer         | 1 / 1 - 256     |

| Command Line                                  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File                                   | Scope           | Dynamic         |
| From Version                                  | Type            | Default, Range  |
| <b>Notes</b>                                  |                 |                 |
| 5.1.19-ndb-6.3.0                              | integer         | 32 / 1 - 256    |
| 5.1.23-ndb-6.3.7                              | integer         | 1 / 1 - 256     |
| 5.1.41-ndb-6.3.31                             | integer         | 1 / 1 - 65536   |
| 5.1.30-ndb-6.4.0                              | integer         | 32 / 1 - 256    |
| 5.1.41-ndb-7.0.11                             | integer         | 1 / 1 - 65536   |
| 5.5.15-ndb-7.2.1                              | integer         | 1 / 1 - 65536   |
| DESCRIPTION: NDB auto-increment prefetch size |                 |                 |

Determines the probability of gaps in an autoincremented column. Set it to [1](#) to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. The minimum and default value is 1. The maximum value for `ndb_autoincrement_prefetch_sz` is 65536.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time. The default value is 1.

#### Important

This variable does not affect inserts performed using `INSERT ... SELECT`.

- [ndb\\_cache\\_check\\_time](#)

**Table 20.38** Type and value information for `ndb_cache_check_time`

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <a href="#">ndb_cache_check_time</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| NDB 7.5   | integer         | 0 / -           |
| DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache |                 |                 |

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- [ndb\\_clear\\_apply\\_status](#)

**Table 20.39 Type and value information for `ndb_clear_apply_status`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_clear_apply_status</a>   |                 |                 |
| Yes  | Yes             | No              |
| No   | Global          | Yes             |
| NDB 7.5  | boolean         | ON              |
| DESCRIPTION: Causes RESET SLAVE to clear all rows from the <code>ndb_apply_status</code> table. ON by default. |                 |                 |

By the default, executing `RESET SLAVE` causes an NDB Cluster replication slave to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- [ndb\\_data\\_node\\_neighbour](#)

**Table 20.40 Type and value information for `ndb_data_node_neighbour`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_data_node_neighbour</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| 5.7.12-ndb-7.5.2   | integer         | 0 / 0 - 255     |
| DESCRIPTION: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables |                 |                 |

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See [Section 14.1.18.9, “Setting NDB\\_TABLE Options in Table Comments”](#), for further information.

Added in NDB 7.5.2.

#### Note

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

- [ndb\\_default\\_column\\_format](#)

**Table 20.41 Type and value information for `ndb_default_column_format`**

| Command Line   | System Variable | Status Variable          |
|--|-----------------|--------------------------|
| Option File  | Scope           | Dynamic                  |
| From Version   | Type            | Default, Range           |
| <b>Notes</b>   |                 |                          |
| <a href="#">ndb_default_column_format</a>  |                 |                          |
| Yes  | Yes             | No                       |
| Yes  | Global          | Yes                      |
| 5.7.11-ndb-7.5.1   | enumeration     | DYNAMIC / FIXED, DYNAMIC |
| 5.7.16-ndb-7.5.4   | enumeration     | FIXED / FIXED, DYNAMIC   |
| DESCRIPTION: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables. |                 |                          |

In NDB 7.5.1 and later, sets the default [COLUMN\\_FORMAT](#) and [ROW\\_FORMAT](#) for new tables (see [Section 14.1.18, “CREATE TABLE Syntax”](#)).

In NDB 7.5.1, the default for this variable was [DYNAMIC](#); in NDB 7.5.4, the default was changed to [FIXED](#) to maintain backwards compatibility with older release series (Bug #24487363).

- [ndb\\_deferred\\_constraints](#)

**Table 20.42 Type and value information for `ndb_deferred_constraints`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <a href="#">ndb_deferred_constraints</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| NDB 7.5   | integer         | 0 / 0 - 1       |
| DESCRIPTION: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only. |                 |                 |

Controls whether or not constraint checks are deferred, where these are supported. [0](#) is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- [ndb\\_distribution](#)

**Table 20.43 Type and value information for `ndb_distribution`**

| Command Line                     | System Variable | Status Variable |
|----------------------------------|-----------------|-----------------|
| Option File                      | Scope           | Dynamic         |
| From Version                     | Type            | Default, Range  |
| <b>Notes</b>                     |                 |                 |
| <a href="#">ndb_distribution</a> |                 |                 |

| Command Line  | System Variable | Status Variable            |
|---|-----------------|----------------------------|
| Option File   | Scope           | Dynamic                    |
| From Version  | Type            | Default, Range             |
| <b>Notes</b>  |                 |                            |
| Yes   | Yes             | No                         |
| Yes   | Global          | Yes                        |
| NDB 7.5   | enumeration     | KEYHASH / LINHASH, KEYHASH |
| DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH) |                 |                            |

Controls the default distribution method for NDB tables. Can be set to either of [KEYHASH](#) (key hashing) or [LINHASH](#) (linear hashing). [KEYHASH](#) is the default.

- [ndb\\_eventbuffer\\_free\\_percent](#)

**Table 20.44 Type and value information for [ndb\\_eventbuffer\\_free\\_percent](#)**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <a href="#">ndb_eventbuffer_free_percent</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| NDB 7.5   | integer         | 20 / 1 - 99     |
| DESCRIPTION: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by <a href="#">ndb_eventbuffer_max_alloc</a> . |                 |                 |

Sets the percentage of the maximum memory allocated to the event buffer ([ndb\\_eventbuffer\\_max\\_alloc](#)) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- [ndb\\_eventbuffer\\_max\\_alloc](#)

**Table 20.45 Type and value information for [ndb\\_eventbuffer\\_max\\_alloc](#)**

| Command Line   | System Variable | Status Variable    |
|--|-----------------|--------------------|
| Option File  | Scope           | Dynamic            |
| From Version   | Type            | Default, Range     |
| <b>Notes</b>   |                 |                    |
| <a href="#">ndb_eventbuffer_max_alloc</a>  |                 |                    |
| Yes  | Yes             | No                 |
| Yes  | Global          | Yes                |
| NDB 7.5  | integer         | 0 / 0 - 4294967295 |
| DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit). |                 |                    |

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- [ndb\\_extra\\_logging](#)

**Table 20.46 Type and value information for `ndb_extra_logging`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_extra_logging</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| NDB 7.5  | integer         | 0 / -           |
| 5.1.19-ndb-6.3.0   | integer         | 1 / -           |
| DESCRIPTION: Controls logging of MySQL Cluster schema, connection, and data distribution events in the MySQL error log |                 |                 |

This variable enables recording in the MySQL error log of information specific to the [NDB](#) storage engine.

When this variable is set to 0, the only information specific to [NDB](#) that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, [NDB](#) table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other [NDB](#) errors and information. If the value is set to 10 or more, information about [NDB](#) internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- [ndb\\_force\\_send](#)

**Table 20.47 Type and value information for `ndb_force_send`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_force_send</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| NDB 7.5  | boolean         | TRUE            |
| DESCRIPTION: Forces sending of buffers to NDB immediately, without waiting for other threads |                 |                 |

Forces sending of buffers to [NDB](#) immediately, without waiting for other threads. Defaults to [ON](#).

- [ndb\\_fully\\_replicated](#)

**Table 20.48 Type and value information for `ndb_fully_replicated`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <code>ndb_fully_replicated</code>                        |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| 5.7.12-ndb-7-5-2   | boolean         | OFF             |
| DESCRIPTION: Whether new NDB tables are fully replicated |                 |                 |

Determines whether new [NDB](#) tables are fully replicated. This setting can be overridden for an individual table using `COMMENT="NDB_TABLE=FULLY_REPLICATED=..."` in a `CREATE TABLE` or `ALTER TABLE` statement; see [Section 14.1.18.9, "Setting NDB\\_TABLE Options in Table Comments"](#), for syntax and other information.

Added in NDB 7.5.2.

- `ndb_index_stat_enable`

**Table 20.49 Type and value information for `ndb_index_stat_enable`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |

| DESCRIPTION: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces |                 |  |

This variable is used for providing tuning options for NDB index statistics generation. The list consists of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with `h` (hours), `m` (minutes), or `s` (seconds). Millisecond values can optionally be specified using `ms`; millisecond values cannot be specified using `h`, `m`, or `s`.) Integer values can be suffixed with `K`, `M`, or `G`.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

| Name                      | Description                             | Default/Units | Minimum/Maximum |
|---------------------------|---|---------------|-----------------|
| <code>loop_enable</code>  |   | 1000 ms       | 0/4G            |
| <code>loop_idle</code>    | Time to sleep when idle                 | 1000 ms       | 0/4G            |
| <code>loop_busy</code>    | Time to sleep when more work is waiting | 100 ms        | 0/4G            |
| <code>update_batch</code> |   | 1             | 0/4G            |
| <code>read_batch</code>   |   | 4             | 1/4G            |
| <code>idle_batch</code>   |   | 32            | 1/4G            |
| <code>check_batch</code>  |   | 8             | 1/4G            |
| <code>check_delay</code>  | How often to check for new statistics   | 10 m          | 1/4G            |
| <code>delete_batch</code> |   | 8             | 0/4G            |
| <code>clean_delay</code>  |   | 1 m           | 0/4G            |
| <code>error_batch</code>  |   | 4             | 1/4G            |
| <code>error_delay</code>  |   | 1 m           | 1/4G            |
| <code>evict_batch</code>  |   | 8             | 1/4G            |
| <code>evict_delay</code>  | Clean LRU cache, from read time         | 1 m           | 0/4G            |

| Name                      | Description  | Default/Units | Minimum/Maximum |
|---------------------------|--|---------------|-----------------|
| <code>cache_limit</code>  | Maximum amount of memory in bytes used for cached index statistics by this <code>mysqld</code> ; clean up the cache when this is exceeded.             | 32 M          | 0/4G            |
| <code>cache_lowpct</code> |  | 90            | 0/100           |
| <code>zero_total</code>   | Setting this to 1 resets all accumulating counters in <code>ndb_index_stat_status</code> to 0. This option value is also reset to 0 when this is done. | 0             | 0/1             |

- `ndb_join_pushdown`

| 5.1.51-ndb-7.2.0   | boolean         | TRUE            |
| DESCRIPTION: Enables pushing down of joins to data nodes |                 |                 |

This variable controls whether joins on `NDB` tables are pushed down to the `NDB` kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

**Conditions for `NDB` pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type.

This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.
3. Explicit locking is not supported; however, the `NDB` storage engine's characteristic implicit row-based locking is enforced.

This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

Outer joined child tables can only be pushed using `eq_ref`.

If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH, LIST, or RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
->      SELECT e.first_name, e.last_name, t.title, d.dept_name
->      FROM employees e
->      JOIN dept_emp de ON e.emp_no=de.emp_no
->      JOIN departments d ON d.dept_no=de.dept_no
->      JOIN titles t ON e.emp_no=t.emp_no\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: d
        type: ALL
possible_keys: PRIMARY
         key: NULL
      key_len: NULL
         ref: NULL
        rows: 9
      Extra: Parent of 4 pushed join@1
***** 2. row *****
      id: 1
  select_type: SIMPLE
        table: de
        type: ref
possible_keys: PRIMARY,emp_no,dept_no
         key: dept_no
      key_len: 4
         ref: employees.d.dept_no
        rows: 5305
      Extra: Child of 'd' in pushed join@1
***** 3. row *****
      id: 1
  select_type: SIMPLE
        table: e
        type: eq_ref
possible_keys: PRIMARY
         key: PRIMARY
      key_len: 4
         ref: employees.de.emp_no
        rows: 1
      Extra: Child of 'de' in pushed join@1
***** 4. row *****
      id: 1
  select_type: SIMPLE
        table: t
        type: ref
possible_keys: PRIMARY,emp_no
         key: emp_no
      key_len: 4
         ref: employees.de.emp_no
        rows: 19
```

```
Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)
```

**Note**

If inner joined child tables are joined by [ref](#), and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables [Ndb\\_pushed\\_queries\\_defined](#), [Ndb\\_pushed\\_queries\\_dropped](#), [Ndb\\_pushed\\_queries\\_executed](#), and [Ndb\\_pushed\\_reads](#).
  2. The counters in the [ndbinfo.counters](#) table that belong to the [DBSPJ](#) kernel block. See [Section 20.5.10.9, “The ndbinfo counters Table”](#), for information about these counters. See also [The DBSPJ Block](#), in the *NDB Cluster API Developer Guide*.
- [ndb\\_log\\_apply\\_status](#)

**Table 20.52 Type and value information for [ndb\\_log\\_apply\\_status](#)**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <a href="#">ndb_log_apply_status</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| NDB 7.5   | boolean         | OFF             |
| DESCRIPTION: Whether or not a MySQL server acting as a slave logs <a href="#">mysql.ndb_apply_status</a> updates received from its immediate master in its own binary log, using its own server ID. |                 |                 |

A read-only variable which shows whether the server was started with the [--ndb-log-apply-status](#) option.

- [ndb\\_log\\_bin](#)

**Table 20.53 Type and value information for [ndb\\_log\\_bin](#)**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_log_bin</a>  |                 |                 |
| Yes  | Yes             | No              |
| No   | Both            | Yes             |
| NDB 7.5  | boolean         | ON              |
| DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with <a href="#">--log-bin</a> . |                 |                 |

Causes updates to [NDB](#) tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using [log\\_bin](#). [ndb\\_log\\_bin](#) defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- [ndb\\_log\\_binlog\\_index](#)

Table 20.54 Type and value information for `ndb_log_binlog_index`

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_log_binlog_index</a>   |                 |                 |
| Yes  | Yes             | No              |
| No   | Global          | Yes             |
| NDB 7.5  | boolean         | ON              |
| DESCRIPTION: Insert mapping between epochs and binary log positions into the <code>ndb_binlog_index</code> table. Defaults to ON. Effective only if binary logging is enabled on the server. |                 |                 |

Causes a mapping of epochs to positions in the binary log to be inserted into the [ndb\\_binlog\\_index](#) table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, [ndb\\_log\\_bin](#) must not be disabled.) [ndb\\_log\\_binlog\\_index](#) defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- [ndb\\_log\\_empty\\_epochs](#)

Table 20.55 Type and value information for `ndb_log_empty_epochs`

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndb_log_empty_epochs</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| NDB 7.5  | boolean         | OFF             |
| DESCRIPTION: When enabled, epochs in which there were no changes are written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>log_slave_updates</code> is enabled. |                 |                 |

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in [ndb\\_binlog\\_index](#).

- [ndb\\_log\\_empty\\_update](#)

Table 20.56 Type and value information for `ndb_log_empty_update`

| <b>Notes</b>                         |                 |                 |
| <a href="#">ndb_log_empty_update</a> |                 |                 |
| Yes                                  | Yes             | No              |
| Yes                                  | Global 3083     | Yes             |

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| NDB 7.5   | boolean         | OFF             |
| DESCRIPTION: When enabled, updates which produce no changes are written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>log_slave_updates</code> is enabled. |                 |                 |

When this variable is set to [ON \(1\)](#), update transactions with no changes are written to the binary log, even when `--log-slave-updates` is enabled.

- [ndb\\_log\\_exclusive\\_reads](#)

**Table 20.57 Type and value information for `ndb_log_exclusive_reads`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <a href="#">ndb_log_exclusive_reads</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Both            | Yes             |
| NDB 7.5   | boolean         | 0               |
| DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts. |                 |                 |

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of [ndb\\_log\\_exclusive\\_reads](#) to 1. 0, which disables such locking, is the default.

For more information, see [Read conflict detection and resolution](#).

- [ndb\\_log\\_orig](#)

**Table 20.58 Type and value information for `ndb_log_orig`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|

| No   | Global          | No              |
| NDB 7.5  | boolean         | OFF             |
| DESCRIPTION: Whether NDB transaction IDs are written into the binary log. (Read-only.) |                 |                 |

This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 5.7.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `ndb_optimized_node_selection`

| 5.1.22-ndb-6.3.4  | integer         | 3 / 0 - 3       |
| DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator |                 |                 |

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- **0**: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- **1**: Proximity to the SQL node is used to determine the transaction coordinator.
- **2**: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to **0**.
- **3**: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).
2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. (*NDB 7.5.2 and later*;) Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

- `ndb_read_backup`

**Table 20.61** Type and value information for `ndb_read_backup`

| No  | Yes             | No              |
| No  | Global          | Yes             |
| NDB 7.5   | bitmap          | [empty]         |
| DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details. |                 |                 |

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask; for example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set on startup using the `--ndb-recv-thread-cpu-mask` option.

- [ndb\\_report\\_thresh\\_binlog\\_epoch\\_slip](#)

**Table 20.64 Type and value information for `ndb_report_thresh_binlog_epoch_slip`**

| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| NDB 7.5   | integer         | 3 / 0 - 256     |
| 5.7.16-ndb-7.5.4  | integer         | 10 / 0 - 256    |
| DESCRIPTION: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates <code>BUFFERED_EPOCHS_OVER_THRESHOLD</code> event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status |                 |                 |

In NDB 7.5.4 and later, this represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see [Section 20.5.7.3, “Event Buffer Reporting in the Cluster Log”](#)). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

Prior to NDB 7.5.4, the value of this variable served as a threshold for the number of epochs to be behind before reporting binary log status. In these previous releases, a value of `3`—the default—means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message is then sent to the cluster log.

- [ndb\\_report\\_thresh\\_binlog\\_mem\\_usage](#)

**Table 20.65 Type and value information for `ndb_report_thresh_binlog_mem_usage`**

| Command Line   | System Variable | Status Variable |

| <b>Notes</b>                            |                 |                 |
| <a href="#">ndb_slave_conflict_role</a> |                 |                 |
| Yes                                     | Yes             | No              |
| Yes                                     | Global          | Yes             |

| Command Line  | System Variable | Status Variable                       |
|---|-----------------|---------------------------------------|
| Option File   | Scope           | Dynamic                               |
| From Version  | Type            | Default, Range                        |
| <b>Notes</b>  |                 |                                       |
| NDB 7.5   | enumeration     | NONE / NONE, PRIMARY, SECONDARY, PASS |
| DESCRIPTION: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information. |                 |                                       |

Determine the role of this SQL node (and NDB Cluster ) in a circular (“active-active”) replication setup. `ndb_slave_conflict_role` can take any one of the values `PRIMARY`, `SECONDARY`, `PASS`, or `NULL` (the default). The slave SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between `PASS` and either of `PRIMARY` or `SECONDARY` directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `ndb_table_no_logging`

**Table 20.69 Type and value information for `ndb_table_no_logging`**

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <code>ndb_table_no_logging</code>  |                 |                 |
| No   | Yes             | No              |
| No   | Session         | Yes             |
| NDB 7.5  | boolean         | FALSE           |
| DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table. |                 |                 |

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;
```

```
SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables [A](#) and [B](#) are not checkpointed; [A](#) was created with [ENGINE NDB](#) and [B](#) was altered to use [NDB](#), both while [ndb\\_table\\_no\\_logging](#) was enabled. However, tables [C](#) and [D](#) are logged; [C](#) was altered to use [NDB](#) and [D](#) was created using [ENGINE NDB](#), both while [ndb\\_table\\_no\\_logging](#) was disabled. Setting [ndb\\_table\\_no\\_logging](#) back to [1](#) or [ON](#) does *not* cause table [C](#) or [D](#) to be checkpointed.

**Note**

[ndb\\_table\\_no\\_logging](#) has no effect on the creation of [NDB](#) table schema files; to suppress these, use [ndb\\_table\\_temporary](#) instead.

- [ndb\\_table\\_temporary](#)

**Table 20.70 Type and value information for [ndb\\_table\\_temporary](#)**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <a href="#">ndb_table_temporary</a>   |                 |                 |
| No  | Yes             | No              |
| No  | Session         | Yes             |
| NDB 7.5   | boolean         | FALSE           |
| DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged |                 |                 |

When set to [ON](#) or [1](#), this variable causes [NDB](#) tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

**Note**

Setting this variable currently has no effect. This is a known issue; see Bug [#34036](#).

- [ndb\\_use\\_copying\\_alter\\_table](#)

| 5.1.47-ndb-7.1.8                                       | boolean         | OFF             |
| DESCRIPTION: Use exact row count when planning queries |                 |                 |

Forces NDB to use a count of records during `SELECT COUNT( *)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- [ndb\\_use\\_transactions](#)

**Table 20.73 Type and value information for `ndb_use_transactions`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|

| NDB 7.5  | string          |                 |
| DESCRIPTION: Shows build information including NDB engine version in ndb-x.y.z format. |                 |                 |

NDB engine version in `ndb-x.y.z` format.

- `server_id_bits`

**Table 20.76** Type and value information for `server_id_bits`

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>server_id_bits</code>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| NDB 7.5   | integer         | 32 / 7 - 32     |
| DESCRIPTION: The effective value of <code>server_id</code> if the server was started with the <code>--server-id-bits</code> option set to a nondefault value. |                 |                 |

The effective value of `server_id` if the server was started with the `--server-id-bits` option set to a nondefault value.

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster . `server_id_bits` is not supported by the standard MySQL Server.

- `transaction_allow_batching`

**Table 20.77** Type and value information for `transaction_allow_batching`

| Command Line                            | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File                             | Scope           | Dynamic         |
| From Version                            | Type            | Default, Range  |
| <b>Notes</b>                            |                 |                 |
| <code>transaction_allow_batching</code> |                 |                 |

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| No  | Yes             | No              |
| No  | Session         | Yes             |
| NDB 7.5   | boolean         | FALSE           |
| DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use. |                 |                 |

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

#### Important

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

**Table 20.78 Type and value information for `ndbinfo_database`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <code>ndbinfo_database</code>   |                 |                 |
| No  | Yes             | No              |
| No  | Global          | No              |
| NDB 7.5   | string          | ndbinfo         |
| DESCRIPTION: The name used for the NDB information database; read only. |                 |                 |

Shows the name used for the `NDB` information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--ndbinfo-database=name`, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- `ndbinfo_max_bytes`

**Table 20.79 Type and value information for `ndbinfo_max_bytes`**

| Command Line                          | System Variable | Status Variable |
|---------------------------------------|-----------------|-----------------|

| From Version                          | Type            | Default, Range  |
| <b>Notes</b>                          |                 |                 |
| <a href="#">ndbinfo_max_bytes</a>     |                 |                 |
| Yes                                   | Yes             | No              |
| No                                    | Both            | Yes             |
| NDB 7.5                               | integer         | 0 / -           |
| DESCRIPTION: Used for debugging only. |                 |                 |

Used in testing and debugging only.

- [ndbinfo\\_max\\_rows](#)

**Table 20.80 Type and value information for `ndbinfo_max_rows`**

| Command Line                          | System Variable | Status Variable |
|---------------------------------------|-----------------|-----------------|
| Option File                           | Scope           | Dynamic         |
| From Version                          | Type            | Default, Range  |
| <b>Notes</b>                          |                 |                 |
| <a href="#">ndbinfo_max_rows</a>      |                 |                 |
| Yes                                   | Yes             | No              |
| No                                    | Both            | Yes             |
| NDB 7.5                               | integer         | 10 / -          |
| DESCRIPTION: Used for debugging only. |                 |                 |

Used in testing and debugging only.

- [ndbinfo\\_offline](#)

**Table 20.81 Type and value information for `ndbinfo_offline`**

| Command Line  | System Variable | Status Variable |
|---|-----------------|-----------------|
| Option File   | Scope           | Dynamic         |
| From Version  | Type            | Default, Range  |
| <b>Notes</b>  |                 |                 |
| <a href="#">ndbinfo_offline</a>   |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| NDB 7.5   | boolean         | OFF             |
| DESCRIPTION: Put the <code>ndbinfo</code> database into offline mode, in which no rows are returned from tables or views. |                 |                 |

Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in `NDB`. No rows are returned from such tables (or views).

- [ndbinfo\\_show\\_hidden](#)

**Table 20.82** Type and value information for `ndbinfo_show_hidden`

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndbinfo_show_hidden</a>  |                 |                 |
| Yes  | Yes             | No              |
| No   | Both            | Yes             |
| NDB 7.5  | boolean         | OFF             |
| DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF. |                 |                 |

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- [ndbinfo\\_table\\_prefix](#)

**Table 20.83** Type and value information for `ndbinfo_table_prefix`

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| <a href="#">ndbinfo_table_prefix</a>                                   |                 |                 |
| Yes  | Yes             | No              |
| No   | Both            | Yes             |
| NDB 7.5  | string          | ndb\$           |
| DESCRIPTION: The prefix to use for naming ndbinfo internal base tables |                 |                 |

The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- [ndbinfo\\_version](#)

**Table 20.84** Type and value information for `ndbinfo_version`

| Command Line                    | System Variable | Status Variable |

| From Version                    | Type            | Default, Range  |
| <b>Notes</b>                    |                 |                 |
| <a href="#">ndbinfo_version</a> |                 |                 |
| No                              | Yes             | No              |
| No                              | Global          | No              |
| NDB 7.5                         | string          |                 |

| Command Line   | System Variable | Status Variable |
|--|-----------------|-----------------|
| Option File  | Scope           | Dynamic         |
| From Version   | Type            | Default, Range  |
| <b>Notes</b>   |                 |                 |
| DESCRIPTION: The version of the ndbinfo engine; read only. |                 |                 |

Shows the version of the `ndbinfo` engine in use; read-only.

## NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the `NDB` storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see [Section 6.1.7, “Server Status Variables”](#).

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_bytes_sent_count_session`

Amount of data (in bytes) sent to the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count_slave`

Amount of data (in bytes) sent to the data nodes by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_sent_count`

Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_session`

Amount of data (in bytes) received from the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count_slave`

Amount of data (in bytes) received from the data nodes by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_bytes_received_count`

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count_injector`

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_data_count`

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count_injector`

The number of events received, other than row change events, by the NDB binary log injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_nondata_count`

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count_injector`

The number of bytes of events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_event_bytes_count`

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_session`

The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count_slave`

The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_session`

The number of scans in this client session that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count_slave`

The number of scans by this slave that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_pruned_scan_count`

The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_session`

The number of range scans that have been started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count_slave`

The number of range scans that have been started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_range_scan_count`

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count_slave`

The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_session`

The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count_slave`

The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_scan_batch_count`

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_session`

The number of table scans that have been started in this client session, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count_slave`

The number of table scans that have been started by this slave, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_table_scan_count`

The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_session`

The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count_slave`

The number of transactions aborted by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_abort_count`

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_session`

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count_slave`

The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_close_count`

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_session`

The number of transactions committed in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count_slave`

The number of transactions committed by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_commit_count`

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_session`

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count_slave`

The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_local_read_row_count`

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_session`

The number of transactions started in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count_slave`

The number of transactions started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_trans_start_count`

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_session`

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count_slave`

The number of operations by this slave based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_uk_op_count`

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_session`

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count_slave`

The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_exec_complete_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_session`

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count_slave`

The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_meta_request_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_session`

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count_slave`

Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_nanos_count`

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_session`

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count_slave`

The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_api_wait_scan_result_count`

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see [Section 20.5.16, “NDB API Statistics Counters and Variables”](#).

- `Ndb_cluster_node_id`

If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- `Ndb_config_from_port`

If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_conflict_fn_max_del_win`

Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_max`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_old`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch2`

Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the master designated as the primary since the last time it was restarted.

For more information, see [NDB\\$EPOCH2\(\)](#).

- `Ndb_conflict_fn_epoch_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_fn_epoch2_trans`

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see `NDB$EPOCH2_TRANS()`.

- `Ndb_conflict_last_conflict_epoch`

The most recent epoch in which a conflict was detected on this slave. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

See [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_discard_count`

When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

See [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_reflected_op_prepare_count`

When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

See [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_refresh_op_count`

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

See [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_last_stable_epoch`

Number of rows found to be in conflict by a transactional conflict function

See [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#), for more information.

- `Ndb_conflict_trans_row_conflict_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

---

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_row_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_reject_count`

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_detect_iter_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_conflict_trans_conflict_commit_count`

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

- `Ndb_epoch_delete_delete_count`

When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- `Ndb_execute_count`

Provides the number of round trips to the `NDB` kernel made by operations.

- `Ndb_last_commit_epoch_server`

The epoch most recently committed by `NDB`.

- `Ndb_last_commit_epoch_session`

The epoch most recently committed by this `NDB` client.

- `Ndb_number_of_data_nodes`

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_pushed_queries_defined`

The total number of joins pushed down to the `NDB` kernel for distributed handling on the data nodes.

**Note**

Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

- `Ndb_pushed_queries_dropped`

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- `Ndb_pushed_queries_executed`

The number of joins successfully pushed down to `NDB` and executed there.

- `Ndb_pushed_reads`

The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.

#### Note

Executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number.

- `Ndb_pruned_scan_count`

This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

- `Ndb_scan_count`

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

- `Ndb_slave_max_replicated_epoch`

The most recently committed epoch on this slave. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

### 20.3.3.9 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster . Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

#### Note

For an exception to this rule, see [Section 20.3.3.10, “NDB Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

#### Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]`

section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `NodeId1`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | [none]  | ...          | N            |

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `NodeId2`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | [none]  | ...          | N            |

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#).

- `HostName1`

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `OverloadLimit`

| Effective Version | Type/Units | Default | Range/Values                | Restart Type |
|-------------------|------------|---------|-----------------------------|--------------|
| NDB 7.5.0         | bytes      | 0       | 0 - 4294967039 (0xFFFFFFFF) | N            |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#), for more information.

- [SendBufferMemory](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 2M      | 256K - 4294967039 (0xFFFFFFFF) | N            |

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, [TotalSendBufferMemory](#)) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#).

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- [SendSignalId](#)

| Effective Version | Type/Units | Default    | Range/Values | Restart Type |
|-------------------|------------|------------|--------------|--------------|
| NDB 7.5.0         | boolean    | [see text] | true, false  | N            |

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to [Y](#), message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [Checksum](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

This parameter is a boolean parameter (enabled by setting it to [Y](#) or [1](#), disabled by setting it to [N](#) or [0](#)). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- [PortNumber](#) (*OBSOLETE*)

This parameter formerly specified the port number to be used for listening for connections from other nodes. It is now deprecated (and removed in NDB Cluster 7.5); use the [ServerPort](#) data node configuration parameter for this purpose instead (Bug #77405, Bug #21280456).

- [ReceiveBufferMemory](#)

| Effective Version | Type/Units | Default | Range/Values                  | Restart Type |
|-------------------|------------|---------|-------------------------------|--------------|
| NDB 7.5.0         | bytes      | 2M      | 16K - 4294967039 (0xFFFFFFFF) | N            |

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- [TCP\\_RCV\\_BUF\\_SIZE](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 2G       | N            |

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- [TCP\\_SND\\_BUF\\_SIZE](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 2G       | N            |

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- [TCP\\_MAXSEG\\_SIZE](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 2G       | N            |

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- [TcpBind\\_INADDR\\_ANY](#)

Setting this parameter to [TRUE](#) or [1](#) binds [IP\\_ADDR\\_ANY](#) so that connections can be made from anywhere (for autogenerated connections). The default is [FALSE](#) (0).

- [Group](#)

When [ndb\\_optimized\\_node\\_selection](#) is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

### 20.3.3.10 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [\[tcp\]](#) section of the cluster [config.ini](#) file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the [172.23.72.\\*](#) subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the [1.1.0.\\*](#) address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
```

```

Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2

```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

#### Note

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 20.3.3.11 NDB Cluster Shared-Memory Connections

NDB Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

#### Important

*SHM functionality is considered experimental only.* It is not officially supported in any current NDB Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- `NodeId1`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | [none]  | ...          | N            |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeId2`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | [none]  | ...          | N            |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `HostName1`

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [OverloadLimit](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | bytes      | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#), for more information.

- [ShmKey](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- [ShmSize](#)

| Effective Version | Type/Units | Default | Range/Values                     | Restart Type |
|-------------------|------------|---------|----------------------------------|--------------|
| NDB 7.5.0         | bytes      | 1M      | 64K - 4294967039<br>(0xFFFFFFFF) | N            |

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value is 1MB.

- [SendSignalId](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | true    | true, false  | N            |

This parameter is a boolean (`Y/N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- `SigNum`

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of `SigNum` is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

### 20.3.3.12 SCI Transport Connections in NDB Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in NDB Cluster requires specialized hardware as well as specially-built MySQL binaries; compiling such binaries is not supported using an NDB 7.2 or later distribution.

The following parameters are present in NDB source code as well as the output of `ndb_config` and other NDB programs, but are nonfunctional in NDB 7.2 and later.

- `NodeId1`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | [none]  | ...          | N            |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeId2`

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | numeric    | [none]  | ...          | N            |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `Host1SciId0`

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This identifies the SCI node ID on the first Cluster node (identified by [NodeId1](#)).

- [Host1SciId1](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- [Host2SciId0](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | [none]  | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

This identifies the SCI node ID on the second Cluster node (identified by [NodeId2](#)).

- [Host2SciId1](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- [HostName1](#)

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [HostName2](#)

| Effective Version | Type/Units         | Default | Range/Values | Restart Type |
|-------------------|--------------------|---------|--------------|--------------|
| NDB 7.5.0         | name or IP address | [none]  | ...          | N            |

The [HostName1](#) and [HostName2](#) parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- [SharedBufferSize](#)

| Effective Version | Type/Units | Default | Range/Values                     | Restart Type |
|-------------------|------------|---------|----------------------------------|--------------|
| NDB 7.5.0         | unsigned   | 10M     | 64K - 4294967039<br>(0xFFFFFFFF) | N            |

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- [SendLimit](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | unsigned   | 8K      | 128 - 32K    | N            |

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- [SendSignalId](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | true    | true, false  | N            |

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [Checksum](#)

| Effective Version | Type/Units | Default | Range/Values | Restart Type |
|-------------------|------------|---------|--------------|--------------|
| NDB 7.5.0         | boolean    | false   | true, false  | N            |

This parameter is a boolean value, and is disabled by default. When [Checksum](#) is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- [OverloadLimit](#)

| Effective Version | Type/Units | Default | Range/Values                   | Restart Type |
|-------------------|------------|---------|--------------------------------|--------------|
| NDB 7.5.0         | bytes      | 0       | 0 - 4294967039<br>(0xFFFFFFFF) | N            |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See [Section 20.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”](#), for more information.

### 20.3.3.13 Configuring NDB Cluster Send Buffer Parameters

The `NDB` kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can be accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It

represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

| Transporter | Maximum Send Buffer Size (bytes)               |
|-------------|--|
| TCP         | <code>SendBufferMemory</code> (default = 2M)   |
| SCI         | <code>SendLimit</code> (default = 8K) plus 16K |
| SHM         | 20K  |

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.
- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.
- **ReservedSendBufferMemory.** Removed in NDB 7.5.2.

Prior to NDB 7.5.2, this data node parameter was present, but was not actually used (Bug #77404, Bug #21280428).

## 20.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See [Section 20.3.3.10, “NDB Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 20.3.3.11, “NDB Cluster Shared-Memory Connections”](#).

**Note**

SHM is considered experimental only, and is not officially supported.

- *Scalable Coherent Interface (SCI)*. For more information about SHM, see [Section 20.3.3.12, “SCI Transport Connections in NDB Cluster”](#).

**Note**

Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available using an NDB 7.2 or later distribution.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

## 20.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Information about the program `ndb_setup.py`, used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that [Section 20.4.23, “`ndb\_setup.py` — Start browser-based Auto-Installer for NDB Cluster”](#), contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see [Section 20.2.1, “The NDB Cluster Auto-Installer”](#).

For information about using `mysqld` as an NDB Cluster process, see [Section 20.5.4, “MySQL Server Usage for NDB Cluster”](#).

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

### 20.4.1 `ndbd` — The NDB Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the NDB Cluster data node program `ndbd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbd`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.85** This table describes command-line options for the `ndbd` program

| Format                                      | Description   | Added or Removed             |
|---|---|------------------------------|
| <code>--initial</code>                      | Perform initial start of <code>ndbd</code> , including cleaning the file system. Consult the documentation before using this option     | All MySQL 5.7 based releases |
| <code>--nostart</code> ,<br><code>-n</code> | Don't start <code>ndbd</code> immediately; <code>ndbd</code> waits for command to start from <code>ndb_mgmd</code>                      | All MySQL 5.7 based releases |
| <code>--daemon</code> ,<br><code>-d</code>  | Start <code>ndbd</code> as daemon (default); override with <code>--nodaemon</code>  | All MySQL 5.7 based releases |
| <code>--nodaemon</code>                     | Do not start <code>ndbd</code> as daemon; provided for testing purposes   | All MySQL 5.7 based releases |
| <code>--foreground</code>                   | Run <code>ndbd</code> in foreground, provided for debugging purposes (implies <code>--nodaemon</code> )                                 | All MySQL 5.7 based releases |
| <code>--nowait-nodes=list</code>            | Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires <code>--ndb-nodeid</code> to be used. | All MySQL 5.7 based releases |
| <code>--initial-start</code>                | Perform partial initial start (requires <code>--nowait-nodes</code> )   | All MySQL 5.7 based releases |
| <code>--bind-address=name</code>            | Local bind address  | All MySQL 5.7 based releases |
| <code>--install[=name]</code>               | Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.                                    | All MySQL 5.7 based releases |
| <code>--remove[=name]</code>                | Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.         | All MySQL 5.7 based releases |
| <code>--connect-retries=#</code>            | Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries)                                 | All MySQL 5.7 based releases |
| <code>--connect-delay=#</code>              | Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts                          | All MySQL 5.7 based releases |
| <code>--connect-retry-delay=#</code>        | Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts                          | All MySQL 5.7 based releases |

**Note**

All of these options also apply to the multi-threaded version of this program (`ndbmt`) and you may substitute “`ndbmt`” for “`ndbd`” wherever the latter occurs in this section.

- `--bind-address`

|                            |                                  |        |
|----------------------------|----------------------------------|--------|
| <b>Command-Line Format</b> | <code>--bind-address=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                      | string |
|                            | <b>Default</b>                   |        |

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

- `--daemon, -d`

|                            |                       |                   |
|----------------------------|-----------------------|-------------------|
| <b>Command-Line Format</b> | <code>--daemon</code> |                   |
| <b>Permitted Values</b>    | <b>Type</b>           | boolean           |
|                            | <b>Default</b>        | <code>TRUE</code> |

Instructs `ndbd` or `ndbmt` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--nodaemon`

|                            |                         |                    |
|----------------------------|-------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--nodaemon</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>             | boolean            |
|                            | <b>Default</b>          | <code>FALSE</code> |

Prevents `ndbd` or `ndbmt` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmt` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--foreground`

|                            |                           |                    |
|----------------------------|---------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--foreground</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>               | boolean            |
|                            | <b>Default</b>            | <code>FALSE</code> |

Causes `ndbd` or `ndbmt` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--initial`

|                            |                        |                    |
|----------------------------|------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--initial</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>            | boolean            |
|                            | <b>Default</b>         | <code>FALSE</code> |

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

### Warning

To avoid the possibility of eventual data loss, it is recommended that you *not* use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

### Important

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- NDB Cluster Disk Data files (see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#)).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

|                            |                              |                    |
|----------------------------|------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--initial-start</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                  | boolean            |
|                            | <b>Default</b>               | <code>FALSE</code> |

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

### Important

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

|                            |                                  |        |
|----------------------------|----------------------------------|--------|
| <b>Command-Line Format</b> | <code>--nowait-nodes=list</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                      | string |
|                            | <b>Default</b>                   |        |

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

- `--nostart, -n`

|                            |                        |                    |
|----------------------------|------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--nostart</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>            | boolean            |
|                            | <b>Default</b>         | <code>FALSE</code> |

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#)).

- `--install[=name]`

|                            |                               |                   |
|----------------------------|-------------------------------|-------------------|
| <b>Command-Line Format</b> | <code>--install[=name]</code> |                   |
| <b>Platform Specific</b>   | Windows                       |                   |
| <b>Permitted Values</b>    | <b>Type</b>                   | string            |
|                            | <b>Default</b>                | <code>ndbd</code> |

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--remove[=name]`

|                            |                              |        |
|----------------------------|------------------------------|--------|
| <b>Command-Line Format</b> | <code>--remove[=name]</code> |        |
| <b>Platform Specific</b>   | Windows                      |        |
| <b>Permitted Values</b>    | <b>Type</b>                  | string |
|                            | <b>Default</b>               | ndbd   |

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--connect-retries=#`

|                            |                                  |         |
|----------------------------|----------------------------------|---------|
| <b>Command-Line Format</b> | <code>--connect-retries=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                      | numeric |
|                            | <b>Default</b>                   | 12      |
|                            | <b>Min Value</b>                 | 0       |
|                            | <b>Max Value</b>                 | 65535   |

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option.

- `--connect-delay=#`

|                            |                                |         |
|----------------------------|--------------------------------|---------|
| <b>Deprecated</b>          | 5.6.28-ndb-7.4.9               |         |
| <b>Command-Line Format</b> | <code>--connect-delay=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                    | numeric |
|                            | <b>Default</b>                 | 5       |
|                            | <b>Min Value</b>               | 0       |
|                            | <b>Max Value</b>               | 3600    |

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option is deprecated, and is subject to removal in a future release of NDB Cluster . Use `--connect-retry-delay` instead.

- `--connect-retry-delay=#`

|                            |                                      |         |
|----------------------------|--------------------------------------|---------|
| <b>Command-Line Format</b> | <code>--connect-retry-delay=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                          | numeric |
|                            | <b>Default</b>                       | 5       |
|                            | <b>Min Value</b>                     | 0       |

|  |                  |            |
|--|------------------|------------|
|  | <b>Max Value</b> | 4294967295 |
|--|------------------|------------|

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option takes the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster .

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is and represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [Data Node Error Messages](#).

#### Important

*The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.*

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 20.3.3.3, “NDB Cluster Connection Strings”](#), for additional information about this issue. [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#), describes other command-line options which can be used with `ndbd`. For information about data node configuration parameters, see [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#).

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.7 in a production setting. See [Section 20.1.6, “Known Limitations of NDB Cluster”](#).

## 20.4.2 ndbinfo\_select\_all — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database

Not all `ndbinfo` tables available in the `mysql` client can be read by this program. In addition, `ndbinfo_select_all` can show information about some tables internal to `ndbinfo` which cannot be accessed using SQL, including the `tables` and `columns` metadata tables.

To select from one or more `ndbinfo` tables using `ndbinfo_select_all`, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==

```

The following table includes options that are specific to `ndbinfo_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbinfo_select_all`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.86** This table describes command-line options for the `ndbinfo_select_all` program

| Format   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--delay=#</code>                               | Set the delay in seconds between loops. Default is 5.        | All MySQL 5.7 based releases |
| <code>--loops=#</code> ,<br><code>-l</code>          | Set the number of times to perform the select. Default is 1. | All MySQL 5.7 based releases |
| <code>--database=db_name</code> ,<br><code>-d</code> | Name of the database where the table located.                | All MySQL 5.7 based releases |
| <code>--parallelism=#</code> ,<br><code>-p</code>    | Set the degree of parallelism.                               | All MySQL 5.7 based releases |

- `--delay=seconds`

| Command-Line Format | <code>--delay=#</code> |                      |
|---------------------|------------------------|----------------------|
| Permitted Values    | Type                   | numeric              |
|                     | Default                | 5                    |
|                     | Min Value              | 0                    |
|                     | Max Value              | <code>MAX_INT</code> |

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- `--loops=number`, `-l number`

| Command-Line Format | <code>--loops=#</code> |                      |
|---------------------|------------------------|----------------------|
| Permitted Values    | Type                   | numeric              |
|                     | Default                | 1                    |
|                     | Min Value              | 0                    |
|                     | Max Value              | <code>MAX_INT</code> |

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

## 20.4.3 ndbmttd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmttd` is a multi-threaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmttd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmttd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmttd` differs from `ndbd`, and you should consult [Section 20.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#), for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multi-threaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmttd`. For more information about these options and parameters, see [Section 20.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#), and [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#), respectively.

`ndbmttd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmttd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmttd` to run in multi-threaded fashion.) Similarly, an `ndbmttd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multi-threaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmttd` differs from using `ndbd` in two key respects:

1. Because `ndbmttd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see [Multi-Threading Configuration Parameters \(ndbmttd\)](#).
2. Trace files are generated by critical errors in `ndbmttd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmttd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmttd` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmttd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmttd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmttd`. See [Data Node Error Messages](#), for a listing of these.

**Note**

It is possible to use `ndbd` and `ndbmt` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

## 20.4.4 `ndb_mgmd` — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the NDB Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgmd`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.87** This table describes command-line options for the `ndb_mgmd` program

| Format   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--config-file=file,</code><br><code>-f</code>                        | Specify the cluster configuration file; in NDB-6.4.0 and later, needs <code>--reload</code> or <code>--initial</code> to override configuration cache if present | All MySQL 5.7 based releases |
| <code>--configdir=directory,</code><br><code>--config-dir=directory</code> | Specify the cluster management server's configuration cache directory  | All MySQL 5.7 based releases |
| <code>--bind-address=ip_address</code>                                     | Local bind address   | All MySQL 5.7 based releases |
| <code>--print-full-config,</code><br><code>-P</code>                       | Print full configuration and exit  | All MySQL 5.7 based releases |
| <code>--daemon,</code><br><code>-d</code>                                  | Run <code>ndb_mgmd</code> in daemon mode (default)   | All MySQL 5.7 based releases |
| <code>--nodaemon</code>  | Do not run <code>ndb_mgmd</code> as a daemon   | All MySQL 5.7 based releases |
| <code>--interactive</code>   | Run <code>ndb_mgmd</code> in interactive mode (not officially supported in production; for testing purposes only)  | All MySQL 5.7 based releases |
| <code>--log-name=name</code>   | A name to use when writing messages applying to this node in the cluster log.  | All MySQL 5.7 based releases |
| <code>--no-nodeid-checks</code>  | Do not provide any node id checks  | All MySQL 5.7 based releases |
| <code>--mycnf</code>   | Read cluster configuration data from the <code>my.cnf</code> file  | All MySQL 5.7 based releases |
| <code>--reload</code>  | Causes the management server to compare the configuration file with its configuration cache  | All MySQL 5.7 based releases |
| <code>--initial</code>   | Causes the management server reload its configuration data from  | All MySQL 5.7 based releases |

| Format                                   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--nowait-nodes=list</code>         | the configuration file, bypassing the configuration cache<br>Do not wait for these management nodes when starting this management server. Also requires <code>--ndb-nodeid</code> to be used.        | All MySQL 5.7 based releases |
| <code>--config-cache[=TRUE FALSE]</code> | Enable the management server configuration cache; TRUE by default.   | All MySQL 5.7 based releases |
| <code>--install[=name]</code>            | Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.   | All MySQL 5.7 based releases |
| <code>--remove[=name]</code>             | Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms. | All MySQL 5.7 based releases |

- `--bind-address=host[:port]`

|                            |  |                     |
|----------------------------|--|---------------------|
| <b>Command-Line Format</b> | <code>--bind-address=ip_address</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                            | string              |
|                            | <b>Default</b>                         | <code>[none]</code> |

When specified, this option limits management server connections by management clients to clients at the specified host name or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `Unable to setup port: host:port!`

If the `port` is not specified, the management client attempts to use port 1186.

- `--no-nodeid-checks`

|                            |                                 |                    |
|----------------------------|---------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--no-nodeid-checks</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                     | boolean            |
|                            | <b>Default</b>                  | <code>FALSE</code> |

Do not perform any checks of node IDs.

- `--configdir=dir_name`

|                            |                                     |   |
|----------------------------|-------------------------------------|---|
| <b>Command-Line Format</b> | <code>--configdir=directory</code>  |   |
|                            | <code>--config-dir=directory</code> |   |
| <b>Permitted Values</b>    | <b>Type</b>                         | file name                               |
|                            | <b>Default</b>                      | <code>\$INSTALLDIR/mysql-cluster</code> |

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

- `--config-cache`

|                            |  |                   |
|----------------------------|--|-------------------|
| <b>Command-Line Format</b> | <code>--config-cache[=TRUE FALSE]</code> |                   |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean           |
|                            | <b>Default</b>                           | <code>TRUE</code> |

This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see [Section 20.3.3, “NDB Cluster Configuration Files”](#)). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`
- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to `0`, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename, -f filename`

|                            |                                 |                     |
|----------------------------|---------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--config-file=file</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                     | file name           |
|                            | <b>Default</b>                  | <code>[none]</code> |

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. This option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See [Section 20.3.3, “NDB Cluster Configuration Files”](#), for more information.

- `--mycnf`

|                            |                      |                    |
|----------------------------|----------------------|--------------------|
| <b>Command-Line Format</b> | <code>--mycnf</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>          | boolean            |
|                            | <b>Default</b>       | <code>FALSE</code> |

Read configuration data from the `my.cnf` file.

- `--daemon, -d`

|                            |                       |                   |
|----------------------------|-----------------------|-------------------|
| <b>Command-Line Format</b> | <code>--daemon</code> |                   |
| <b>Permitted Values</b>    | <b>Type</b>           | boolean           |
|                            | <b>Default</b>        | <code>TRUE</code> |

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--interactive`

|                            |                            |                    |
|----------------------------|----------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--interactive</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                | boolean            |
|                            | <b>Default</b>             | <code>FALSE</code> |

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- `--initial`

|                            |                        |                    |
|----------------------------|------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--initial</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>            | boolean            |
|                            | <b>Default</b>         | <code>FALSE</code> |

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see [Section 20.3.3, “NDB Cluster Configuration Files”](#)). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data; `ndb_mgmd` ignores `--initial` unless it is the only management server running. This behavior also has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

When used together with the `--config-file` option, the cache is cleared only if the configuration file is actually found.

- `--log-name=name`

|                            |                              |                       |
|----------------------------|------------------------------|-----------------------|
| <b>Command-Line Format</b> | <code>--log-name=name</code> |                       |
| <b>Permitted Values</b>    | <b>Type</b>                  | string                |
|                            | <b>Default</b>               | <code>MgmtSrvr</code> |

Provides a name to be used for this node in the cluster log.

- `--nodaemon`

|                            |                         |                    |
|----------------------------|-------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--nodaemon</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>             | boolean            |
|                            | <b>Default</b>          | <code>FALSE</code> |

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- `--print-full-config, -P`

|                            |                                  |                    |
|----------------------------|----------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--print-full-config</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean            |
|                            | <b>Default</b>                   | <code>FALSE</code> |

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

|                            |                       |                    |
|----------------------------|-----------------------|--------------------|
| <b>Command-Line Format</b> | <code>--reload</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>           | boolean            |
|                            | <b>Default</b>        | <code>FALSE</code> |

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 20.3.3, “NDB Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data; `ndb_mgmd` ignores `--reload` unless it is the only management server running. This behavior also has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#), for more information.

- `--nowait-nodes`

| Command-Line Format | <code>--nowait-nodes=list</code> |         |
|---------------------|----------------------------------|---------|
| Permitted Values    | Type                             | numeric |
|                     | Default                          |         |
|                     | Min Value                        | 1       |
|                     | Max Value                        | 255     |

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 192.168.0.101

[ndbd]
NodeId = 2
HostName = 192.168.0.102

[ndbd]
NodeId = 3
HostName = 192.168.0.103

[ndbd]
NodeId = 4
HostName = 192.168.0.104

[ndb_mgmd]
NodeId = 10
HostName = 192.168.0.150

[ndb_mgmd]
NodeId = 11
HostName = 192.168.0.151

[api]
NodeId = 20
HostName = 192.168.0.200

[api]
NodeId = 21
HostName = 192.168.0.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 192.168.0.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 192.168.0.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 192.168.0.150,192.168.0.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See [Section 20.3.3.3, “NDB Cluster Connection Strings”](#), for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

#### Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 20.3.3.3, “NDB Cluster Connection Strings”](#), for information about using connection strings. [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 20.3, “Configuration of NDB Cluster”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage.

A complete listing of cluster events with descriptions may be found in [Section 20.5, “Management of NDB Cluster”](#).

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.
- `--install[=name]`

|                            |                               |                       |
|----------------------------|-------------------------------|-----------------------|
| <b>Command-Line Format</b> | <code>--install[=name]</code> |                       |
| <b>Platform Specific</b>   | Windows                       |                       |
| <b>Permitted Values</b>    | <b>Type</b>                   | string                |
|                            | <b>Default</b>                | <code>ndb_mgmd</code> |

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--remove[=name]`

|                            |                              |                       |
|----------------------------|------------------------------|-----------------------|
| <b>Command-Line Format</b> | <code>--remove[=name]</code> |                       |
| <b>Platform Specific</b>   | Windows                      |                       |
| <b>Permitted Values</b>    | <b>Type</b>                  | string                |
|                            | <b>Default</b>               | <code>ndb_mgmd</code> |

Causes an `ndb_mgmd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndb_mgmd`.

The `--remove` option has no effect on non-Windows platforms.

## 20.4.5 `ndb_mgm` — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the NDB Cluster management client program `ndb_mgm`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgm`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.88 This table describes command-line options for the `ndb_mgm` program**

| Format  | Description  | Added or Removed             |
|---|--|------------------------------|
| <code>--try-reconnect=#</code> ,<br><code>-t</code> | Set the number of times to retry a connection before giving up; synonym for <code>--connect-retries</code> | All MySQL 5.7 based releases |
| <code>--execute=name</code> ,<br><code>-e</code>    | Execute command and exit   | All MySQL 5.7 based releases |

- `--connect-retries=#`

| Command-Line Format | <code>--connect-retries=#</code> |            |
|---------------------|----------------------------------|------------|
| Permitted Values    | Type                             | numeric    |
|                     | Default                          | 3          |
|                     | Min Value                        | 0          |
|                     | Max Value                        | 4294967295 |

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

The default for this option this option differs from its default when used with other NDB programs. See [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#), for more information.

- `--execute=command`, `-e command`

| Command-Line Format | <code>--execute=name</code> |
|---------------------|-----------------------------|
|---------------------|-----------------------------|

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 5.2.4, “Using Options on the Command Line”](#).

**Note**

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--try-reconnect=number`

|  |                                |            |
|--|--------------------------------|------------|
| Deprecated                             | 5.6.28-ndb-7.4.9               |            |
| Command-Line Format                    | <code>--try-reconnect=#</code> |            |
| Permitted Values                       | Type                           | integer    |
|  | Default                        | 3          |
|  | Min Value                      | 0          |
|  | Max Value                      | 4294967295 |
| Permitted Values (>= 5.7.10-ndb-7.5.0) | Type                           | numeric    |
|  | Default                        | 12         |
|  | Min Value                      | 0          |
|  | Max Value                      | 4294967295 |

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

Additional information about using `ndb_mgm` can be found in [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#).

### 20.4.6 ndb\_blob\_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from [NDB](#) tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged [NDB](#) tables containing [BLOB](#) or [TEXT](#) columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause `ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more [BLOB](#) or [TEXT](#)

columns from that table. If no columns are listed, the tool works on all of the table's **BLOB** and **TEXT** columns. If you need to specify a database, use the `--database` (`-d`) option.

The `--verbose` option provides additional information in the output about the tool's progress.

The following table includes options that are specific to `ndb_blob_tool`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_blob_tool`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.89 This table describes command-line options for the `ndb_blob_tool` program**

| Format  | Description                         | Added or Removed             |
|---|-------------------------------------|------------------------------|
| <code>--check-orphans</code>                        | Check for orphan blob parts         | All MySQL 5.7 based releases |
| <code>--database=db_name,</code><br><code>-d</code> | Database to find the table in.      | All MySQL 5.7 based releases |
| <code>--delete-orphans</code>                       | Delete orphan blob parts            | All MySQL 5.7 based releases |
| <code>--dump-file=file</code>                       | Write orphan keys to specified file | All MySQL 5.7 based releases |
| <code>--verbose,</code><br><code>-v</code>          | Verbose output                      | All MySQL 5.7 based releases |

- `--check-orphans`

|                            |                              |                    |
|----------------------------|------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--check-orphans</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                  | boolean            |
|                            | <b>Default</b>               | <code>FALSE</code> |

Check for orphaned BLOB parts in NDB Cluster tables.

- `--database=db_name, -d`

|                            |                                 |                     |
|----------------------------|---------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--database=db_name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                     | string              |
|                            | <b>Default</b>                  | <code>[none]</code> |

Specify the database to find the table in.

- `--delete-orphans`

|                            |                               |                    |
|----------------------------|-------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--delete-orphans</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                   | boolean            |
|                            | <b>Default</b>                | <code>FALSE</code> |

Remove orphaned BLOB parts from NDB Cluster tables.

- `--dump-file=file`

|                            |                               |                     |
|----------------------------|-------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--dump-file=file</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                   | file name           |
|                            | <b>Default</b>                | <code>[none]</code> |

Writes a list of orphaned BLOB column parts to `file`. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--verbose`

|                            |                        |                    |
|----------------------------|------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--verbose</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>            | boolean            |
|                            | <b>Default</b>         | <code>FALSE</code> |

Provide extra information in the tool's output regarding its progress.

## Example

First we create an NDB table in the `test` database, using the `CREATE TABLE` statement shown here:

```
USE test;

CREATE TABLE btest (
  c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c1 TEXT,
  c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected

NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no NDB BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an NDB table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by NDB for this column. See [Section 12.8, “Data Type Storage Requirements”](#), for more information.

## 20.4.7 ndb\_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By

default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

The following table includes options that are specific to `ndb_config`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_config`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.90** This table describes command-line options for the `ndb_config` program

| Format   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--nodes</code>                             | Print node information ([ <code>ndbd</code> ] or [ <code>ndbd default</code> ] section of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--connections</code> .  | All MySQL 5.7 based releases |
| <code>--connections</code>                       | Print connections information ([ <code>tcp</code> ], [ <code>tcp default</code> ], [ <code>sci</code> ], [ <code>sci default</code> ], [ <code>shm</code> ], or [ <code>shm default</code> ] sections of cluster configuration file) only. Cannot be used with <code>--system</code> or <code>--nodes</code> . | All MySQL 5.7 based releases |
| <code>--query=string,</code><br><code>-q</code>  | One or more query options (attributes)   | All MySQL 5.7 based releases |
| <code>--host=name</code>                         | Specify host   | All MySQL 5.7 based releases |
| <code>--type=name</code>                         | Specify node type  | All MySQL 5.7 based releases |
| <code>--nodeid,</code><br><code>--id</code>      | Get configuration of node with this ID   | All MySQL 5.7 based releases |
| <code>--fields=string,</code><br><code>-f</code> | Field separator  | All MySQL 5.7 based releases |
| <code>--rows=string,</code><br><code>-r</code>   | Row separator  | All MySQL 5.7 based releases |
| <code>--config-file=file_name</code>             | Set the path to <code>config.ini</code> file   | All MySQL 5.7 based releases |
| <code>--mycnf</code>                             | Read configuration data from <code>my.cnf</code> file  | All MySQL 5.7 based releases |
| <code>-c</code>                                  | Short form for <code>--ndb-connectstring</code>  | All MySQL 5.7 based releases |
| <code>--configinfo</code>                        | Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output.   | All MySQL 5.7 based releases |

| Format                            | Description   | Added or Removed             |
|-----------------------------------|---|------------------------------|
| <code>--configinfo --xml</code>   | Use <code>--xml</code> with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values. | All MySQL 5.7 based releases |
| <code>--system</code>             | Print SYSTEM section information only (see <code>ndb_config --configinfo</code> output). Cannot be used with <code>--nodes</code> or <code>--connections</code> .   | All MySQL 5.7 based releases |
| <code>--config_from_node=#</code> | Obtain configuration data from the node having this ID (must be a data node).   | All MySQL 5.7 based releases |

- `--usage`, `--help`, or `-?`

|                            |                      |
|----------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--help</code>  |
|                            | <code>--usage</code> |

Causes `ndb_config` to print a list of available options, and then exit.

- `--config_from_node=#`

|                            |                                   |                   |
|----------------------------|-----------------------------------|-------------------|
| <b>Command-Line Format</b> | <code>--config_from_node=#</code> |                   |
| <b>Permitted Values</b>    | <b>Type</b>                       | numeric           |
|                            | <b>Default</b>                    | <code>none</code> |
|                            | <b>Min Value</b>                  | 1                 |
|                            | <b>Max Value</b>                  | 48                |

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--version`, `-V`

|                            |                        |
|----------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--version</code> |
|----------------------------|------------------------|

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connection_string`, `-c connection_string`

|                            |  |                             |
|----------------------------|--|-----------------------------|
| <b>Command-Line Format</b> | <code>--ndb-connectstring=connectstring</code> |                             |
|                            | <code>--connect-string=connectstring</code>    |                             |
| <b>Permitted Values</b>    | <b>Type</b>                                    | string                      |
|                            | <b>Default</b>                                 | <code>localhost:1186</code> |

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in [Section 20.3.3.3, “NDB Cluster Connection Strings”](#), and defaults to `localhost:1186`.

- `--config-file=path-to-file`

|                            |                                      |           |
|----------------------------|--------------------------------------|-----------|
| <b>Command-Line Format</b> | <code>--config-file=file_name</code> |           |
| <b>Permitted Values</b>    | <b>Type</b>                          | file name |
|                            | <b>Default</b>                       |           |

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--mycnf`

|                            |                      |                    |
|----------------------------|----------------------|--------------------|
| <b>Command-Line Format</b> | <code>--mycnf</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>          | boolean            |
|                            | <b>Default</b>       | <code>FALSE</code> |

Read configuration data from the `my.cnf` file.

- `--query=query-options, -q query-options`

|                            |                             |        |
|----------------------------|-----------------------------|--------|
| <b>Command-Line Format</b> | <code>--query=string</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                 | string |
|                            | <b>Default</b>              |        |

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `id` (node ID), `type` (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` returns the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

#### Note

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

|                            |                          |        |
|----------------------------|--------------------------|--------|
| <b>Command-Line Format</b> | <code>--host=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>              | string |
|                            | <b>Default</b>           |        |

Specifies the host name of the node for which configuration information is to be obtained.

#### Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- `--id=node_id`

`--nodeid=node_id`

|                            |                             |         |
|----------------------------|-----------------------------|---------|
| <b>Command-Line Format</b> | <code>--ndb-nodeid=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                 | numeric |
|                            | <b>Default</b>              | 0       |

Either of these options can be used to specify the node ID of the node for which configuration information is to be obtained. `--nodeid` is the preferred form.

- `--nodes`

|                            |                      |                    |
|----------------------------|----------------------|--------------------|
| <b>Command-Line Format</b> | <code>--nodes</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>          | boolean            |
|                            | <b>Default</b>       | <code>FALSE</code> |

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#)).

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- `--connections`

|                            |                            |                    |
|----------------------------|----------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--connections</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                | boolean            |
|                            | <b>Default</b>             | <code>FALSE</code> |

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[sci]`, `[sci default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see [Section 20.3.3.9, “NDB Cluster TCP/IP Connections”](#), [Section 20.3.3.12, “SCI Transport Connections in NDB Cluster”](#), and [Section 20.3.3.11, “NDB Cluster Shared-Memory Connections”](#), for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--system`

|                            |                       |                    |
|----------------------------|-----------------------|--------------------|
| <b>Command-Line Format</b> | <code>--system</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>           | boolean            |
|                            | <b>Default</b>        | <code>FALSE</code> |

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `***** SYSTEM *****`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=node_type`

|                            |                          |             |
|----------------------------|--------------------------|-------------|
| <b>Command-Line Format</b> | <code>--type=name</code> |             |
| <b>Permitted Values</b>    | <b>Type</b>              | enumeration |

|  |                |          |
|--|----------------|----------|
|  | <b>Default</b> | [none]   |
|  | <b>Valid</b>   | ndbd     |
|  | <b>Values</b>  | mysqld   |
|  |                | ndb_mgmd |

Filters results so that only configuration values applying to nodes of the specified *node\_type* (ndbd, mysqld, or ndb\_mgmd) are returned.

- `--fields=delimiter, -f delimiter`

|                            |                              |        |
|----------------------------|------------------------------|--------|
| <b>Command-Line Format</b> | <code>--fields=string</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                  | string |
|                            | <b>Default</b>               |        |

Specifies a *delimiter* string used to separate the fields in the result. The default is , (the comma character).

#### Note

If the *delimiter* contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- `--rows=separator, -r separator`

|                            |                            |        |
|----------------------------|----------------------------|--------|
| <b>Command-Line Format</b> | <code>--rows=string</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                | string |
|                            | <b>Default</b>             |        |

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

#### Note

If the *separator* contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo
***** SYSTEM *****
```

```

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

...

```

--configinfo --xml

| Command-Line Format | --configinfo --xml |         |
|---------------------|--------------------|---------|
| Permitted Values    | Type               | boolean |
|                     | Default            | false   |

You can obtain the output of `ndb_config --configinfo` as XML by adding the `--xml` option. A portion of the resulting output is shown in this example:

```

shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.7.16-ndb-7.5.5"
  ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
  ndbversionbuild="0">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="MYSQLD" primarykeys="NodeId">
    <param name="wan" comment="Use WAN TCP setting as default" type="bool"
      default="false"/>
    <param name="HostName" comment="Name of computer for this node"
      type="string" default=""/>
    <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
      min="1" max="255" deprecated="true"/>
    <param name="NodeId" comment="Number identifying application node (mysqld(API))"
      type="unsigned" mandatory="true" min="1" max="255"/>
    <param name="ExecuteOnComputer" comment="HostName" type="string"
      deprecated="true"/>
    ...
  </section>
  ...
</configvariables>

```

**Note**

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
      restart="system" initial="true" />
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```
<param name="ExecuteOnComputer" comment="HostName" type="string" deprecated="true" />
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with `mandatory="true"`, as shown here:

```
<param name="NodeId"
      comment="Number identifying application node (mysqld(API))"
      type="unsigned" mandatory="true" min="1" max="255" />
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

**Important**

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` or `--xml` is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time.* In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

## Examples

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysql
7:mysql
8:mysql
9:mysql
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
192.168.0.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,databmemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

## 20.4.8 ndb\_cpcd — Automate Testing for NDB Development

A utility having this name was formerly part of an internal automated test framework used in testing and debugging NDB Cluster. It is no longer included in NDB Cluster distributions provided by Oracle.

## 20.4.9 ndb\_delete\_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

### Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named *tbl\_name* in the database named *db\_name*. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_delete_all`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.91** This table describes command-line options for the `ndb_delete_all` program

| Format   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--database=dbname,</code><br><code>-d</code> | Name of the database in which the table is found                       | All MySQL 5.7 based releases |
| <code>--transactional,</code><br><code>-t</code>   | Perform the delete in a single transaction (may run out of operations) | All MySQL 5.7 based releases |
| <code>--tupscan</code>                             | Run tup scan   | All MySQL 5.7 based releases |
| <code>--diskscan</code>                            | Run disk scan  | All MySQL 5.7 based releases |

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

#### Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

## 20.4.10 ndb\_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

### Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
```

```
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

### Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
```

```

    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);

```

Output from `ndb_desc`:

```

shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80

```

| Partition | Row count | Commit count | Frag fixed memory | Frag var sized memory | Extent |
|-----------|-----------|--------------|-------------------|-----------------------|--------|
| 0         | 2         | 2            | 32768             | 32768                 | 0      |
| 1         | 4         | 4            | 32768             | 32768                 | 0      |

```

NDBT_ProgramExit: 0 - OK

```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```

shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0

```

```

Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20:latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
-- Attributes --
name Varchar(20:latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

NDBT_ProgramExit: 0 - OK

```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see [NDB Schema Object Versions](#).

Three of the table properties that can be set using `NDB_TABLE` comments embedded in `CREATE TABLE` and `ALTER TABLE` statements are also visible in `ndb_desc` output. The table's `FRAGMENT_COUNT_TYPE` is always shown in the `FragmentCountType` column. `READ_ONLY` and `FULLY_REPLICATED`, if set to 1, are shown in the `Table options` column. You can see this after executing the following `ALTER TABLE` statement in the `mysql` client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
```

```

+-----+-----+-----+
| Level | Code | Message
+-----+-----+-----+
| Warning | 1296 | Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not in co
+-----+-----+-----+
1 row in set (0.00 sec)

```

The warning is issued because `READ_ONLY=1` requires that the table's fragment count type is (or be set to) `ONE_PER_LDM_PER_NODE_GROUP`; NDB sets this automatically in such cases. You can check that the `ALTER TABLE` statement has the desired effect using `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE fish\G
***** 1. row *****
      Table: fish
Create Table: CREATE TABLE `fish` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL,
```

```
`length_mm` int(11) NOT NULL,
`weight_gm` int(11) NOT NULL,
PRIMARY KEY (`id`),
UNIQUE KEY `uk` (`name`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because `FRAGMENT_COUNT_TYPE` was not set explicitly, its value is not shown in the comment text printed by `SHOW CREATE TABLE`. `ndb_desc`, however, displays the updated value for this attribute. The `Table options` column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 380
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 1
FragmentCount: 1
FragmentCountType: ONE_PER_LDM_PER_NODE_GROUP
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup, fullyreplicated
HashMap: DEFAULT-HASHMAP-3840-1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag var sized memory      Extent_
NDBT_ProgramExit: 0 - OK
```

For more information about these table properties, see [Section 14.1.18.9, “Setting NDB\\_TABLE Options in Table Comments”](#).

The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;

ALTER LOGFILE GROUP lg_1
```

```

ADD UNDOFILE 'undo_2.log'
INITIAL_SIZE 12M
ENGINE NDB;

CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;

```

(For more information on the statements just shown and the objects created by them, see [Section 20.5.13.1, “NDB Cluster Disk Data Objects”](#), as well as [Section 14.1.15, “CREATE LOGFILE GROUP Syntax”](#), and [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT(11) NOT NULL,
  weight_gm INT(11) NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);

```

When run against this version of the table, `ndb_desc` displays the following output:

```

shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 346
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK

```

```
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition      Row count      Commit count      Frag fixed memory      Frag varsized memory      Extent_
0              2              2              32768              32768              1048576
1              4              4              32768              32768              1048576

NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words,  $1048576 - 1044440 = 4136$  bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

For fully replicated tables, `ndb_desc` shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. Beginning with NDB 7.5.4, you can obtain such information, using the `mysql` client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.

The following table includes options that are specific to `ndb_desc`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_desc`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.92** This table describes command-line options for the `ndb_desc` program

| Format  | Description  | Added or Removed             |
|---|--|------------------------------|
| <code>--blob-info,</code><br><code>-b</code>            | Include partition information for BLOB tables in output. Requires that the <code>-p</code> option also be used                             | All MySQL 5.7 based releases |
| <code>--database=dbname,</code><br><code>-d</code>      | Name of database containing table  | All MySQL 5.7 based releases |
| <code>--extra-node-info,</code><br><code>-n</code>      | Include partition-to-data-node mappings in output. Requires that the <code>-p</code> option also be used                                   | All MySQL 5.7 based releases |
| <code>--extra-partition-info,</code><br><code>-p</code> | Display information about partitions   | All MySQL 5.7 based releases |
| <code>--retries=#,</code><br><code>-r</code>            | Number of times to retry the connection (once per second)  | All MySQL 5.7 based releases |
| <code>--table=tbl_name,</code><br><code>-t</code>       | Specify the table in which to find an index. When this option is used, <code>-p</code> and <code>-n</code> have no effect and are ignored. | All MySQL 5.7 based releases |
| <code>--unqualified,</code><br><code>-u</code>          | Use unqualified table names  | All MySQL 5.7 based releases |

- `--blob-info, -b`

Include information about subordinate `BLOB` and `TEXT` columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--database=db_name, -d`

Specify the database in which the table should be found.

- `--extra-node-info, -n`

Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster .

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

- `--extra-partition-info, -p`

Print additional information about the table's partitions.

- `--retries=#, -r`

Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=tbl_name, -t`

Specify the table in which to look for an index.

- `--unqualified, -u`

Use unqualified table names.

In NDB 7.5.3 and later, table indexes listed in the output are ordered by ID. Previously, this was not deterministic and could vary between platforms. (Bug #81763, Bug #23547742)

## 20.4.11 ndb\_drop\_index — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an [NDB](#) table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

### Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

The following table includes options that are specific to `ndb_drop_index`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_index`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.93** This table describes command-line options for the `ndb_drop_index` program

| Format   | Description                                      | Added or Removed             |
|--|--|------------------------------|
| <code>--database=dbname,</code><br><code>-d</code> | Name of the database in which the table is found | All MySQL 5.7 based releases |

#### Warning

*Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:*

```

shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.16-ndb-7.5.5

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a                 |
| bt1               |
| bt2               |
| dogs              |
| employees         |
| fish              |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER

```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 20.4.12, “ndb\\_drop\\_table — Drop an NDB Table”](#)) to drop the table.

## 20.4.12 ndb\_drop\_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error `723: No such table exists`.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_table`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.94** This table describes command-line options for the `ndb_drop_table` program

| Format   | Description                                      | Added or Removed             |
|--|--|------------------------------|
| <code>--database=dbname,</code><br><code>-d</code> | Name of the database in which the table is found | All MySQL 5.7 based releases |

## 20.4.13 ndb\_error\_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

The following table includes command options specific to the NDB Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_error_reporter`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.95 This table describes command-line options for the `ndb_error_reporter` program**

| Format                                     | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--connection-timeout=timeout</code>  | Number of seconds to wait when connecting to nodes before timing out.          | All MySQL 5.7 based releases |
| <code>--dry-scp</code>                     | Disable scp with remote hosts; used only for testing.                          | All MySQL 5.7 based releases |
| <code>--fs</code>                          | Include file system data in error report; can use a large amount of disk space | All MySQL 5.7 based releases |
| <code>--skip-nodegroup=nodegroup_id</code> | Skip all nodes in the node group having this ID.                               | All MySQL 5.7 based releases |

## Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--connection-timeout=timeout</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer |
|                            | <b>Default</b>                            | 0       |

Wait this many seconds when trying to connect to nodes before timing out.

- `--dry-scp`

|                            |                        |         |
|----------------------------|------------------------|---------|
| <b>Command-Line Format</b> | <code>--dry-scp</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>            | boolean |
|                            | <b>Default</b>         | TRUE    |

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- `--fs`

|                            |                   |         |
|----------------------------|-------------------|---------|
| <b>Command-Line Format</b> | <code>--fs</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>       | boolean |
|                            | <b>Default</b>    | FALSE   |

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- `--skip-nodgroup=nodgroup_id`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--connection-timeout=timeout</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer |
|                            | <b>Default</b>                            | 0       |

Skip all nodes belong to the node group having the supplied node group ID.

## 20.4.14 ndb\_index\_stat — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

### Usage

To obtain basic index statistics about a given NDB table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database (-d)` option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an NDB table named `mytable` in the `test` database:

```
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000

NDBT_ProgramExit: 0 - OK
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes `sampleVersion` to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

`sampleCount` can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

`keyBytes` is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from `INFORMATION_SCHEMA.COLUMNS` (this requires a MySQL Server and a MySQL client application).

`totalBytes` is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

shell>
```

## Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table. For options common to most NDB Cluster programs (including `ndb_index_stat`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.96** This table describes command-line options for the `ndb_index_stat` program

| Format  | Description  | Added or Removed             |
|---|--|------------------------------|
| <code>--database=name</code> ,<br><code>-d</code> | Name of the database containing the table.   | All MySQL 5.7 based releases |
| <code>--delete</code>                             | Delete index statistics for the given table, stopping any auto-update previously configured.                             | All MySQL 5.7 based releases |
| <code>--update</code>                             | Update index statistics for the given table, restarting any auto-update previously configured.                           | All MySQL 5.7 based releases |
| <code>--dump</code>                               | Print the query cache.   | All MySQL 5.7 based releases |
| <code>--query=#</code>                            | Perform a number of random range queries on first key attr (must be int unsigned).                                       | All MySQL 5.7 based releases |
| <code>--sys-drop</code>                           | Drop any statistics tables and events in NDB kernel (all statistics are lost)  | All MySQL 5.7 based releases |
| <code>--sys-create</code>                         | Create all statistics tables and events in NDB kernel, if none of them already exist                                     | All MySQL 5.7 based releases |
| <code>--sys-create-if-not-exist</code>            | Create any statistics tables and events in NDB kernel that do not already exist.   | All MySQL 5.7 based releases |
| <code>--sys-create-if-not-valid</code>            | Create any statistics tables or events that do not already exist in the NDB kernel. after dropping any that are invalid. | All MySQL 5.7 based releases |

| Format                                      | Description   | Added or Removed             |
|---|---|------------------------------|
| <code>--sys-check</code>                    | Verify that NDB system index statistics and event tables exist.   | All MySQL 5.7 based releases |
| <code>--sys-skip-tables</code>              | Do not apply sys-* options to tables.                             | All MySQL 5.7 based releases |
| <code>--sys-skip-events</code>              | Do not apply sys-* options to events.                             | All MySQL 5.7 based releases |
| <code>--verbose</code> ,<br><code>-v</code> | Turn on verbose output  | All MySQL 5.7 based releases |
| <code>--loops=#</code>                      | Set the number of times to perform a given command. Default is 0. | All MySQL 5.7 based releases |

**ndb\_index\_stat statistics options.** The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see [ndb\\_index\\_stat system options](#)).

- `--database=name`, `-d name`

|                            |                              |                     |
|----------------------------|------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--database=name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                  | string              |
|                            | <b>Default</b>               | <code>[none]</code> |
|                            | <b>Min Value</b>             |                     |
|                            | <b>Max Value</b>             |                     |

The name of the database that contains the table being queried.

- `--delete`

|                            |                       |                    |
|----------------------------|-----------------------|--------------------|
| <b>Command-Line Format</b> | <code>--delete</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>           | boolean            |
|                            | <b>Default</b>        | <code>false</code> |
|                            | <b>Min Value</b>      |                    |
|                            | <b>Max Value</b>      |                    |

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--update`

|                            |                       |                    |
|----------------------------|-----------------------|--------------------|
| <b>Command-Line Format</b> | <code>--update</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>           | boolean            |
|                            | <b>Default</b>        | <code>false</code> |
|                            | <b>Min Value</b>      |                    |
|                            | <b>Max Value</b>      |                    |

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--dump`

|                            |                     |                    |
|----------------------------|---------------------|--------------------|
| <b>Command-Line Format</b> | <code>--dump</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>         | boolean            |
|                            | <b>Default</b>      | <code>false</code> |
|                            | <b>Min Value</b>    |                    |
|                            | <b>Max Value</b>    |                    |

Dump the contents of the query cache.

- `--query=#`

|                            |                        |                      |
|----------------------------|------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--query=#</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>            | numeric              |
|                            | <b>Default</b>         | 0                    |
|                            | <b>Min Value</b>       | 0                    |
|                            | <b>Max Value</b>       | <code>MAX_INT</code> |

Perform random range queries on first key attribute (must be int unsigned).

**ndb\_index\_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see [ndb\\_index\\_stat statistics options](#)).

- `--sys-drop`

|                            |                         |                    |
|----------------------------|-------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--sys-drop</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>             | boolean            |
|                            | <b>Default</b>          | <code>false</code> |
|                            | <b>Min Value</b>        |                    |
|                            | <b>Max Value</b>        |                    |

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- `--sys-create`

|                            |                           |                    |
|----------------------------|---------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--sys-create</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>               | boolean            |
|                            | <b>Default</b>            | <code>false</code> |
|                            | <b>Min Value</b>          |                    |
|                            | <b>Max Value</b>          |                    |

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `sys-create-if-not-exist`

|                            |  |                    |
|----------------------------|--|--------------------|
| <b>Command-Line Format</b> | <code>--sys-create-if-not-exist</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                            | boolean            |
|                            | <b>Default</b>                         | <code>false</code> |
|                            | <b>Min Value</b>                       |                    |
|                            | <b>Max Value</b>                       |                    |

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

|                            |  |                    |
|----------------------------|--|--------------------|
| <b>Command-Line Format</b> | <code>--sys-create-if-not-valid</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                            | boolean            |
|                            | <b>Default</b>                         | <code>false</code> |
|                            | <b>Min Value</b>                       |                    |
|                            | <b>Max Value</b>                       |                    |

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

|                            |                          |                    |
|----------------------------|--------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--sys-check</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>              | boolean            |
|                            | <b>Default</b>           | <code>false</code> |
|                            | <b>Min Value</b>         |                    |
|                            | <b>Max Value</b>         |                    |

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

|                            |                                |                    |
|----------------------------|--------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--sys-skip-tables</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                    | boolean            |
|                            | <b>Default</b>                 | <code>false</code> |
|                            | <b>Min Value</b>               |                    |
|                            | <b>Max Value</b>               |                    |

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

|                            |                                |                    |
|----------------------------|--------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--sys-skip-events</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                    | boolean            |
|                            | <b>Default</b>                 | <code>false</code> |
|                            | <b>Min Value</b>               |                    |
|                            | <b>Max Value</b>               |                    |

Do not apply any `--sys-*` options to any events.

- `--verbose`

|                            |                        |                    |
|----------------------------|------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--verbose</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>            | boolean            |
|                            | <b>Default</b>         | <code>false</code> |
|                            | <b>Min Value</b>       |                    |
|                            | <b>Max Value</b>       |                    |

Turn on verbose output.

- `--loops=#`

|                            |                        |                      |
|----------------------------|------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--loops=#</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>            | numeric              |
|                            | <b>Default</b>         | 0                    |
|                            | <b>Min Value</b>       | 0                    |
|                            | <b>Max Value</b>       | <code>MAX_INT</code> |

Repeat commands this number of times (for use in testing).

## 20.4.15 ndb\_print\_backup\_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

### Usage

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 20.5.3.1, “NDB Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be

used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 20.4.16 ndb\_print\_file — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from an NDB Cluster Disk Data file.

### Usage

```
ndb_print_file [-v] [-q] file_name+
```

*file\_name* is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.
- `-q`: Suppress output (quiet mode).
- `--help`, `-h`, `-?`: Print help message.

For more information, see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#).

## 20.4.17 ndb\_print\_schema\_file — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

### Usage

```
ndb_print_schema_file file_name
```

*file\_name* is the name of a cluster schema file. For more information about cluster schema files, see [NDB Cluster Data Node File System Directory Files](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 20.4.18 ndb\_print\_sys\_file — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.

## Usage

```
ndb_print_sys_file file_name
```

*file\_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBD/H/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see [NDB Cluster Data Node File System Directory Files](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## Additional Options

None.

## 20.4.19 ndbd\_redo\_log\_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndbd_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for `ndbd_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the NDB Cluster program `ndbd_redo_log_reader`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbd_redo_log_reader`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.97** This table describes command-line options for the `ndbd_redo_log_reader` program

| Format                | Description                     | Added or Removed             |
|-----------------------|---------------------------------|------------------------------|
| <code>-noprint</code> | Do not print records            | All MySQL 5.7 based releases |
| <code>-nocheck</code> | Do not check records for errors | All MySQL 5.7 based releases |
| <code>--help</code>   | Print usage information         | All MySQL 5.7 based releases |

## Usage

```
ndbd_redo_log_reader file_name [options]
```

*file\_name* is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_#_fs/D#/LCP/#/T#F#.Data`. In each case, the `#` represents a number (not necessarily the same number). For more information, see [NDB Cluster Data Node File System Directory Files](#).

The name of the file to be read may be followed by one or more of the options listed here:

|   |                            |                       |         |
|---|----------------------------|-----------------------|---------|
| • | <b>Command-Line Format</b> | <code>-noprint</code> |         |
|   | <b>Permitted Values</b>    | <b>Type</b>           | boolean |

|  |                |       |
|--|----------------|-------|
|  | <b>Default</b> | FALSE |
|--|----------------|-------|

`-noprint`: Do not print the contents of the log file.

|                              |                       |         |
|------------------------------|-----------------------|---------|
| • <b>Command-Line Format</b> | <code>-nocheck</code> |         |
| <b>Permitted Values</b>      | <b>Type</b>           | boolean |
|                              | <b>Default</b>        | FALSE   |

`-nocheck`: Do not check the log file for errors.

|                              |                     |
|------------------------------|---------------------|
| • <b>Command-Line Format</b> | <code>--help</code> |
|------------------------------|---------------------|

`--help`: Print usage information.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndbd_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### 20.4.20 ndb\_restore — Restore an NDB Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 20.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

**Note**

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 20.5.8, “NDB Cluster Single User Mode”](#), for more information.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_restore`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.98** This table describes command-line options for the `ndb_restore` program

| Format                              | Description   | Added or Removed             |
|-------------------------------------|---|------------------------------|
| <code>--append</code>               | Append data to a tab-delimited file   | All MySQL 5.7 based releases |
| <code>--backup_path=dir_name</code> | Path to backup files directory  | All MySQL 5.7 based releases |
| <code>--backupid=#,</code>          | Restore from the backup with the given ID   | All MySQL 5.7 based releases |
| <code>-b</code>                     |   |                              |
| <code>--connect,</code>             | Alias for <code>--connectstring</code> .  | All MySQL 5.7 based releases |
| <code>-c</code>                     |   |                              |
| <code>--disable-indexes</code>      | Causes indexes from a backup to be ignored; may decrease time needed to restore data. | All MySQL 5.7 based releases |

| Format  | Description   | Added or Removed             |
|---|---|------------------------------|
| <code>--dont_ignore_systab_0,</code><br><code>-f</code>     | Do not ignore system table during restore. Experimental only; not for production use  | All MySQL 5.7 based releases |
| <code>--exclude-databases=db-list</code>                    | List of one or more databases to exclude (includes those not named)   | All MySQL 5.7 based releases |
| <code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code> | If TRUE (the default), do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations. | All MySQL 5.7 based releases |
| <code>--exclude-missing-columns</code>                      | Causes columns from the backup version of a table that are missing from the version of the table in the database to be ignored.                             | All MySQL 5.7 based releases |
| <code>--exclude-missing-tables</code>                       | Causes tables from the backup that are missing from the database to be ignored.   | All MySQL 5.7 based releases |
| <code>--exclude-tables=table-list</code>                    | List of one or more tables to exclude (includes those in the same database that are not named); each table reference must include the database name         | All MySQL 5.7 based releases |
| <code>--fields-enclosed-by=char</code>                      | Fields are enclosed with the indicated character  | All MySQL 5.7 based releases |
| <code>--fields-optionally-enclosed-by</code>                | Fields are optionally enclosed with the indicated character   | All MySQL 5.7 based releases |
| <code>--fields-terminated-by=char</code>                    | Fields are terminated by the indicated character  | All MySQL 5.7 based releases |
| <code>--hex</code>  | Print binary types in hexadecimal format  | All MySQL 5.7 based releases |
| <code>--include-databases=db-list</code>                    | List of one or more databases to restore (excludes those not named)   | All MySQL 5.7 based releases |
| <code>--include-tables=table-list</code>                    | List of one or more tables to restore (excludes those in same database that are not named); each table reference must include the database name             | All MySQL 5.7 based releases |
| <code>--lines-terminated-by=char</code>                     | Lines are terminated by the indicated character   | All MySQL 5.7 based releases |
| <code>--lossy-conversions,</code><br><code>-L</code>        | Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup  | All MySQL 5.7 based releases |
| <code>--no-binlog</code>                                    | If a mysqld is connected and using binary logging, do not log the restored data   | All MySQL 5.7 based releases |

| Format                                   | Description   | Added or Removed             |
|--|---|------------------------------|
| <code>--no-restore-disk-objects,</code>  | Do not restore objects relating to Disk Data  | All MySQL 5.7 based releases |
| <code>-d</code>                          |   |                              |
| <code>--no-upgrade,</code>               | Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes  | All MySQL 5.7 based releases |
| <code>-u</code>                          |   |                              |
| <code>--ndb-nodegroup-map=map,</code>    | Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)  | All MySQL 5.7 based releases |
| <code>-z</code>                          |   |                              |
| <code>--nodeid=#,</code>                 | Backup is taken on node having this ID  | All MySQL 5.7 based releases |
| <code>-n</code>                          |   |                              |
| <code>--parallelism=#,</code>            | Number of parallel transactions to use while restoring data   | All MySQL 5.7 based releases |
| <code>-p</code>                          |   |                              |
| <code>--preserve-trailing-spaces,</code> | Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types   | All MySQL 5.7 based releases |
| <code>-P</code>                          |   |                              |
| <code>--print</code>                     | Print metadata, data and log to stdout (equivalent to --print_meta --print_data --print_log)  | All MySQL 5.7 based releases |
| <code>--print_data</code>                | Print data to stdout  | All MySQL 5.7 based releases |
| <code>--print_log</code>                 | Print to stdout   | All MySQL 5.7 based releases |
| <code>--print_meta</code>                | Print metadata to stdout  | All MySQL 5.7 based releases |
| <code>print-sql-log</code>               | Write SQL log to stdout; default is FALSE   | ADDED: NDB 7.5.4             |
| <code>--progress-frequency=#</code>      | Print status of restoration each given number of seconds  | All MySQL 5.7 based releases |
| <code>--promote-attributes,</code>       | Allow attributes to be promoted when restoring data from backup   | All MySQL 5.7 based releases |
| <code>-A</code>                          |   |                              |
| <code>--rebuild-indexes</code>           | Causes multi-threaded rebuilding of ordered indexes found in the backup. Number of threads used is determined by setting BuildIndexThreads parameter.                                     | All MySQL 5.7 based releases |
| <code>--restore_data,</code>             | Restore table data and logs into NDB Cluster using the NDB API  | All MySQL 5.7 based releases |
| <code>-r</code>                          |   |                              |
| <code>--restore_epoch,</code>            | Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted. | All MySQL 5.7 based releases |
| <code>-e</code>                          |   |                              |

| Format   | Description   | Added or Removed             |
|--|---|------------------------------|
| <code>--restore-meta,</code><br><code>-m</code>          | Restore metadata to NDB Cluster using the NDB API   | All MySQL 5.7 based releases |
| <code>--restore-privilege-tables</code>                  | Restore MySQL privilege tables that were previously moved to NDB.   | All MySQL 5.7 based releases |
| <code>--rewrite-database=olddb,newdb</code>              | Restores to a database with a different name than the original  | All MySQL 5.7 based releases |
| <code>--skip-broken-objects</code>                       | Causes missing blob tables in the backup file to be ignored.  | All MySQL 5.7 based releases |
| <code>--skip-table-check,</code><br><code>-s</code>      | Skip table structure check during restoring of data   | All MySQL 5.7 based releases |
| <code>--skip-unknown-objects</code>                      | Causes schema objects not recognized by <code>ndb_restore</code> to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version. | All MySQL 5.7 based releases |
| <code>--tab=dir_name,</code><br><code>-T dir_name</code> | Creates a tab-separated .txt file for each table in the given path  | All MySQL 5.7 based releases |
| <code>--verbose=#</code>                                 | Level of verbosity in output  | All MySQL 5.7 based releases |

Normally, when restoring from an NDB Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup_path` options. In addition, when `ndb_restore` is used to restore any tables containing unique indexes, you must include `--disable-indexes` or `--rebuild-indexes`. (Bug #57782, Bug #11764893)

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
  [-m] -r --backup_path=/path/to/backup/files
```

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server. (See [Section 20.3.3.3, “NDB Cluster Connection Strings”](#), for information on connection strings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 20.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”](#)).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

The `--nodeid` or `-n` is used to specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such

cases, multiple files usually need to be restored to a single data node.) The next few paragraphs provide an example.

**Restore to a different number of data nodes.** You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server's `config.ini` file:

```
[ndbd]
NodeId=2
HostName=host2

[ndbd]
NodeId=4
HostName=host4

[ndbd]
NodeId=6
HostName=host6

[ndbd]
NodeId=8
HostName=host8
```

We assume that each data node was originally started with `ndbmtbd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See [Section 20.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”](#), for information about how to do this.
3. The files created by the backup on each data node are listed here, where *N* is the node ID and *B* is the backup ID.
  - `BACKUP-B-0.N.Data`
  - `BACKUP-B.Nctl`
  - `BACKUP-B.N.log`

These files are found under `BackupDataDir/BACKUP/BACKUP-B`, on each data node. For the rest of this example, we assume that the backup ID is 1.

Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the management server `config.ini` file on `host20`:

```
[ndbd]
NodeId=3
hostname=host3

[ndbd]
NodeId=5
hostname=host5
```

Each of the data node processes on `host3` and `host5` should be started with `ndbmtbd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 6 from the original cluster to node 3 in the target cluster. These files are listed here:

- `BACKUP-1-0.2.Data`
- `BACKUP-1.2.ctl`
- `BACKUP-1.2.log`
- `BACKUP-1-0.6.Data`
- `BACKUP-1.6.ctl`
- `BACKUP-1.6.log`

Then copy the backup files from nodes 4 and 8 to node 5; these files are shown in the following list:

- `BACKUP-1-0.4.Data`
- `BACKUP-1.4.ctl`
- `BACKUP-1.4.log`
- `BACKUP-1-0.8.Data`
- `BACKUP-1.8.ctl`
- `BACKUP-1.8.log`

For the remainder of this example, we assume that the respective backup files have been saved to the directory `/BACKUP-1` on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 6 to node 3 by invoking `ndb_restore` on `host3` as shown here:

```
shell> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore_data --backup_path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore_data --backup_path=/BACKUP-1
```

Then restore the backups from nodes 4 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

```
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore_data --backup_path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore_data --backup_path=/BACKUP-1
```

It is possible to restore data without restoring table metadata. The default behavior when doing this is for `ndb_restore` to fail with an error if table data do not match the table schema; this can be overridden using the `--skip-table-check` or `-s` option.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

`ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See [Replication of Columns Having Different Data Types](#), for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named `table_name$Stnode_id`. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

`--lossy-conversions, -L`

| Command-Line Format | <code>--lossy-conversions</code> |                    |
|---------------------|----------------------------------|--------------------|
| Permitted Values    | Type                             | boolean            |
|                     | Default                          | <code>FALSE</code> |

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see [Replication of Columns Having Different Data Types](#), for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

The `--preserve-trailing-spaces` option (short form `-R`) causes trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR` or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

**Note**

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 20.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”](#).)

**Important**

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

`--restore_epoch` (short form: `-e`) adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 20.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#).)

`--restore_data`

This option causes `ndb_restore` to output NDB table data and logs.

`--restore_meta`

This option causes `ndb_restore` to print NDB table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore_meta` (`-m`) option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

**Note**

The cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore.)

`--restore-privilege-tables`

`ndb_restore` does not by default restore distributed MySQL privilege tables. This option causes `ndb_restore` to restore the privilege tables.

This works only if the privilege tables were converted to NDB before the backup was taken. For more information, see [Section 20.5.15, “Distributed MySQL Privileges for NDB Cluster”](#).

`--backup_path`

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup_path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes

having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 20.2.8, “Upgrading and Downgrading NDB Cluster”](#), for more information.

**Important**

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.5 to a cluster running NDB Cluster 7.4.14, you must use the `ndb_restore` that comes with the NDB Cluster 7.5.5 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

`--no-upgrade`

When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden using the `--no-upgrade` option (short form: `-u`) when running `ndb_restore`.

`--print_data`

The `--print_data` option causes `ndb_restore` to direct its output to `stdout`.

`TEXT` and `BLOB` column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using `--print_data`.

Several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following list:

- `--tab, -T`

|                            |                             |                |
|----------------------------|-----------------------------|----------------|
| <b>Command-Line Format</b> | <code>--tab=dir_name</code> |                |
| <b>Permitted Values</b>    | <b>Type</b>                 | directory name |

This option causes `--print_data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--fields-enclosed-by=string`

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--fields-enclosed-by=char</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                            | string |
|                            | <b>Default</b>                         |        |

Each column values are enclosed by the string passed to this option (regardless of data type; see next item).

- `--fields-optionally-enclosed-by=string`

|                            |  |
|----------------------------|--|
| <b>Command-Line Format</b> | <code>--fields-optionally-enclosed-by</code> |
|----------------------------|--|

|                  |         |        |
|------------------|---------|--------|
| Permitted Values | Type    | string |
|                  | Default |        |

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=string`

|                     |  |                       |
|---------------------|--|-----------------------|
| Command-Line Format | <code>--fields-terminated-by=char</code> |                       |
| Permitted Values    | Type                                     | string                |
|                     | Default                                  | <code>\t (tab)</code> |

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--hex`

|                     |                    |
|---------------------|--------------------|
| Command-Line Format | <code>--hex</code> |
|---------------------|--------------------|

If this option is used, all binary values are output in hexadecimal format.

- `--fields-terminated-by=string`

|                     |  |                       |
|---------------------|--|-----------------------|
| Command-Line Format | <code>--fields-terminated-by=char</code> |                       |
| Permitted Values    | Type                                     | string                |
|                     | Default                                  | <code>\t (tab)</code> |

This option specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--append`

|                     |                       |
|---------------------|-----------------------|
| Command-Line Format | <code>--append</code> |
|---------------------|-----------------------|

When used with the `--tab` and `--print_data` options, this causes the data to be appended to any existing files having the same names.

#### Note

If a table has no explicit primary key, then the output generated when using the `--print_data` option includes the table's hidden primary key.

`--print_meta`

This option causes `ndb_restore` to print all metadata to `stdout`.

`--print_log`

The `--print_log` option causes `ndb_restore` to output its log to `stdout`.

`--print`

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print_data`, `--print_meta`, and `--print_log` options together.

#### Note

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected

to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

#### `--print-sql-log`

Causes `ndb_restore` to log SQL statements to `stdout`. Use the option to enable; normally disabled. This option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

The `--print-sql-log` option was added in NDB 7.5.4. (Bug #13511949)

#### `--dont_ignore_systab_0`

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont_ignore_systab_0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

#### `--ndb-nodegroup-map, -z`

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group, target_node_group`.

#### `--no-binlog`

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

#### `--no-restore-disk-objects, -d`

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#), for more information about these.

#### `--parallelism=#, -p`

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

#### `--progress-frequency=N`

Print a status report each `N` seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

#### `--verbose=#`

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

It is possible to restore only selected databases, or selected tables from a single database, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

```
--include-databases=db_name[,db_name][,...]
```

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--include-databases=db-list</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                              | string |
|                            | <b>Default</b>                           |        |

```
--include-tables=db_name.tbl_name[,db_name.tbl_name][,...]
```

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--include-tables=table-list</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                              | string |
|                            | <b>Default</b>                           |        |

Use the `--include-databases` option or the `--include-tables` option for restoring only specific databases or tables, respectively. `--include-databases` takes a comma-delimited list of databases to be restored. `--include-tables` takes a comma-delimited list of tables (in `database.table` format) to be restored.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

| Option Used  | Result   |
|--|--|
| <code>--include-databases=db1</code>   | Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored   |
| <code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code> )    | Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored   |
| <code>--include-tables=db1.t1</code>   | Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored   |
| <code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code> ) | Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code> , <code>db2</code> , or any other database are restored |

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

```
--exclude-databases=db_name[,db_name][,...]
```

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--exclude-databases=db-list</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                              | string |
|                            | <b>Default</b>                           |        |

|  |         |
|--|---------|
|  | Default |
|--|---------|

```
--exclude-tables=db_name.tbl_name[ ,db_name.tbl_name][ ,...]
```

|                     |                             |        |
|---------------------|-----------------------------|--------|
| Command-Line Format | --exclude-tables=table-list |        |
| Permitted Values    | Type                        | string |
|                     | Default                     |        |

It is possible to prevent one or more databases or tables from being restored using the `ndb_restore` options `--exclude-databases` and `--exclude-tables`. `--exclude-databases` takes a comma-delimited list of one or more databases which should not be restored. `--exclude-tables` takes a comma-delimited list of one or more tables (using `database.table` format) which should not be restored.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

| Option Used  | Result   |
|--|--|
| <code>--exclude-databases=db1</code>   | All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored   |
| <code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code> )    | All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored  |
| <code>--exclude-tables=db1.t1</code>   | All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored   |
| <code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code> ) | All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored |

You can use these two options together. For example, the following causes all tables in all databases except for databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

```
--exclude-missing-columns
```

|                            |  |
|----------------------------|--|
| <b>Command-Line Format</b> | <code>--exclude-missing-columns</code> |
|----------------------------|--|

It is also possible to restore only selected table columns using the `--exclude-missing-columns` option. When this option is used, `ndb_restore` ignores any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the options described in the previous paragraph to do so, then restore data to the remaining tables using a complementary set of these options.

```
--exclude-missing-tables
```

|                            |                                       |
|----------------------------|---------------------------------------|
| <b>Command-Line Format</b> | <code>--exclude-missing-tables</code> |
|----------------------------|---------------------------------------|

It is also possible to restore only selected tables columns using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

```
--disable-indexes
```

|                            |                                |
|----------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--disable-indexes</code> |
|----------------------------|--------------------------------|

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multi-threaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

```
--rebuild-indexes
```

|                            |                                |
|----------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--rebuild-indexes</code> |
|----------------------------|--------------------------------|

You can use this option with `ndb_restore` to cause multi-threaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase

the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

`--skip-broken-objects`

|                            |                                    |
|----------------------------|------------------------------------|
| <b>Command-Line Format</b> | <code>--skip-broken-objects</code> |
|----------------------------|------------------------------------|

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

`--skip-unknown-objects`

|                            |                                     |
|----------------------------|-------------------------------------|
| <b>Command-Line Format</b> | <code>--skip-unknown-objects</code> |
|----------------------------|-------------------------------------|

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running NDB 7.5 to a cluster running NDB Cluster 7.4.

`--rewrite-database=old_dbname,new_dbname`

|                            |   |                   |
|----------------------------|---|-------------------|
| <b>Command-Line Format</b> | <code>--rewrite-database=olddb,newdb</code> |                   |
| <b>Permitted Values</b>    | <b>Type</b>                                 | string            |
|                            | <b>Default</b>                              | <code>none</code> |

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

**Important**

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

`--exclude-intermediate-sql-tables[=TRUE|FALSE]`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--exclude-intermediate-sql-tables[=TRUE FALSE]</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>   | boolean |

|  |                |      |
|--|----------------|------|
|  | <b>Default</b> | TRUE |
|--|----------------|------|

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from such operations. This option is `TRUE` by default.

#### Error reporting.

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

#### Important

After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in NDB Cluster .

## 20.4.21 ndb\_select\_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

### Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_select_all`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.99** This table describes command-line options for the `ndb_select_all` program

| Format   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--database=dbname,</code><br><code>-d</code> | Name of the database in which the table is found           | All MySQL 5.7 based releases |
| <code>--parallelism=#,</code><br><code>-p</code>   | Degree of parallelism                                      | All MySQL 5.7 based releases |
| <code>--lock=#,</code><br><code>-l</code>          | Lock type  | All MySQL 5.7 based releases |
| <code>--order=index,</code><br><code>-o</code>     | Sort resultset according to index whose name is supplied   | All MySQL 5.7 based releases |
| <code>--descending,</code><br><code>-z</code>      | Sort resultset in descending order (requires order flag)   | All MySQL 5.7 based releases |
| <code>--header,</code><br><code>-h</code>          | Print header (set to 0 FALSE to disable headers in output) | All MySQL 5.7 based releases |
| <code>--useHexFormat,</code>                       | Output numbers in hexadecimal format                       | All MySQL 5.7 based releases |

| Format  | Description  | Added or Removed             |
|---|--|------------------------------|
| <code>-x</code><br><code>--delimiter=char,</code> | Set a column delimiter   | All MySQL 5.7 based releases |
| <code>-D</code><br><code>--disk</code>            | Print disk references (useful only for Disk Data tables having nonindexed columns) | All MySQL 5.7 based releases |
| <code>--rowid</code>                              | Print rowid  | All MySQL 5.7 based releases |
| <code>--gci</code>                                | Include GCI in output  | All MySQL 5.7 based releases |
| <code>--gci64</code>                              | Include GCI and row epoch in output  | All MySQL 5.7 based releases |
| <code>--tupscan,</code>                           | Scan in tup order  | All MySQL 5.7 based releases |
| <code>-t</code><br><code>--no data</code>         | Do not print table column data   | All MySQL 5.7 based releases |

- `--database=dbname, -d dbname`

Name of the database in which the table is found. The default value is `TEST_DB`.

- `parallelism=#, -p #`

Specifies the degree of parallelism.

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`.

#### Note

This is the name of an index, not of a column; the index must have been explicitly named when created.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--header=FALSE`

Excludes column headers from the output.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character, -D character`

Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See [Section 20.1, “NDB Cluster Overview”](#), and [Section 20.5.6.2, “NDB Cluster Log Events”](#), for more information about checkpoints.

- `--gci64`

Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--tupscan, -t`

Scan the table in the order of the tuples.

- `--nodata`

Causes any table data to be omitted.

## Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----+
| id | name |
+----+-----+
| 3 | shark |
| 6 | puffer |
| 2 | tuna |
| 4 | manta ray |
| 5 | grouper |
| 1 | guppy |
+----+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
```

```
NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets (`[...]`) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (  
  id INT(11) NOT NULL AUTO_INCREMENT,  
  name VARCHAR(25) NOT NULL,  
  breed VARCHAR(50) NOT NULL,  
  PRIMARY KEY pk (id),  
  KEY ix (name)  
)  
TABLESPACE ts STORAGE DISK  
ENGINE=NDBCLUSTER;  
  
INSERT INTO dogs VALUES  
  ('', 'Lassie', 'collie'),  
  ('', 'Scooby-Doo', 'Great Dane'),  
  ('', 'Rin-Tin-Tin', 'Alsatian'),  
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk  
GCI      id name          breed          DISK_REF  
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]  
834878   4 [Rosscoe]   [Mutt]        [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]  
834463   3 [Rin-Tin-Tin] [Alsatian]   [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]  
835657   1 [Lassie]    [Collie]      [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]  
4 rows returned  
  
NDBT_ProgramExit: 0 - OK
```

### 20.4.22 ndb\_select\_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

#### Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_select_count`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_select_count`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.100** This table describes command-line options for the `ndb_select_count` program

| Format   | Description                                      | Added or Removed             |
|--|--|------------------------------|
| <code>--database=dbname,</code><br><code>-d</code> | Name of the database in which the table is found | All MySQL 5.7 based releases |
| <code>--parallelism=#,</code><br><code>-p</code>   | Degree of parallelism                            | All MySQL 5.7 based releases |
| <code>--lock=#,</code><br><code>-l</code>          | Lock type  | All MySQL 5.7 based releases |

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

## Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

## 20.4.23 ndb\_setup.py — Start browser-based Auto-Installer for NDB Cluster

`ndb_setup.py` starts the NDB Cluster Auto-Installer and opens the installer's Start page in the default Web browser.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when `ndb_setup.py` is invoked, see [Section 20.2.1, “The NDB Cluster Auto-Installer”](#).

## Usage

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:

```
setup.bat [options]
```

The following table includes all options that are supported by the NDB Cluster installation and configuration program `ndb_setup.py`. Additional descriptions follow the table.

**Table 20.101** This table describes command-line options for the `ndb_setup.py` program

| Format   | Description   | Added or Removed             |
|--|---|------------------------------|
| <code>--browser-start-page=filename,</code><br><code>-s</code> | Page that the web browser opens when starting.  | All MySQL 5.7 based releases |
| <code>--ca-certs-file=filename,</code><br><code>-a</code>      | File containing list of client certificates allowed to connect to the server                  | All MySQL 5.7 based releases |
| <code>--cert-file=filename,</code><br><code>-c</code>          | File containing X509 certificate that identifies the server. (Default: <code>cfg.pem</code> ) | All MySQL 5.7 based releases |
| <code>--debug-level=level,</code><br><code>-d</code>           | Python logging module debug level. One of DEBUG, INFO, WARNING (default), ERROR, or CRITICAL. | All MySQL 5.7 based releases |
| <code>--help,</code><br><code>-h</code>                        | Print help message  | All MySQL 5.7 based releases |

| Format   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--key-file=file,</code><br><code>-k</code>       | Specify file containing private key (if not included in <code>--cert-file</code> ) | All MySQL 5.7 based releases |
| <code>--no-browser,</code><br><code>-n</code>          | Do not open the start page in a browser, merely start the tool                     | All MySQL 5.7 based releases |
| <code>--port=#,</code><br><code>-p</code>              | Specify the port used by the web server  | All MySQL 5.7 based releases |
| <code>--server-log-file=file,</code><br><code>o</code> | Log requests to this file. Use '-' to force logging to stderr instead.             | All MySQL 5.7 based releases |
| <code>--server-name=name,</code><br><code>-N</code>    | The name of the server to connect with   | All MySQL 5.7 based releases |
| <code>--use-https,</code><br><code>-S</code>           | Use secure (HTTPS) client-server connection  | All MySQL 5.7 based releases |

- `--browser-start-page=file, -s`

|                            |  |                         |
|----------------------------|--|-------------------------|
| <b>Command-Line Format</b> | <code>--browser-start-page=filename</code> |                         |
| <b>Permitted Values</b>    | <b>Type</b>                                | string                  |
|                            | <b>Default</b>                             | <code>index.html</code> |

Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- `--ca-certs-file=file, -a`

|                            |                                       |                     |
|----------------------------|---------------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--ca-certs-file=filename</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                           | file name           |
|                            | <b>Default</b>                        | <code>[none]</code> |

Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- `--cert-file=file, -c`

|                            |                                   |                      |
|----------------------------|-----------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--cert-file=filename</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                       | file name            |
|                            | <b>Default</b>                    | <code>cfg.pem</code> |

Specify a file containing an X509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- `--debug-level=level, -d`

|                            |                                  |                      |
|----------------------------|----------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--debug-level=level</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                      | enumeration          |
|                            | <b>Default</b>                   | <code>WARNING</code> |
|                            | <b>Valid Values</b>              | <code>WARNING</code> |

|  |  |          |
|--|--|----------|
|  |  | DEBUG    |
|  |  | INFO     |
|  |  | ERROR    |
|  |  | CRITICAL |

Set the Python logging module debug level. This is one of [DEBUG](#), [INFO](#), [WARNING](#), [ERROR](#), or [CRITICAL](#). [WARNING](#) is the default.

- [--help, -h](#)

|                            |                        |
|----------------------------|------------------------|
| <b>Command-Line Format</b> | <a href="#">--help</a> |
|----------------------------|------------------------|

Print a help message.

- [--key-file=file, -d](#)

|                            |                                 |                        |
|----------------------------|---------------------------------|------------------------|
| <b>Command-Line Format</b> | <a href="#">--key-file=file</a> |                        |
| <b>Permitted Values</b>    | <b>Type</b>                     | file name              |
|                            | <b>Default</b>                  | <a href="#">[none]</a> |

Specify a file containing the private key if this is not included in the X509 certificate file ([--cert-file](#)). The default is an empty string, which means that no such file is used.

- [--no-browser, -n](#)

|                            |                              |
|----------------------------|------------------------------|
| <b>Command-Line Format</b> | <a href="#">--no-browser</a> |
|----------------------------|------------------------------|

Start the installation and configuration tool, but do not open the Start page in a browser.

- [--port=#, -p](#)

|                            |                          |                       |
|----------------------------|--------------------------|-----------------------|
| <b>Command-Line Format</b> | <a href="#">--port=#</a> |                       |
| <b>Permitted Values</b>    | <b>Type</b>              | numeric               |
|                            | <b>Default</b>           | <a href="#">8081</a>  |
|                            | <b>Min Value</b>         | <a href="#">1</a>     |
|                            | <b>Max Value</b>         | <a href="#">65535</a> |

Set the port used by the web server. The default is 8081.

- [--server-log-file=file, -o](#)

|                            |  |                               |
|----------------------------|--|-------------------------------|
| <b>Command-Line Format</b> | <a href="#">--server-log-file=file</a> |                               |

| Command-Line Format | --use-https |
|---------------------|-------------|

Make the browser use a secure (HTTPS) connection with the server.

### 20.4.24 ndb\_show\_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all [NDB](#) database objects in the cluster. By default, this includes not only both user-created tables and [NDB](#) system tables, but [NDB](#)-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_show_tables`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.102** This table describes command-line options for the `ndb_show_tables` program

| Format   | Description   | Added or Removed             |
|--|---|------------------------------|
| <code>--database=string,</code><br><code>-d</code> | Specifies the database in which the table is found          | All MySQL 5.7 based releases |
| <code>--loops=#,</code><br><code>-l</code>         | Number of times to repeat output                            | All MySQL 5.7 based releases |
| <code>--type=#,</code><br><code>-t</code>          | Limit output to objects of this type                        | All MySQL 5.7 based releases |
| <code>--unqualified,</code><br><code>-u</code>     | Do not qualify table names                                  | All MySQL 5.7 based releases |
| <code>--parsable,</code><br><code>-p</code>        | Return output suitable for MySQL LOAD DATA INFILE statement | All MySQL 5.7 based releases |
| <code>--show-temp-status</code>                    | Show table temporary flag                                   | All MySQL 5.7 based releases |

### Usage

```
ndb_show_tables [-c connection_string]
```

- `--database, -d`

Specifies the name of the database in which the tables are found. If this option has not been specified, and no tables are found in the `TEST_DB` database, `ndb_show_tables` issues a warning.

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all NDB database objects to be listed (the default).

- `--unqualified, -u`

If specified, this causes unqualified object names to be displayed.

#### Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see [Section 20.4.21, “ndb\\_select\\_all — Print Rows from an NDB Table”](#)).

## 20.4.25 ndb\_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

### Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster .
- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

The following table includes options that are specific to the NDB Cluster program `ndb_size.pl`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including

ndb\_size.pl), see Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 20.103** This table describes command-line options for the ndb\_size.pl program

| Format                                | Description  | Added or Removed             |
|---------------------------------------|--|------------------------------|
| <code>--database=dbname</code>        | The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server) | All MySQL 5.7 based releases |
| <code>--hostname[:port]</code>        | Specify host and optional port as host[:port]  | All MySQL 5.7 based releases |
| <code>--socket=file_name</code>       | Specify a socket to connect to   | All MySQL 5.7 based releases |
| <code>--user=string</code>            | Specify a MySQL user name  | All MySQL 5.7 based releases |
| <code>--password=string</code>        | Specify a MySQL user password  | All MySQL 5.7 based releases |
| <code>--format=string</code>          | Set output format (text or HTML)   | All MySQL 5.7 based releases |
| <code>--excludetables=tbl_list</code> | Skip any tables in a comma-separated list of tables  | All MySQL 5.7 based releases |
| <code>--excludedbs=db_list</code>     | Skip any databases in a comma-separated list of databases  | All MySQL 5.7 based releases |
| <code>--savequeries=file</code>       | Saves all queries to the database into the file specified  | All MySQL 5.7 based releases |
| <code>--loadqueries=file</code>       | Loads all queries from the file specified; does not connect to a database  | All MySQL 5.7 based releases |
| <code>--real_table_name=table</code>  | Designates a table to handle unique index size calculations  | All MySQL 5.7 based releases |

## Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
  [--user=user] [--password=password] \
  [--help|-h] [--format={html|text}] \
  [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name can be specified using `--hostname`; the default is `localhost`. You can specify a port in addition to the host using `host:port` format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-----
Connected to: DBI:mysql:host=localhost:mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1
```

```

test.tl

NoOfUniqueHashIndexes      64      0      0      0
NoOfAttributes      1000      3      3      3
NoOfTriggers      768      5      5      5

```

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read in during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

## 20.4.26 ndb\_waiter — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- `STARTED`: The node is operational, and has joined the cluster.
- `SHUTTING_DOWN`: The node is shutting down.
- `SINGLE USER MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_waiter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_waiter`), see [Section 20.4.27, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”](#).

**Table 20.104** This table describes command-line options for the `ndb_waiter` program

| Format   | Description  | Added or Removed             |
|--|--|------------------------------|
| <code>--no-contact</code> ,<br><code>-n</code> | Wait for cluster to reach NO CONTACT state   | All MySQL 5.7 based releases |
| <code>--not-started</code>                     | Wait for cluster to reach NOT STARTED state  | All MySQL 5.7 based releases |
| <code>--single-user</code>                     | Wait for cluster to enter single user mode   | All MySQL 5.7 based releases |
| <code>--timeout=#</code> ,<br><code>-t</code>  | Wait this many seconds, then exit whether or not cluster has reached desired state; default is 2 minutes (120 seconds) | All MySQL 5.7 based releases |
| <code>--nowait-nodes=list</code>               | List of nodes not to be waited for.  | All MySQL 5.7 based releases |
| <code>--wait-nodes=list</code> ,               | List of nodes to be waited for.  | All MySQL 5.7 based releases |

| Format | Description | Added or Removed |
|--------|-------------|------------------|
| -w     |             |                  |

## Usage

```
ndb_waiter [-c connection_string]
```

## Additional Options

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

### Important

Do *not* use this option together with the `--wait-nodes` option.

- `--wait-nodes=list, -w list`

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

### Important

Do *not* use this option together with the `--nowait-nodes` option.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by ...) are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
```

```

State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK

```

#### Note

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

## 20.4.27 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

All NDB Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`
- `ndb_print_backup_file`

- `ndb_print_schema_file`
- `ndb_print_sys_file`

**Note**

Users of earlier NDB Cluster versions should note that some of these options have been changed to make them consistent with one another, and also with `mysqld`. You can use the `--help` option with any NDB Cluster program—with the exception of `ndb_print_backup_file`, `ndb_print_schema_file`, and `ndb_print_sys_file`—to view a list of the options which the program supports.

The options in the following table are common to all NDB Cluster executables (except those noted previously in this section).

**Table 20.105** This table describes command-line options common to all MySQL Cluster programs

| Format   | Description   | Added or Removed             |
|--|---|------------------------------|
| <code>--help,</code><br><code>--usage,</code><br><code>-?</code> | Display help message and exit   | All MySQL 5.7 based releases |
| <code>--character-sets-dir=dir_name</code>                       | Directory where character sets are installed  | All MySQL 5.7 based releases |
| <code>--connect-retries=#</code>                                 | Set the number of times to retry a connection before giving up  | All MySQL 5.7 based releases |
| <code>--connect-retry-delay=#</code>                             | Time to wait between attempts to contact a management server, in seconds  | All MySQL 5.7 based releases |
| <code>--core-file</code>   | Write core on errors (defaults to TRUE in debug builds)   | All MySQL 5.7 based releases |
| <code>--debug=options</code>                                     | Enable output from debug calls. Can be used only for versions compiled with debugging enabled   | All MySQL 5.7 based releases |
| <code>--ndb-connectstring=connectstring</code>                   | Set connection string for connecting to <code>ndb_mgmd</code> . Syntax: <code>[nodeid=&lt;id&gt;:]</code><br><code>[host=]&lt;hostname&gt;[:&lt;port&gt;]</code> . Overrides entries specified in <code>NDB_CONNECTSTRING</code> or <code>my.cnf</code> . | All MySQL 5.7 based releases |
| <code>-c</code><br><code>--ndb-mgmd-host=host[:port]</code>      | Set the host (and port, if desired) for connecting to management server   | All MySQL 5.7 based releases |
| <code>--ndb-nodeid=#</code>                                      | Set node id for this node   | All MySQL 5.7 based releases |
| <code>--ndb-optimized-node-selection</code>                      | Select nodes for transactions in a more optimal way   | All MySQL 5.7 based releases |
| <code>--version,</code><br><code>-V</code>                       | Output version information and exit   | All MySQL 5.7 based releases |

For options specific to individual NDB Cluster programs, see [Section 20.4, “NDB Cluster Programs”](#).

See [MySQL Server Options for NDB Cluster](#), for `mysqld` options relating to NDB Cluster .

- `--help, --usage, -?`

|                            |                      |
|----------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--help</code>  |
|                            | <code>--usage</code> |

Prints a short list with descriptions of the available command options.

- `--character-sets-dir=name`

|                            |  |                |
|----------------------------|--|----------------|
| <b>Command-Line Format</b> | <code>--character-sets-dir=dir_name</code> |                |
| <b>Permitted Values</b>    | <b>Type</b>                                | directory name |
|                            | <b>Default</b>                             |                |

Tells the program where to find character set information.

- `--ndb-connectstring=connection_string, --connect-string=connection_string, -c connection_string`

|                            |  |                             |
|----------------------------|--|-----------------------------|
| <b>Command-Line Format</b> | <code>--ndb-connectstring=connectstring</code> |                             |
|                            | <code>--connect-string=connectstring</code>    |                             |
| <b>Permitted Values</b>    | <b>Type</b>                                    | string                      |
|                            | <b>Default</b>                                 | <code>localhost:1186</code> |

This option takes an NDB Cluster connection string that specifies the management server for the application to connect to, as shown here:

```
shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see [Section 20.3.3.3, “NDB Cluster Connection Strings”](#).

- `--connect-retries=#`

|                            |                                  |                         |
|----------------------------|----------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--connect-retries=#</code> |                         |
| <b>Permitted Values</b>    | <b>Type</b>                      | numeric                 |
|                            | <b>Default</b>                   | <code>12</code>         |
|                            | <b>Min Value</b>                 | <code>0</code>          |
|                            | <b>Max Value</b>                 | <code>4294967295</code> |

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

#### Note

When used with `ndb_mgm`, this option has 3 as its default. See [Section 20.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#), for more information.

- `--connect-retry-delay=#`

|                            |                                      |
|----------------------------|--------------------------------------|
| <b>Command-Line Format</b> | <code>--connect-retry-delay=#</code> |
|----------------------------|--------------------------------------|

|   |                  |            |
|---|------------------|------------|
| <b>Permitted Values</b>                       | <b>Type</b>      | numeric    |
|   | <b>Default</b>   | 5          |
|   | <b>Min Value</b> | 0          |
|   | <b>Max Value</b> | 4294967295 |
| <b>Permitted Values</b> (>= 5.7.10-ndb-7.5.0) | <b>Type</b>      | numeric    |
|   | <b>Default</b>   | 5          |
|   | <b>Min Value</b> | 1          |
|   | <b>Max Value</b> | 4294967295 |

This option specifies the length of time to wait per attempt a connection before giving up. The number of times to try connecting is set by `--connect-retries`.

- `--core-file`

|                            |                          |                    |
|----------------------------|--------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--core-file</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>              | boolean            |
|                            | <b>Default</b>           | <code>FALSE</code> |

Write a core file if the program dies. The name and location of the core file are system-dependent. (For NDB Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If NDB Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

|                            |                              |   |
|----------------------------|------------------------------|---|
| <b>Command-Line Format</b> | <code>--debug=options</code> |   |
| <b>Permitted Values</b>    | <b>Type</b>                  | string                                    |
|                            | <b>Default</b>               | <code>d:t:0,/tmp/ndb_restore.trace</code> |

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--ndb-mgmd-host=host[:port]`

|                            |  |                             |
|----------------------------|--|-----------------------------|
| <b>Command-Line Format</b> | <code>--ndb-mgmd-host=host[:port]</code> |                             |
| <b>Permitted Values</b>    | <b>Type</b>                              | string                      |
|                            | <b>Default</b>                           | <code>localhost:1186</code> |

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

|                            |                             |
|----------------------------|-----------------------------|
| <b>Command-Line Format</b> | <code>--ndb-nodeid=#</code> |
|----------------------------|-----------------------------|

|                  |         |         |
|------------------|---------|---------|
| Permitted Values | Type    | numeric |
|                  | Default | 0       |

Sets this node's NDB Cluster node ID. *The range of permitted values depends on the node's type (data, management, or API) and the NDB Cluster software version.* See [Section 20.1.6.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”](#), for more information.

- `--ndb-optimized-node-selection`

|                     |   |         |
|---------------------|---|---------|
| Command-Line Format | <code>--ndb-optimized-node-selection</code> |         |
| Permitted Values    | Type  | boolean |
|                     | Default                                     | TRUE    |

Optimize selection of nodes for transactions. Enabled by default.

- `--version, -V`

|                     |                        |
|---------------------|------------------------|
| Command-Line Format | <code>--version</code> |
|---------------------|------------------------|

Prints the NDB Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the NDB Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of NDB Cluster .

See [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)), for more information.

## 20.5 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster . This is covered in [Section 20.3, “Configuration of NDB Cluster”](#), and [Section 20.4, “NDB Cluster Programs”](#).

The next few sections cover the management of a running NDB Cluster .

For information about security issues relating to management and deployment of an NDB Cluster , see [Section 20.5.12, “NDB Cluster Security Issues”](#).

There are essentially two methods of actively managing a running NDB Cluster . The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see [Section 20.5.10, “The ndbinfo NDB Cluster Information Database”](#).

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster . The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the `SESSION_STATUS` table or the `GLOBAL_STATUS` table (in the `INFORMATION_SCHEMA` database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster .

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster . See [MySQL™ Cluster Manager 1.4.1 User Manual](#), for more information.

## 20.5.1 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in [NDB Cluster Start Phases](#), in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#)). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

**Start types.** There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

### Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNT` blocks start (see [NDB Kernel Blocks](#)). Data node file systems are cleared on those data nodes that were started with `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

#### Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNT` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 20.5.2 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 20.5.6, “Event Reports Generated in NDB Cluster”](#); commands for creating backups and restoring from them are provided in [Section 20.5.3, “Online Backup of NDB Cluster”](#).

**Using `ndb_mgm` with MySQL Cluster Manager.** MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended *not* to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see [MySQL Cluster Manager Process Commands](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`

Displays information on all available commands.

- `CONNECT connection-string`

Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- `SHOW`

Displays information on the cluster's status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`. The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`).

- `node_id START`

Brings online the data node identified by `node_id` (or all data nodes).

`ALL START` works on all data nodes only, and does not affect management nodes.

#### Important

To use this command to bring a data node online, the data node must have been started using `--nostream` or `-n`.

- `node_id STOP [-a] [-f]`

Stops the data or management node identified by `node_id`.

#### Note

`ALL STOP` works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

### Warning

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in NDB.

- `node_id RESTART [-n] [-i] [-a] [-f]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

### Note

Backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

The output from this command also indicates when the cluster is in single user mode.

- `node_id REPORT report-type`

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

- `BackupStatus` provides a status report on a cluster backup in progress
- `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
```

```
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- `EventLog` reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

Currently, it is not possible for data nodes to join an NDB Cluster while it is running in single user mode. (Bug #20395)

- `EXIT SINGLE USER MODE`

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

#### Note

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `QUIT, EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `CREATE NODEGROUP nodeid[, nodeid, ...]`

Creates a new NDB Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#).

- `DROP NODEGROUP nodegroup_id`

Drops the NDB Cluster node group with the given `nodegroup_id`.

This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3      @10.100.2.67  (5.7.16-ndb-7.5.5, no nodegroup)
```

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#).

- `PROMPT [prompt]`

Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```
jon@valhaj:~/bin> ./ndb_mgm
-- NDB Cluster -- Management Client --
Connected to Management Server at: localhost:1186
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration
...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm: '
'mymgm: ' PROMPT mymgm:
mymgm: PROMPT
ndb_mgm> EXIT
jon@valhaj:~/bin>
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

The `PROMPT` command was added in NDB 7.5.0.

**Additional commands.** A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- `START BACKUP` is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see [Section 20.5.3, “Online Backup of NDB Cluster”](#).
- The `CLUSTERLOG` command is used to perform various logging functions. See [Section 20.5.6, “Event Reports Generated in NDB Cluster”](#), for more information and examples.
- For testing and diagnostics work, the client also supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see [NDB Cluster Internals Manual](#).

## 20.5.3 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see [Section 5.5.4, “mysqldump — A Database Backup Program”](#).) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see [Section 20.4.20, “ndb\\_restore — Restore an NDB Cluster Backup”](#).

### 20.5.3.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_idctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

### 20.5.3.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 20.5.3.3, “Configuration for NDB Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the *backup\_id*, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing *backup\_id* value is used, the backup fails with the error `Backup failed: file already exists`. If used, the *backup\_id* must follow `START BACKUP` immediately, before any other options are used.

The *wait\_option* can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

A *snapshot\_option* can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

#### Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a *wait\_option* and a *snapshot\_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
```

```
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

*backup\_id* is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node\_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup\_id* is the unique identifier for this particular backup, and *node\_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using **START BACKUP** in this way, you must specify the backup ID.

Cluster backups are created by default in the **BACKUP** subdirectory of the **DataDir** on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given *backup\_id* are stored in a subdirectory named **BACKUP-*backup\_id*** in the backup directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

#### Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

#### Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

#### Note

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 20.5.3.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

The amount of memory used to buffer data before it is written to disk.

- [BackupLogBufferSize](#)

The amount of memory used to buffer log records before these are written to disk.

- [BackupMemory](#)

The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- [BackupWriteSize](#)

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- [BackupMaxWriteSize](#)

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

You can also set a location for the backup files using the [BackupDataDir](#) configuration parameter. The default is [FileSystemPath/BACKUP/BACKUP-backup\\_id](#).

#### 20.5.3.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

##### Important

If you have set [BackupDataBufferSize](#) and [BackupLogBufferSize](#) and their sum is greater than 4MB, then you must also set [BackupMemory](#) as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

[NDB](#) does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

### 20.5.4 MySQL Server Usage for NDB Cluster

[mysqld](#) is the traditional MySQL server process. To be used with NDB Cluster, [mysqld](#) needs to be built with support for the [NDB](#) storage engine, as it is in the precompiled binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke [CMake](#) with the `-DWITH_NDBCLUSTER=1` option to include support for [NDB](#).

For more information about compiling NDB Cluster from source, see [Section 20.2.2.4, “Building NDB Cluster from Source on Linux”](#), and [Section 20.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”](#).

(For information about [mysqld](#) options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see [Section 20.3.3.8, “MySQL Server Options and Variables for NDB Cluster”](#).)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 20.3.3.3, “NDB Cluster Connection Strings”](#), for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
      Id: 1
     User: system user
      Host:
       db:
Command: Daemon
      Time: 1
     State: Waiting for event from ndbcluster
      Info: NULL
```

### Important

To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB

tables, *nor is it possible to create any new tables regardless of storage engine.* The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server *without* the `--ndbcluster` option.

## 20.5.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

### **Configuration change.**

To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

### **System reset (cluster reset).**

To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmtd`) with the `--initial` option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.
- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See [Section 20.5.3, “Online Backup of NDB Cluster”](#), and [Section 20.4.20, “ndb\\_restore — Restore an NDB Cluster Backup”](#), for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA INFILE`.

### **Resource Recovery.**

To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See [Rolling restarts with multiple management servers.](#))
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.
3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

The specifics for implementing a given rolling upgrade depend upon the changes being made. A more detailed view of the process is presented here:

**Figure 20.23 NDB Cluster Rolling Restarts By Type**

| RESTART TYPE:  |                |   |   |   |   |
|--|----------------|---|---|---|---|
| Cluster Configuration Change   |                | Cluster Software Upgrade or Downgrade   | Change on Node Host   | Cluster Reset   |   |
| A. Management node (ndb_mgmd) processes...   |                |   |   |   |   |
| 1. Stop all ndb_mgmd processes<br><br>2. Make changes in global configuration file(s)<br><br>3. Start all ndb_mgmd processes |                | 1. Stop all ndb_mgmd processes<br><br>2. Replace each ndb_mgmd binary with new version<br><br>3. Start ndb_mgmd processes | 1. Stop all ndb_mgmd processes<br><br>2. Make desired changes in hardware, operating system, or both<br><br>3. Start all ndb_mgmd processes | ( OR )  |   |
|  |                |   |   | 1. Stop all ndb_mgmd processes<br><br>2. Start all ndb_mgmd processes | Restart all ndb_mgmd processes (optional) |
| B. For each data node (ndbd) process...  |                |   |   |   |   |
| ( OR )   |                | 1. Stop ndbd<br><br>2. Replace ndbd binary with new version<br><br>3. Start ndbd  | 1. Stop ndbd<br><br>2. Make desired changes in hardware, operating system, or both<br><br>3. Start ndbd                                     | ( OR )  |   |
| 1. Stop ndbd<br><br>2. Start ndbd  | Restart ndbd   |   |   | 1. Stop ndbd<br><br>2. Start ndbd                                     | Restart ndbd                              |
| C. For each SQL node (mysqld) process...   |                |   |   |   |   |
| ( OR )   |                | 1. Stop mysqld<br><br>2. Replace mysqld binary with new version<br><br>3. Start mysqld                                    | 1. Stop mysqld<br><br>2. Make desired changes in hardware, operating system, or both<br><br>3. Start mysqld                                 | ( OR )  |   |
| 1. Stop mysqld<br><br>2. Start mysqld  | Restart mysqld |   |   | 1. Stop mysqld<br><br>2. Start mysqld                                 | Restart mysqld                            |

In the previous diagram, the **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. On Windows, you can also use the system `NET START` and `NET STOP` commands or the Windows Service Manager to start and stop nodes which have been installed as Windows services (see [Section 20.2.3.4, “Installing NDB Cluster Processes as Windows Services”](#)).

**Restart** indicates that the process may be restarted using the `ndb_mgm` management client `RESTART` command.

NDB Cluster supports a flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

See also Bug #48528 and Bug #49163.

**Note**

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart.

**Rolling restarts with multiple management servers.** When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to reread its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.
4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See [Section 20.5.10.26, “The ndbinfo nodes Table”](#).

## 20.5.6 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the management server's `DataDir`.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- **Category:** This can be any one of the following values: [STARTUP](#), [SHUTDOWN](#), [STATISTICS](#), [CHECKPOINT](#), [NODERESTART](#), [CONNECTION](#), [ERROR](#), or [INFO](#).
- **Priority:** This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”
- **Severity Level:** This can be any one of the following values: [ALERT](#), [CRITICAL](#), [ERROR](#), [WARNING](#), [INFO](#), or [DEBUG](#).

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Resource 0 min: 0 max: 639 curr: 0

2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 1: Node 9: API 5.7.16-ndb-7.5.5
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9: API 5.7.16-ndb-7.5.5
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9: API 5.7.16-ndb-7.5.5
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 4: Node 9: API 5.7.16-ndb-7.5.5
2007-01-26 19:59:22 [MgmSrvr] ALERT     -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT     -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 20.5.6.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log. In the listing that follows, `node_id` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CLUSTERLOG ON`

Turns the cluster log on.

- `CLUSTERLOG OFF`

Turns the cluster log off.

- `CLUSTERLOG INFO`

Provides information about cluster log settings.

- `node_id CLUSTERLOG category=threshold`

Logs *category* events with priority less than or equal to *threshold* in the cluster log.

- `CLUSTERLOG FILTER severity_level`

Toggles cluster logging of events of the specified *severity\_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

#### Note

Events are reported per data node, and that the threshold can be set to different values on different nodes.

| Category    | Default threshold (All data nodes) |
|-------------|------------------------------------|
| STARTUP     | 7                                  |
| SHUTDOWN    | 7                                  |
| STATISTICS  | 7                                  |
| CHECKPOINT  | 7                                  |
| NODERESTART | 7                                  |
| CONNECTION  | 7                                  |
| ERROR       | 15                                 |
| INFO        | 7                                  |

The `STATISTICS` category can provide a great deal of useful data. See [Section 20.5.6.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

#### Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

| Severity Level Value | Severity | Description   |
|----------------------|----------|---|
| 1                    | ALERT    | A condition that should be corrected immediately, such as a corrupted system database |
| 2                    | CRITICAL | Critical conditions, such as device errors or insufficient resources                  |
| 3                    | ERROR    | Conditions that should be corrected, such as configuration errors                     |
| 4                    | WARNING  | Conditions that are not errors, but that might require special handling               |

| Severity Level Value | Severity | Description  |
|----------------------|----------|--|
| 5                    | INFO     | Informational messages   |
| 6                    | DEBUG    | Debugging messages used for <a href="#">NDBCLUSTER</a> development |

Event severity levels can be turned on or off (using [CLUSTERLOG FILTER](#)—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

#### Important

Cluster log levels are set on a per [ndb\\_mgmd](#), per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a [CLUSTERLOG](#) command in an instance of [ndb\\_mgm](#) connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

### 20.5.6.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

#### CONNECTION Events

These events are associated with connections between Cluster nodes.

| Event                               | Priority | Severity Level | Description                             |
|-------------------------------------|----------|----------------|---|
| <a href="#">Connected</a>           | 8        | INFO           | Data nodes connected                    |
| <a href="#">Disconnected</a>        | 8        | ALERT          | Data nodes disconnected                 |
| <a href="#">CommunicationClosed</a> | 8        | INFO           | SQL node or data node connection closed |
| <a href="#">CommunicationOpened</a> | 8        | INFO           | SQL node or data node connection open   |
| <a href="#">ConnectedApiVersion</a> | 8        | INFO           | Connection using API version            |

#### CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

| Event                                   | Priority | Severity Level | Description                               |
|---|----------|----------------|---|
| <a href="#">GlobalCheckpointStarted</a> | 9        | INFO           | Start of GCP: REDO log is written to disk |

| Event                     | Priority | Severity Level | Description                                |
|---------------------------|----------|----------------|--|
| GlobalCheckpointCompleted | 10       | INFO           | GCP finished                               |
| LocalCheckpointStarted    | 7        | INFO           | Start of LCP: data written to disk         |
| LocalCheckpointCompleted  | 7        | INFO           | LCP completed normally                     |
| LCPStoppedInCalcKeepGci   | 0        | ALERT          | LCP stopped                                |
| LCPFragmentCompleted      | 11       | INFO           | LCP on a fragment has been completed       |
| UndoLogBlocked            | 7        | INFO           | UNDO logging blocked; buffer near overflow |
| RedoStatus                | 7        | INFO           | Redo status                                |

## STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

| Event                 | Priority | Severity Level | Description   |
|-----------------------|----------|----------------|---|
| NDBStartStarted       | 1        | INFO           | Data node start phases initiated (all nodes starting)   |
| NDBStartCompleted     | 1        | INFO           | Start phases completed, all data nodes  |
| STTORRYRecieved       | 15       | INFO           | Blocks received after completion of restart   |
| StartPhaseCompleted   | 4        | INFO           | Data node start phase <i>x</i> completed  |
| CM_REGCONF            | 3        | INFO           | Node has been successfully included into the cluster; shows the node, managing node, and dynamic ID   |
| CM_REGREF             | 8        | INFO           | Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem |
| FIND_NEIGHBOURS       | 8        | INFO           | Shows neighboring data nodes  |
| NDBStopStarted        | 1        | INFO           | Data node shutdown initiated  |
| NDBStopCompleted      | 1        | INFO           | Data node shutdown complete   |
| NDBStopForced         | 1        | ALERT          | Forced shutdown of data node  |
| NDBStopAborted        | 1        | INFO           | Unable to shut down data node normally  |
| StartREDOLog          | 4        | INFO           | New redo log started; GCI keep <i>x</i> , newest restorable GCI <i>y</i>  |
| StartLog              | 10       | INFO           | New log started; log part <i>x</i> , start MB <i>y</i> , stop MB <i>z</i>   |
| UNDORecordsExecuted   | 15       | INFO           | Undo records executed   |
| StartReport           | 4        | INFO           | Report started  |
| LogFileInitStatus     | 7        | INFO           | Log file initialization status  |
| LogFileInitCompStatus | 7        | INFO           | Log file completion status  |
| StartReadLCP          | 10       | INFO           | Start read for local checkpoint   |
| ReadLCPComplete       | 10       | INFO           | Read for local checkpoint completed   |
| RunRedo               | 8        | INFO           | Running the redo log  |
| RebuildIndex          | 10       | INFO           | Rebuilding indexes  |

**NODERESTART Events**

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

| Event                | Priority | Severity Level | Description  |
|----------------------|----------|----------------|--|
| NR_CopyDict          | 7        | INFO           | Completed copying of dictionary information  |
| NR_CopyDistr         | 7        | INFO           | Completed copying distribution information   |
| NR_CopyFragStarted   | 7        | INFO           | Starting to copy fragments   |
| NR_CopyFragDone      | 10       | INFO           | Completed copying a fragment   |
| NR_CopyFragCompleted | 7        | INFO           | Completed copying all fragments  |
| NodeFailCompleted    | 8        | ALERT          | Node failure phase completed   |
| NODE_FAILREP         | 8        | ALERT          | Reports that a node has failed   |
| ArbitState           | 6        | INFO           | Report whether an arbitrator is found or not; there are seven different possible outcomes when seeking an arbitrator, listed here: <ul style="list-style-type: none"> <li>• Management server restarts arbitration thread [state=<i>x</i>]</li> <li>• Prepare arbitrator node <i>x</i> [ticket=<i>y</i>]</li> <li>• Receive arbitrator node <i>x</i> [ticket=<i>y</i>]</li> <li>• Started arbitrator node <i>x</i> [ticket=<i>y</i>]</li> <li>• Lost arbitrator node <i>x</i> - process failure [state=<i>y</i>]</li> <li>• Lost arbitrator node <i>x</i> - process exit [state=<i>y</i>]</li> <li>• Lost arbitrator node <i>x</i> &lt;error msg&gt; [state=<i>y</i>]</li> </ul> |
| ArbitResult          | 2        | ALERT          | Report arbitrator results; there are eight different possible results for arbitration attempts, listed here: <ul style="list-style-type: none"> <li>• Arbitration check failed: less than 1/2 nodes left</li> <li>• Arbitration check succeeded: node group majority</li> <li>• Arbitration check failed: missing node group</li> <li>• Network partitioning: arbitration required</li> <li>• Arbitration succeeded: affirmative response from node <i>x</i></li> <li>• Arbitration failed: negative response from node <i>x</i></li> <li>• Network partitioning: no arbitrator available</li> </ul>   |

| Event                 | Priority | Severity Level | Description  |
|-----------------------|----------|----------------|--|
|                       |          |                | <ul style="list-style-type: none"> <li>Network partitioning: no arbitrator configured</li> </ul> |
| GCP_TakeoverStarted   | 7        | INFO           | GCP takeover started   |
| GCP_TakeoverCompleted | 7        | INFO           | GCP takeover complete  |
| LCP_TakeoverStarted   | 7        | INFO           | LCP takeover started   |
| LCP_TakeoverCompleted | 7        | INFO           | LCP takeover complete (state = <i>x</i> )  |
| ConnectCheckStarted   | 6        | INFO           | Connection check started   |
| ConnectCheckCompleted | 6        | INFO           | Connection check completed   |
| NodeFailRejected      | 6        | ALERT          | Node failure phase failed  |

## STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

| Event                   | Priority | Severity Level | Description  |
|-------------------------|----------|----------------|--|
| TransReportCounters     | 8        | INFO           | Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts |
| OperationReportCounters | 8        | INFO           | Number of operations   |
| TableCreated            | 7        | INFO           | Report number of tables created  |
| JobStatistic            | 9        | INFO           | Mean internal job scheduling statistics  |
| ThreadConfigLoop        | 9        | INFO           | Number of thread configuration loops   |
| SendBytesStatistic      | 9        | INFO           | Mean number of bytes sent to node <i>x</i>   |
| ReceiveBytesStatistic   | 9        | INFO           | Mean number of bytes received from node <i>x</i>   |
| MemoryUsage             | 5        | INFO           | Data and index memory usage (80%, 90%, and 100%)   |
| MTSignalStatistics      | 9        | INFO           | Multi-threaded signals   |

## SCHEMA Events

These events relate to NDB Cluster schema operations.

| Event              | Priority | Severity | Description           |
|--------------------|----------|----------|-----------------------|
| CreateSchemaObject | 8        | INFO     | Schema object created |
| AlterSchemaObject  | 8        | INFO     | Schema object updated |
| DropSchemaObject   | 8        | INFO     | Schema object dropped |

## ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

| Event              | Priority | Severity | Description         |
|--------------------|----------|----------|---------------------|
| TransporterError   | 2        | ERROR    | Transporter error   |
| TransporterWarning | 8        | WARNING  | Transporter warning |

| Event                              | Priority | Severity                | Description   |
|------------------------------------|----------|-------------------------|---|
| <a href="#">MissedHeartbeat</a>    | 8        | <a href="#">WARNING</a> | Node <i>X</i> missed heartbeat number <i>Y</i>        |
| <a href="#">DeadDueToHeartbeat</a> | 8        | <a href="#">ALERT</a>   | Node <i>X</i> declared “dead” due to missed heartbeat |
| <a href="#">WarningEvent</a>       | 2        | <a href="#">WARNING</a> | General warning event                                 |
| <a href="#">SubscriptionStatus</a> | 4        | <a href="#">WARNING</a> | Change in subscription status                         |

## INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

| Event                              | Priority | Severity             | Description  |
|------------------------------------|----------|----------------------|--|
| <a href="#">SentHeartbeat</a>      | 12       | <a href="#">INFO</a> | Sent heartbeat   |
| <a href="#">CreateLogBytes</a>     | 11       | <a href="#">INFO</a> | Create log: Log part, log file, size in MB                   |
| <a href="#">InfoEvent</a>          | 2        | <a href="#">INFO</a> | General informational event                                  |
| <a href="#">EventBufferStatus</a>  | 7        | <a href="#">INFO</a> | Event buffer status  |
| <a href="#">EventBufferStatus2</a> | 7        | <a href="#">INFO</a> | Improved event buffer status information; added in NDB 7.5.1 |

### Note

[SentHeartbeat](#) events are available only if NDB Cluster was compiled with [VM\\_TRACE](#) enabled.

```
Node node_id: Event buffer status:
used=bytes_used (used as a percent of alloc)
alloc=bytes_allocated (alloc as a % of max. If max is 0 (unlimited) the % will
not be printed)
max=bytes_available (if not configured, max will be 0, meaning unlimited, i.e.
no limit on event buffer memory usage)
latest_consumed_epoch=epoch that was consumed completely (using nextEvent())
latest_buffered_epoch=epoch which is buffered completely in the event buffer
ndb_reference=the object id of the Ndb that originates the report
report_reason=the reason for reporting this log event

Note: latest_consumed_epoch is the same as apply_gci of the old
EventBufferStatus and latest_buffered_epoch is the same as latest_gci of the old
EventBufferStatus. Remember to change the explanations of apply_gci and
latest_gci in the old EventBufferStatus.
```

## SINGLEUSER Events

These events are associated with entering and exiting single user mode.

| Event                      | Priority | Severity             | Description                          |
|----------------------------|----------|----------------------|--------------------------------------|
| <a href="#">SingleUser</a> | 7        | <a href="#">INFO</a> | Entering or exiting single user mode |

## BACKUP Events

These events provide information about backups being created or restored.

| Event                               | Priority | Severity              | Description            |
|-------------------------------------|----------|-----------------------|------------------------|
| <a href="#">BackupStarted</a>       | 7        | <a href="#">INFO</a>  | Backup started         |
| <a href="#">BackupStatus</a>        | 7        | <a href="#">INFO</a>  | Backup status          |
| <a href="#">BackupCompleted</a>     | 7        | <a href="#">INFO</a>  | Backup completed       |
| <a href="#">BackupFailedToStart</a> | 7        | <a href="#">ALERT</a> | Backup failed to start |

| Event                            | Priority | Severity | Description                     |
|----------------------------------|----------|----------|---------------------------------|
| <a href="#">BackupAborted</a>    | 7        | ALERT    | Backup aborted by user          |
| <a href="#">RestoreStarted</a>   | 7        | INFO     | Started restoring from backup   |
| <a href="#">RestoreMetaData</a>  | 7        | INFO     | Restoring metadata              |
| <a href="#">RestoreData</a>      | 7        | INFO     | Restoring data                  |
| <a href="#">RestoreLog</a>       | 7        | INFO     | Restoring log files             |
| <a href="#">RestoreCompleted</a> | 7        | INFO     | Completed restoring from backup |
| <a href="#">SavedEvent</a>       | 7        | INFO     | Event saved                     |

### 20.5.6.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's [CLUSTERLOG STATISTICS](#) command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

#### Note

You can determine which TC selection method is used for transactions started from a given SQL node using the [ndb\\_optimized\\_node\\_selection](#) system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

#### Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for [Commit count](#) to be greater than [Trans count](#).
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.
- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

**Note**

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in [AttrInfoCount](#).

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

The maximum value that [Concurrent Operations](#) can have is the maximum number of operations that a TC block can support; currently, this is  $(2 * \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}$ . (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 20.3.3.6, “Defining NDB Cluster Data Nodes”](#).)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, [Abort count](#) can sometimes be greater than [Trans count](#).
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.
- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the [LOCAL\\_READS](#) counter in the [ndbinfo.counters](#) table.
- **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the [LOCAL\\_WRITES](#) counter in the [ndbinfo.counters](#) table.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

**Note**

A single transaction may operate on data stored in multiple LQH blocks.

The [Operations](#) statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations;

however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

#### Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see [Section 20.5.6.1, “NDB Cluster Logging Management Commands”](#).

## 20.5.7 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on `NDB` transporter errors.

### 20.5.7.1 NDB Cluster : Messages in the Cluster Log

The following table lists the most common `NDB` cluster log messages. For information about the cluster log, log events, and event types, see [Section 20.5.6, “Event Reports Generated in NDB Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The Ndb\\_logevent\\_type Type](#), for related information of interest to Cluster API developers.

| Log Message  | Description   | Event Name             | Event Type              | Priority | Severity          |
|--|---|------------------------|-------------------------|----------|-------------------|
| <code>Node<br/>mgm_node_id:<br/>Node<br/>data_node_id<br/>Connected</code> | The data node having node ID <code>node_id</code> has connected to the management | <code>Connected</code> | <code>Connection</code> | 8        | <code>INFO</code> |

### 20.5.7.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
- Initial start with nodes %s [ missing: %s no-wait: %s ]
- Start with all nodes %s
- Start with nodes %s [ missing: %s no-wait: %s ]
- Start potentially partitioned with nodes %s [ missing: %s no-wait: %s ]
- Unknown startreport: 0x%x [ %s %s %s %s ]

### 20.5.7.3 Event Buffer Reporting in the Cluster Log

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each Ndb object subscribing to table events, which means that there are usually two buffers for each mysqld performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes). These messages and the data structures underlying them were changed significantly in NDB 7.5.1, with the addition of the NDB\_LE\_EventBufferStatus2 event type and the ndb\_logevent\_EventBufferStatus2 data structure (see [The Ndb\\_logevent\\_type Type](#)). The remainder of this discussion focuses on the implementation based on NDB\_LE\_EventBufferStatus2.

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
used=bytes_used (percent_used% of alloc)
alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
latest_consumed_epoch=latest_consumed_epoch
```

```
latest_buffered_epoch=latest_buffered_epoch
report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- *node\_id*: ID of the node where the report originated.
- *object\_id*: ID of the `Ndb` object where the report originated.
- *bytes\_used*: Number of bytes used by the buffer.
- *percent\_used*: Percentage of allocated bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- *bytes\_allocated*: Number of bytes allocated to this buffer.
- *percent\_alloc*: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- *bytes\_available*: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- *latest\_consumed\_epoch*: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- *latest\_buffered\_epoch*: The epoch most recently buffered (completely) in the event buffer.
- *report\_reason*: The reason for making the report. Possible reasons are shown later in this section.

The `latest_consumed_epoch` and `latest_buffered_epoch` fields correspond, respectively, to the `apply_gci` and `latest_gci` fields of the old-style event buffer logging messages used prior to NDB 7.5.1.

Possible reasons for reporting are described in the following list:

- `ENOUGH_FREE_EVENTBUFFER`: The event buffer has sufficient space.
- `LOW_FREE_EVENTBUFFER`: The event buffer is running low on free space.  
  
The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.
- `BUFFERED_EPOCHS_OVER_THRESHOLD`: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.
- `PARTIALLY_DISCARDING`: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.
- `COMPLETELY_DISCARDING`: No epochs are buffered.
- `PARTIALLY_BUFFERING`: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.
- `COMPLETELY_BUFFERING`: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

### 20.5.7.4 NDB Cluster : NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

| Error Code | Error Name                       | Error Text   |
|------------|----------------------------------|--|
| 0x00       | TE_NO_ERROR                      | No error   |
| 0x01       | TE_ERROR_CLOSING_SOCKET          | Error found during closing of socket                   |
| 0x02       | TE_ERROR_IN_SELECT_BEFORE_ACCEPT | Error found before accept. The transporter will retry  |
| 0x03       | TE_INVALID_MESSAGE_LENGTH        | Error found in message (invalid message length)        |
| 0x04       | TE_INVALID_CHECKSUM              | Error found in message (checksum)                      |
| 0x05       | TE_COULD_NOT_CREATE_SOCKET       | Error found while creating socket(can't create socket) |
| 0x06       | TE_COULD_NOT_BIND_SOCKET         | Error found while binding server socket                |
| 0x07       | TE_LISTEN_FAILED                 | Error found while listening to server socket           |
| 0x08       | TE_ACCEPT_RETURN_ERROR           | Error found during accept(accept return error)         |
| 0x0b       | TE_SHM_DISCONNECT                | The remote node has disconnected                       |
| 0x0c       | TE_SHM_IPC_STAT                  | Unable to check shm segment                            |
| 0x0d       | TE_SHM_UNABLE_TO_CREATE_SEGMENT  | Unable to create shm segment                           |
| 0x0e       | TE_SHM_UNABLE_TO_ATTACH_SEGMENT  | Unable to attach shm segment                           |
| 0x0f       | TE_SHM_UNABLE_TO_REMOVE_SEGMENT  | Unable to remove shm segment                           |
| 0x10       | TE_TOO_SMALL_SIGID               | Sig ID too small                                       |
| 0x11       | TE_TOO_LARGE_SIGID               | Sig ID too large                                       |
| 0x12       | TE_WAIT_STACK_FULL               | Wait stack was full                                    |
| 0x13       | TE_RECEIVE_BUFFER_FULL           | Receive buffer was full                                |
| 0x14       | TE_SIGNAL_LOST_SEND_BUFFER_FULL  | Send buffer was full,and trying to force send fails    |
| 0x15       | TE_SIGNAL_LOST                   | Send failed for unknown reason(signal lost)            |

| Error Code | Error Name                          | Error Text  |
|------------|-------------------------------------|---|
| 0x16       | TE_SEND_BUFFER_FULL                 | The send buffer was full, but sleeping for a while solved                                       |
| 0x0017     | TE_SCI_LINK_ERROR                   | There is no link from this node to the switch   |
| 0x18       | TE_SCI_UNABLE_TO_START_SEQUENCE     | Could not start a sequence, because system resources are exumed or no sequence has been created |
| 0x19       | TE_SCI_UNABLE_TO_REMOVE_SEQUENCE    | Could not remove a sequence   |
| 0x1a       | TE_SCI_UNABLE_TO_CREATE_SEQUENCE    | Could not create a sequence, because system resources are exempted. Must reboot                 |
| 0x1b       | TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR | Tried to send data on redundant link but failed   |
| 0x1c       | TE_SCI_CANNOT_INIT_LOCALSEGMENT     | Cannot initialize local segment   |
| 0x1d       | TE_SCI_CANNOT_MAP_REMOTESEGMENT     | Cannot map remote segment   |
| 0x1e       | TE_SCI_UNABLE_TO_UNMAP_SEGMENT      | Cannot free the resources used by this segment (step 1)   |
| 0x1f       | TE_SCI_UNABLE_TO_REMOVE_SEGMENT     | Cannot free the resources used by this segment (step 2)   |
| 0x20       | TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT | Cannot disconnect from a remote segment   |
| 0x21       | TE_SHM_IPC_PERMANENT                | Shm ipc Permanent error   |
| 0x22       | TE_SCI_UNABLE_TO_CLOSE_CHANNEL      | Unable to close the sci channel and the resources allocated                                     |

## 20.5.8 NDB Cluster Single User Mode

*Single user mode* enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see [Section 20.5.10.26, “The ndbinfo nodes Table”](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

#### Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes

- Method 2:

Restart database nodes prior to entering single user mode.

## 20.5.9 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS`, `SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

See [Section 14.7.5.15, “SHOW ENGINE Syntax”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 14.7.5.16, “SHOW ENGINES Syntax”](#), for more detailed information.

**Note**

This statement does not support a [LIKE](#) clause. However, you can use [LIKE](#) to filter queries against the [INFORMATION\\_SCHEMA.ENGINES](#) table, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the [ENGINES](#) table of the [INFORMATION\\_SCHEMA](#) database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a [LIKE](#) clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with [NDB](#) support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
+-----+
| support |
+-----+
| ENABLED |
+-----+
```

See [Section 23.6, “The INFORMATION\\_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the [NDB](#) storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ndb_autoincrement_prefetch_sz | 32 |
| ndb_cache_check_time | 0 |
| ndb_extra_logging | 0 |
| ndb_force_send | ON |
| ndb_index_stat_cache_entries | 32 |
| ndb_index_stat_enable | OFF |
| ndb_index_stat_update_freq | 20 |
| ndb_report_thresh_binlog_epoch_slip | 3 |
| ndb_report_thresh_binlog_mem_usage | 10 |
| ndb_use_copying_alter_table | OFF |
| ndb_use_exact_count | ON |
| ndb_use_transactions | ON |
+-----+-----+
```

See [Section 6.1.5, “Server System Variables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME LIKE 'NDB%';
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| NDB_AUTOINCREMENT_PREFETCH_SZ | 32 |
| NDB_CACHE_CHECK_TIME | 0 |
| NDB_EXTRA_LOGGING | 0 |
| NDB_FORCE_SEND | ON |
+-----+-----+
```

|                                     |     |  |
|-------------------------------------|-----|--|
| NDB_INDEX_STAT_CACHE_ENTRIES        | 32  |  |
| NDB_INDEX_STAT_ENABLE               | OFF |  |
| NDB_INDEX_STAT_UPDATE_FREQ          | 20  |  |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3   |  |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE  | 10  |  |
| NDB_USE_COPYING_ALTER_TABLE         | OFF |  |
| NDB_USE_EXACT_COUNT                 | ON  |  |
| NDB_USE_TRANSACTIONS                | ON  |  |

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
      -> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
      -> WHERE VARIABLE_NAME = 'ndb_force_send';
```

|                |
|----------------|
| VARIABLE_VALUE |
| ON             |

See [Section 23.10, “The INFORMATION\\_SCHEMA GLOBAL\\_VARIABLES and SESSION\\_VARIABLES Tables”](#), and [Section 6.1.5, “Server System Variables”](#), for more information.

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

| Variable_name            | Value         |
|--------------------------|---------------|
| Ndb_cluster_node_id      | 10            |
| Ndb_config_from_host     | 192.168.0.103 |
| Ndb_config_from_port     | 1186          |
| Ndb_number_of_data_nodes | 4             |

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

| Variable_name            | Value |
|--------------------------|-------|
| Ndb_cluster_node_id      | 0     |
| Ndb_config_from_host     |       |
| Ndb_config_from_port     | 0     |
| Ndb_number_of_data_nodes | 0     |

See also [Section 14.7.5.35, “SHOW STATUS Syntax”](#).

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement provides similar output to the `SHOW` command discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See [Section 23.9, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#), for more information.

You can also query the tables in the [ndbinfo](#) information database for real-time data about many NDB Cluster operations. See [Section 20.5.10, “The ndbinfo NDB Cluster Information Database”](#).

## 20.5.10 The ndbinfo NDB Cluster Information Database

[ndbinfo](#) is a database containing information specific to NDB Cluster .

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

[ndbinfo](#) is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that [ndbinfo](#) support is active in a given MySQL Server instance using [SHOW PLUGINS](#); if [ndbinfo](#) support is enabled, you should see a row containing [ndbinfo](#) in the [Name](#) column and [ACTIVE](#) in the [Status](#) column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
```

| Name                             | Status        | Type                  | Library     | License    |
|----------------------------------|---------------|-----------------------|-------------|------------|
| binlog                           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| mysql_native_password            | ACTIVE        | AUTHENTICATION        | NULL        | GPL        |
| sha256_password                  | ACTIVE        | AUTHENTICATION        | NULL        | GPL        |
| MRG_MYISAM                       | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MEMORY                           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| CSV                              | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MyISAM                           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| InnoDB                           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| INNODB_TRX                       | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_LOCKS                     | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_LOCK_WAITS                | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_CMP                       | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_CMP_RESET                 | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_CMPMEM                    | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_CMPMEM_RESET              | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_CMP_PER_INDEX             | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_CMP_PER_INDEX_RESET       | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_BUFFER_PAGE               | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_BUFFER_PAGE_LRU           | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |
| INNODB_BUFFER_POOL_STATS         | ACTIVE        | INFORMATION SCHEMA    | NULL        | GPL        |

10 rows in set (0.00 sec)

```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```

mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| ndbinfo |
| performance_schema |
| sys |
+-----+
5 rows in set (0.04 sec)

```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```

mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+-----+
| Tables_in_ndbinfo |
+-----+
| arbitrator_validity_detail |
| arbitrator_validity_summary |
| blocks |
| cluster_locks |
| cluster_operations |
| cluster_transactions |
| config_params |
| config_values |
| counters |
| cpustat |
| cpustat_1sec |
| cpustat_20sec |
| cpustat_50ms |
| dict_obj_types |

```

```

| disk_write_speed_aggregate
| disk_write_speed_aggregate_node
| disk_write_speed_base
| diskpagebuffer
| locks_per_fragment
| logbuffers
| logspaces
| membership
| memory_per_fragment
| memoryusage
| nodes
| operations_per_fragment
| resources
| restart_info
| server_locks
| server_operations
| server_transactions
| tc_time_track_stats
| threadblocks
| threads
| threadstat
| transporters
+-----+
36 rows in set (0.00 sec)

```

In NDB 7.5.0 (and later), all `ndbinfo` tables use the `NDB` storage engine; however, an `ndbinfo` entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

The `config_values` table was added in NDB 7.5.0.

The `cpustat`, `cpustat_50ms`, `cpustat_1sec`, `cpustat_20sec`, and `threads` tables were added in NDB 7.5.2.

The `cluster_locks`, `locks_per_fragment`, and `server_locks` tables were added in NDB 7.5.3.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```

mysql> SELECT * FROM memoryusage;
+-----+-----+-----+-----+-----+-----+
| node_id | memory_type | used | used_pages | total | total_pages |
+-----+-----+-----+-----+-----+-----+
| 5 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 5 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 5 | Long message buffer | 2304 | 9 | 67108864 | 262144 |
| 6 | Data memory | 753664 | 23 | 1073741824 | 32768 |
| 6 | Index memory | 163840 | 20 | 1074003968 | 131104 |
| 6 | Long message buffer | 2304 | 9 | 67108864 | 262144 |
+-----+-----+-----+-----+-----+-----+
6 rows in set (0.02 sec)

```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```

mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
> FROM memoryusage
> WHERE memory_type = 'Data memory';
+-----+
| Data Memory Used, All Nodes |
+-----+
| 6460 |
+-----+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
> FROM memoryusage
> WHERE memory_type = 'Index memory';
+-----+
| Total IndexMemory Available |

```

```

+-----+
|                25664 |
+-----+
1 row in set (0.33 sec)

```

`ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```

mysql> SELECT * FROM nodes;
+-----+
| node_id | uptime | status | start_phase |
+-----+
|        1 | 13602 | STARTED |            0 |
|        2 | 16    | STARTED |            0 |
+-----+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist

```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for NDB Cluster Disk Data storage, and the `ndb_transid_mysql_connection_map` table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or [Section 20.5.11, “INFORMATION\\_SCHEMA Tables for NDB Cluster”](#).

### 20.5.10.1 The ndbinfo arbitrator\_validity\_detail Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the `membership` table.

The following table provides information about the columns in the `arbitrator_validity_detail` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                | Type                   | Description                                      |
|----------------------------|------------------------|--|
| <code>node_id</code>       | integer                | This node's node ID                              |
| <code>arbitrator</code>    | integer                | Node ID of arbitrator                            |
| <code>arb_ticket</code>    | string                 | Internal identifier used to track arbitration    |
| <code>arb_connected</code> | Yes or No              | Whether this node is connected to the arbitrator |
| <code>arb_state</code>     | Enumeration (see text) | Arbitration state                                |

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitrator`.

### 20.5.10.2 The ndbinfo arbitrator\_validity\_summary Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The following table provides information about the columns in the `arbitrator_validity_summary` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                  | Type      | Description   |
|------------------------------|-----------|---|
| <code>arbitrator</code>      | integer   | Node ID of arbitrator                                 |
| <code>arb_ticket</code>      | string    | Internal identifier used to track arbitration         |
| <code>arb_connected</code>   | Yes or No | Whether this arbitrator is connected to the cluster   |
| <code>consensus_count</code> | integer   | Number of data nodes that see this node as arbitrator |

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

### 20.5.10.3 The ndbinfo blocks Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see [NDB Kernel Blocks](#)). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the `blocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name               | Type    | Description  |
|---------------------------|---------|--------------|
| <code>block_number</code> | integer | Block number |
| <code>block_name</code>   | string  | Block name   |

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

### 20.5.10.4 The ndbinfo cluster\_locks Table

The `cluster_locks` table provides information about current lock requests holding and waiting for locks on NDB tables in an NDB Cluster, and is intended as a companion table to `cluster_operations`. Information obtain from the `cluster_locks` table may be useful in investigating stalls and deadlocks.

The following table provides information about the columns in the `cluster_locks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                 | Type    | Description                          |
|-----------------------------|---------|--------------------------------------|
| <code>node_id</code>        | integer | ID of reporting node                 |
| <code>block_instance</code> | integer | ID of reporting LDM instance         |
| <code>tableid</code>        | integer | ID of table containing this row      |
| <code>fragmentid</code>     | integer | ID of fragment containing locked row |
| <code>rowid</code>          | integer | ID of locked row                     |
| <code>transid</code>        | integer | Transaction ID                       |

| Column Name                     | Type    | Description  |
|---------------------------------|---------|--|
| <a href="#">mode</a>            | string  | Lock request mode                                    |
| <a href="#">state</a>           | string  | Lock state   |
| <a href="#">detail</a>          | string  | Whether this is first holding lock in row lock queue |
| <a href="#">op</a>              | string  | Operation type                                       |
| <a href="#">duration_millis</a> | integer | Milliseconds spent waiting or holding lock           |
| <a href="#">lock_num</a>        | integer | ID of lock object                                    |
| <a href="#">waiting_for</a>     | integer | Waiting for lock with this ID                        |

The table ID ([tableid](#) column) is assigned internally, and is the same as that used in other [ndbinfo](#) tables. It is also shown in the output of [ndb\\_show\\_tables](#).

The transaction ID ([transid](#) column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The [mode](#) column shows the lock mode; this is always one of [S](#) (indicating a shared lock) or [X](#) (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The [state](#) column shows the lock state. Its value is always one of [H](#) (holding) or [W](#) (waiting). A waiting lock request waits for a lock held by a different transaction.

When the [detail](#) column contains a [\\*](#) (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The [op](#) column shows the type of operation requesting the lock. This is always one of the values [READ](#), [INSERT](#), [UPDATE](#), [DELETE](#), [SCAN](#), or [REFRESH](#).

The [duration\\_millis](#) column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID ([lockid](#) column) is unique to this node and block instance.

The lock state is shown in the [lock\\_state](#) column; if this is [W](#), the lock is waiting to be granted, and the [waiting\\_for](#) column shows the lock ID of the lock object this request is waiting for. Otherwise, the [waiting\\_for](#) column is empty. [waiting\\_for](#) can refer only to locks on the same row, as identified by [node\\_id](#), [block\\_instance](#), [tableid](#), [fragmentid](#), and [rowid](#).

The [cluster\\_locks](#) table was added in NDB 7.5.3.

### 20.5.10.5 The ndbinfo cluster\_operations Table

The [cluster\\_operations](#) table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see [The DBLQH Block](#)).

The following table provides information about the columns in the [cluster\\_operations](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                    | Type    | Description                                   |
|--------------------------------|---------|---|
| <a href="#">node_id</a>        | integer | Node ID of reporting LQH block                |
| <a href="#">block_instance</a> | integer | LQH block instance                            |
| <a href="#">transid</a>        | integer | Transaction ID                                |
| <a href="#">operation_type</a> | string  | Operation type (see text for possible values) |

| Column Name                    | Type    | Description                                    |
|--------------------------------|---------|--|
| <code>state</code>             | string  | Operation state (see text for possible values) |
| <code>tableid</code>           | integer | Table ID                                       |
| <code>fragmentid</code>        | integer | Fragment ID                                    |
| <code>client_node_id</code>    | integer | Client node ID                                 |
| <code>client_block_ref</code>  | integer | Client block reference                         |
| <code>tc_node_id</code>        | integer | Transaction coordinator node ID                |
| <code>tc_block_no</code>       | integer | Transaction coordinator block number           |
| <code>tc_block_instance</code> | integer | Transaction coordinator block instance         |

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

### 20.5.10.6 The ndbinfo cluster\_transactions Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The following table provides information about the columns in the `cluster_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                   | Type    | Description   |
|-------------------------------|---------|---|
| <code>node_id</code>          | integer | Node ID of transaction coordinator  |
| <code>block_instance</code>   | integer | TC block instance   |
| <code>transid</code>          | integer | Transaction ID  |
| <code>state</code>            | string  | Operation state (see text for possible values)  |
| <code>count_operations</code> | integer | Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations) |

| Column Name                            | Type    | Description   |
|--|---------|---|
| <a href="#">outstanding_operations</a> | integer | Operations still being executed in local data management blocks |
| <a href="#">inactive_seconds</a>       | integer | Time spent waiting for API                                      |
| <a href="#">client_node_id</a>         | integer | Client node ID  |
| <a href="#">client_block_ref</a>       | integer | Client block reference  |

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's [getTransactionId\(\)](#) method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The [state](#) column can have any one of the values [CS\\_ABORTING](#), [CS\\_COMMITTING](#), [CS\\_COMMIT\\_SENT](#), [CS\\_COMPLETE\\_SENT](#), [CS\\_COMPLETING](#), [CS\\_CONNECTED](#), [CS\\_DISCONNECTED](#), [CS\\_FAIL\\_ABORTED](#), [CS\\_FAIL\\_ABORTING](#), [CS\\_FAIL\\_COMMITTED](#), [CS\\_FAIL\\_COMMITTING](#), [CS\\_FAIL\\_COMPLETED](#), [CS\\_FAIL\\_PREPARED](#), [CS\\_PREPARE\\_TO\\_COMMIT](#), [CS\\_RECEIVING](#), [CS\\_REC\\_COMMITTING](#), [CS\\_RESTART](#), [CS\\_SEND\\_FIRE\\_TRIG\\_REQ](#), [CS\\_STARTED](#), [CS\\_START\\_COMMITTING](#), [CS\\_START\\_SCAN](#), [CS\\_WAIT\\_ABORT\\_CONF](#), [CS\\_WAIT\\_COMMIT\\_CONF](#), [CS\\_WAIT\\_COMPLETE\\_CONF](#), [CS\\_WAIT\\_FIRE\\_TRIG\\_REQ](#). (If the MySQL Server is running with [ndbinfo\\_show\\_hidden](#) enabled, you can view this list of states by selecting from the [ndb \\$dbtc\\_apiconnect\\_state](#) table, which is normally hidden.)

In [client\\_node\\_id](#) and [client\\_block\\_ref](#), [client](#) refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

### 20.5.10.7 The ndbinfo config\_params Table

The [config\\_params](#) table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters.

The following table provides information about the columns in the [config\\_params](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table. This table can also be used in conjunction with the [config\\_values](#) table for obtaining realtime information about node configuration parameters.

| Column Name                       | Type    | Description   |
|-----------------------------------|---------|---|
| <a href="#">param_number</a>      | integer | The parameter's internal ID number                  |
| <a href="#">param_name</a>        | string  | The name of the parameter                           |
| <a href="#">param_description</a> | string  | A brief description of the parameter                |
| <a href="#">param_type</a>        | string  | The parameter's data type                           |
| <a href="#">param_default</a>     | string  | The parameter's default value, if any               |
| <a href="#">param_min</a>         | string  | The parameter's maximum value, if any               |
| <a href="#">param_max</a>         | string  | The parameter's minimum value, if any               |
| <a href="#">param_mandatory</a>   | integer | This is 1 if the parameter is required, otherwise 0 |
| <a href="#">param_status</a>      | string  | Currently unused                                    |

In NDB Cluster 7.5 (and later), this table is read-only. The [param\\_description](#), [param\\_type](#), [param\\_default](#), [param\\_min](#), [param\\_max](#), [param\\_mandatory](#), and [param\\_status](#) columns were all added in NDB 7.5.0.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

### 20.5.10.8 The ndbinfo config\_values Table

The `config_values` table, implemented in NDB 7.5.0, provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

| Column Name               | Type    | Description                        |
|---------------------------|---------|------------------------------------|
| <code>node_id</code>      | integer | ID of the node in the cluster      |
| <code>config_param</code> | integer | The parameter's internal ID number |
| <code>config_value</code> | string  | Current value of the parameter     |

This table's `config_param` column and the `config_params` table's `param_number` column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters by name, as shown in the following example:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p.param_name IN ('NodeId', 'NoOfReplicas', 'HostName',
                        'DataMemory', 'IndexMemory', 'TotalSendBufferMemory');
```

### 20.5.10.9 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                 | Type    | Description  |
|-----------------------------|---------|--|
| <code>node_id</code>        | integer | The data node ID   |
| <code>block_name</code>     | string  | Name of the associated NDB kernel block (see <a href="#">NDB Kernel Blocks</a> ).  |
| <code>block_instance</code> | integer | Block instance   |
| <code>counter_id</code>     | integer | The counter's internal ID number; normally an integer between 1 and 10, inclusive.   |
| <code>counter_name</code>   | string  | The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated. |
| <code>val</code>            | integer | The counter's value  |

Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see [The DBLQH Block](#)). A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per replica.

The `ATTRINFO`, `TRANSACTIONS`, `COMMITTS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the `DBTC` (transaction co-ordinator) kernel block (see [The DBTC Block](#)).

[LOCAL\\_WRITES](#) and [LOCAL\\_READS](#) are primary-key operations using a transaction coordinator in a node that also holds the primary replica of the record.

The [READS](#) counter includes all reads. [LOCAL\\_READS](#) includes only those reads of the primary replica on the same node as this transaction coordinator. [SIMPLE\\_READS](#) includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once [DBTC](#) has routed them to the relevant LQH block, it holds no state for them.

[ATTRINFO](#) keeps a count of the number of times an interpreted program is sent to the data node. See [NDB Protocol Messages](#), for more information about [ATTRINFO](#) messages in the [NDB](#) kernel.

The [LOCAL\\_TABLE\\_SCANS\\_SENT](#), [READS\\_RECEIVED](#), [PRUNED\\_RANGE\\_SCANS\\_RECEIVED](#), [RANGE\\_SCANS\\_RECEIVED](#), [LOCAL\\_READS\\_SENT](#), [CONST\\_PRUNED\\_RANGE\\_SCANS\\_RECEIVED](#), [LOCAL\\_RANGE\\_SCANS\\_SENT](#), [REMOTE\\_READS\\_SENT](#), [REMOTE\\_RANGE\\_SCANS\\_SENT](#), [READS\\_NOT\\_FOUND](#), [SCAN\\_BATCHES\\_RETURNED](#), [TABLE\\_SCANS\\_RECEIVED](#), and [SCAN\\_ROWS\\_RETURNED](#) counters are associated with the [DBSPJ](#) (select push-down join) kernel block (see [The DBSPJ Block](#)).

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- [LQHKEY\\_OVERLOAD](#): Number of primary key requests rejected at the LQH block instance due to transporter overload
- [LQHKEY\\_OVERLOAD\\_TC](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where the TC node transporter was overloaded
- [LQHKEY\\_OVERLOAD\\_READER](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where the API reader (reads only) node was overloaded.
- [LQHKEY\\_OVERLOAD\\_NODE\\_PEER](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where the next backup data node (writes only) was overloaded
- [LQHKEY\\_OVERLOAD\\_SUBSCRIBER](#): Count of instances of [LQHKEY\\_OVERLOAD](#) where a event subscriber (writes only) was overloaded.
- [LQHSCAN\\_SLOWDOWNS](#): Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

#### 20.5.10.10 The ndbinfo cpustat Table

The [cpustat](#) table provides per-thread CPU statistics gathered each second, for each thread running in the [NDB](#) kernel.

The following table provides information about the columns in the [cpustat](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name               | Type    | Description                                    |
|---------------------------|---------|--|
| <a href="#">node_id</a>   | integer | ID of the node where the the thread is running |
| <a href="#">thr_no</a>    | integer | Thread ID (specific to this node)              |
| <a href="#">OS_user</a>   | integer | OS user time                                   |
| <a href="#">OS_system</a> | integer | OS system time                                 |
| <a href="#">OS_idle</a>   | integer | OS idle time                                   |

| Column Name                     | Type    | Description             |
|---------------------------------|---------|-------------------------|
| <code>thread_exec</code>        | integer | Thread execution time   |
| <code>thread_sleeping</code>    | integer | Thread sleep time       |
| <code>thread_send</code>        | integer | Thread send time        |
| <code>thread_buffer_full</code> | integer | Thread buffer full time |
| <code>elapsed_time</code>       | integer | Elapsed time            |

This table was added in NDB 7.5.2.

#### 20.5.10.11 The ndbinfo cpustat\_50ms Table

The `cpustat_50ms` table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the NDB kernel.

Like `cpustat_1sec` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_50ms` provides 1 second of history.

The following table provides information about the columns in the `cpustat_50ms` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                   | Type    | Description                                |
|-------------------------------|---------|--|
| <code>node_id</code>          | integer | ID of the node where the thread is running |
| <code>thr_no</code>           | integer | Thread ID (specific to this node)          |
| <code>OS_user_time</code>     | integer | OS user time                               |
| <code>OS_system_time</code>   | integer | OS system time                             |
| <code>OS_idle_time</code>     | integer | OS idle time                               |
| <code>exec_time</code>        | integer | Thread execution time                      |
| <code>sleep_time</code>       | integer | Thread sleep time                          |
| <code>send_time</code>        | integer | Thread send time                           |
| <code>buffer_full_time</code> | integer | Thread buffer full time                    |
| <code>elapsed_time</code>     | integer | Elapsed time                               |

This table was added in NDB 7.5.2.

#### 20.5.10.12 The ndbinfo cpustat\_1sec Table

The `cpustat_1sec` table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like `cpustat_50ms` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpustat_1sec` provides 20 seconds of history.

The following table provides information about the columns in the `cpustat_1sec` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name               | Type    | Description                                |
|---------------------------|---------|--|
| <code>node_id</code>      | integer | ID of the node where the thread is running |
| <code>thr_no</code>       | integer | Thread ID (specific to this node)          |
| <code>OS_user_time</code> | integer | OS user time                               |

| Column Name                      | Type    | Description             |
|----------------------------------|---------|-------------------------|
| <a href="#">OS_system_time</a>   | integer | OS system time          |
| <a href="#">OS_idle_time</a>     | integer | OS idle time            |
| <a href="#">exec_time</a>        | integer | Thread execution time   |
| <a href="#">sleep_time</a>       | integer | Thread sleep time       |
| <a href="#">send_time</a>        | integer | Thread send time        |
| <a href="#">buffer_full_time</a> | integer | Thread buffer full time |
| <a href="#">elapsed_time</a>     | integer | Elapsed time            |

This table was added in NDB 7.5.2.

### 20.5.10.13 The ndbinfo cpustat\_20sec Table

The [cpustat\\_20sec](#) table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the [NDB](#) kernel.

Like [cpustat\\_50ms](#) and [cpustat\\_1sec](#), this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, [cpsustat\\_20sec](#) provides 400 seconds of history.

The following table provides information about the columns in the [cpustat\\_20sec](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                      | Type    | Description                                    |
|----------------------------------|---------|--|
| <a href="#">node_id</a>          | integer | ID of the node where the the thread is running |
| <a href="#">thr_no</a>           | integer | Thread ID (specific to this node)              |
| <a href="#">OS_user_time</a>     | integer | OS user time                                   |
| <a href="#">OS_system_time</a>   | integer | OS system time                                 |
| <a href="#">OS_idle_time</a>     | integer | OS idle time                                   |
| <a href="#">exec_time</a>        | integer | Thread execution time                          |
| <a href="#">sleep_time</a>       | integer | Thread sleep time                              |
| <a href="#">send_time</a>        | integer | Thread send time                               |
| <a href="#">buffer_full_time</a> | integer | Thread buffer full time                        |
| <a href="#">elapsed_time</a>     | integer | Elapsed time                                   |

This table was added in NDB 7.5.2.

### 20.5.10.14 The ndbinfo dict\_obj\_info Table

The [dict\\_obj\\_info](#) table provides information about [NDB](#) data dictionary ([DICT](#)) objects such as tables and indexes. (The [dict\\_obj\\_types](#) table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The following table provides information about the columns in the [dict\\_obj\\_info](#) table. For each column, the table shows the name, data type, and a brief description.

| Column Name             | Type    | Description  |
|-------------------------|---------|--|
| <a href="#">type</a>    | integer | Type of <a href="#">DICT</a> object; join on <a href="#">dict_obj_types</a> to obtain the name |
| <a href="#">id</a>      | integer | Object identifier  |
| <a href="#">version</a> | integer | Object version   |

| Column Name                  | Type    | Description   |
|------------------------------|---------|---|
| <code>state</code>           | integer | Object state  |
| <code>parent_obj_type</code> | integer | Parent object's type (a <code>dict_obj_types</code> type ID); 0 indicates that the object has no parent   |
| <code>parent_obj_id</code>   | integer | Parent object ID (such as a base table); 0 indicates that the object has no parent  |
| <code>fq_name</code>         | string  | Fully qualified object name; for a table, this has the form <code>database_name/def/table_name</code> , for a primary key, the form is <code>sys/def/table_id/PRIMARY</code> , and for a unique key it is <code>sys/def/table_id/uk_name\$unique</code> |

This table was added in NDB 7.5.4.

#### 20.5.10.15 The ndbinfo dict\_obj\_types Table

The `dict_obj_types` table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by `Object::Type` in the NDB API.

The following table provides information about the columns in the `dict_obj_types` table. For each column, the table shows the name, data type, and a brief description.

| Column Name            | Type    | Description               |
|------------------------|---------|---------------------------|
| <code>type_id</code>   | integer | The type ID for this type |
| <code>type_name</code> | string  | The name of this type     |

#### 20.5.10.16 The ndbinfo disk\_write\_speed\_base Table

The `disk_write_speed_base` table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the `disk_write_speed_base` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                           | Type    | Description  |
|---------------------------------------|---------|--|
| <code>node_id</code>                  | integer | Node ID of this node   |
| <code>thr_no</code>                   | integer | Thread ID of this LDM thread   |
| <code>millis_ago</code>               | integer | Milliseconds since this reporting period ended   |
| <code>millis_passed</code>            | integer | Milliseconds elapsed in this reporting period  |
| <code>backup_lcp_bytes_written</code> | integer | Number of bytes written to disk by local checkpoints and backup processes during this period |
| <code>redo_bytes_written</code>       | integer | Number of bytes written to REDO log during this period                                       |
| <code>target_disk_write_speed</code>  | integer | Actual speed of disk writes per LDM thread (base data)                                       |

#### 20.5.10.17 The ndbinfo disk\_write\_speed\_aggregate Table

The [disk\\_write\\_speed\\_aggregate](#) table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the [disk\\_write\\_speed\\_aggregate](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                         | Type    | Description   |
|-------------------------------------|---------|---|
| node_id                             | integer | Node ID of this node  |
| thr_no                              | integer | Thread ID of this LDM thread  |
| backup_lcp_speed_last_sec           | integer | Number of bytes written to disk by backup and LCP processes in the last second  |
| redo_speed_last_sec                 | integer | Number of bytes written to REDO log in the last second  |
| backup_lcp_speed_last_10sec         | integer | Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds                       |
| redo_speed_last_10sec               | integer | Number of bytes written to REDO log per second, averaged over the last 10 seconds   |
| std_dev_backup_lcp_speed_last_10sec | integer | Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds |
| std_dev_redo_speed_last_10sec       | integer | Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds                         |
| backup_lcp_speed_last_60sec         | integer | Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds                       |
| redo_speed_last_60sec               | integer | Number of bytes written to REDO log per second, averaged over the last 10 seconds   |
| std_dev_backup_lcp_speed_last_60sec | integer | Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds |
| std_dev_redo_speed_last_60sec       | integer | Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds                         |
| slowdowns_due_to_io_lag             | integer | Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag                                    |
| slowdowns_due_to_high_cpu           | integer | Number of seconds since last node start that disk writes were slowed due to high CPU usage                                      |
| disk_write_speed_set_to_min         | integer | Number of seconds since last node start that disk write speed was set to minimum  |
| current_target_disk_write_speed     | integer | Actual speed of disk writes per LDM thread (aggregated)   |

### 20.5.10.18 The ndbinfo disk\_write\_speed\_aggregate\_node Table

The [disk\\_write\\_speed\\_aggregate\\_node](#) table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the [disk\\_write\\_speed\\_aggregate\\_node](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                 | Type    | Description   |
|-----------------------------|---------|---|
| node_id                     | integer | Node ID of this node  |
| backup_lcp_speed_last_sec   | numeric | Number of bytes written to disk by backup and LCP processes in the last second                            |
| redo_speed_last_sec         | numeric | Number of bytes written to REDO log in the last second  |
| backup_lcp_speed_last_10sec | numeric | Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds |
| redo_speed_last_10sec       | numeric | Number of bytes written to REDO log per second, averaged over the last 10 seconds                         |
| backup_lcp_speed_last_60sec | numeric | Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds |
| redo_speed_last_60sec       | numeric | Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds |

### 20.5.10.19 The ndbinfo diskpagebuffer Table

The [diskpagebuffer](#) table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The following table provides information about the columns in the [diskpagebuffer](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                                 | Type    | Description   |
|---|---------|---|
| <a href="#">node_id</a>                     | integer | The data node ID  |
| <a href="#">block_instance</a>              | integer | Block instance  |
| <a href="#">pages_written</a>               | integer | Number of pages written to disk.  |
| <a href="#">pages_written_lcp</a>           | integer | Number of pages written by local checkpoints.                               |
| <a href="#">pages_read</a>                  | integer | Number of pages read from disk  |
| <a href="#">log_waits</a>                   | integer | Number of page writes waiting for log to be written to disk                 |
| <a href="#">page_requests_direct_return</a> | integer | Number of requests for pages that were available in buffer                  |
| <a href="#">page_requests_wait_queue</a>    | integer | Number of requests that had to wait for pages to become available in buffer |

| Column Name                        | Type    | Description  |
|------------------------------------|---------|--|
| <code>page_requests_wait_io</code> | integer | Number of requests that had to be read from pages on disk (pages were unavailable in buffer) |

You can use this table with NDB Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
    AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+-----+-----+
| node_id | hit_ratio |
+-----+-----+
|      5 | 97.6744 |
|      6 | 97.6879 |
|      7 | 98.1776 |
|      8 | 98.1343 |
+-----+-----+
4 rows in set (0.00 sec)
```

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

#### Note

A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

### 20.5.10.20 The ndbinfo locks\_per\_fragment Table

The `locks_per_fragment` table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to `operations_per_fragment` and `memory_per_fragment`. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The following table provides information about the columns in the `locks_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                 | Type    | Description                              |
|-----------------------------|---------|--|
| <code>fq_name</code>        | string  | Fully qualified table name               |
| <code>parent_fq_name</code> | string  | Fully qualified name of parent object    |
| <code>type</code>           | string  | Table type; see text for possible values |
| <code>table_id</code>       | integer | Table ID                                 |

| Column Name                   | Type    | Description   |
|-------------------------------|---------|---|
| <code>node_id</code>          | integer | Reporting node ID   |
| <code>block_instance</code>   | integer | LDM instance ID   |
| <code>fragment_num</code>     | integer | Fragment identifier   |
| <code>ex_req</code>           | integer | Exclusive lock requests started   |
| <code>ex_imm_ok</code>        | integer | Exclusive lock requests immediately granted                             |
| <code>ex_wait_ok</code>       | integer | Exclusive lock requests granted following wait                          |
| <code>ex_wait_fail</code>     | integer | Exclusive lock requests not granted                                     |
| <code>sh_req</code>           | integer | Shared lock requests started  |
| <code>sh_imm_ok</code>        | integer | Shared lock requests immediately granted                                |
| <code>sh_wait_ok</code>       | integer | Shared lock requests granted following wait                             |
| <code>sh_wait_fail</code>     | integer | Shared lock requests not granted  |
| <code>wait_ok_millis</code>   | integer | Time spent waiting for lock requests that were granted, in milliseconds |
| <code>wait_fail_millis</code> | integer | Time spent waiting for lock requests that failed, in milliseconds       |

`fq_name` is a fully qualified database object name in `database/schema/name` format, such as `test/def/t1` or `sys/def/10/b$unique`.

`parent_fq_name` is the fully qualified name of this object's parent object (table).

`table_id` is the table's internal ID generated by NDB. This is the same internal table ID shown in other ndbinfo tables; it is also visible in the output of `ndb_show_tables`.

The `type` column shows the type of table. This is always one of `System table`, `User table`, `Unique hash index`, `Hash index`, `Unique ordered index`, `Ordered index`, `Hash index trigger`, `Subscription trigger`, `Read only constraint`, `Index trigger`, `Reorganize trigger`, `Tablespace`, `Log file group`, `Data file`, `Undo file`, `Hash map`, `Foreign key definition`, `Foreign key parent trigger`, `Foreign key child trigger`, or `Schema transaction`.

The values shown in all of the columns `ex_req`, `ex_req_imm_ok`, `ex_wait_ok`, `ex_wait_fail`, `sh_req`, `sh_req_imm_ok`, `sh_wait_ok`, and `sh_wait_fail` represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the `wait_ok_millis` and `wait_fail_millis` columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

```
ex_req >= (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)
sh_req >= (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

```
[exclusive lock requests in progress] =
  ex_req - (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)

[shared lock requests in progress] =
  sh_req - (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

```
[aborts while waiting for locks] = ex_wait_fail + sh_wait_fail
```

The `locks_per_fragment` table was added in NDB 7.5.3.

### 20.5.10.21 The ndbinfo logbuffers Table

The `logbuffer` table provides information on NDB Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

| Column Name           | Type    | Description  |
|-----------------------|---------|--|
| <code>node_id</code>  | integer | The ID of this data node.  |
| <code>log_type</code> | string  | Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> . |
| <code>log_id</code>   | integer | The log ID.  |
| <code>log_part</code> | integer | The log part number.   |
| <code>total</code>    | integer | Total space available for this log.                              |
| <code>used</code>     | integer | Space used by this log.  |

### 20.5.10.22 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

| Column Name           | Type    | Description  |
|-----------------------|---------|--|
| <code>node_id</code>  | integer | The ID of this data node.  |
| <code>log_type</code> | string  | Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> . |
| <code>log_id</code>   | integer | The log ID.  |
| <code>log_part</code> | integer | The log part number.   |
| <code>total</code>    | integer | Total space available for this log.                              |
| <code>used</code>     | integer | Space used by this log.  |

### 20.5.10.23 The ndbinfo membership Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The following table provides information about the columns in the `membership` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name             | Type    | Description                           |
|-------------------------|---------|---------------------------------------|
| <code>node_id</code>    | integer | This node's node ID                   |
| <code>group_id</code>   | integer | Node group to which this node belongs |
| <code>left_node</code>  | integer | Node ID of the previous node          |
| <code>right_node</code> | integer | Node ID of the next node              |
| <code>president</code>  | integer | President's node ID                   |

| Column Name                       | Type                   | Description                                      |
|-----------------------------------|------------------------|--|
| <code>successor</code>            | integer                | Node ID of successor to president                |
| <code>succession_order</code>     | integer                | Order in which this node succeeds to presidency  |
| <code>Conf_HB_order</code>        | integer                | -  |
| <code>arbitrator</code>           | integer                | Node ID of arbitrator                            |
| <code>arb_ticket</code>           | string                 | Internal identifier used to track arbitration    |
| <code>arb_state</code>            | Enumeration (see text) | Arbitration state                                |
| <code>arb_connected</code>        | Yes or No              | Whether this node is connected to the arbitrator |
| <code>connected_rank1_arbs</code> | List of node IDs       | Connected arbitrators of rank 1                  |
| <code>connected_rank2_arbs</code> | List of node IDs       | Connected arbitrators of rank 1                  |

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

**Figure 20.24 Circular Arrangement of NDB Cluster Nodes**

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id, left_node, right_node
-> FROM ndbinfo.membership;
```

| node_id | left_node | right_node |
|---------|-----------|------------|
| 5       | 15        | 6          |
| 6       | 5         | 7          |
| 7       | 6         | 8          |
| 8       | 7         | 12         |
| 12      | 8         | 13         |
| 13      | 12        | 14         |
| 14      | 13        | 15         |
| 15      | 14        | 5          |

8 rows in set (0.00 sec)

The designations “left” and “right” are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see [NDB Cluster Start Phases](#)). If the president fails or becomes disconnected, the current node

expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as 1 in the order of succession, the `successor` node should see itself as 2, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's `arbitorator`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` equal to 1, or to 2, respectively.

#### Note

Both management nodes and API nodes are eligible to become arbitrators.

### 20.5.10.24 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The following table provides information about the columns in the `memoryusage` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name              | Type    | Description   |
|--------------------------|---------|---|
| <code>node_id</code>     | integer | The node ID of this data node.  |
| <code>memory_type</code> | string  | One of <code>Data memory</code> , <code>Index memory</code> , or <code>Long message buffer</code> . |
| <code>used</code>        | integer | Number of bytes currently used for data memory or index memory by this data node.                   |
| <code>used_pages</code>  | integer | Number of pages currently used for data memory or index memory by this data node; see text.         |
| <code>total</code>       | integer | Total number of bytes of data memory or index memory available for this data node; see text.        |
| <code>total_pages</code> | integer | Total number of memory pages available for data memory or index memory on this data node; see text. |

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
```

| node_id | memory_type         | total      |
|---------|---------------------|------------|
| 5       | Data memory         | 1073741824 |
| 5       | Index memory        | 1074003968 |
| 5       | Long message buffer | 67108864   |
| 6       | Data memory         | 1073741824 |
| 6       | Index memory        | 1074003968 |
| 6       | Long message buffer | 67108864   |

```
6 rows in set (0.00 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

### 20.5.10.25 The ndbinfo memory\_per\_fragment Table

The `memory_per_fragment` table provides information about the usage of memory by individual fragments.

The following table provides information about the columns in the `memory_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                         | Type    | Description  |
|-------------------------------------|---------|--|
| <code>fq_name</code>                | string  | Name of this fragment  |
| <code>parent_fq_name</code>         | string  | Name of this fragment's parent                                 |
| <code>type</code>                   | string  | Type of object; see text for possible values                   |
| <code>table_id</code>               | integer | Table ID for this table  |
| <code>node_id</code>                | integer | Node ID for this node  |
| <code>block_instance</code>         | integer | Kernel block instance ID                                       |
| <code>fragment_num</code>           | integer | Fragment ID (number)   |
| <code>fixed_elem_alloc_bytes</code> | integer | Number of bytes allocated for fixed-sized elements             |
| <code>fixed_elem_free_bytes</code>  | integer | Free bytes remaining in pages allocated to fixed-size elements |
| <code>fixed_elem_size_bytes</code>  | integer | Length of each fixed-size element in bytes                     |
| <code>fixed_elem_count</code>       | integer | Number of fixed-size elements                                  |
| <code>fixed_elem_free_rows</code>   | decimal | Number of free rows for fixed-size elements                    |
| <code>var_elem_alloc_bytes</code>   | integer | Number of bytes allocated for variable-size elements           |

| Column Name            | Type    | Description   |
|------------------------|---------|---|
| var_elem_free_bytes    | integer | Free bytes remaining in pages allocated to variable-size elements |
| var_elem_count         | integer | Number of variable-size elements                                  |
| hash_index_alloc_bytes | integer | Number of bytes allocated to hash indexes                         |

The `type` column from this table shows the dictionary object type used for this fragment (`Object::Type`, in the NDB API), and can take any one of the values shown in the following list:

- System table
- User table
- Unique hash index
- Hash index
- Unique ordered index
- Ordered index
- Hash index trigger
- Subscription trigger
- Read only constraint
- Index trigger
- Reorganize trigger
- Tablespace
- Log file group
- Data file
- Undo file
- Hash map
- Foreign key definition
- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

#### 20.5.10.26 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                    | Type    | Description   |
|--------------------------------|---------|---|
| <code>node_id</code>           | integer | The data node's unique node ID in the cluster.                          |
| <code>uptime</code>            | integer | Time since the node was last started, in seconds.                       |
| <code>status</code>            | string  | Current status of the data node; see text for possible values.          |
| <code>start_phase</code>       | integer | If the data node is starting, the current start phase.                  |
| <code>config_generation</code> | integer | The version of the cluster configuration file in use on this data node. |

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtid` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a non-zero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see [Section 20.5.8, "NDB Cluster Single User Mode"](#)). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see [Section 20.5.2, "Commands in the NDB Cluster Management Client"](#)). If the node is not currently starting, then this column shows `0`. For a listing of NDB Cluster start phases with descriptions, see [Section 20.5.1, "Summary of NDB Cluster Start Phases"](#).

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (`6`) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
```

| node_id | uptime | status  | start_phase | config_generation |
|---------|--------|---------|-------------|-------------------|
| 1       | 10462  | STARTED | 0           | 6                 |
| 2       | 10460  | STARTED | 0           | 6                 |
| 3       | 10457  | STARTED | 0           | 5                 |
| 4       | 10455  | STARTED | 0           | 6                 |

```
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
```

```
mysql> SELECT * FROM nodes;
```

```
+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
|      1 | 11776 | STARTED |          0 |          6 |
|      2 | 11774 | STARTED |          0 |          6 |
|      3 | 11771 | STARTED |          0 |          6 |
|      4 | 11769 | STARTED |          0 |          6 |
+-----+-----+-----+-----+-----+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
```

```
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
```

```
+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
|      1 | 11807 | STARTED |          0 |          6 |
|      3 | 11802 | STARTED |          0 |          6 |
|      4 | 11800 | STARTED |          0 |          6 |
+-----+-----+-----+-----+-----+
3 rows in set (0.02 sec)
```

### 20.5.10.27 The ndbinfo operations\_per\_fragment Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The following table provides information about the columns in the `operations_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name     | Type    | Description   |
|-----------------|---------|---|
| fq_name         | string  | Name of this fragment                                 |
| parent_fq_name  | string  | Name of this fragment's parent                        |
| type            | string  | Type of object; see text for possible values          |
| table_id        | integer | Table ID for this table                               |
| node_id         | integer | Node ID for this node                                 |
| block_instance  | integer | Kernel block instance ID                              |
| fragment_num    | integer | Fragment ID (number)                                  |
| tot_key_reads   | integer | Total number of key reads for this fragment replica   |
| tot_key_inserts | integer | Total number of key inserts for this fragment replica |
| tot_key_updates | integer | total number of key updates for this fragment replica |
| tot_key_writes  | integer | Total number of key writes for this fragment replica  |
| tot_key_deletes | integer | Total number of key deletes for this fragment replica |

| Column Name             | Type    | Description   |
|-------------------------|---------|---|
| tot_key_refs            | integer | Number of key operations refused  |
| tot_key_attrinfo_bytes  | integer | Total size of all <a href="#">attrinfo</a> attributes                                 |
| tot_key_keyinfo_bytes   | integer | Total size of all <a href="#">keyinfo</a> attributes                                  |
| tot_key_prog_bytes      | integer | Total size of all interpreted programs carried by <a href="#">attrinfo</a> attributes |
| tot_key_inst_exec       | integer | Total number of instructions executed by interpreted programs for key operations      |
| tot_key_bytes_returned  | integer | Total size of all data and metadata returned from key read operations                 |
| tot_frag_scans          | integer | Total number of scans performed on this fragment replica                              |
| tot_scan_rows_examined  | integer | Total number of rows examined by scans  |
| tot_scan_rows_returned  | integer | Total number of rows returned to client   |
| tot_scan_bytes_returned | integer | Total size of data and metadata returned to the client                                |
| tot_scan_prog_bytes     | integer | Total size of interpreted programs for scan operations                                |
| tot_scan_bound_bytes    | integer | Total size of all bounds used in ordered index scans                                  |
| tot_scan_inst_exec      | integer | Total number of instructions executed for scans                                       |
| tot_qd_frag_scans       | integer | Number of times that scans of this fragment replica have been queued                  |
| conc_frag_scans         | integer | Number of scans currently active on this fragment replica (excluding queued scans)    |
| conc_qd_frag_scans      | integer | Number of scans currently queued for this fragment replica                            |
| tot_commits             | integer | Total number of row changes committed to this fragment replica                        |

The [fq\\_name](#) contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- Base table: - [DbName/def/TblName](#)
- BLOB table: - [DbName/def/NDB\\$BLOB\\_BaseTblId\\_ColNo](#)
- Ordered index: - [sys/def/BaseTblId/IndexName](#)
- Unique index: - [sys/def/BaseTblId/IndexName\\$unique](#)

The [\\$unique](#) suffix shown for unique indexes is added by [mysql](#); for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table [t1](#) created and modified by the following SQL statements:

```
CREATE DATABASE mydb;

USE mydb;

CREATE TABLE t1 (
  a INT NOT NULL,
  b INT NOT NULL,
  t TEXT NOT NULL,
  PRIMARY KEY (b)
) ENGINE=ndbcluster;

CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- Base table: `mydb/def/t1`
- BLOB table: `mydb/def/NDB$BLOB_11_2`
- Ordered index (primary key): `sys/def/11/PRIMARY`
- Unique index: `sys/def/11/ix1$unique`

For indexes or BLOB tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always `NULL`.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. BLOB tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. The first such instance is always numbered 0.

Since there are typically two replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since NDB does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

#### Note

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the NDB implementation of the `REPLACE` SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), `Key not found` errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an `LQHKEYREQ` signal (see [The NDB Communication Protocol](#)) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and BLOB tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can be limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a `LIMIT` or `EXISTS` clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the `DBSPJ` block in the NDB kernel.

`tot_qd_frag_scans` can be effected by the setting for the `MaxParallelScansPerFragment` data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

## 20.5.10.28 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the `resources` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                | Type    | Description  |
|----------------------------|---------|--|
| <code>node_id</code>       | integer | The unique node ID of this data node.                                      |
| <code>resource_name</code> | string  | Name of the resource; see text.  |
| <code>reserved</code>      | integer | The amount reserved for this resource.                                     |
| <code>used</code>          | integer | The amount actually used by this resource.                                 |
| <code>max</code>           | integer | The maximum amount of this resource used, since the node was last started. |

The `resource_name` can be one of the names shown in the following table:

| Resource name                    | Description   |
|----------------------------------|---|
| <code>RESERVED</code>            | Reserved by the system; cannot be overridden.   |
| <code>DISK_OPERATIONS</code>     | If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by <code>CREATE LOGFILE GROUP</code> .                               |
| <code>DISK_RECORDS</code>        | Records allocated for Disk Data operations.   |
| <code>DATA_MEMORY</code>         | Used for main memory tuples, indexes, and hash indexes. Sum of <code>DataMemory</code> and <code>IndexMemory</code> , plus 8 pages of 32 KB each if <code>IndexMemory</code> has been set. Cannot be overallocated.   |
| <code>JOBBUFFER</code>           | Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consumes several GB.   |
| <code>FILE_BUFFERS</code>        | Used by the redo log handler in the <code>DBLQH</code> kernel block; cannot be overallocated. Size is <code>NoOfFragmentLogParts * RedoBuffer</code> , plus 1 MB per log file part.   |
| <code>TRANSPORTER_BUFFERS</code> | Used for send buffers by <code>ndbmtd</code> ; the sum of <code>TotalSendBufferMemory</code> and <code>ExtraSendBufferMemory</code> . This resource that can be overallocated by up to 25 percent. <code>TotalSendBufferMemory</code> is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, |

| Resource name                       | Description  |
|-------------------------------------|--|
|                                     | in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. <a href="#">ExtraSendBufferMemory</a> is used by <a href="#">ndbmtd</a> and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, <a href="#">ExtraSendBufferMemory</a> is 10 * 2 MB. Overallocation of this resource can be performed by setting the <a href="#">SharedGlobalMemory</a> data node configuration parameter. |
| <a href="#">DISK_PAGE_BUFFER</a>    | Used for the disk page buffer; determined by the <a href="#">DiskPageBufferMemory</a> configuration parameter. Cannot be overallocated.  |
| <a href="#">QUERY_MEMORY</a>        | Used by the <a href="#">DBSPJ</a> kernel block.  |
| <a href="#">SCHEMA_TRANS_MEMORY</a> | Minimum is 2 MB; can be overallocated to use any remaining available memory.   |

### 20.5.10.29 The ndbinfo restart\_info Table

The [restart\\_info](#) table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The following table provides information about the columns in the [restart\\_info](#) table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name  | Type         | Description  |
|--|--------------|--|
| <a href="#">node_id</a>                                      | integer      | Node ID in the cluster   |
| <a href="#">node_restart_status</a>                          | VARCHAR(256) | Node status; see text for values. Each of these corresponds to a possible value of <a href="#">node_restart_status_int</a> . |
| <a href="#">node_restart_status_int</a>                      | integer      | Node status code; see text for values.   |
| <a href="#">secs_to_complete_node_failure</a>                | integer      | Time in seconds to complete node failure handling  |
| <a href="#">secs_to_allocate_node_id</a>                     | integer      | Time in seconds from node failure completion to allocation of node ID  |
| <a href="#">secs_to_include_in_heartbeat_protocol</a>        | integer      | Time in seconds from allocation of node ID to inclusion in heartbeat protocol  |
| <a href="#">secs_until_wait_for_ndbmaster</a>                | integer      | Time in seconds from being included in heartbeat protocol until waiting for <a href="#">NDBCNTR</a> master began             |
| <a href="#">secs_wait_for_ndbcntr_master</a>                 | integer      | Time in seconds spent waiting to be accepted by <a href="#">NDBCNTR</a> master for starting                                  |
| <a href="#">secs_to_get_start_permission</a>                 | integer      | Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node  |
| <a href="#">secs_to_wait_for_lcp_for_copy_meta_data</a>      | integer      | Time in seconds spent waiting for LCP completion before copying meta data  |
| <a href="#">secs_to_copy_meta_data</a>                       | integer      | Time in seconds required to copy metadata from master to newly starting node   |
| <a href="#">secs_to_include_node</a>                         | integer      | Time in seconds waited for GCP and inclusion of all nodes into protocols   |
| <a href="#">secs_starting_node_to_request_local_recovery</a> | integer      | Time in seconds that the node just starting spent waiting to request local recovery  |

| Column Name                                    | Type    | Description  |
|--|---------|--|
| <code>secs_for_local_recovery</code>           | integer | Time in seconds required for local recovery by node just starting                  |
| <code>secs_restore_fragments</code>            | integer | Time in seconds required to restore fragments from LCP files                       |
| <code>secs_undo_disk_data</code>               | integer | Time in seconds required to execute undo log on disk data part of records          |
| <code>secs_exec_redo_log</code>                | integer | Time in seconds required to execute redo log on all restored fragments             |
| <code>secs_index_rebuild</code>                | integer | Time in seconds required to rebuild indexes on restored fragments                  |
| <code>secs_to_synchronize_starting_node</code> | integer | Time in seconds required to synchronize starting node from live nodes              |
| <code>secs_wait_lcp_for_restart</code>         | integer | Time in seconds required for LCP start and completion before restart was completed |
| <code>secs_wait_subscription_handover</code>   | integer | Time in seconds spent waiting for handover of replication subscriptions            |
| <code>total_restart_secs</code>                | integer | Total number of seconds from node failure until node is started again              |

Defined values for `node_restart_status_int` and corresponding status names and messages (`node_restart_status`) are shown in the following table:

| <code>node_restart_status_int</code> value | Status                                   | Message ( <code>node_restart_status</code> )      |
|--|--|---|
| 0  | <code>ALLOCATED_NODE_ID</code>           | Allocated node id                                 |
| 1  | <code>INCLUDED_IN_HB_PROTOCOL</code>     | Included in heartbeat protocol                    |
| 2  | <code>NDBCNTR_START_WAIT</code>          | Wait for NDBCNTR master to permit us to start     |
| 3  | <code>NDBCNTR_STARTED</code>             | NDBCNTR master permitted us to start              |
| 4  | <code>START_PERMITTED</code>             | All nodes permitted us to start                   |
| 5  | <code>WAIT_LCP_TO_COPY_DICT</code>       | Wait for LCP completion to start copying metadata |
| 6  | <code>COPY_DICT_TO_STARTING_NODE</code>  | Copying metadata to starting node                 |
| 7  | <code>INCLUDE_NODE_IN_LCP_AND_GCP</code> | Include node in LCP and GCP protocols             |
| 8  | <code>LOCAL_RECOVERY_START</code>        | Restore fragments ongoing                         |
| 9  | <code>COPY_FRAGMENTS_START</code>        | Synchronizing starting node with live nodes       |
| 10   | <code>WAIT_LCP_FOR_RESTART</code>        | Wait for LCP to ensure durability                 |
| 11   | <code>WAIT_SUMA_HANDOVER</code>          | Wait for handover of subscriptions                |
| 12   | <code>RESTART_COMPLETED</code>           | Restart completed                                 |
| 13   | <code>NODE_FAILED</code>                 | Node failed, failure handling in progress         |
| 14   | <code>NODE_FAILURE_COMPLETED</code>      | Node failure handling completed                   |
| 15   | <code>NODE_GETTING_PERMITTED</code>      | All nodes permitted us to start                   |

| node_restart_status_int value | Status                   | Message (node_restart_status)               |
|-------------------------------|--------------------------|---|
| 16                            | NODE_GETTING_INCLUDED    | Include node in LCP and GCP protocols       |
| 17                            | NODE_GETTING_SYNCED      | Synchronizing starting node with live nodes |
| 18                            | NODE_GETTING_LCP_WAITING | [none]                                      |
| 19                            | NODE_ACTIVE              | Restart completed                           |
| 20                            | NOT_DEFINED_IN_CLUSTER   | [none]                                      |
| 21                            | NODE_NOT_RESTARTED_YET   | Initial state                               |

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also [Section 20.5.1, “Summary of NDB Cluster Start Phases”](#).

### 20.5.10.30 The ndbinfo server\_locks Table

The `server_locks` table is similar in structure to the `cluster_locks` table, and provides a subset of the information found in the latter table, but which is specific to the SQL node (MySQL server) where it resides. (The `cluster_locks` table provides information about all locks in the cluster.) More precisely, `server_locks` contains information about locks requested by threads belonging to the current `mysqld` instance, and serves as a companion table to `server_operations`. This may be useful for correlating locking patterns with specific MySQL user sessions, queries, or use cases.

The following table provides information about the columns in the `server_locks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                      | Type    | Description  |
|----------------------------------|---------|--|
| <code>mysql_connection_id</code> | integer | MySQL connection ID                                  |
| <code>node_id</code>             | integer | ID of reporting node                                 |
| <code>block_instance</code>      | integer | ID of reporting LDM instance                         |
| <code>tableid</code>             | integer | ID of table containing this row                      |
| <code>fragmentid</code>          | integer | ID of fragment containing locked row                 |
| <code>rowid</code>               | integer | ID of locked row                                     |
| <code>transid</code>             | integer | Transaction ID                                       |
| <code>mode</code>                | string  | Lock request mode                                    |
| <code>state</code>               | string  | Lock state   |
| <code>detail</code>              | string  | Whether this is first holding lock in row lock queue |
| <code>op</code>                  | string  | Operation type                                       |
| <code>duration_millis</code>     | integer | Milliseconds spent waiting or holding lock           |
| <code>lock_num</code>            | integer | ID of lock object                                    |
| <code>waiting_for</code>         | integer | Waiting for lock with this ID                        |

The `mysql_connection_id` column shows the MySQL connection or thread ID as shown by `SHOW PROCESSLIST`.

The `tableid` is assigned to the table by NDB; the same ID is used for this table in other `ndbinfo` tables, as well as in the output of `ndb_show_tables`.

The transaction ID shown in the `transid` column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode, which is always one of `S` (shared lock) or `X` (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

The `detail` column indicates whether this lock is the first holding lock in the affected row's lock queue, in which case it contains a `*` (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

If the `lock_state` column's value is `W`, this lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, `waiting_for` is empty. `waiting_for` can refer only to locks on the same row (as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`).

The `server_locks` table was added in NDB 7.5.3.

### 20.5.10.31 The ndbinfo server\_operations Table

The `server_operations` table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the `server_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                      | Type    | Description                                    |
|----------------------------------|---------|--|
| <code>mysql_connection_id</code> | integer | MySQL Server connection ID                     |
| <code>node_id</code>             | integer | Node ID  |
| <code>block_instance</code>      | integer | Block instance                                 |
| <code>transid</code>             | integer | Transaction ID                                 |
| <code>operation_type</code>      | string  | Operation type (see text for possible values)  |
| <code>state</code>               | string  | Operation state (see text for possible values) |
| <code>tableid</code>             | integer | Table ID                                       |
| <code>fragmentid</code>          | integer | Fragment ID                                    |
| <code>client_node_id</code>      | integer | Client node ID                                 |
| <code>client_block_ref</code>    | integer | Client block reference                         |
| <code>tc_node_id</code>          | integer | Transaction coordinator node ID                |
| <code>tc_block_no</code>         | integer | Transaction coordinator block number           |
| <code>tc_block_instance</code>   | integer | Transaction coordinator block instance         |

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblg_h_tconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

### 20.5.10.32 The ndbinfo server\_transactions Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The following table provides information about the columns in the `server_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                         | Type    | Description   |
|-------------------------------------|---------|---|
| <code>mysql_connection_id</code>    | integer | MySQL Server connection ID  |
| <code>node_id</code>                | integer | Transaction coordinator node ID   |
| <code>block_instance</code>         | integer | Transaction coordinator block instance                                      |
| <code>transid</code>                | integer | Transaction ID  |
| <code>state</code>                  | string  | Operation state (see text for possible values)                              |
| <code>count_operations</code>       | integer | Number of stateful operations in the transaction                            |
| <code>outstanding_operations</code> | integer | Operations still being executed by local data management layer (LQH blocks) |
| <code>inactive_seconds</code>       | integer | Time spent waiting for API  |
| <code>client_node_id</code>         | integer | Client node ID  |
| <code>client_block_ref</code>       | integer | Client block reference  |

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

### 20.5.10.33 The ndbinfo table\_distribution\_status Table

The `table_distribution_status` table provides information about the progress of table distribution for NDB tables.

The following table provides information about the columns in `table_distribution_status`. For each column, the table shows the name, data type, and a brief description.

| Column Name                    | Type    | Description   |
|--------------------------------|---------|---|
| <code>node_id</code>           | integer | Node id   |
| <code>table_id</code>          | integer | Table ID  |
| <code>tab_copy_status</code>   | string  | Status of copying of table distribution data to disk; one of <code>IDLE</code> , <code>SR_PHASE1_READ_PAGES</code> , <code>SR_PHASE2_READ_TABLE</code> , <code>SR_PHASE3_COPY_TABLE</code> , <code>REMOVE_NODE</code> , <code>LCP_READ_TABLE</code> , <code>COPY_TAB_REQ</code> , <code>COPY_NODE_STATE</code> , <code>ADD_TABLE_MASTER</code> , <code>ADD_TABLE_SLAVE</code> , <code>INVALIDATE_NODE_LCP</code> , <code>ALTER_TABLE</code> , <code>COPY_TO_SAVE</code> , or <code>GET_TABINFO</code> |
| <code>tab_update_status</code> | string  | Status of updating of table distribution data; one of <code>IDLE</code> , <code>LOCAL_CHECKPOINT</code> , <code>LOCAL_CHECKPOINT_QUEUED</code> , <code>REMOVE_NODE</code> , <code>COPY_TAB_REQ</code> , <code>ADD_TABLE_MASTER</code> , <code>ADD_TABLE_SLAVE</code> , <code>INVALIDATE_NODE_LCP</code> , or <code>CALLBACK</code>  |
| <code>tab_lcp_status</code>    | string  | Status of table LCP; one of <code>ACTIVE</code> (waiting for local checkpoint to be performed), <code>WRITING_TO_FILE</code> (checkpoint performed but not yet written to disk), or <code>COMPLETED</code> (checkpoint performed and persisted to disk)   |
| <code>tab_status</code>        | string  | Table internal status; one of <code>ACTIVE</code> (table exists), <code>CREATING</code> (table is being created), or <code>DROPPING</code> (table is being dropped)   |
| <code>tab_storage</code>       | string  | Table recoverability; one of <code>NORMAL</code> (fully recoverable with redo logging and checkpointing), <code>NOLOGGING</code> (recoverable   |

| Column Name                     | Type    | Description   |
|---------------------------------|---------|---|
|                                 |         | from node crash, empty following cluster crash), or <code>TEMPORARY</code> (not recoverable)  |
| <code>tab_partitions</code>     | integer | Number of partitions in table   |
| <code>tab_fragments</code>      | integer | Number of fragments in table; normally same as <code>tab_partitions</code> ; for fully replicated tables equal to <code>tab_partitions * [number of node groups]</code> |
| <code>current_scan_count</code> | integer | Current number of active scans  |
| <code>scan_count_wait</code>    | integer | Current number of scans waiting to be performed before <code>ALTER TABLE</code> can complete.   |
| <code>is_reorg_ongoing</code>   | integer | Whether table is currently being reorganized (1 if true)  |

The `table_distribution_status` table was added in NDB 7.5.4.

#### 20.5.10.34 The ndbinfo table\_fragments Table

The `table_fragments` table provides information about the fragmentation, partitioning, distribution, and (internal) replication of NDB tables.

The following table provides information about the columns in `table_fragments`. For each column, the table shows the name, data type, and a brief description.

| Column Name                        | Type    | Description   |
|------------------------------------|---------|---|
| <code>node_id</code>               | integer | Node ID ( <code>DIH</code> master)                                  |
| <code>table_id</code>              | integer | Table ID  |
| <code>partition_id</code>          | integer | Partition ID  |
| <code>fragment_id</code>           | integer | Fragment ID (same as partition ID unless table is fully replicated) |
| <code>partition_order</code>       | integer | Order of fragment in partition                                      |
| <code>log_part_id</code>           | integer | Log part ID of fragment   |
| <code>no_of_replicas</code>        | integer | Number of replicas  |
| <code>current_primary</code>       | integer | Current primary node ID   |
| <code>preferred_primary</code>     | integer | Preferred primary node ID   |
| <code>current_first_backup</code>  | integer | Current first backup node ID  |
| <code>current_second_backup</code> | integer | Current second backup node ID                                       |
| <code>current_third_backup</code>  | integer | Current third backup node ID  |
| <code>num_alive_replicas</code>    | integer | Current number of live replicas                                     |
| <code>num_dead_replicas</code>     | integer | Current number of dead replicas                                     |
| <code>num_lcp_replicas</code>      | integer | Number of replicas remaining to be checkpointed                     |

The `table_fragments` table was added in NDB 7.5.4.

#### 20.5.10.35 The ndbinfo table\_info Table

The `table_info` table provides information about logging, checkpointing, distribution, and storage options in effect for individual NDB tables.

The following table provides information about the columns in `table_info`. For each column, the table shows the name, data type, and a brief description.

| Column Name                        | Type    | Description   |
|------------------------------------|---------|---|
| <code>table_id</code>              | integer | Table ID  |
| <code>logged_table</code>          | integer | Whether table is logged (1) or not (0)  |
| <code>row_contains_gci</code>      | integer | Whether table rows contain GCI (1 true, 0 false)  |
| <code>row_contains_checksum</code> | integer | Whether table rows contain checksum (1 true, 0 false)   |
| <code>read_backup</code>           | integer | If backup replicas are read this is 1, otherwise 0  |
| <code>fully_replicated</code>      | integer | If table is fully replicated this is 1, otherwise 0   |
| <code>storage_type</code>          | string  | Table storage type; one of <code>MEMORY</code> or <code>DISK</code>   |
| <code>hashmap_id</code>            | integer | Hashmap ID  |
| <code>partition_balance</code>     | string  | Partition balance (fragment count type) used for table; one of <code>FOR_RP_BY_NODE</code> , <code>FOR_RA_BY_NODE</code> , <code>FOR_RP_BY_LDM</code> , or <code>FOR_RA_BY_LDM</code> |
| <code>create_gci</code>            | integer | GCI in which table was created  |

The `table_info` table was added in NDB 7.5.4.

### 20.5.10.36 The ndbinfo table\_replicas Table

The `table_replicas` table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The following table provides information about the columns in `table_replicas`. For each column, the table shows the name, data type, and a brief description.

| Column Name                         | Type    | Description  |
|-------------------------------------|---------|--|
| <code>node_id</code>                | integer | ID of the node from which data is fetched ( <code>DIH</code> master) |
| <code>table_id</code>               | integer | Table ID   |
| <code>fragment_id</code>            | integer | Fragment ID  |
| <code>initial_gci</code>            | integer | Initial GCI for table  |
| <code>replica_node_id</code>        | integer | ID of node where replica is stored                                   |
| <code>is_lcp_ongoing</code>         | integer | Is 1 if LCP is ongoing on this fragment, 0 otherwise                 |
| <code>num_crashed_replicas</code>   | integer | Number of crashed replica instances                                  |
| <code>last_max_gci_started</code>   | integer | Highest GCI started in most recent LCP                               |
| <code>last_max_gci_completed</code> | integer | Highest GCI completed in most recent LCP                             |
| <code>last_lcp_id</code>            | integer | ID of most recent LCP  |
| <code>prev_lcp_id</code>            | integer | ID of previous LCP   |
| <code>prev_max_gci_started</code>   | integer | Highest GCI started in previous LCP                                  |
| <code>prev_max_gci_completed</code> | integer | Highest GCI completed in previous LCP                                |
| <code>last_create_gci</code>        | integer | Last Create GCI of last crashed replica instance                     |

| Column Name                   | Type    | Description                               |
|-------------------------------|---------|---|
| <code>last_replica_gci</code> | integer | Last GCI of last crashed replica instance |
| <code>is_replica_alive</code> | integer | 1 if this replica is alive, 0 otherwise   |

The `table_replicas` table was added in NDB 7.5.4.

### 20.5.10.37 The ndbinfo tc\_time\_track\_stats Table

The `tc_time_track_stats` table provides time-tracking information obtained from the `DBTC` block (TC) instances in the data nodes, through API nodes access `NDB`. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. `tc_time_track_stats` presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The following table provides information about the columns in `tc_time_track_stats`. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                       | Type    | Description  |
|-----------------------------------|---------|--|
| <code>node_id</code>              | integer | Requesting node ID   |
| <code>block_number</code>         | integer | TC block number  |
| <code>block_instance</code>       | integer | TC block instance number   |
| <code>comm_node_id</code>         | integer | Node ID of communicating API or data node  |
| <code>upper_bound</code>          | integer | Upper bound of interval (in microseconds)  |
| <code>scans</code>                | integer | Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.                        |
| <code>scan_errors</code>          | integer | Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.                            |
| <code>scan_fragments</code>       | integer | Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them                        |
| <code>scan_fragment_errors</code> | integer | Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them                            |
| <code>transactions</code>         | integer | Based on duration of successful transactions from beginning until sending of commit <code>ACK</code> , tracked against the API or data nodes |

| Column Name                     | Type    | Description  |
|---------------------------------|---------|--|
|                                 |         | requesting them. Stateless transactions are not included.  |
| <code>transaction_errors</code> | integer | Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.   |
| <code>read_key_ops</code>       | integer | Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.                |
| <code>write_key_ops</code>      | integer | Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.                          |
| <code>index_key_ops</code>      | integer | Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables. |
| <code>key_op_errors</code>      | integer | Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.          |

### 20.5.10.38 The ndbinfo threadblocks Table

The `threadblocks` table associates data nodes, threads, and instances of NDB kernel blocks.

The following table provides information about the columns in the `threadblocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                 | Type    | Description           |
|-----------------------------|---------|-----------------------|
| <code>node_id</code>        | integer | Node ID               |
| <code>thr_no</code>         | integer | Thread ID             |
| <code>block_name</code>     | string  | Block name            |
| <code>block_instance</code> | integer | Block instance number |

The `block_name` is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

### 20.5.10.39 The ndbinfo threads Table

The `threads` table provides information about threads running in the NDB kernel.

The following table provides information about the columns in the `threads` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name              | Type    | Description                                |
|--------------------------|---------|--|
| <code>node_id</code>     | integer | ID of the node where the thread is running |
| <code>thr_no</code>      | integer | Thread ID (specific to this node)          |
| <code>thread_name</code> | string  | Thread name (type of thread)               |

| Column Name                     | Type   | Description               |
|---------------------------------|--------|---------------------------|
| <code>thread_description</code> | string | Thread (type) description |

Sample output from a 2-node example cluster, including thread descriptions, is shown here:

```
mysql> SELECT * FROM threads;
```

| node_id | thr_no | thread_name | thread_description  |
|---------|--------|-------------|---|
| 5       | 0      | main        | main thread, schema and distribution handling                   |
| 5       | 1      | rep         | rep thread, asynch replication and proxy block handling         |
| 5       | 2      | ldm         | ldm thread, handling a set of data partitions                   |
| 5       | 3      | recv        | receive thread, performing receive and polling for new receives |
| 6       | 0      | main        | main thread, schema and distribution handling                   |
| 6       | 1      | rep         | rep thread, asynch replication and proxy block handling         |
| 6       | 2      | ldm         | ldm thread, handling a set of data partitions                   |
| 6       | 3      | recv        | receive thread, performing receive and polling for new receives |

8 rows in set (0.01 sec)

This table was added in NDB 7.5.2.

## 20.5.10.40 The ndbinfo threadstat Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the NDB kernel.

The following table provides information about the columns in the `threadstat` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                 | Type    | Description                                      |
|-----------------------------|---------|--|
| <code>node_id</code>        | integer | Node ID  |
| <code>thr_no</code>         | integer | Thread ID  |
| <code>thr_nm</code>         | string  | Thread name                                      |
| <code>c_loop</code>         | string  | Number of loops in main loop                     |
| <code>c_exec</code>         | string  | Number of signals executed                       |
| <code>c_wait</code>         | string  | Number of times waiting for additional input     |
| <code>c_l_sent_prioa</code> | integer | Number of priority A signals sent to own node    |
| <code>c_l_sent_priob</code> | integer | Number of priority B signals sent to own node    |
| <code>c_r_sent_prioa</code> | integer | Number of priority A signals sent to remote node |
| <code>c_r_sent_priob</code> | integer | Number of priority B signals sent to remote node |
| <code>os_tid</code>         | integer | OS thread ID                                     |
| <code>os_now</code>         | integer | OS time (ms)                                     |
| <code>os_ru_utime</code>    | integer | OS user CPU time (µs)                            |
| <code>os_ru_stime</code>    | integer | OS system CPU time (µs)                          |
| <code>os_ru_minflt</code>   | integer | OS page reclaims (soft page faults)              |
| <code>os_ru_majflt</code>   | integer | OS page faults (hard page faults)                |
| <code>os_ru_nvcsw</code>    | integer | OS voluntary context switches                    |
| <code>os_ru_nivcsw</code>   | integer | OS involuntary context switches                  |

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see [Section 22.4, "Using the Event Scheduler"](#).

#### 20.5.10.41 The ndbinfo transporters Table

This table contains information about NDB transporters.

The following table provides information about the columns in the `transporters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name                 | Type    | Description   |
|-----------------------------|---------|---|
| <code>node_id</code>        | integer | This data node's unique node ID in the cluster.                                   |
| <code>remote_node_id</code> | integer | The remote data node's node ID.   |
| <code>status</code>         | string  | Status of the connection.   |
| <code>remote_address</code> | string  | Name or IP address of the remote host   |
| <code>bytes_sent</code>     | integer | Number of bytes sent using this connection  |
| <code>bytes_received</code> |         | Number of bytes received using this connection                                    |
| <code>connect_count</code>  |         | Number of times connection established on this transporter                        |
| <code>overloaded</code>     |         | 1 if this transporter is currently overloaded, otherwise 0                        |
| <code>overload_count</code> |         | Number of times this transporter has entered overload state since connecting      |
| <code>slowdown</code>       |         | 1 if this transporter is in scan slowdown state, otherwise 0                      |
| <code>slowdown_count</code> |         | Number of times this transporter has entered scan slowdown state since connecting |

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data nodes which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is `CONNECTING` or `DISCONNECTED`, these columns always display 0.

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_send`

and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @10.100.10.1 (5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=2 @10.100.10.2 (5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @10.100.10.10 (5.7.16-ndb-7.5.5)

[mysqld(API)] 2 node(s)
id=20 @10.100.10.20 (5.7.16-ndb-7.5.5)
id=21 @10.100.10.21 (5.7.16-ndb-7.5.5)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
+-----+-----+-----+
| node_id | remote_node_id | status |
+-----+-----+-----+
| 1 | 1 | DISCONNECTED |
| 1 | 2 | CONNECTED |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
| 2 | 1 | CONNECTED |
| 2 | 2 | DISCONNECTED |
| 2 | 10 | CONNECTED |
| 2 | 20 | CONNECTED |
| 2 | 21 | CONNECTED |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command `2 STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
+-----+-----+-----+
| node_id | remote_node_id | status |
+-----+-----+-----+
| 1 | 1 | DISCONNECTED |
| 1 | 2 | CONNECTING |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
+-----+-----+-----+
5 rows in set (0.02 sec)
```

## 20.5.11 INFORMATION\_SCHEMA Tables for NDB Cluster

Two `INFORMATION_SCHEMA` tables provide information that is of particular use when managing an NDB Cluster. The `FILES` table provides information about NDB Cluster Disk Data files. The

`ndb_transid_mysql_connection_map` table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. For information about these tables, see [Section 20.5.10, “The ndbinfo NDB Cluster Information Database”](#).

## 20.5.12 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster .

Topics covered in this section include the following:

- NDB Cluster and network security issues
- Configuration issues relating to running NDB Cluster securely
- NDB Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to NDB Cluster

### 20.5.12.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster . It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster . As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 20.5.12.2, “NDB Cluster and MySQL Privileges”](#), for more information about this and related issues.)

#### Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available [elsewhere in this chapter](#) about the `HostName` parameter. Also see [Section 20.3.1, “Quick Test Setup of NDB Cluster”](#), for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:

**Figure 20.25 NDB Cluster with Hardware Firewall**

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

#### Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 7.1.3, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

**Figure 20.26 NDB Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

| Type of Node to be Accessed  | Traffic to Permit  |
|------------------------------|--|
| SQL or API node              | <ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from within the network in which the cluster resides and is on the port that your application is using.</li> </ul> |
| Data node or Management node | <ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from the IP address of an SQL or API node.</li> </ul>  |

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to

implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 20.27 NDB Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

#### Note

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

### 20.5.12.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see [Section 20.5.15, “Distributed MySQL Privileges for NDB Cluster”](#), for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
- The host name or IP address of the NDB Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster --ndb-connectstring=management_host` and access this NDB Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all NDB databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all NDB tables in a given database
- Run any legal MySQL statements on any of the discovered tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table
  - `DELETE FROM some_table` to delete all the data from a table
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  - `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than [NDB](#), and so not visible to a “rogue” SQL node.

A user who can log in as [root](#) can also access the [INFORMATION\\_SCHEMA](#) database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in [INFORMATION\\_SCHEMA](#).

It is also a very good idea to use different passwords for the [root](#) accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

#### Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster .

If you wish to employ NDB Cluster 's distributed privilege capabilities, you should not simply convert the system tables in the [mysql](#) database to use the [NDB](#) storage engine manually. Use the stored procedure provided for this purpose instead; see [Section 20.5.15, “Distributed MySQL Privileges for NDB Cluster”](#).

Otherwise, if you need to synchronize [mysql](#) system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.
2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.
3. Once a MySQL user is granted privileges on an [NDB](#) table from one SQL node in an NDB Cluster , that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

### 20.5.12.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster .

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster . First and foremost, you should always run a MySQL Server as the [mysql](#) system user; this is no different from running MySQL in a standard (non-Cluster) environment. The [mysql](#) system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the [mysqld](#) process is running as the system user [mysql](#) by using the system command such as the one shown here:

```

shell> ps aux | grep mysql
root      10467  0.0  0.1  3616  1380 pts/3    S   11:53   0:00 \
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql     10512  0.2  2.5  58528 26636 pts/3    Sl  11:53   0:00 \
/usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
--datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
--ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
--log-error=/usr/local/mysql/var/mothra.err
jon       10579  0.0  0.0   2736   688 pts/0    S+  11:54   0:00 grep mysql

```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

### Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see [Section 20.5.12.2, “NDB Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```

shell> mysql -u root

mysql> UPDATE mysql.user
->     SET Password=PASSWORD('secure_password')
->     WHERE User='root';

mysql> DELETE FROM mysql.user
->     WHERE User='';

mysql> FLUSH PRIVILEGES;

```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

### Note

Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 20.4, “NDB Cluster Programs”](#), for more information about these utilities.

## 20.5.13 NDB Cluster Disk Data Tables

It is possible to store the nonindexed columns of `NDB` tables on disk, rather than in RAM.

As part of implementing NDB Cluster Disk Data work, a number of improvements were made in NDB Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and

restart. These include a “no-steal” algorithm for synchronizing a starting node with very large data sets. For more information, see the paper [Recovery Principles of NDB Cluster 5.1](#), by NDB Cluster developers Mikael Ronström and Jonas Orelund.

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [NDB Cluster Disk Data configuration parameters](#) and [NDB Cluster Disk Data storage and GCP Stop errors](#)

The performance of an NDB Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see [Section 20.5.13.2, “Using Symbolic Links with Disk Data Objects”](#).

### 20.5.13.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.
- *Undo log files* undo information required for rolling back transactions.
- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.
- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

NDB Cluster tablespaces and log file groups are not implemented as files.

#### Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

#### Note

Undo log files are necessary only for Disk Data tables; they are not used for `NDBCLUSTER` tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume

the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognisable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

#### Important

There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
  - `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
  - For more information about the `CREATE LOGFILE GROUP` statement, see [Section 14.1.15, “CREATE LOGFILE GROUP Syntax”](#). For more information about `ALTER LOGFILE GROUP`, see [Section 14.1.5, “ALTER LOGFILE GROUP Syntax”](#).
2. Now we can create a tablespace, which contains files to be used by NDB Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;
```

```
ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.
  - When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
  - All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For NDB Cluster tablespaces, the only permitted values for this option are `NDBCLUSTER` and `NDB`.
  - For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#), and [Section 14.1.9, “ALTER TABLESPACE Syntax”](#).
3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

#### Note

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 14.1.18, “CREATE TABLE Syntax”](#), for more information.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see [Section 20.5.13.2, “Using Symbolic Links with Disk Data Objects”](#), for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
-> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
-> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra “NULL row” provides additional information about undo log files. For more information and examples, see [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

It is also possible to view information about allocated and free disk space for each Disk Data table or table partition using the `ndb_desc` utility. For more information, see [Section 20.4.10, “ndb\\_desc — Describe NDB Tables”](#).

### 20.5.13.2 Using Symbolic Links with Disk Data Objects

The performance of an NDB Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. In early versions of NDB Cluster, there was no direct support for this in NDB Cluster, but it was possible to achieve this separation using symbolic links as described in this section. NDB Cluster supports the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`, which make the use of symbolic links for this purpose unnecessary. For more information about these parameters, see [Disk Data file system parameters](#).

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

#### Note

In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute your operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

```
shell> cd /data0/ndb_2_fs
shell> ls
D1 D10 D11 D2 D8 D9 LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata
```

You should now have two symbolic links:

```
shell> ls -l --hide=D*
lrwxrwxrwx 1 user group 30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group 30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'dnlogs/undo1.log'
-> INITIAL_SIZE 150M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'dndata/data1.log'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 1G
-> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```

shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 1073741824 2007-03-19 14:02 data1.dat

```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using `/data0` for both data node file systems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do something similar to what is shown here:

```

shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ln -s /data1/dn3 ndb_3_fs/dd
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn3

```

- Now you can create a logfile group and tablespace using the symbolic link, like this:

```

mysql> CREATE LOGFILE GROUP lg1
->     ADD UNDOFILE 'dd/undo1.log'
->     INITIAL_SIZE 150M
->     UNDO_BUFFER_SIZE = 1M
->     ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
->     ADD DATAFILE 'dd/data1.log'
->     USE LOGFILE GROUP lg1
->     INITIAL_SIZE 1G
->     ENGINE=NDBCLUSTER;

```

Verify that the files were created and placed correctly as shown here:

```

shell> cd /data1
shell> ls
dn2      dn3
shell> ls dn2
undo1.log      data1.log
shell> ls dn3
undo1.log      data1.log

```

### 20.5.13.3 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 12.8, “Data Type Storage Requirements”](#).

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

**Note**

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

**Important**

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

## 20.5.14 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

**Important**

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

### 20.5.14.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued

while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

**Failure handling.** Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

| Failure occurs during: | Failure occurs in:  |   |   |
|------------------------|---|---|---|
|                        | “Old” data nodes  | “New” data nodes  | System  |
| Node group creation    | <ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b><br/>The creation of the node group is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b><br/>The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul> | <ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b><br/>The creation of the node group is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b><br/>The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul> | <ul style="list-style-type: none"> <li>• <b>If the execution of CREATE NODEGROUP has reached the internal commit point:</b><br/>When restarted, the cluster includes the new node group. Otherwise it without.</li> <li>• <b>If the execution of CREATE NODEGROUP has not yet reached the internal commit point:</b> When restarted, the cluster does not include the new node group.</li> </ul>  |
| Table reorganization   | <ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>                          | <ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>                          | <ul style="list-style-type: none"> <li>• <b>If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the internal commit point:</b><br/>When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using the “new” data nodes.</li> <li>• <b>If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point:</b> When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes.</li> </ul> |

**Dropping node groups.** The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

### 20.5.14.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster . This procedure applies whether you are using `ndbd` or `ndbmtbd` binaries for the data node processes. For a more detailed example, see [Section 20.5.14.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”](#).

Assuming that you already have a running NDB Cluster , adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

#### Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster .
5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes will belong.
7. Redistribute the cluster's data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table. *Exception:* For tables created using the `MAX_ROWS`

option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables.

#### Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. Reclaim the space freed on the “old” nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

### 20.5.14.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.** For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

#### Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
```

## Cluster Configuration

```
-----
[ndbd(NDB)]      2 node(s)
id=1      @192.168.0.1  (5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=2      @192.168.0.2  (5.7.16-ndb-7.5.5, Nodegroup: 0)

[ndb_mgmd(MGM)]  1 node(s)
id=10     @192.168.0.10 (5.7.16-ndb-7.5.5)

[mysqld(API)]    2 node(s)
id=20     @192.168.0.20 (5.7.16-ndb-7.5.5)
id=21     @192.168.0.21 (5.7.16-ndb-7.5.5)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  country_code CHAR(2) NOT NULL,
  type CHAR(4) NOT NULL,
  ip_address varchar(15) NOT NULL,
  addresses BIGINT UNSIGNED DEFAULT NULL,
  date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

**Note**

In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the multi-threaded `ndbmt` by substituting `ndbmt` for `ndbd` wherever it appears in the steps that follow.

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10
```

```
[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

shell>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO      -- NDB Cluster Management Server. 5.7.16-ndb-7.5.5
2008-12-08 17:29:23 [MgmSrvr] INFO      -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1      @192.168.0.1  (5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=2      @192.168.0.2  (5.7.16-ndb-7.5.5, Nodegroup: 0)
id=3 (not connected, accepting connect from 192.168.0.3)
id=4 (not connected, accepting connect from 192.168.0.4)

[ndb_mgmd(MGM)]  1 node(s)
id=10     @192.168.0.10 (5.7.16-ndb-7.5.5)

[mysqld(API)]    2 node(s)
id=20     @192.168.0.20 (5.7.16-ndb-7.5.5)
id=21     @192.168.0.21 (5.7.16-ndb-7.5.5)
```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.5.5)
Node 1: Started (version 7.5.5)
```

```

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.5.5)

ndb_mgm> Node 2: Started (version 7.5.5)

```

### Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```

shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var

```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```

shell> ndbd -c 192.168.0.10 --initial

```

### Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step.* Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold text here):

```

ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=2 @192.168.0.2 (5.7.16-ndb-7.5.5, Nodegroup: 0)
id=3 @192.168.0.3 (5.7.16-ndb-7.5.5, no nodegroup)
id=4 @192.168.0.4 (5.7.16-ndb-7.5.5, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.7.16-ndb-7.5.5)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.7.16-ndb-7.5.5)

```

```
id=21 @192.168.0.21 (5.7.16-ndb-7.5.5)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.7.16-ndb-7.5.5, Nodegroup: 0, *)
id=2 @192.168.0.2 (5.7.16-ndb-7.5.5, Nodegroup: 0)
id=3 @192.168.0.3 (5.7.16-ndb-7.5.5, Nodegroup: 1)
id=4 @192.168.0.4 (5.7.16-ndb-7.5.5, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.7.16-ndb-7.5.5)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.7.16-ndb-7.5.5)
id=21 @192.168.0.21 (5.7.16-ndb-7.5.5)
```

**Step 7: Redistribute cluster data.** When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
```

```

id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag varsize memory
0          26086      26086         1572864            557056
1          26329      26329         1605632            557056

NDBT_ProgramExit: 0 - OK

```

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an `ALTER TABLE ... ALGORITHM=INPLACE REORGANIZE PARTITION` statement in the `mysql` client.

### Important

`ALTER TABLE ... ALGORITHM=INPLACE REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```

shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 341
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 4

NDBT\_ProgramExit: 0 - OK

### Note

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see [Section 14.1.8, “ALTER TABLE Syntax”](#).

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
  FROM INFORMATION_SCHEMA.TABLES
 WHERE ENGINE = 'NDBCLUSTER';
```

### Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY
```

```
Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

### Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior* to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.** It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndb default]
```

```

DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 192.168.0.4
Nodegroup = 65536

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21

```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 192.168.0.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

#### Note

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 192.168.0.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

## 20.5.15 Distributed MySQL Privileges for NDB Cluster

NDB Cluster supports distribution of MySQL users and privileges across all SQL nodes in an NDB Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. An SQL file `ndb_dist_priv.sql` provided with the NDB Cluster distribution can be found in the `share` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where *options* stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL `root` user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
-> FROM INFORMATION_SCHEMA.ROUTINES
-> WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
-> ORDER BY ROUTINE_TYPE;
```

| ROUTINE_NAME                                | ROUTINE_SCHEMA | ROUTINE_TYPE |
|---|----------------|--------------|
| mysql_cluster_privileges_are_distributed    | mysql          | FUNCTION     |
| mysql_cluster_backup_privileges             | mysql          | PROCEDURE    |
| mysql_cluster_move_grant_tables             | mysql          | PROCEDURE    |
| mysql_cluster_move_privileges               | mysql          | PROCEDURE    |
| mysql_cluster_restore_local_privileges      | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges            | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges_from_local | mysql          | PROCEDURE    |

7 rows in set (0.01 sec)

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to `NDB`.

`mysql_cluster_move_privileges` performs the backup and conversion in two steps. The first step is to call `mysql_cluster_backup_privileges`, which creates two sets of copies in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine. Their names are generated by adding the suffix `_backup` to the original privilege table names.
- A set of distributed copies that use the `NDBCLUSTER` storage engine. These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

After the copies are created, `mysql_cluster_move_privileges` invokes `mysql_cluster_move_grant_tables`, which contains the `ALTER TABLE ... ENGINE = NDB` statements that convert the `mysql` system tables to `NDB`.

Normally, you should not invoke either `mysql_cluster_backup_privileges` or `mysql_cluster_move_grant_tables` manually; these stored procedures are intended only for use by `mysql_cluster_move_privileges`.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
mysql user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT(
-> 'Conversion ',
-> IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
-> '.')
-> AS Result;
+-----+
| Result |
+-----+
| Conversion succeeded. |
+-----+
1 row in set (0.00 sec)
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns `1` if all of the privilege tables are distributed; otherwise, it returns `0`.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
-> ORDER BY ENGINE;
+-----+-----+
| TABLE_NAME | ENGINE |
+-----+-----+
| host_backup | MyISAM |
| db_backup | MyISAM |
| columns_priv_backup | MyISAM |
| user_backup | MyISAM |
| tables_priv_backup | MyISAM |
| proxies_priv_backup | MyISAM |
| procs_priv_backup | MyISAM |
| ndb_user_backup | ndbcluster |
| ndb_tables_priv_backup | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup | ndbcluster |
| ndb_host_backup | ndbcluster |
| ndb_db_backup | ndbcluster |
| ndb_columns_priv_backup | ndbcluster |
+-----+-----+
14 rows in set (0.00 sec)
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

**Note**

For clients connected to SQL nodes at the time that `mysql_cluster_move_privileges` is executed, you may need to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes any privileges associated with views and stored routines, even though distribution of views and stored routines themselves is not currently supported.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` from a backup made using `START BACKUP` in the `ndb_mgm` client. (The `MyISAM` tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` option causes it to do so.

You can restore the SQL node's local privileges using either of two procedures. `mysql_cluster_restore_privileges` works as follows:

1. If copies of the `mysql.ndb_*_backup` tables are available, attempt to restore the system tables from these.
2. Otherwise, attempt to restore the system tables from the local backups named `*_backup` (without the `ndb_` prefix).

The other procedure, named `mysql_cluster_restore_local_privileges`, restores the system tables from the local backups only, without checking the `ndb_*` backups.

The system tables re-created by `mysql_cluster_restore_privileges` or `mysql_cluster_restore_local_privileges` use the MySQL server default storage engine; they are not shared or distributed in any way, and do not use NDB Cluster's `NDB` storage engine.

The additional stored procedure `mysql_cluster_restore_privileges_from_local` is intended for the use of `mysql_cluster_restore_privileges` and `mysql_cluster_restore_local_privileges`. It should not be invoked directly.

**Important**

Applications that access NDB Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other `NDB` tables. In particular, you should keep in mind that *NDB API and ClusterJ applications*

*can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions.*

## 20.5.16 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
```

| Variable_name                              | Value    |
|--|----------|
| Ndb_api_wait_exec_complete_count_session   | 0        |
| Ndb_api_wait_scan_result_count_session     | 0        |
| Ndb_api_wait_meta_request_count_session    | 0        |
| Ndb_api_wait_nanos_count_session           | 0        |
| Ndb_api_bytes_sent_count_session           | 0        |
| Ndb_api_bytes_received_count_session       | 0        |
| Ndb_api_trans_start_count_session          | 0        |
| Ndb_api_trans_commit_count_session         | 0        |
| Ndb_api_trans_abort_count_session          | 0        |
| Ndb_api_trans_close_count_session          | 0        |
| Ndb_api_pk_op_count_session                | 0        |
| Ndb_api_uk_op_count_session                | 0        |
| Ndb_api_table_scan_count_session           | 0        |
| Ndb_api_range_scan_count_session           | 0        |
| Ndb_api_pruned_scan_count_session          | 0        |
| Ndb_api_scan_batch_count_session           | 0        |
| Ndb_api_read_row_count_session             | 0        |
| Ndb_api_trans_local_read_row_count_session | 0        |
| Ndb_api_event_data_count_injector          | 0        |
| Ndb_api_event_nondata_count_injector       | 0        |
| Ndb_api_event_bytes_count_injector         | 0        |
| Ndb_api_wait_exec_complete_count_slave     | 0        |
| Ndb_api_wait_scan_result_count_slave       | 0        |
| Ndb_api_wait_meta_request_count_slave      | 0        |
| Ndb_api_wait_nanos_count_slave             | 0        |
| Ndb_api_bytes_sent_count_slave             | 0        |
| Ndb_api_bytes_received_count_slave         | 0        |
| Ndb_api_trans_start_count_slave            | 0        |
| Ndb_api_trans_commit_count_slave           | 0        |
| Ndb_api_trans_abort_count_slave            | 0        |
| Ndb_api_trans_close_count_slave            | 0        |

| 60 rows in set (0.00 sec)          |   |  |

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multi-threaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client.* This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as “`_session` variables”, with a leading underscore.

- *Slave counters (global)*

This set of counters relates to the `Ndb` objects used by the replication slave SQL thread, if any. If this `mysqld` does not act as a replication slave, or does not use `NDB` tables, then all of these counts are 0.

We refer to the related status variables as “`_slave` variables” (with a leading underscore).

- *Injector counters (global)*

Injector counters relate to the `Ndb` object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, `mysqld` processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as “`_injector` variables” (with a leading underscore).

- *Server (Global) counters (global)*

This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the `NDB` utility thread.

We refer to the status variables that correspond to these counters as “global variables” or “`mysqld`-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
```

| Variable_name                              | Value   |
|--|---------|
| Ndb_api_wait_exec_complete_count_session   | 2       |
| Ndb_api_wait_scan_result_count_session     | 0       |
| Ndb_api_wait_meta_request_count_session    | 1       |
| Ndb_api_wait_nanos_count_session           | 8144375 |
| Ndb_api_bytes_sent_count_session           | 68      |
| Ndb_api_bytes_received_count_session       | 84      |
| Ndb_api_trans_start_count_session          | 1       |
| Ndb_api_trans_commit_count_session         | 1       |
| Ndb_api_trans_abort_count_session          | 0       |
| Ndb_api_trans_close_count_session          | 1       |
| Ndb_api_pk_op_count_session                | 1       |
| Ndb_api_uk_op_count_session                | 0       |
| Ndb_api_table_scan_count_session           | 0       |
| Ndb_api_range_scan_count_session           | 0       |
| Ndb_api_pruned_scan_count_session          | 0       |
| Ndb_api_scan_batch_count_session           | 0       |
| Ndb_api_read_row_count_session             | 1       |
| Ndb_api_trans_local_read_row_count_session | 1       |

```
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
-> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
```

| VARIABLE_NAME                      | VARIABLE_VALUE |
|------------------------------------|----------------|
| NDB_API_WAIT_EXEC_COMPLETE_COUNT   | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT     | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT    | 28             |
| NDB_API_WAIT_NANOS_COUNT           | 53756398       |
| NDB_API_BYTES_SENT_COUNT           | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT       | 9724           |
| NDB_API_TRANS_START_COUNT          | 3              |
| NDB_API_TRANS_COMMIT_COUNT         | 2              |
| NDB_API_TRANS_ABORT_COUNT          | 0              |
| NDB_API_TRANS_CLOSE_COUNT          | 3              |
| NDB_API_PK_OP_COUNT                | 2              |
| NDB_API_UK_OP_COUNT                | 0              |
| NDB_API_TABLE_SCAN_COUNT           | 1              |
| NDB_API_RANGE_SCAN_COUNT           | 0              |
| NDB_API_PRUNED_SCAN_COUNT          | 0              |
| NDB_API_SCAN_BATCH_COUNT           | 0              |
| NDB_API_READ_ROW_COUNT             | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT           | 0              |
| NDB_API_EVENT_NONDATA_COUNT        | 0              |
| NDB_API_EVENT_BYTES_COUNT          | 0              |

```
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
```

| Variable_name                        | Value |
|--------------------------------------|-------|
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
| Ndb_api_event_data_count             | 0     |

```
| Ndb_api_event_nondata_count | 0 |
| Ndb_api_event_bytes_count  | 0 |
+-----+-----+
6 rows in set (0.00 sec)
```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nondata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |
+-----+-----+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

| Counter Name          | Description   |
|-----------------------|---|
|                       | Status Variables (by statistic type):   |
|                       | <ul style="list-style-type: none"> <li>• Session</li> <li>• Slave</li> <li>• Injector</li> <li>• Server</li> </ul>  |
| WaitExecCompleteCount | <p>Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients.</p> <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_exec_complete_count_session</code></li> <li>• <code>Ndb_api_wait_exec_complete_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_wait_exec_complete_count</code></li> </ul> |
| WaitScanResultCount   | <p>Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.</p> <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_scan_result_count_session</code></li> <li>• <code>Ndb_api_wait_scan_result_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_wait_scan_result_count</code></li> </ul>  |
| WaitMetaRequestCount  | <p>Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).</p> <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_meta_request_count_session</code></li> <li>• <code>Ndb_api_wait_meta_request_count_slave</code></li> <li>• [none]</li> </ul>  |

| Counter Name     | Description  |
|------------------|--|
|                  | <b>Status Variables (by statistic type):</b> <ul style="list-style-type: none"> <li>• <b>Session</b></li> <li>• <b>Slave</b></li> <li>• <b>Injector</b></li> <li>• <b>Server</b></li> </ul>  |
|                  | <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_meta_request_count</code></li> </ul>   |
| WaitNanosCount   | Total time (in nanoseconds) spent waiting for some type of signal from the data nodes. <ul style="list-style-type: none"> <li>• <code>Ndb_api_wait_nanos_count_session</code></li> <li>• <code>Ndb_api_wait_nanos_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_wait_nanos_count</code></li> </ul> |
| BytesSentCount   | Amount of data (in bytes) sent to the data nodes <ul style="list-style-type: none"> <li>• <code>Ndb_api_bytes_sent_count_session</code></li> <li>• <code>Ndb_api_bytes_sent_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_bytes_sent_count</code></li> </ul>                                       |
| BytesRecvdCount  | Amount of data (in bytes) received from the data nodes <ul style="list-style-type: none"> <li>• <code>Ndb_api_bytes_received_count_session</code></li> <li>• <code>Ndb_api_bytes_received_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_bytes_received_count</code></li> </ul>                     |
| TransStartCount  | Number of transactions started. <ul style="list-style-type: none"> <li>• <code>Ndb_api_trans_start_count_session</code></li> <li>• <code>Ndb_api_trans_start_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_trans_start_count</code></li> </ul>   |
| TransCommitCount | Number of transactions committed. <ul style="list-style-type: none"> <li>• <code>Ndb_api_trans_commit_count_session</code></li> <li>• <code>Ndb_api_trans_commit_count_slave</code></li> <li>• [none]</li> <li>• <code>Ndb_api_trans_commit_count</code></li> </ul>  |
| TransAbortCount  | Number of transactions aborted. <ul style="list-style-type: none"> <li>• <code>Ndb_api_trans_abort_count_session</code></li> <li>• <code>Ndb_api_trans_abort_count_slave</code></li> </ul>   |

| Counter Name    | Description  |
|-----------------|--|
|                 | <b>Status Variables (by statistic type):</b> <ul style="list-style-type: none"> <li>• <b>Session</b></li> <li>• <b>Slave</b></li> <li>• <b>Injector</b></li> <li>• <b>Server</b></li> </ul>  |
|                 | <ul style="list-style-type: none"> <li>• [none]</li> <li>• <a href="#">Ndb_api_trans_abort_count</a></li> </ul>  |
| TransCloseCount | <p>Number of transactions aborted. (This value may be greater than the sum of <a href="#">TransCommitCount</a> and <a href="#">TransAbortCount</a>.)</p> <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_trans_close_count_session</a></li> <li>• <a href="#">Ndb_api_trans_close_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_trans_close_count</a></li> </ul>   |
| PkOpCount       | <p>Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to MySQL clients.</p> <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_pk_op_count_session</a></li> <li>• <a href="#">Ndb_api_pk_op_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_pk_op_count</a></li> </ul> |
| UkOpCount       | <p>Number of operations based on or using unique keys.</p> <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_uk_op_count_session</a></li> <li>• <a href="#">Ndb_api_uk_op_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_uk_op_count</a></li> </ul>   |
| TableScanCount  | <p>Number of table scans that have been started. This includes scans of internal tables.</p> <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_table_scan_count_session</a></li> <li>• <a href="#">Ndb_api_table_scan_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_table_scan_count</a></li> </ul>  |
| RangeScanCount  | <p>Number of range scans that have been started.</p> <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_range_scan_count_session</a></li> <li>• <a href="#">Ndb_api_range_scan_count_slave</a></li> <li>• [none]</li> </ul>  |

| Counter Name            | Description  |
|-------------------------|--|
|                         | <b>Status Variables (by statistic type):</b> <ul style="list-style-type: none"> <li>• <b>Session</b></li> <li>• <b>Slave</b></li> <li>• <b>Injector</b></li> <li>• <b>Server</b></li> </ul>  |
|                         | <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_range_scan_count</a></li> </ul>   |
| PrunedScanCount         | Number of scans that have been pruned to a single partition. <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_pruned_scan_count_session</a></li> <li>• <a href="#">Ndb_api_pruned_scan_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_pruned_scan_count</a></li> </ul>   |
| ScanBatchCount          | Number of batches of rows received. (A <i>batch</i> in this context is a set of scan results from a single fragment.) <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_scan_batch_count_session</a></li> <li>• <a href="#">Ndb_api_scan_batch_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_scan_batch_count</a></li> </ul> |
| ReadRowCount            | Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations. <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_read_row_count_session</a></li> <li>• <a href="#">Ndb_api_read_row_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_read_row_count</a></li> </ul>            |
| TransLocalReadRowCount  | Number of rows read from the data same node on which the transaction was being run. <ul style="list-style-type: none"> <li>• <a href="#">Ndb_api_trans_local_read_row_count_session</a></li> <li>• <a href="#">Ndb_api_trans_local_read_row_count_slave</a></li> <li>• [none]</li> <li>• <a href="#">Ndb_api_trans_local_read_row_count</a></li> </ul>     |
| DataEventsRecvdCount    | Number of row change events received. <ul style="list-style-type: none"> <li>• [none]</li> <li>• [none]</li> <li>• <a href="#">Ndb_api_event_data_count_injector</a></li> <li>• <a href="#">Ndb_api_event_data_count</a></li> </ul>  |
| NondataEventsRecvdCount | Number of events received, other than row change events. <ul style="list-style-type: none"> <li>• [none]</li> </ul>  |

| Counter Name                      | Description   |
|-----------------------------------|---|
|                                   | Status Variables (by statistic type):   |
|                                   | <ul style="list-style-type: none"> <li>• Session</li> <li>• Slave</li> <li>• Injector</li> <li>• Server</li> </ul>  |
|                                   | <ul style="list-style-type: none"> <li>• [none]</li> <li>• <code>Ndb_api_event_nondata_count_injector</code></li> <li>• <code>Ndb_api_event_nondata_count</code></li> </ul>               |
|                                   | Number of bytes of events received.   |
| <code>EventBytesRecvdCount</code> | <ul style="list-style-type: none"> <li>• [none]</li> <li>• [none]</li> <li>• <code>Ndb_api_event_bytes_count_injector</code></li> <li>• <code>Ndb_api_event_bytes_count</code></li> </ul> |

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_commit_count_slave   | 0 |
| Ndb_api_trans_commit_count         | 2 |
+-----+-----+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an NDB table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session   | 0 |
| Ndb_api_wait_meta_request_count_session  | 3 |
| Ndb_api_wait_nanos_count_session         | 820705 |
| Ndb_api_bytes_sent_count_session         | 132 |
| Ndb_api_bytes_received_count_session     | 372 |
| Ndb_api_trans_start_count_session        | 1 |
| Ndb_api_trans_commit_count_session       | 1 |
| Ndb_api_trans_abort_count_session        | 0 |
| Ndb_api_trans_close_count_session        | 1 |
| Ndb_api_pk_op_count_session              | 1 |
| Ndb_api_uk_op_count_session              | 0 |
| Ndb_api_table_scan_count_session         | 0 |
+-----+-----+
```

```

| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)

```

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 8 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 17 |
| Ndb_api_wait_nanos_count_session | 706871709 |
| Ndb_api_bytes_sent_count_session | 2376 |
| Ndb_api_bytes_received_count_session | 3844 |
| Ndb_api_trans_start_count_session | 4 |
| Ndb_api_trans_commit_count_session | 4 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 4 |
| Ndb_api_pk_op_count_session | 6 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 2 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)

```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```

mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 11 |
| Ndb_api_wait_scan_result_count_session | 6 |
| Ndb_api_wait_meta_request_count_session | 20 |
| Ndb_api_wait_nanos_count_session | 707370418 |
| Ndb_api_bytes_sent_count_session | 2724 |
| Ndb_api_bytes_received_count_session | 4116 |
| Ndb_api_trans_start_count_session | 7 |
| Ndb_api_trans_commit_count_session | 6 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 7 |
| Ndb_api_pk_op_count_session | 8 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 1 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 3 |
+-----+-----+

```

```
| Ndb_api_trans_local_read_row_count_session | 2 |
+-----+-----+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the `NDB` storage engine.
- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer ( $706871709 - 820705 = 706051004$  nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` ( $707370418 - 706871709 = 498709$  ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

## 20.6 NDB Cluster Replication

NDB Cluster supports *asynchronous replication*, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 18, Replication](#)).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the `NDB` storage engine for clustering functionality, it is not necessary to use `NDB` as the storage engine for the slave's copies of the replicated tables (see [Replication from NDB to other storage engines](#)). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

**Figure 20.28 NDB Cluster -to-Cluster Replication Layout**

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log ([binlog](#)). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see [Section 20.6.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”](#).

**NDB API `_slave` status variables.** NDB API counters can provide enhanced monitoring capabilities on NDB Cluster replication slaves. These are implemented as NDB statistics `_slave` status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a slave in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated [NDB](#) tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting NDB Cluster Replication. [Section 20.5.16, “NDB API Statistics Counters and Variables”](#), provides additional information.

**Replication from NDB to non-NDB tables.** It is possible to replicate [NDB](#) tables from an NDB Cluster acting as the master to tables using other MySQL storage engines such as [InnoDB](#) or [MyISAM](#) on a slave `mysqld`. This is subject to a number of conditions; see [Replication from NDB to other storage engines](#), and [Replication from NDB to a nontransactional storage engine](#), for more information.

## 20.6.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

| Symbol or Abbreviation  | Description (Refers to...)                              |
|-------------------------|---|
| <i>M</i>                | The cluster serving as the (primary) replication master |
| <i>S</i>                | The cluster acting as the (primary) replication slave   |
| <code>shellM&gt;</code> | Shell command to be issued on the master cluster        |

| Symbol or Abbreviation   | Description (Refers to...)   |
|--------------------------|--|
| <code>mysqlM&gt;</code>  | MySQL client command issued on a single MySQL server running as an SQL node on the master cluster  |
| <code>mysqlM*&gt;</code> | MySQL client command to be issued on all SQL nodes participating in the replication master cluster |
| <code>shellS&gt;</code>  | Shell command to be issued on the slave cluster  |
| <code>mysqlS&gt;</code>  | MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster   |
| <code>mysqlS*&gt;</code> | MySQL client command to be issued on all SQL nodes participating in the replication slave cluster  |
| <i>C</i>                 | Primary replication channel  |
| <i>C'</i>                | Secondary replication channel  |
| <i>M'</i>                | Secondary replication master   |
| <i>S'</i>                | Secondary replication slave  |

## 20.6.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in [Section 20.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 18.2.1, “Replication Formats”](#).

### Important

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see [Section 20.6.4, “NDB Cluster Replication Schema and Tables”](#)). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

The default value for the `--binlog-format` option in NDB 7.5 is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where *id* is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see [Section 18.4.2, “Replication Compatibility Between MySQL Versions”](#)). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 5.7 distributions that NDB Cluster Replication has the additional requirement that both `mysqld` binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same NDB Cluster distribution for all master and slave `mysqld` binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

#### Note

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more specific information concerning the differences between the two replication formats.

## 20.6.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster 7.5.

**Loss of master-slave connection.** A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master's binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See [Section 20.6.8, “Implementing Failover with NDB Cluster Replication”](#), for more information about what to do in such circumstances.

#### Important

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary

line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see [Section 20.6.7, “Using Two Replication Channels for NDB Cluster Replication”](#), and [Section 20.6.8, “Implementing Failover with NDB Cluster Replication”](#).

However, if you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

**Circular replication.** NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Cluster s numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

**Figure 20.29 NDB Cluster Circular Replication With All Masters As Slaves**

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication

line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

**Figure 20.30 NDB Cluster Circular Replication Where Not All Masters Are Slaves**

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

#### Note

The [NDB](#) storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

**NDB Cluster replication and primary keys.** In the event of a node failure, errors in replication of [NDB](#) tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all [NDB](#) tables being replicated have primary keys.

**NDB Cluster Replication and Unique Keys.** In older versions of NDB Cluster, operations that updated values of unique key columns of [NDB](#) tables could result in duplicate-key errors when

replicated. This issue is solved for replication between [NDB](#) tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by [NDB](#). Thus, updates of unique keys when replicating from [NDB](#) to a different storage engine such as [MyISAM](#) or [InnoDB](#) are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using [NDB](#) table such as `t`, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
  p INT PRIMARY KEY,
  c INT,
  UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following [UPDATE](#) statement on `t` succeeded on the master, since the rows affected are processed in the order determined by the [ORDER BY](#) option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

#### Note

Every [NDB](#) table is implicitly partitioned by key when it is created. See [Section 21.2.5, “KEY Partitioning”](#), for more information.

**GTIDs not supported.** Replication using global transaction IDs is not compatible with the [NDB](#) storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

**Multi-threaded slaves not supported.** NDB Cluster does not support multi-threaded slaves, and setting related system variables such as [slave\\_parallel\\_workers](#), [slave\\_checkpoint\\_group](#), and [slave\\_checkpoint\\_group](#) (or the equivalent `mysqld` startup options) has no effect.

This is because the slave may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the [NDB](#) storage engine involves at least two databases—the target database and the `mysql` system database—due to the requirement for updating the `mysql.ndb_apply_status` table (see [Section 20.6.4, “NDB Cluster Replication Schema and Tables”](#)). This in turn breaks the requirement for multi-threading that the transaction is specific to a given database.

**Restarting with `--initial`.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the [RESET MASTER](#) and [RESET SLAVE](#) statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

**Replication from NDB to other storage engines.** It is possible to replicate an [NDB](#) table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the [NDB](#) storage engine for this to work).
- Using a storage engine which does not perform binary logging for slave tables requires special handling.

- Use of a nontransactional storage engine for slave tables also requires special handling.
- The master `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple masters not supported when replicating NDB to other storage engines.** For replication from NDB to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (However, an NDB Cluster database *can* simultaneously replicate to multiple slave NDB Cluster databases.) If the master uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

**Replicating NDB to a slave storage engine that does not perform binary logging.** If you attempt to replicate from an NDB Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0`.
- **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
- **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

#### Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See [Replication and binary log filtering rules with replication between NDB Cluster s](#), for details.

**Replication from NDB to a nontransactional storage engine.** When replicating from NDB to a nontransactional storage engine such as `MyISAM`, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

**Replication and binary log filtering rules with replication between NDB Cluster s.** If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Cluster s to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-`

`do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).
2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see [Section 6.4.4, “The Binary Log”](#).

If you are replicating an NDB Cluster to a slave that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

**NDB Cluster Replication and IPv6.** Currently, the NDB API and MGM API do not support IPv6. However, MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between NDB Cluster s using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

**Figure 20.31 Replication Between SQL Nodes Connected Using IPv6**

However, all connections originating *within* the NDB Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.** NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see [Row-based replication: attribute promotion and demotion](#).

NDB, unlike [InnoDB](#) or [MyISAM](#), does not write changes to virtual columns to the binary log; however, this has no detrimental effects on NDB Cluster Replication or replication between NDB and other storage engines. Changes to stored generated columns are logged.

## 20.6.4 NDB Cluster Replication Schema and Tables

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the [InnoDB](#) storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
  `Position` BIGINT(20) UNSIGNED NOT NULL,
  `File` VARCHAR(255) NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `inserts` INT(10) UNSIGNED NOT NULL,
  `updates` INT(10) UNSIGNED NOT NULL,
  `deletes` INT(10) UNSIGNED NOT NULL,
  `schemaops` INT(10) UNSIGNED NOT NULL,
  `orig_server_id` INT(10) UNSIGNED NOT NULL,
  `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
  `gci` INT(10) UNSIGNED NOT NULL,
  `next_position` bigint(20) unsigned NOT NULL,
  `next_file` varchar(255) NOT NULL,
  PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

### Note

Prior to NDB 7.5.2, this table always used the [MyISAM](#) storage engine. If you are upgrading from an earlier release, you can use `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options to cause it to execute an `ALTER TABLE ... ENGINE=INNODB` statement on this table. Use of the [MyISAM](#) storage engine for this table continues to be supported in NDB 7.5.2 and later for backward compatibility.

`ndb_binlog_index` may require additional disk space after being converted to [InnoDB](#). If this becomes an issue, you may be able to conserve space by using an [InnoDB](#) tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#), and [Section 14.1.18, “CREATE TABLE Syntax”](#), as well as [Section 15.7, “InnoDB Tablespaces”](#).

The size of this table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table,

even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; that is,

```
[number of epochs per file] = [time spent per file] / TimeBetweenEpochs
```

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple masters. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the slave in a multi-master setup (see [Section 20.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”](#)) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the master has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-master failover times by adding an index to these columns, as shown here:

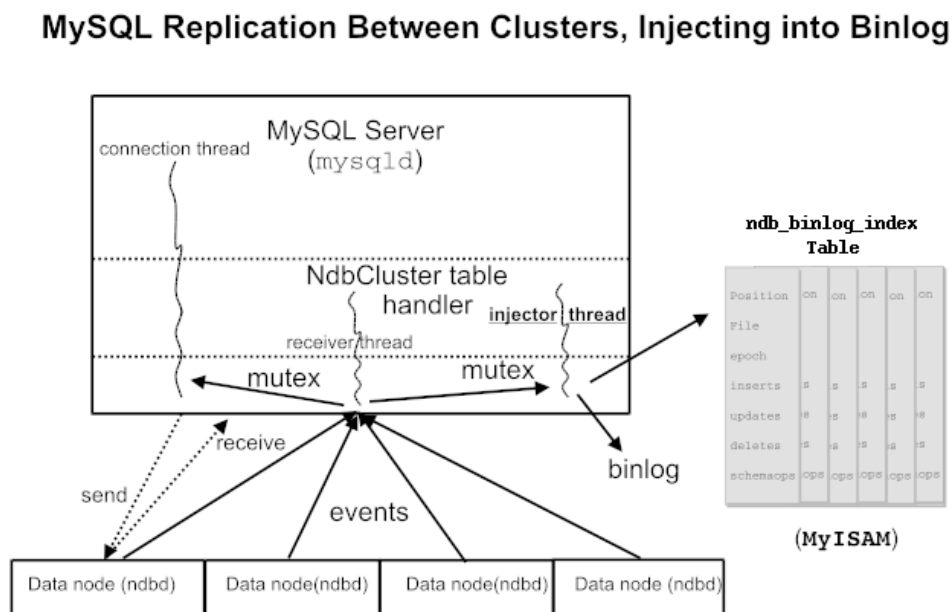

```
ALTER TABLE mysql.ndb_binlog_index
  ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single master to a single slave, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See [Section 20.6.8, “Implementing Failover with NDB Cluster Replication”](#), for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication master server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

**Figure 20.32 The Replication Master Cluster**

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
  `server_id` INT(10) UNSIGNED NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
  `start_pos` BIGINT(20) UNSIGNED NOT NULL,
  `end_pos` BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on slaves, which means that, on the master, this table never contains any rows; thus, there is no need to allow for `DataMemory` or `IndexMemory` to be allotted to `ndb_apply_status` there.

Because this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see [Replication and binary log filtering rules with replication between NDB Cluster s](#).

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the `NDB` binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the `NDB` storage engine. The `NDB binlog injector thread` receives events directly from the `NDB` storage engine. The `NDB` injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an `NDB` Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See [Section 14.7.5.2, "SHOW BINLOG EVENTS Syntax"](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to `NDB` tables. It is defined as shown here:

```
CREATE TABLE ndb_schema (
  `db` VARBINARY(63) NOT NULL,
  `name` VARBINARY(63) NOT NULL,
  `slock` BINARY(32) NOT NULL,
  `query` BLOB NOT NULL,
  `node_id` INT UNSIGNED NOT NULL,
  `epoch` BIGINT UNSIGNED NOT NULL,
  `id` INT UNSIGNED NOT NULL,
  `version` INT UNSIGNED NOT NULL,
  `type` INT UNSIGNED NOT NULL,
  PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```
shell> ndb_show_tables -t 2
```

| id | type      | state  | logging | database | schema | name             |
|----|-----------|--------|---------|----------|--------|------------------|
| 4  | UserTable | Online | Yes     | mysql    | def    | ndb_apply_status |
| 5  | UserTable | Online | Yes     | ndbworld | def    | city             |
| 6  | UserTable | Online | Yes     | ndbworld | def    | country          |
| 3  | UserTable | Online | Yes     | mysql    | def    | NDB\$BLOB_2_3    |
| 7  | UserTable | Online | Yes     | ndbworld | def    | countrylanguage  |
| 2  | UserTable | Online | Yes     | mysql    | def    | ndb_schema       |

NDBT\_ProgramExit: 0 - OK

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='city' \G
***** 1. row *****
      db: ndbworld
      name: city
      slock:
      query: alter table City engine=ndb
node_id: 4
  epoch: 0
    id: 0
version: 0
  type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.

## Note

When performing schema changes on `NDB` tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the `ndb_apply_status` table or the `ndb_schema` table does not exist on the slave, `ndb_restore` re-creates the missing table or tables (Bug #14612).

Conflict resolution for NDB Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see [Section 20.6.11, “NDB Cluster Replication Conflict Resolution”](#).

## 20.6.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 20.6.2, “General Requirements for NDB Cluster Replication”](#)).
2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'slave_user'@'slave_host'
-> IDENTIFIED BY 'slave_password';
```

In the previous statement, `slave_user` is the slave account user name, `slave_host` is the host name or IP address of the replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name `myslave`, logging in from the host named `rep-slave`, and using the password `53cr37`, use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'myslave'@'rep-slave'
```

```
-> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='master_host',
-> MASTER_PORT=master_port,
-> MASTER_USER='slave_user',
-> MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is `rep-master`, using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='rep-master',
-> MASTER_PORT=3306,
-> MASTER_USER='myslave',
-> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#).

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See [Section 20.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#), for details.

For additional options that can be set in `my.cnf` for replication slaves, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in [Section 20.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using NDB Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 5.5.4, “mysqldump — A Database Backup Program”](#).

#### Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See [Section 18.2.1, “Replication Formats”](#).) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See [Section 20.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#), for information regarding the latter option.

## 20.6.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
--log-bin &
```

In the previous statement, `id` is this server's unique ID (see [Section 20.6.2, “General Requirements for NDB Cluster Replication”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

#### Note

You can also start the master with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. `STATEMENT` based binary logging is not supported for NDB Cluster Replication (see [Section 20.6.2, “General Requirements for NDB Cluster Replication”](#)).

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the command just shown, `id` is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

#### Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO
-> MASTER_LOG_FILE='',
-> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see [Section 20.6.8, “Implementing Failover with NDB Cluster Replication”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 20.6.7, “Using Two Replication Channels for NDB Cluster Replication”](#).

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

#### Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON |
| slave_compressed_protocol | OFF |
| slave_load_tmpdir | /tmp |
| slave_net_timeout | 3600 |
| slave_skip_errors | OFF |
| slave_transaction_retries | 10 |
+-----+-----+
6 rows in set (0.00 sec)
```

## 20.6.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

| Server ID | Description  |
|-----------|--|
| 1         | Master - primary replication channel ( <i>M</i> )    |
| 2         | Master - secondary replication channel ( <i>M'</i> ) |
| 3         | Slave - primary replication channel ( <i>S</i> )     |
| 4         | Slave - secondary replication channel ( <i>S'</i> )  |

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
           --log-bin &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
           --log-bin &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
           --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
           --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

### Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in [Section 20.6.8, “Implementing Failover with NDB Cluster Replication”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

## 20.6.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
->        FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a master and a slave running on each host, when you are using `ndb_log_apply_status=1`, NDB Cluster epochs are written in the slave binary logs. This means that the `ndb_apply_status` table contains information for the slave on this host as well as for any other host which acts as a slave of the master running on this host.

In this case, you need to determine the latest epoch on this slave to the exclusion of any epochs from any other slaves in this slave's binary log that were not listed in the `IGNORE_SERVER_IDS` options of the `CHANGE MASTER TO` statement used to set up this slave. The reason for excluding such epochs is that rows in the `mysql.ndb_apply_status` table whose server IDs have a match in the `IGNORE_SERVER_IDS` list used with the `CHANGE MASTER TO` statement used to prepare this slave's master are also considered to be from local servers, in addition to those having the slave's own server ID. You can retrieve this list as `Replicate_Ignore_Server_Ids` from the output of `SHOW SLAVE STATUS`. We assume that you have obtained this list and are substituting it for `ignore_server_ids` in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named `@latest`:

```
mysqlS'> SELECT @latest:=MAX(epoch)
->        FROM mysql.ndb_apply_status
->        WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and `server_id IN server_id_list` in the `WHERE` condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster.

You can use the following query to obtain the needed records from the master's `ndb_binlog_index` table:

```
mysqlM'> SELECT
->        @file:=SUBSTRING_INDEX(next_file, '/', -1),
->        @pos:=next_position
->        FROM mysql.ndb_binlog_index
->        WHERE epoch = @latest
->        ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

### Important

You must ensure that the slave `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
->     MASTER_LOG_FILE='@file',
->     MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

#### Note

`@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

#### Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from `M` to `S'`, or from `M'` to `S`; however, this has not yet been tested.

## 20.6.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 20.6.5, “Preparing the NDB Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.
  - **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the master cluster, and `port` is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

#### Note

The port number needs to be specified only if the default port (1186) is not being used. See [Section 20.2.4, “Initial Configuration of NDB Cluster”](#), for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellM> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see [Section 20.6.5, “Preparing the NDB Cluster for Replication”](#)), this would be executed as follows:

```
shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It *is* necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

#### Important

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \
          -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in [Section 20.6, “NDB Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
          -r ./var/BACKUPS/BACKUP-1
```

```

shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
-r ./var/BACKUPS/BACKUP-1

```

### Important

The `-e` (or `--restore_epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See [Section 20.4.20, “ndb\\_restore — Restore an NDB Cluster Backup”](#).)

- Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in [Section 20.6.8, “Implementing Failover with NDB Cluster Replication”](#)):

```

mysqlS> SELECT @latest:=MAX(epoch)
        FROM mysql.ndb_apply_status;

```

- Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```

mysqlM> SELECT
->     @file:=SUBSTRING_INDEX(File, '/', -1),
->     @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;

```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

- Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```

mysqlS> CHANGE MASTER TO
->     MASTER_LOG_FILE='@file',
->     MASTER_LOG_POS=@pos;

```

- Now that the slave “knows” from what point in which binary log file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```

mysqlS> START SLAVE;

```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 20.5.3, “Online Backup of NDB Cluster”](#).

## 20.6.9.1 NDB Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see [Section 20.6.9, “NDB Cluster Backups With NDB Cluster Replication”](#)). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

# file: reset-slave.pl

}

# end reset-slave.pl

```

### 20.6.9.2 Point-In-Time Recovery Using NDB Cluster Replication

*Point-in-time* recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native [NDB](#) data backup (taken by issuing [CREATE BACKUP](#) in the [ndb\\_mgm](#) client) and restoring the [ndb\\_binlog\\_index](#) table (from a dump made using [mysqldump](#)).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all [NDB](#) databases in the cluster, using the [START BACKUP](#) command in the [ndb\\_mgm](#) client (see [Section 20.5.3, “Online Backup of NDB Cluster”](#)).
2. At some later point, prior to restoring the cluster, make a backup of the [mysql.ndb\\_binlog\\_index](#) table. It is probably simplest to use [mysqldump](#) for this task. Also back up the binary log files at this time.

This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)
4. Locate the last known good backup.
5. Clear the data node file systems (using [ndbd --initial](#) or [ndbmtdd --initial](#)).

**Note**

NDB Cluster Disk Data tablespace and log files are not removed by `--initial`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.
7. Execute `ndb_restore`, restoring all data. You must include the `--restore_epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See [Section 20.4.20, “ndb\\_restore — Restore an NDB Cluster Backup”](#), for more information.)
8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.
9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

```
SELECT @LATEST_EPOCH:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

```
SELECT Position, @FIRST_FILE:=File
FROM mysql.ndb_binlog_index
WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See [Section 5.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).)

See also [Section 8.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#), for more information about the binary log, replication, and incremental recovery.

## 20.6.10 NDB Cluster Replication: Multi-Master and Circular Replication

It is possible to use NDB Cluster in multi-master replication, including circular replication between a number of NDB Cluster s.

**Circular replication example.** In the next few paragraphs we consider the example of a replication setup involving three NDB Cluster s numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

**Figure 20.33 NDB Cluster Circular Replication with All Masters As Slaves**

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:

**Figure 20.34 NDB Cluster Circular Replication Where Not All Masters Are Slaves**

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a slave NDB Cluster.** When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second NDB Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

This is a known issue which we intend to address in a future release.

**Multi-master failover example.** In this section, we discuss failover in a multi-master NDB Cluster replication setup with three NDB Cluster s having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

**Figure 20.35 NDB Cluster Multi-Master Replication With 3 Masters**

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

**Figure 20.36 NDB Cluster Multi-Master Replication, With MySQL Servers**

MySQL servers acting as replication slaves must be run with the `--log-slave-updates` option. Which `mysqld` processes require this option is also shown in the preceding diagram.

**Note**

Using the `--log-slave-updates` option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Cluster s is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
->     FROM mysql.ndb_apply_status
->     WHERE server_id=1;

mysqlC> SELECT
->     @file:=SUBSTRING_INDEX(File, '/', -1),
->     @pos:=Position
->     FROM mysql.ndb_binlog_index
->     WHERE orig_epoch >= @latest
->     AND orig_server_id = 1
->     ORDER BY epoch ASC LIMIT 1;
```

#### Note

You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See [Section 20.6.4, “NDB Cluster Replication Schema and Tables”](#), for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
->     MASTER_HOST = 'serverC'
->     MASTER_LOG_FILE='@file',
->     MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#), and [Section 14.7.5.34, “SHOW SLAVE STATUS Syntax”](#). For information about how this option interacts with the `ndb_log_apply_status` variable, see [Section 20.6.8, “Implementing Failover with NDB Cluster Replication”](#).

## 20.6.11 NDB Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given master should be applied on the slave.

Some types of conflict resolution supported by NDB Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a “timestamp” column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

**Requirements.** Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:

- On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see [The ndb\\_replication system table](#)).

#### Note

If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

See [Section 18.4.1.22, “Replication and max\\_allowed\\_packet”](#), for more information about this issue.

- On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see [The ndb\\_replication system table](#)).
- NDB Cluster also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting `ndb_log_exclusive_reads` equal to 1 on the slave. All rows read by a conflicting read are logged in the exceptions table. For more information, see [Read conflict detection and resolution](#).

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT` (`INTEGER`) or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

**Master column control.** We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master's binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

#### Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

## Logging Full or Partial Rows (--ndb-log-updated-only Option)

|                     |                                     |                                   |
|---------------------|-------------------------------------|-----------------------------------|
| Command-Line Format | <code>--ndb-log-updated-only</code> |                                   |
| System Variable     | Name                                | <code>ndb_log_updated_only</code> |
|                     | Variable Scope                      | Global                            |
|                     | Dynamic Variable                    | Yes                               |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | ON      |

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to 0 or OFF.

### `--ndb-log-update-as-write` Option: Logging Changed Data as Updates

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--ndb-log-update-as-write</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                            | <code>ndb_log_update_as_write</code> |
|                            | <b>Variable Scope</b>                  | Global                               |
|                            | <b>Dynamic Variable</b>                | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                            | boolean                              |
|                            | <b>Default</b>                         | ON                                   |

The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.)

To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a different storage engine; see [Replication from NDB to other storage engines](#), and [Replication from NDB to a nontransactional storage engine](#), for more information.

**Conflict resolution control.** Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

**The `ndb_replication` system table.** To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
```

```
PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db, table_name);
```

The columns in this table are described in the next few paragraphs.

**db.** The name of the database containing the table to be replicated. You may employ either or both of the wildcards `_` and `%` as part of the database name. Matching is similar to what is implemented for the `LIKE` operator.

**table\_name.** The name of the table to be replicated. The table name may include either or both of the wildcards `_` and `%`. Matching is similar to what is implemented for the `LIKE` operator.

**server\_id.** The unique server ID of the MySQL instance (SQL node) where the table resides.

**binlog\_type.** The type of binary logging to be employed. This is determined as shown in the following table:

| Value | Internal Value   | Description  |
|-------|--|--|
| 0     | <code>NBT_DEFAULT</code>   | Use server default   |
| 1     | <code>NBT_NO_LOGGING</code>  | Do not log this table in the binary log  |
| 2     | <code>NBT_UPDATED_ONLY</code>  | Only updated attributes are logged   |
| 3     | <code>NBT_FULL</code>  | Log full row, even if not updated (MySQL server default behavior)  |
| 4     | <code>NBT_USE_UPDATE</code>  | (For generating <code>NBT_UPDATED_ONLY_USE_UPDATE</code> and <code>NBT_FULL_USE_UPDATE</code> values only—not intended for separate use) |
| 5     | <code>[Not used]</code>  | ---  |
| 6     | <code>NBT_UPDATED_ONLY_USE_UPDATE</code> (equal to <code>NBT_UPDATED_ONLY</code>   <code>NBT_USE_UPDATE</code> ) | Use updated attributes, even if values are unchanged   |
| 7     | <code>NBT_FULL_USE_UPDATE</code> (equal to <code>NBT_FULL</code>   <code>NBT_USE_UPDATE</code> )                 | Use full row, even if values are unchanged   |

**conflict\_fn.** The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- `NDB$OLD(column_name)`
- `NDB$MAX(column_name)`
- `NDB$MAX_DELETE_WIN()`
- `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`
- `NDB$EPOCH_TRANS()`
- `NDB$EPOCH2()`
- `NDB$EPOCH2_TRANS()`
- `NULL`: Indicates that conflict resolution is not to be used for the corresponding table.

These functions are described in the next few paragraphs.

**NDB\$OLD(column\_name).** If the value of `column_name` is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (master_old_column_value == slave_current_column_value)
    apply_update();
else
    log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

### Important

The column value from the master's “before” image is used by this function.

**NDB\$MAX(column\_name).** If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```
if (master_new_column_value > slave_current_column_value)
    apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

### Important

The column value from the master's “after” image is used by this function.

**NDB\$MAX\_DELETE\_WIN().** This is a variation on [NDB\\$MAX\(\)](#). Due to the fact that no timestamp is available for a delete operation, a delete using [NDB\\$MAX\(\)](#) is in fact processed as [NDB\\$OLD](#). However, for some use cases, this is not optimal. For [NDB\\$MAX\\_DELETE\\_WIN\(\)](#), if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```
if ( (master_new_column_value > slave_current_column_value)
    ||
    operation.type == "delete")
    apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

### Note

As with [NDB\\$MAX\(\)](#), the column value from the master's “after” image is the value used by this function.

**NDB\$EPOCH() and NDB\$EPOCH\_TRANS().** The [NDB\\$EPOCH\(\)](#) function tracks the order in which replicated epochs are applied on a slave NDB Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of [NDB\\$EPOCH\(\)](#) also applies to [NDB\\$EPOCH\\_TRANS\(\)](#). Any exceptions are noted in the text.

[NDB\\$EPOCH\(\)](#) is asymmetric, operating on one NDB Cluster in a two-cluster circular replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible

for detecting and handling conflicts, while the slave on the secondary is not involved in any conflict detection or handling.

When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.
- Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than

```
CEIL( LOG2( TimeBetweenGlobalCheckpoints / TimeBetweenEpochs ), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints`, `TimeBetweenEpochs`, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see `NDB$OLD(column_name)`). You need to create any exceptions table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are activated by including relevant entries in the `mysql.ndb_replication` table (see [The ndb\\_replication system table](#)). The roles of the primary and secondary NDB Cluster s in this scenario are fully determined by `mysql.ndb_replication` table entries.

Because the conflict detection algorithms employed by `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are asymmetric, you must use different values for the primary slave's and secondary slave's `server_id` entries.

A conflict between `DELETE` operations alone is not sufficient to trigger a conflict using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`, and the relative placement within epochs does not matter. (Bug #18459944)

**Conflict detection status variables.** Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this slave was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

`Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`. `Ndb_conflict_fn_epoch2` and `Ndb_conflict_fn_epoch2_trans` show the number of rows found in conflict by `NDB$EPOCH2()` and `NDB$EPOCH2_TRANS()`, respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

For more information, see [NDB Cluster Status Variables](#).

**Limitations on NDB\$EPOCH().** The following limitations currently apply when using `NDB$EPOCH()` to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to `TimeBetweenEpochs` (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to  $2 * (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})$ . This implies that—assuming the default for `TimeBetweenEpochs` and ignoring any latency between clusters (as well as any queueing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.
- Additional storage is required for tables using the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.
- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Cluster s in a circular “active-active” configuration are currently supported when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` for conflict detection.
- Tables having `BLOB` or `TEXT` columns are not currently supported with `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`.

**NDB\$EPOCH\_TRANS().** `NDB$EPOCH_TRANS()` extends the `NDB$EPOCH()` function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see [NDB\\$EPOCH\(\)](#) and [NDB\\$EPOCH\\_TRANS\(\)](#)) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where `NDB$EPOCH()` realigns individual conflicting rows on the secondary, `NDB$EPOCH_TRANS()` realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that Version 2 binary log row events are used (`--log-bin-use-v1-row-events` equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all

transaction IDs must be recorded in the secondary's binary log (`--ndb-log-transaction-id` option), which adds a further variable overhead (up to 13 bytes per row).

See `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

**Status information.** A server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

**NDB\$EPOCH2().** The `NDB$EPOCH2()` function is similar to `NDB$EPOCH()`, except that `NDB$EPOCH2()` provides for delete-delete handling with a circular replication (“master-master”) topology. In this scenario, primary and secondary roles are assigned to the two masters by setting the `ndb_slave_conflict_role` system variable to the appropriate value on each master (usually one each of `PRIMARY`, `SECONDARY`). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

**NDB\$EPOCH2\_TRANS().** `NDB$EPOCH2_TRANS()` extends the `NDB$EPOCH2()` function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, `NDB$EPOCH2()` realigns individual conflicting rows on the secondary, while `NDB$EPOCH_TRANS()` realigns conflicting transactions.

Where `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operations are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

`NDB$EPOCH2()` bypasses the issue just described—storing information about deleted rows on the PRIMARY—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using `NDB$EPOCH2()`, you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary's following changes immediately. Because of this, the secondary's state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary's logbinary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count` and `Ndb_conflict_reflected_op_discard_count` status variables. The number

of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist; for insert operations, the row must *not* exist.
